### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **samples**    | The number of labels that have to be processed before an imbalance is evaluated. The rule might not be triggered until it has seen sufficient samples across several steps. The more classes that your dataset contains, the larger this sample number should be.  
 **Optional**  
 Valid values: Integer  
 Default value: 500 (assuming a dataset like MNIST with 10 classes) |
| **argmax**     | If True, `np.argmax` is applied to the prediction tensor. Required when you have a vector of probabilities for each class. It is used to determine which class has the highest probability.  
 **Conditional**  
 Valid values: Boolean  
 Default value: False |
| **labels_regex** | The name of the tensor that contains the labels.  
 **Optional**  
 Valid values: String  
 Default value: ".*labels" |
| **predictions_regex** | The name of the tensor that contains the predictions.  
 **Optional**  
 Valid values: String  
 Default value: ".*predictions" |

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.class_imbalance(),
        rule_parameters={
            "threshold_imbalance": "10",
            "threshold_misprediction": "0.7",
            "samples": "500",
            "argmax": "False",
            "labels_regex": ".*labels",
            "predictions_regex": ".*predictions"
        },
        collections_to_save=[
            CollectionConfig(name="custom_output_collection")
        ]
    )
]```
LossNotDecreasing

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Overfit

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Note**

A standard way to prevent overfitting is to regularize your model.

### Parameter Descriptions for the Overfit Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.overfit(),
        rule_parameters=
            {
                "tensor_regex": ".*",
                "start_step": "0",
                "patience": "1",
                "ratio_threshold": "0.1"
            },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters=
                    {
                        "train.save_interval": "100",
                        "eval.save_interval": "10"
                    }
            )
        ]
    )
]
```

**Overtraining**

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation
loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Note
Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early (p. 2206). For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

Parameter Descriptions for the Overtraining Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>

        parameters={
            "save_interval": "500"
        }
    )
],
]}

**SimilarAcrossRuns**

This rule compares tensors gathered from a base trial with tensors from another trial. This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Parameter Descriptions for the SimilarAcrossRuns Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>
<td>other_trial</td>
<td>A completed training job name whose tensors you want to compare to those tensors gathered from the current base_trial. <strong>Required</strong> Valid values: String</td>
</tr>
<tr>
<td>collection_names</td>
<td>The list of collection names whose tensors the rule inspects. <strong>Optional</strong> Valid values: List of strings or a comma-separated string Default value: None</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter Name</strong></td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: List of strings or a comma-separated string</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.similar_across_runs(),
        rule_parameters={
            "other_trial": "<specify-another-job-name>",
            "collection_names": "losses",
            "tensor_regex": ".*"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**StalledTrainingRule**

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its `threshold` parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

### Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>base_trial</strong></td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td><strong>threshold</strong></td>
<td>A threshold that defines by how much time in seconds the rule waits for a tensor output until it fires a stalled training issue. Default value is 1800 seconds.</td>
</tr>
<tr>
<td><strong>stop_training_on_fire</strong></td>
<td>If set to True, watches if the base training job outputs tensors in &quot;threshold&quot; seconds.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: Boolean</td>
</tr>
<tr>
<td>training_job_name_prefix</td>
<td>The prefix of base training job name. If stop_training_on_fire is true, the rule searches for SageMaker training jobs with this prefix in the same account. If there is an inactivity found, the rule takes a StopTrainingJob action. Note if there are multiple jobs found with same prefix, the rule skips termination. It is important that the prefix is set unique per each training job. Optional Valid values: String</td>
</tr>
</tbody>
</table>

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            "threshold": "1800",
            "stop_training_on_fire": "True",
            "training_job_name_prefix": "<specify-training-base-job-name>"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**TensorVariance**

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

            "collection_names": "weights",
        },
    )
```
UnchangedTensor

This rule detects whether a tensor is no longer changing across steps.

This rule runs the `numpy.allclose` method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Parameter Descriptions for the UnchangedTensor Rule

            "num_steps": "3",
            "rtol": "1e-05",
```
CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Parameter Descriptions for the CheckInputImages Rule

### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Channel</strong></td>
<td>The position of the color channel in the input tensor shape array.</td>
</tr>
<tr>
<td><strong>Default value:</strong></td>
<td>1 (for example, MXNet expects input data in the form of (batch_size, channel, height, width))</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
            "regex": ".*hybridsequential0_input_0",
            "channel": "1"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*hybridsequential0_input_0",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

### NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.nlp_sequence_ratio(),
        rule_parameters={
            "tensor_regex": ".*embedding0_input_0",
            "token_values": ":0",
            "token_thresholds_percent": "50"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_inputs_collection",
                parameters={
                    "include_regex": ".*embedding0_input_0"
                }
            )
        ]
    )
]```
Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size category_no x category_no and populates it with data coming from (labels, predictions) pairs. For each (labels, predictions) pair, the count in confusion[labels][predictions] is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: confusion[i][i]/sum_j(confusion[j][j]) >= min_diag
- For elements off the diagonal: confusion[j][i]/sum_j(confusion[j][i]) <= max_off_diag

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Parameter Descriptions for the Confusion Rule

<table>
<thead>
<tr>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.confusion(),
        rule_parameters={
            "category_no": "10",
            "labels": "labels",
            "predictions": "predictions",
            "labels_collection": "labels",
            "predictions_collection": "predictions",
            "min_diag": "0.9",
            "max_off_diag": "0.1"
        },
        collections_to_save=[
            CollectionConfig(
                name="labels",
                parameters={
                    "save_interval": "500"
                }
            ),
            CollectionConfig(
                name="predictions",
                parameters={
                    "include_regex": "500"
                }
            )
        ],
    )
]
```
### Note
This rule infers default values for the optional parameters if their values aren't specified.

**FeatureImportanceOverweight**

This rule accumulates the weights of the $n$ largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

built_in_rules = [
```
TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the depth parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Parameter Descriptions for the TreeDepth Rule**

<table>
<thead>
<tr>

</tbody>
</table>

```python
built_in_rules = [  
    Rule.sagemaker(  
        base_config=rule_configs.tree_depth(),  
        rule_parameters={  
            "depth": "4"  
        },  
        collections_to_save=[  
            CollectionConfig(  
                name="tree",  
            )  
        ]  
    )  
]  
```
Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source `smdebug` Python library that provide tools to build your own rule containers.

**Topics**

- Prerequisites for Creating Debugger Custom Rules (p. 2109)
- Use the Debugger Client Library `smdebug` to Create a Custom Rule Python Script (p. 2109)
- Use the Debugger APIs to Run Your Own Custom Rules (p. 2110)

**Prerequisites for Creating Debugger Custom Rules**

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule.custom API
- The open source `smdebug` Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2180)

**Use the Debugger Client Library `smdebug` to Create a Custom Rule Python Script**

The `smdebug` Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, `CustomGradientRule`. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule
class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.
Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at 'path/to/my_custom_rule.py'.

```python
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
    rule_to_invoke='CustomGradientRule',
    collections_to_save=[CollectionConfig("gradients")],
    rule_parameters={"threshold": "20.0"}
)
```

The following list explains the Debugger `Rule.custom` API arguments.

- **name (str)**: Specify a custom rule name as you want.
- **image_uri (str)**: This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2180).
- **instance_type (str)**: You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source (str)**: This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke (str)**: This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save (str)**: This specifies which tensor collections you will save for the rule to run.
- **rule_parameters (dictionary)**: This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the `custom_rule` object, you can use it for building a SageMaker estimator for any training jobs. Specify the `entry_point` to your training script. You do not need to make any change of your training script.

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py'
    train_instance_type='ml.p2.xlarge'
...

    # debugger-specific arguments below
    rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.
Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 2111).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

Tip
This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 2761) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```bash
### debugger_custom_container_test_notebook.ipynb  # a notebook to run python snippet codes
### debugger_custom_container_test_folder          # this is a docker folder
   ### your-training-script.py                    # your training script with Debugger hook
   ### Dockerfile                                  # a Dockerfile to build your own container
```

Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

**Note**
This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.
# An example of training script (your-training-script.py)

```python
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...
    model.fit(X_train, Y_train,
        batch_size=batch_size,
        epochs=epoch,
        validation_data=(X_valid, Y_valid),
        shuffle=True,

        callback
    # smdebug modification: Pass the Debugger hook in the main() as a Keras callback
    callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")

    # hyperparameter settings
    parser.add_argument(...)  
    
    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

    if __name__ == "__main__":
        main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithm, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
- SMDebug PyTorch hook
- SMDebug MXNet hook
- SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

- Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.

In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script. The training script imports the smdebug library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the smdebug hook functionality by adding the callbacks=[hook] argument...
inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.

This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example. The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

- **Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode**

  This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.

  The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

  This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

### Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```bash
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug

CMD ["bin/bash"]
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

### Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```python
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'
region = boto3.session.Session().region_name
urisuffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    urisuffix = 'amazonaws.com.cn'
```
Action on Debugger Rules

byoc_image_uri = '{}.dkr.ecr.{}.{}'.format(account_id, region, uri_suffix,
            ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $byoc_image_uri
!docker push $byoc_image_uri

**Tip**
If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.

! aws ecr get-login-password --region {region} | docker login --username AWS --
            password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com

Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs
profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point='./debugger_custom_container_test_folder/your-training-script.py'
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
# start training
estimator.fit()
```

Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can
also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

**Topics**
- Debugger Built-in Actions for Rules (p. 2115)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 2119)

**Debugger Built-in Actions for Rules**

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 2066). The Debugger `rule_configs` class provides tools to configure a list of actions, including automatically stopping training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

**Step 1: Set Up Amazon SNS, Create an SMDdebugRules Topic, and Subscribe to the Topic**

This section walks you through how to set up an Amazon SNS `SMDdebugRules` topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

*Note*
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

**To create a SMDdebugRules topic**

2. In the left navigation pane, choose Topics.
3. On the Topics page, choose Create topic.
4. On the Create topic page, in the Details section, do the following:
   a. For Type, choose Standard for topic type.
   b. In Name, enter SMDdebugRules.
5. Skip all other optional settings and choose Create topic. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

**To subscribe to the SMDdebugRules topic**

2. In the left navigation pane, choose Subscriptions.
3. On the Subscriptions page, choose Create subscription.
4. On the Create subscription page, in the Details section, do the following:
   a. For Topic ARN, choose the SMDdebugRules topic ARN. The ARN should be in format of `arn:aws:sns:<region-id>:111122223333:SMDdebugRules`.
   b. For Protocol, choose Email or SMS.
   c. For Endpoint, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

*Note*
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.
5. Skip all other optional settings and choose **Create subscription**. If you want to learn more about the optional settings, see *Subscribing to an Amazon SNS topic*.

After you subscribe to the **SMDebugRules** topic, you receive the following confirmation message in email or by phone:

**AWS Notification - Subscription Confirmation**

You have chosen to subscribe to the topic:

```
```

To confirm this subscription, click or visit the link below (If this was in error no action is necessary):

[Confirm subscription](https://sns.amazonaws.com)

Please do not reply directly to this email. If you wish to remove yourself from receiving all future SNS subscription confirmation requests please send an email to sns-opt-out

For more information about Amazon SNS, see Mobile text messaging (SMS) and Email notifications in the *Amazon SNS Developer Guide*.

**Step 2: Set Up Your IAM Role to Attach Required Policies**

In this step, you add the required policies to your IAM role.

**To add the required policies to your IAM role**

1. Sign in to the AWS Management Console and open the IAM console at `https://console.aws.amazon.com/iam/`
2. In the left navigation pane, choose **Policies**, and choose **Create policy**.
3. On the **Create policy** page, do the following to create a new sns-access policy:
   a. Choose the **JSON** tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "VisualEditor0",
   "Effect": "Allow",
   "Action": [
   "sns:Publish",
   "sns:CreateTopic",
   "sns:Subscribe"
   ],
   "Resource": "arn:aws:sns:*":111122223333:SMDebugRules"
   }
   ]
   }
   ```
   c. At the bottom of the page, choose **Review policy**.
   d. On the **Review policy** page, for **Name**, enter **sns-access**.
   e. At the bottom of the page, choose **Create policy**.
4. Go back to the IAM console, and choose **Roles** in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the Permissions tab of the Summary page, choose Attach policies.
7. Search for the sns-access policy, select the check box next to the policy, and then choose Attach policy.

For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

Step 3: Configure Debugger Rules with the Built-in Actions

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The rule_configs is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- rule_configs.StopTraining() – Stops a training job when the Debugger rule finds an issue.
- rule_configs.Email("abc@abc.com") – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- rule_configs.SMS("+1234567890") – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

Note
Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the rule_configs.ActionList() method, which takes the built-in actions and configures a list of actions.

To add all of the three built-in actions to a single rule

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),  # Required
        rule_parameters={"parameter_key": value },  # Optional
        actions=actions
    )
]

estimator = Estimator(
    ...
```

2117
To create multiple built-in action objects to assign different actions to a single rule

If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 2097) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
import time

base_job_name_prefix = 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)

stalled_training_job_rule_email.name = "StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)

stalled_training_job_rule.name = "StalledTrainingJobRuleStopTraining"

estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.
The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Debugger ProfilerRule (p. 2065).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, `None` appears at the end of messages. This does not have any meaning, so you can disregard the text `None`.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
   - Choose /aws/sagemaker/TrainingJobs for training job logs.
• Choose /aws/sagemaker/ProcessingJobs for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

Step 1: Create a Lambda Function

To create a Lambda function

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose Functions and then choose Create function.
3. On the Create function page, choose Author from scratch option.
4. In the Basic information section, enter a Function name (for example, debugger-rule-stop-training-job).
5. For Runtime, choose Python 3.7.
6. For Permissions, expand the drop down option, and choose Change default execution role.
7. For Execution role, choose Use an existing role and choose the IAM role that you use for training jobs on SageMaker.

   **Note**
   Make sure you use the execution role with AmazonSageMakerFullAccess and AWSLambdaBasicExecutionRole attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:

   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose Create function.

The following figure shows an example of the Create function page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) client for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```python
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f'\nEvaluating Debugger rules for training job: {training_job_name}')
    ...  # Stop training job logic
```
eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

# should only attempt stopping jobs with InProgress status
training_job_status = event.get("detail").get("TrainingJobStatus", None)
if training_job_status != 'InProgress':
    logging.debug(f"Current Training job status({training_job_status}) is not 'InProgress'. Exiting")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

client = boto3.client('sagemaker')

for status in eval_statuses:
    logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' + str(status))
    if status.get("RuleEvaluationStatus") == "IssuesFound":
        secondary_status = event.get("detail").get("SecondaryStatus", None)
        logging.info(f'About to stop training job, since evaluation of rule configuration {status.get("RuleConfigurationName")) resulted in "IssuesFound". ' + f'\n\n\nAttempting to stop training job "{training_job_name}"'
    )
    try:
        client.stop_training_job(
            TrainingJobName=training_job_name
        )
    except Exception as e:
        logging.error("Encountered error while trying to "
            "stop training job {}": {}.format(
            training_job_name, str(e)
        )
    }
return None

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose Save at the top of the configuration page.

Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger

To create a CloudWatch Events rule and link to the Lambda function for Debugger

2. In the left navigation pane, choose Rules under the Events node.
3. Choose Create rule.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```json
{
  "source": [
    "aws.sagemaker"
  ],
  "detail-type": [
    "SageMaker Training Job State Change"
  ]
}
```

5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

Run Example Notebooks to Test Automated Training Job Termination

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- Amazon SageMaker Debugger - Reacting to CloudWatch Events from Rules
This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient (p. 2085) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- **Detect Stalled Training and Invoke Actions Using SageMaker Debugger Rule**

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule (p. 2097) built-in rule invokes issues and stops the training job.

**Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination**

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda Designer panel, choose the EventBridge (CloudWatch Events) block linked to the Lambda function. This shows an EventBridge panel below the Designer panel (for example, see the previous screen shot). Select the check box next to EventBridge (CloudWatch Events): debugger-cw-event-rule, and then choose Disable. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

**Amazon SageMaker Debugger in Amazon SageMaker Studio**

Use the Amazon SageMaker Debugger dashboards in Amazon SageMaker Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud (Amazon EC2) instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

**Important**

If you're using existing Studio apps, restart them to use the new features. For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.
Open the Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard in Studio to see profiling progress, results of resource utilization, and system bottlenecks of your training job running on Amazon EC2 instances.

**Note**
The Studio Debugger insights dashboard runs a Studio app on an \textit{ml.m5.4xlarge} instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the \textit{ml.m5.4xlarge} instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**
When you are done using the Debugger insights dashboard, you must shut down the \textit{ml.m5.4xlarge} instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2137).

**To open the Debugger insights dashboard**

1. Choose the \textit{SageMaker Components and registries} icon (✓).
2. Open the dropdown list, and choose \textit{Experiments and trials}.
3. Look up your training job name. If you have not assigned a SageMaker Experiments trial component to the training job, the job is collected under the \textit{Unassigned trial components} list.
4. **Right-click** (or an equivalent UI interaction) to open the context menu of the training job trial component. There are two menu items to access the Debugger features in Studio: **Open Debugger for insights** and **Open in trial details**.

5. Choose **Open Debugger for insights**. This opens a **Debug [your-training-job-name]** tab. On this tab, Debugger provides an overview of your model training performance on Amazon EC2 instances and identifies system bottleneck problems. While monitoring the system resource utilization, you can also enable **profiling** to capture framework metrics that consist of data from neural network operations executed during the forward and backward pass and data loading. For more information about how to enable profiling using the Debugger insights dashboard controller, see [Enable and Configure Debugger Profiling for Detailed Insights](p. 2127).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see [Amazon SageMaker Debugger Insights Dashboard Controller](p. 2126).

### Amazon SageMaker Debugger Insights Dashboard Controller

There are different components of the Debugger controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

**Note**
The Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the ml.m5.4xlarge instance usage. For information about pricing, see the [Amazon SageMaker Pricing page](p. 2126).

**Important**
When you are done using the Debugger insights dashboard, shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see [Shut Down the Amazon SageMaker Debugger Insights Instance](p. 2137).

### SageMaker Debugger Insights Controller UI

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop a training job, and download a Debugger profiling report.

- If you want to manually refresh the **Debug [your-training-job-name]** page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks.
and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 2065).

Enable and Configure Debugger Profiling for Detailed Insights

When you enable Profiling, Debugger starts collecting framework metrics. Framework metrics are model data collected from the ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the Debugger Built-in Rules for Profiling Framework Metrics (p. 2065).

**Note**
After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling can help you understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using Amazon SageMaker Python SDK, see Configure Debugger Framework Profiling (p. 2037) and Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 2041).

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In Studio, turn on Profiling to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.

2. The Configure Debugger monitoring and profiling, S3 bucket URI and Collect monitoring data every fields are already set to the default values.

   You can choose to change the monitoring interval using the dropdown list. Select from the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.
Specify values for the following fields:

- **S3 bucket URI**: Specify the base S3 bucket URI.
- **Collect monitoring data every**: Select a time interval to collect system metrics.

**Note**

If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.

3. In **Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values are automatically configured to use the current step and for 1-step duration.
• **Detailed profiling**: Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if you’re using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

**Note**
The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

• **Python profiling**: Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

  • cProfile – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

  • Pyinstrument – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

  **Note**
  Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

• **Dataloader profiling**: Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
Note
The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps.
Debugger is pre-configured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose Confirm to finish your profiling configuration. When the configuration is successfully updated, you should be able to see a Debugger configuration updated successfully confirmation message, as shown in following image.

Amazon SageMaker Debugger Insights Dashboard
When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of Amazon EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection status through the insights dashboard. This guide walks you through the content of the Debugger insights dashboard under the following tabs: **Overview**, **Nodes**, and **Model insights**.

**Note**
The Studio Debugger insights dashboard runs a Studio app on an `ml.m5.4xlarge` instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. The Studio app remains active and accrues charges for the `ml.m5.4xlarge` instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**
When you are done using the Debugger insights dashboard, shut down the `ml.m5.4xlarge` instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the Amazon SageMaker Debugger Insights Instance (p. 2137).

**Important**
In the reports, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Debugger Insights – Overview (p. 2130)
- Debugger Insights – Nodes (p. 2133)
- Debugger Insights – Model Insights (p. 2136)

**Debugger Insights – Overview**
On the **Overview** tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.

**Training job summary**
The **Training job summary** section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute
time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.

This section has the following features:

- The **Training progress over time** chart shows the timeline of the different training phases over time. If you're using spot training, you can also find the spot interruptions in the timeline chart.
- The **Training job details** panel shows the exact time stamps and utilization rate percentage numbers.
  - **Start time**: The exact time when the training job started.
  - **End time**: The exact time when the training job finished.
  - **Job duration**: The total training time from the **Start time** to the **End time**.
  - **Training loop start**: The exact time when the first step of the first epoch has started.
  - **Training loop end**: The exact time when the last step of the last epoch has finished.
  - **Training loop duration**: The total time between the training loop start time and the training loop end time.
  - **Initialization**: Time spent on initializing the training job, such as compiling the training script, initiating Amazon EC2 instances, and downloading training data.
  - **Finalization**: Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the Amazon EC2 instances.
  - **Initialization (%):** The percentage of time spent on **Initialization** over the total **Job duration**.
  - **Training loop (%)**: The percentage of time spent on **Training loop** over the total **Job duration**.
  - **Finalization (%)**: The percentage of time spent on **Finalization** over the total **Job duration**.

**Resource utilization summary**

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.
### Resource intensive operations

The **Resource intensive operations** section provides more detailed profiling results that show which training job operations were compute intensive. In the following example, it shows that the convolutional neural network backward pass operators were the most resource intensive on the GPUs.

### Insights

In the **Insights** pane, you can find training issues detected by Debugger built-in rules. You can expand each entry in the list to find useful insights, suggestions, a description of the rule, and criteria for initiating the rule.

For more information about the Debugger built-in rules, see *List of Debugger Built-in Rules (p. 2065).*
Debugger Insights – Nodes

On the Nodes tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

CPU and Network utilization

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores by selecting the labels to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to get a closer look at specific time windows.
**GPU and GPU memory utilization**

The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of an Amazon EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.
Overall system utilization over time

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU core is listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out which color level corresponds to which utilization rate. For example, in the following heatmap, after the initialization phase has ended, around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance: the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

System resource utilization over time and framework event phase

The System metrics over time graph shows the overall CPU, GPU, and data I/O utilization. The Framework metrics over time graph shows the framework metrics, which are the framework event phases that you can correlate with the System metrics over time graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find which time interval was actually spent for the training loop and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.
Time spent in training

The following graph shows framework metrics from the last 30 steps of the last training loop, with cumulative time spent by different events in each step.

Debugger Insights – Model Insights

On the Model insights tab, you can browse autogenerated training reports for SageMaker XGBoost training jobs. The report provides insights into XGBoost training jobs, such as improvement in accuracy over time, loss value with respect to iteration, class imbalance, and other statistics to evaluate model performance. Depending on the type of supervised learning (binary classification, multi classification,
and regression), the **Model insights** tab is rendered automatically based on the Debugger's XGBoost training HTML report.

**Note**
This feature is available for SageMaker XGBoost training jobs. The training jobs must be initiated using the SageMaker XGBoost training containers version 1.2-1 or later.

**Note**
In the report, plots and recommendations are provided for informational purposes only and are not definitive. You are responsible for making your own independent assessment of the information.

To load model insights content, enable the CreateXgboostReport (p. 2077) rule when you start the training job. For more information about enabling the rule through the SageMaker estimator, see Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 2152).

For more information about the content on the model insights tab, see Debugger XGBoost Training Report Walkthrough.

To download the HTML report, follow the instructions at Download the Debugger XGBoost Training Report.

The following GIF image shows an example view of the **Model insights** tab for a SageMaker XGBoost training job.

**Shut Down the Amazon SageMaker Debugger Insights Instance**

When you are not using the Debugger insights dashboard, shut down the instance on which it runs to avoid incurring additional fees.

*To shut down the Debugger insights instance in Studio*
1. In Studio, select the Running Instances and Kernels icon ( ))
2. Under the RUNNING APPS list, look for the sagemaker-debugger-1.0 app. Select the shutdown icon ( )) next to the app. The Debugger insights dashboards run on an ml.m5.4xlarge instance. This instance also disappears from the RUNNING INSTANCES when you shut down the sagemaker-debugger-1.0 app.

Amazon SageMaker Debugger in Studio Experiments

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

Visualize Tensors Using Debugger and Studio

Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.
Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.

Initiating Rules and Viewing Logs from Jobs

When rules are initiated for anomalous conditions, Studio presents logs for the failing rule to help you to analyze the causes of the condition.
SageMaker Debugger Interactive Reports

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger Profiling Report (p. 2141).

**Note**
You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules' evaluation status. You can download a complete Debugger report only after the training job has completed.

**Important**
In the reports, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- SageMaker Debugger Profiling Report (p. 2141)
- SageMaker Debugger XGBoost Training Report (p. 2152)
SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger ProfilerReport (p. 2067) rule invokes all of the monitoring and profiling rules (p. 2065) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

**Important**

In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Download a Debugger Profiling Report (p. 2141)
- Debugger Profiling Report Walkthrough (p. 2144)

Download a Debugger Profiling Report

Download the Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

**Tip**

You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 2125).

Download using SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.

$$\text{estimator.output\_path}$$
2. Check the current job name.

```python
estimator.latest_training_job.job_name
```

3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/ <training-job-name>/rule-output`. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under an autogenerated folder that's named as `ProfilerReport-1234567890`. The folder name is a combination of strings: `ProfilerReport` and a unique 10-digit tag based on the Unix timestamp when the ProfilerReport rule is initiated.

```
file (8)
2020-11-08 21:41:31 -104845 bytes
2020-11-08 21:41:31 -107091 bytes
2020-11-08 21:41:31 -102015 bytes
2020-11-08 21:41:31 -107091 bytes
2020-11-08 21:41:31 -102015 bytes
2020-11-08 21:41:31 -104845 bytes
2020-11-08 21:41:31 -107091 bytes
2020-11-08 21:41:31 -102015 bytes
```

The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```

**Tip**

If using a Jupyter notebook server, run `!pwd` to double check the current working directory.

6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-report.html`. If using JupyterLab, choose **Trust HTML** to see the autogenerated Debugger profiling report.

7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also customize and extend the profiling report using the Jupyter notebook file.

**Download using Amazon S3 Console**

1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).
2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: sagemaker-<region>-111122223333. Look up the base S3 bucket through the **Find bucket by name** field.

![Find bucket by name](image)

3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the **Find objects by prefix** input field. Choose the training job name.

![Find objects by prefix](image)

4. In the training job’s S3 bucket, there must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`. Choose `rule-output/`.

![Objects](image)

5. In the `rule-output/` folder, choose **ProfilerReport-1234567890**, and choose `profiler-output/` folder. The `profiler-output/` folder contains `profiler-report.html` (the autogenerated profiling report in html), `profiler-report.ipynb` (a Jupyter notebook with scripts that are used for generating the report), and a `profiler-report/` folder (contains rule analysis JSON files that are used as components of the report).

6. Select the `profiler-report.html` file, choose **Actions**, and **Download**.
7. Open the downloaded `profiler-report.html` file in a web browser.

**Note**
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators.

To learn how to configure the `profiler_config` parameter before starting a training job, see Configure Debugger Framework Profiling (p. 2037).

To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration (p. 2041).

**Debugger Profiling Report Walkthrough**

This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

**Important**
In the report, plots and and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**
- Training Job Summary (p. 2145)
- System Usage Statistics (p. 2146)
Training Job Summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

### Training job summary

The following table gives a summary about the training job. The table includes information about when the training job started and ended, how much time initialization, training loop and finalization took. Your training job started on 11/26/2020 at 23:12:42 and ran for 707 seconds.

<table>
<thead>
<tr>
<th>#</th>
<th>Job Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start time 23:12:42 11/26/2020</td>
</tr>
<tr>
<td>1</td>
<td>End time 23:24:50 11/26/2020</td>
</tr>
<tr>
<td>2</td>
<td>Job duration 737 seconds</td>
</tr>
<tr>
<td>3</td>
<td>Training loop start 23:17:31 11/26/2020</td>
</tr>
<tr>
<td>4</td>
<td>Training loop end 23:44:59 11/26/2020</td>
</tr>
<tr>
<td>5</td>
<td>Training loop duration 446 seconds</td>
</tr>
<tr>
<td>6</td>
<td>Initialization time 288 seconds</td>
</tr>
<tr>
<td>7</td>
<td>Finalization time 9 seconds</td>
</tr>
<tr>
<td>8</td>
<td>Initialization 36 %</td>
</tr>
<tr>
<td>9</td>
<td>Training loop 60 %</td>
</tr>
<tr>
<td>10</td>
<td>Finalization 0 %</td>
</tr>
</tbody>
</table>

The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the **start_time** to the **end_time**.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the **start_time** to the **training_loop_start** time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the **training_loop_end** time to the **end_time**.
- **initialization (%)** – The percentage of time spent on **initialization** over the total **job_duration_in_seconds**.
• **training loop (%)** – The percentage of time spent on training loop over the total job_duration_in_seconds.

• **finalization (%)** – The percentage of time spent on finalization over the total job_duration_in_seconds.

### System Usage Statistics

In this section, you can see an overview of system utilization statistics.

#### System usage statistics

The 99th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized.

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also includes total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p95 and p50 percentiles.

<table>

<td>3.77828125</td>
<td>0</td>
</tr>
</tbody>
</table>

The Debugger profiling report includes the following information:

• **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.

• **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.

• **unit** – The unit of the system metrics.

• **max** – The maximum value of each system metric.

• **p99** – The 99th percentile of each system utilization.

• **p95** – The 95th percentile of each system utilization.

• **p50** – The 50th percentile (median) of each system utilization.

• **min** – The minimum value of each system metric.

### Framework metrics summary

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.
Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

**Overview: CPU Operators**

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.
Overview: CPU operators

The following table shows a list of operators that your training job run on CPU. The most expensive operator on CPU was "CudnnConvolutionBackward" with 31%.

<table>

Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that’s causing step duration outliers.

GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
CPU Bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above cpu_threshold (90% by default) and also if the GPU utilization is below gpu_threshold (10% by default).

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.

The following pie chart shows a breakdown of the CPU/GPU operations that happened during CPU bottlenecks. It shows that 24% of the time was spent in executing operations in `cpu_forward`.
• **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.

• **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

### I/O Bottlenecks

In this section, you can find a summary of I/O bottlenecks. The rule evaluates the I/O wait time and GPU utilization rates and monitors if the time spent on the I/O requests exceeds a threshold percent of the total training time. It might indicate I/O bottlenecks where GPUs are waiting for data to arrive from storage.

### LoadBalancing in Multi-GPU Training

In this section, you can identify workload balancing issue across GPUs.

![LoadBalancing in Multi-GPU Training](image)

### GPU Memory Analysis

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

![GPU Memory Analysis](image)
SageMaker Debugger XGBoost Training Report

For SageMaker XGBoost training jobs, use the Debugger `CreateXgboostReport` rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the `CreateXgboostReport` rule while constructing an XGBoost estimator, download the report using the Amazon SageMaker Python SDK or the Amazon S3 console, and gain insights into the training results.

**Important**

In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

**Topics**

- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 2152)
- Download the Debugger XGBoost Training Report (p. 2153)
- Debugger XGBoost Training Report Walkthrough (p. 2155)

Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule

The `CreateXgboostReport` rule collects the following output tensors from your training job:

- **hyperparameters** – Saves at the first step.
- **metrics** – Saves loss and accuracy every 5 steps.
- **feature_importance** – Saves every 5 steps.
- **predictions** – Saves every 5 steps.
- **labels** – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

Using the SageMaker generic estimator

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules = [
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator = Estimator(  
    role=sagemaker.get_execution_role(),  
    image_uri=xgboost_container,  
    base_job_name="debugger-xgboost-report-demo",  
    instance_count=1,  
    instance_type="ml.m5.2xlarge",  
)  
```
# Add the Debugger XGBoost report rule
rules=rules
)
estimator.fit(wait=False)

Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Download using the SageMaker Python SDK and AWS CLI

1. Check the current job's default S3 output base URI.
estimator.output_path

2. Check the current job name.
estimator.latest_training_job.job_name

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/
<training-job-name>/rule-output`. Configure the rule output path as follows:

```
rule_output_path = estimator.output_path + "/" +
estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the
`rule_output_path` using `aws s3 ls` with the `--recursive` option.

```
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under autogenerated folders that are named
`CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger Profiling Report (p. 2141).

```
! aws s3 ls {rule_output_path} --recursive
```

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that's used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```
! aws s3 cp {rule_output_path} ./ --recursive
```
Tip
If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose Trust HTML to see the autogenerated Debugger training report.

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in Find objects by prefix and then choosing the training job name.
4. In the training job's S3 bucket, choose rule-output/ subfolder. There must be three subfolders for training data collected by Debugger: debug-output/, profiler-output/, and rule-output/.

5. In the rule-output/ folder, choose the CreateXgboostReport/ folder. The folder contains xboost_report.html (the autogenerated report in html) and xboost_report.ipynb (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the xboost_report.html file, choose Download actions, and then choose Download.

7. Open the downloaded xboost_report.html file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.
Important
In the report, plots and recommendations are provided for informational purposes and are not definitive. You are responsible for making your own independent assessment of the information.

Topics
- Distribution of True Labels of the Dataset (p. 2156)
- Loss versus Step Graph (p. 2156)
- Feature Importance (p. 2157)
- Confusion Matrix (p. 2158)
- Evaluation of the Confusion Matrix (p. 2159)
- Accuracy Rate of Each Diagonal Element Over Iteration (p. 2160)
- Receiver Operating Characteristic Curve (p. 2161)
- Distribution of Residuals at the Last Saved Step (p. 2162)
- Absolute Validation Error per Label Bin Over Iteration (p. 2163)

Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

Loss versus Step Graph

This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it’s also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Overall Accuracy
Overall Accuracy: 0.919

Micro Performance Metrics
Performance metrics calculated globally by counting the total true positives, false negatives, and false positives.

  Micro Precision: 0.919
  Micro Recall: 0.919
  Micro F1-score: 0.919

Macro Performance Metrics
Performance metrics calculated for each label, and find their unweighted mean. This does not take the class imbalance problem into account.

  Macro Precision: 0.919
  Macro Recall: 0.918
  Macro F1-score: 0.918

Weighted Performance Metrics
Performance metrics calculated for each label and their average weighted by support (the number of true instances for each label). This extends the macro option to take the class imbalance into account. It might result in an F-score that is not between precision and recall.

  Weighted Precision: 0.92
  Weighted Recall: 0.919
  Weighted F1-score: 0.919

Classification Report
The summary of the precision, recall, and F1-score for each class.

<table>
<thead>

  weighted avg| 0.92 | 12000    |

Accuracy Rate of Each Diagonal Element Over Iteration
This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that’s centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

**To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel)**

```
! pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

**Analyze system and framework metrics**

- Access the Monitoring and Profiling Data (p. 2164)
- Plot the System Metrics and Framework Metrics Data (p. 2165)
- Access the Profiling Data Using the Pandas Data Parsing Tool (p. 2166)
- Access the Python Profiling Stats Data (p. 2167)
- Merge Timelines of Different Profiling Trace Files (p. 2169)
- Profiling Data Loader (p. 2171)

**Access the Monitoring and Profiling Data**

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

**To set up a `TrainingJob` object and retrieve profiling event files of a training job**

```python
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

**Tip**

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

```python
import sagemaker
training_job_name=estimator.latest_training_job.job_name
region=sagemaker.Session().boto_region_name
```

- Pass strings directly.

```python
training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
region="us-west-2"
```

**Note**

By default, SageMaker Debugger collects system metrics to monitor hardware resource utilization and system bottlenecks. Running the following functions, you might receive error messages regarding unavailability of framework metrics. To retrieve framework profiling data and gain insights into framework operations, you must enable framework profiling.
• If you use SageMaker Python SDK to manipulate your training job request, pass the `framework_profile_params` to the `profiler_config` argument of your estimator. To learn more, see Configure SageMaker Debugger Framework Profiling.

• If you use Studio, turn on profiling using the Profiling toggle button in the Debugger insights dashboard. To learn more, see SageMaker Debugger Insights Dashboard Controller.

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```python
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```

To check if the system and framework metrics are available from the S3 URI

```python
tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```python
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```python
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the System Metrics and Framework Metrics Data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=\["GPU\]`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=\["total\]`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- The MetricsHistogram class

```python
from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram
metrics_histogram = MetricsHistogram(system_metrics_reader)
metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=\["CPU", "GPU", "I/O\], # optional
    select_events=\["total"] # optional
)```
• The `StepTimelineChart` class

```python
from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart

view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
```

• The `StepHistogram` class

```python
from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram

step_histogram = StepHistogram(framework_metrics_reader)
step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
    endtime=step_histogram.last_timestamp,
    show_workers=True
)
```

• The `TimelineCharts` class

```python
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts

view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"] # optional
)
view_timeline_charts.plot_detailed_profiler_data([700,710])
```

• The `Heatmap` class

```python
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap

view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=["CPU", "GPU", "I/O"], # optional
    select_events=["total"], # optional
    plot_height=450
)
```

Access the Profiling Data Using the Pandas Data Parsing Tool

The following `PandasFrame` class provides tools to convert the collected profiling data to Pandas data frame.

```python
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame

pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics()
```

The `PandasFrame` class takes the `tj` object’s S3 bucket output path, and its methods `get_all_system_metrics()` and `get_all_framework_metrics()` return system metrics and framework metrics in the Pandas data format.
Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.

For training modes, use the following `PythonProfileModes` class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```python
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

Python Profiling Analysis Tools
Debugger supports the Python profiling with two profiling tools:

- **cProfile** – The standard python profiler. cProfile collects framework metrics on CPU time for every function called when profiling was enabled.
- **Pyinstrument** – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 2039).

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.

```python
from smdebug.profiler.analysis.python_profile_analysis import PythonProfileAnalysis, cProfileAnalysis, PyinstrumentAnalysis
```

To set Python profiling objects for analysis, use the `cProfileAnalysis` or `PyinstrumentAnalysis` classes as shown in the following example code. It shows how to set a `cProfileAnalysis` object, and if you want to use `PyinstrumentAnalysis`, replace the class name.

```python
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the `cProfileAnalysis` and `PyinstrumentAnalysis` classes to fetch the Python profiling stats data:

- **`python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)`** – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.
- **`python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)`** – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies $\text{start_step} \leq \text{step} < \text{end_step}$.
  - **start_step** and **end_step** (str) – Specify the start step and end step to fetch the Python profiling stats data.
  - **mode** (str) – Specify the mode of training job using the `PythonProfileModes` enumerator class. The default is `PythonProfileModes.TRAIN`. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2167) section.
  - **start_phase** (str) – Specify the start phase in the target step(s) using the `StepPhase` enumerator class. This parameter enables profiling between different phases of training. The default is `StepPhase.STEP_START`. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2167) section.
  - **end_phase** (str) – Specify the end phase in the target step(s) using the `StepPhase` enumerator class. This parameter sets up the end phase of training. Available options are as same as the ones for the `start_phase` parameter. The default is `StepPhase.STEP_END`. Available options are provided in the Training Modes and Phases for Python Profiling (p. 2167) section.
- **`python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)`** – Fetches stats from the Python profiling between the start and end modes.
- **`python_analysis.fetch_pre_step_zero_profile_stats()`** – Fetches the stats from the Python profiling until step 0.
- **`python_analysis.fetch_post_hook_close_profile_stats()`** – Fetches stats from the Python profiling after the hook is closed.
**python_analysis.list_profile_stats()** – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).

**python_analysis.list_available_node_ids()** – Returns a list the available node IDs for the Python profiling stats.

The `cProfileAnalysis` class specific methods:

**fetch_profile_stats_by_training_phase()** – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are \((\text{PRE\_STEP\_ZERO, TRAIN}), (\text{TRAIN, TRAIN}), (\text{TRAIN, EVAL}), (\text{EVAL, EVAL}), \text{and (EVAL, POST\_HOOK\_CLOSE)})\). All stats files within each of these combinations are aggregated.

**fetch_profile_stats_by_job_phase()** – Fetches and aggregates the Python profiling stats by job phase. The job phases are \(\text{initialization} \) (profiling until step 0), \(\text{training\_loop} \) (training and validation), and \(\text{finalization} \) (profiling after the hook is closed).

### Merge Timelines of Different Profiling Trace Files

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

**Tip**

Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the Monitoring and Profiling Data (p. 2164).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- TensorFlow profiler saves events in a `*trace.json.gz` file.

**Tip**

If you want to list all of the JSON trace files, use the following AWS CLI command:

```
! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.
Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following `MergedTimeline` API operation and class method from the `smdebug.profiler.analysis.utils.merge_timelines` module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The `MergedTimeline` API operation passes the following parameters:

- **path (str)** – Specify a root folder (``/profiler-output``) that contains system and framework profiling trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the TrainingJob object. For example, `estimator.latest_job_profiler_artifacts_path()` or `tj.profiler_s3_output_path`.
- **file_suffix_filter (list)** – Specify a list of file suffix filters to merge timelines. Available suffix filters are ["model_timeline.json", "pythontimeline.json", "trace.json.gz"). If this parameter is not manually specified, all of the trace files are merged by default.
- **output_directory (str)** – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- **start (int)** – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- **end (int)** – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
• unit (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the merge_timeline() method and download the merged JSON file.

• Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

• Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline

combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```

Open the Chrome tracing app at chrome://tracing on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

### Profiling Data Loader

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```python
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the Profiling Data Using the Pandas Data Parsing Tool (p. 2166) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The SMDebug S3SystemMetricsReader class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

• `pt_analysis.analyze_dataloaderIter_initialization()`

  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e. duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.
The following list shows what analysis is available from this class method:
- Which type of data loader iterators were initialized.
- The number of workers per iterator.
- Inspect whether the iterator was initialized with or without pin_memory.
- Number of times the iterators were initialized during training.
- `pt_analysis.analyze_dataloaderWorkers()`

The following list shows what analysis is available from this class method:
- The number of worker processes that were spun off during the entire training.
- Median and maximum duration for the worker processes.
- Start and end time for the worker processes that are outliers.
- `pt_analysis.analyze_dataloader_getnext()`

The following list shows what analysis is available from this class method:
- Number of GetNext calls made during the training.
- Median and maximum duration in microseconds for GetNext calls.
- Start time, End time, duration and worker id for the outlier GetNext call duration.
- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=['.*'], select_dimensions=['.*'])`

Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

The following list shows what analysis is available from this class method:
- Profile time spent on each data batch, `BatchTime_in_seconds`, by finding the difference between start times of current and subsequent GetNext calls.
- Find the outliers in `BatchTime_in_seconds` and start and end time for those outliers.
- Obtain the system and framework metrics during those `BatchTime_in_seconds` timestamps. This indicates where the time was spent.
- `pt_analysis.plot_the_window()`

Plots a timeline charts between a start timestamp and the end timestamp.

Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.
You can enable this by passing `DebuggerHookConfig` and `TensorBoardOutputConfig` objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container's local path (the default path is `/opt/ml/output/tensors`) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

To save TensorBoard compatible output tensor files using Debugger

1. Set up a `tensorboard_output_config` configuration object to save TensorBoard output using the Debugger `TensorBoardOutputConfig` class. For the `s3_output_path` parameter, specify the default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the `container_local_output_path` parameter; instead, it is set to the default local path `/opt/ml/output/tensors`.

```python
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(s3_output_path='s3://{}'.format(bucket))
```

For additional information, see the Debugger `TensorBoardOutputConfig` API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default `save_interval` value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

```python
import sagemaker
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(hook_parameters={
    "train.save_interval": "100",
    "eval.save_interval": "10"
},
```
collection_configs=[
    CollectionConfig("weights"),
    CollectionConfig(
        name="biases",
        parameters={
            "save_interval": "10",
            "end_step": "500",
            "save_histogram": "True"
        }
    ),
]
)

For more information about the Debugger configuration APIs, see the Debugger CollectionConfig and DebuggerHookConfig APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace estimator and Estimator with other SageMaker frameworks' estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are TensorFlow, PyTorch, and MXNet.

```python
from sagemaker.estimator import Estimator
estimator = Estimator(
    ...
    # Debugger parameters
d debugger_hook_config=hook_config,
tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```

The estimator.fit() method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use
  estimator.latest_job_debugger_artifacts_path().
- For the TensorBoard S3 output path, use
  estimator.latest_job_tensorboard_artifacts_path().

4. After the training has completed, check the names of saved output tensors:

```python
from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```python
tensorboard_output_path=estimator.latest_job_tensorboard_artifacts_path()
print(tensorboard_output_path)
!aws s3 ls {tensorboard_output_path}/
```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to /logs/fit under the current working directory of your notebook instance.

```bash
!aws s3 cp --recursive {tensorboard_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.
Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

Topics

- Choose a Machine Learning Framework (p. 2175)
- Use Studio Debugger Insights Dashboard (p. 2175)
- Download Debugger Reports and Gain More Insights (p. 2175)
- Capture Data from Your Training Job and Save Data to Amazon S3 (p. 2176)
- Analyze the Data with a Fleet of Debugger Built-in Rules (p. 2176)
- Take Actions Based on the Built-in Rule Status (p. 2176)
- Dive Deep into the Data Using the SMDebug Client Library (p. 2176)
- Monitor and Analyze Training Job Metrics (p. 2176)
- Monitoring System Utilization and Detect Bottlenecks (p. 2177)
- Profiling Framework Operations (p. 2177)
- Debugging Model Output Tensors (p. 2177)

Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers. To learn more, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2032) and Use Debugger with Custom Training Containers (p. 2111).

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see Amazon SageMaker Debugger in Amazon SageMaker Studio (p. 2124).

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find
more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger Interactive Reports (p. 2140).

**Capture Data from Your Training Job and Save Data to Amazon S3**

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure Debugger Hook to Save Tensors (p. 2041).

**Analyze the Data with a Fleet of Debugger Built-in Rules**

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 2047) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 2065). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 2109).

**Take Actions Based on the Built-in Rule Status**

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status, CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 2119).

**Dive Deep into the Data Using the SMDebug Client Library**

You can use the SMDebug tools to access and analyze training data collected by Debugger. The `TrainingJob` and `create_trial` classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze Data Using the SMDebug Client Library (p. 2164).

**Monitor and Analyze Training Job Metrics**

Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see GetMetricStatistics in the Amazon CloudWatch API Reference.

If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as
CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors).

SageMaker Debugger also provides visualizations through Studio and its profiling report. Unlike CloudWatch metrics, which accumulates resource utilization rates of CPU and GPU cores and averages those out across multiple instances, Debugger tracks the utilization rate of each core. This enables you to identify unbalanced usage of hardware resources as you scale up to larger compute clusters. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

### Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2032) and then Configure Debugger Monitoring Hardware System Resource Utilization (p. 2037).

For a full list of available built-in rules for monitoring, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 2065).

### Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2032) and then Configure Debugger Framework Profiling (p. 2037).

For a complete list of available built-in rules for profiling, see Debugger Built-in Rules for Profiling Framework Metrics (p. 2065).

### Debugging Model Output Tensors

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 2020)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.
To learn how to configure Debugger for debugging output tensors, see Configure Debugger Using Amazon SageMaker Python SDK (p. 2032) and then Configure Debugger Hook to Save Tensors (p. 2041).

For a full list of available built-in rules for debugging, see Debugger Built-in Rules for Debugging Model Training Data (Output Tensors) (p. 2066).

Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

Topics

- Amazon SageMaker Debugger API Operations (p. 2178)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 2179)
- Amazon SageMaker Debugger Exceptions (p. 2181)
- Considerations for Amazon SageMaker Debugger (p. 2182)
- Amazon SageMaker Debugger Usage Statistics (p. 2184)

Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source SMDebug Python library at awslabs/sagemaker-debugger that is used to configure built-in rules, define custom rules, and register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- CreateTrainingJob and UpdateTrainingJob use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - CollectionConfiguration
  - DebugHookConfig
  - DebugRuleConfiguration
  - TensorBoardOutputConfig
  - ProfilerConfig
  - ProfilerRuleConfiguration
- DescribeTrainingJob provides a full description of a training job, including the following Debugger configurations and rule evaluation statuses:
  - DebugHookConfig
  - DebugRuleConfiguration
  - DebugRuleEvaluationStatus
  - ProfilerConfig
  - ProfilerRuleConfiguration
• **ProfilerRuleEvaluationStatus**

The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see [Process Data](p. 918).

### Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the `ConfigureTrainingJob` API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the `CreateTrainingJob` API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

**Topics**

- [Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators](p. 2179)
- [Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators](p. 2180)

### Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name:** sagemaker-debugger-rules

**Tag:** latest

**Example of a full registry URL:**

`904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest`

### Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the `smdebug.exceptions` module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:

- **TensorUnavailableForStep** – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.
• **TensorUnavailable** – This tensor is not being saved or has not been saved by the `smdebug` API. This means that this tensor is never seen for any step in `smdebug`.
• **StepUnavailable** – The step was not saved and Debugger has no data from the step.
• **StepNotYetAvailable** – The step has not yet been seen by `smdebug`. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
• **NoMoreData** – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
• **IndexReaderException** – The index reader is not valid.
• **InvalidWorker** – A worker was invoked that was not valid.
• **RuleEvaluationConditionMet** – Evaluation of the rule at the step resulted in the condition being met.
• **InsufficientInformationForRuleInvocation** – Insufficient information was provided to invoke the rule.

## Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

### Considerations for Distributed Training

The following list shows the scope of validity and considerations for using Debugger on training jobs with deep learning frameworks and various distributed training options.

- **Horovod**

  **Scope of validity of using Debugger for training jobs with Horovod**

<table>
<thead>
<tr>

<td>Yes</td>
</tr>
</tbody>
</table>
Deep Learning Framework | TensorFlow 2.x | TensorFlow 2.x with Keras | PyTorch
--- | --- | --- | ---
Debugging model output tensors | Yes | Yes | Yes

* Debugger does not support framework profiling for TensorFlow 2.x.

** SageMaker distributed data parallel does not support TensorFlow 2.x with Keras implementation.

- **SageMaker distributed model parallel** – Debugger does not support SageMaker distributed model parallel training.
- **Distributed training with SageMaker checkpoints** – Debugger is not available for training jobs when both the distributed training option and SageMaker checkpoints are enabled. You might see an error that looks like the following:

    SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled

To use Debugger for training jobs with distributed training options, you need to disable SageMaker checkpointing and add manual checkpointing functions to your training script. For more information about using Debugger with distributed training options and checkpoints, see Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 2248) and Saving Checkpoints (p. 2298).

- **Parameter Server** – Debugger does not support parameter server-based distributed training.
- **Profiling distributed training framework operations**, such as the `AllReduced` operation of SageMaker distributed data parallel and Horovod operations, is not available.

**Considerations for Monitoring System Bottlenecks and Profiling Framework Operations**

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured and end in "/". For example:

    ```python
    FrameworkProfile(local_path="/opt/ml/output/profiler/")
    ```

- For AWS TensorFlow, the data loader profiling configuration cannot be updated while a training job is running.
- For AWS TensorFlow, a `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
- Python profiling and detailed profiling are only supported for Keras API.
- To access the deep profiling feature for TensorFlow and PyTorch, currently you must specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:
   - For TensorFlow

     ```python
     image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
     ```
   - For PyTorch

     ```python
     image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
     ```
Considerations for Debugging Model Output Tensors

- Avoid using functional API operations. Debugger cannot collect model output tensors from PyTorch and MXNet training scripts composed of functional API operations.
- Debugger cannot collect model output tensors from the `torch.nn.functional` API operations. When you write a PyTorch training script, it is recommended to use the `torch.nn` modules instead.
- Debugger cannot collect model output tensors from MXNet functional objects in hybrid blocks. For example, the ReLu activation (`F.relu`) outputs cannot be collected from the following example of `mxnet.gluon.HybridBlock` with `F` in the `hybrid_forward` function.

```python
import mxnet as mx
from mxnet.gluon import HybridBlock

class Model(HybridBlock):
    def __init__(self, **kwargs):
        super(Model, self).__init__(**kwargs)
        # use name_scope to give child Blocks appropriate names.
        with self.name_scope():
            self.dense0 = nn.Dense(20)
            self.dense1 = nn.Dense(20)

    def hybrid_forward(self, F, x):
        x = F.relu(self.dense0(x))
        return F.relu(self.dense1(x))

model = Model()
model.initialize(ctx=mx.cpu(0))
model.hybridize()
model(mx.nd.zeros((10, 10), ctx=mx.cpu(0)))
```

Amazon SageMaker Debugger Usage Statistics

Consider the following when using autogenerated reports by Amazon SageMaker Debugger.

Debugger Profiling Report Usage

Debugger collects profiling report usage statistics by including code in the Jupyter notebook that collects the unique `ProfilerReport` rule's processing job ARN if the user opens the final `profiler-report.html` file.

Debugger only collects information about whether a user opens the final HTML report. It DOES NOT collect any information from training jobs, training data, training scripts, processing jobs, logs, or the content of the profiling report itself.

You can opt out of the collection of usage statistics using either of the following options.

**(Recommended) Option 1: Opt Out before Running a Training Job**

To opt out, you need to add the following Debugger `ProfilerReport` rule configuration to your training job request.

SageMaker Python SDK

```python
estimator=sagemaker.estimator.Estimator(
```

2184
Option 2: Opt Out after a Training Job Has Completed

To opt out after training has completed, you need to modify the profiler-report.ipynb file.

**Note**

HTML reports autogenerated without Option 1 already added to your training job request still report the usage statistics even after you opt out using Option 2.

1. Follow the instructions on downloading the Debugger profiling report files in the Download a Debugger Profiling Report (p. 2141) page.
2. In the /ProfilerReport-1234567890/profiler-output directory, open profiler-report.ipynb.
3. Add **opt_out=True** to the setup_profiler_report() function in the fifth code cell as shown in the following example code:

   ```python
   setup_profiler_report(processing_job_arn, opt_out=True)
   ```
4. Run the code cell to finish opting out.
Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a binary classification problem on a marketing dataset. Your goal is to maximize the area under the curve (auc) metric of the algorithm by training an XGBoost Algorithm (p. 1956) model. You don't know which values of the eta, alpha, min_child_weight, and max_depth hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see Managed Spot Training in Amazon SageMaker (p. 2375).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm you need to train
- A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see Get Started with Amazon SageMaker (p. 34).

**Topics**

- How Hyperparameter Tuning Works (p. 2186)
- Define Metrics (p. 2188)
- Define Hyperparameter Ranges (p. 2189)
- Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model (p. 2190)

- Best Practices for Hyperparameter Tuning (p. 2212)

**How Hyperparameter Tuning Works**

**Random Search**

In a random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn't depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the search.
Bayesian Search

Bayesian search treats hyperparameter tuning like a [regression] problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose. To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing the first set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses a Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not well understood. The explore/exploit trade-off is common in many machine learning problems.

**Note**

Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process.

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate
your productivity by trying many variations of a model, focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore. Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

Define Metrics

When you use one of the Amazon SageMaker built-in algorithms, you don't need to define metrics. Built-in algorithms automatically send metrics to hyperparameter tuning. You do need to choose one of the metrics that the built-in algorithm emits as the objective metric for the tuning job. For a list of metrics that a built-in algorithm emits, see the model tuning section for the appropriate algorithm listed in Use Amazon SageMaker Built-in Algorithms (p. 982).

To optimize hyperparameters for a machine learning model, a tuning job evaluates the training jobs it launches by using a metric that the training algorithm writes to logs. Amazon SageMaker hyperparameter tuning parses your algorithm's stdout and stderr streams to find algorithm metrics, such as loss or validation-accuracy, that show how well the model is performing on the dataset.

Note
These are the same metrics that SageMaker sends to CloudWatch Logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201).

If you use your own algorithm for hyperparameter tuning, make sure that your algorithm emits at least one metric by writing evaluation data to stderr or stdout.

Note
Hyperparameter tuning sends an additional hyperparameter, _tuning_objective_metric to the training algorithm. This hyperparameter specifies the objective metric being used for the hyperparameter tuning job, so that your algorithm can use that information during training.

You can define up to 20 metrics for your tuning job to monitor. You choose one of those metrics to be the objective metric, which hyperparameter tuning uses to evaluate the training jobs. The hyperparameter tuning job returns the training job that returned the best value for the objective metric as the best training job.

You define metrics for a tuning job by specifying a name and a regular expression for each metric that your tuning job monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. You pass these metrics to the CreateHyperParameterTuningJob operation in the TrainingJobDefinition parameter as the MetricDefinitions field of the AlgorithmSpecification field.

The following example defines 4 metrics:

```json
[
  {
    "Name": "loss",
    "Regex": "Loss = (.*?);",
  },
  {
    "Name": "ganloss",
    "Regex": "GAN_loss=(.*?);",
  },
  {
    "Name": "discloss",
    "Regex": "disc_train_loss=(.*?);",
  },
  {
    "Name": "disc-combined",
    "Regex": "disc-combined=(.*?);",
  },
]```
The following is an example of the log that the algorithm writes:

```
GAN_loss=0.138318;  Scaled_reg=2.654134; disc: [-0.017371, 0.102429] real 93.3% gen 0.0% disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744; Iteration 0 took 0.704s;  Elapsed=0s
```

Use the regular expression (regex) to match the algorithm’s log output and capture the numeric values of metrics. For example, in the regex for the loss metric defined above, the first part of the regex finds the exact text "Loss = ", and the expression `(.*?);` captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, . means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the API, specify the value of the name key in the HyperParameterTuningJobObjective field of the HyperParameterTuningJobConfig parameter that you send to the CreateHyperParameterTuningJob operation.

**Define Hyperparameter Ranges**

Hyperparameter tuning finds the best hyperparameter values for your model by searching over a set of values that you specify for each of the hyperparameters that are tunable. Choosing hyperparameters and ranges significantly affects the performance of your tuning job. For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning (p. 2212).

To define hyperparameter ranges by using the low-level API, you specify the names of hyperparameters and ranges of values in the `ParameterRanges` field of the `HyperParameterTuningJobConfig` parameter that you pass to the `CreateHyperParameterTuningJob` operation. The `ParameterRanges` field has three subfields, one for each of the categorical, integer, and continuous hyperparameter ranges. You can define up to 20 hyperparameters to search over. Each value of a categorical hyperparameter range counts as a hyperparameter against the limit. Hyperparameter ranges have the following structure:

```
"ParameterRanges": {
    "CategoricalParameterRanges": [
        {
            "Name": "tree_method",
            "Values": ["auto", "exact", "approx", "hist"]
        }
    ],
    "ContinuousParameterRanges": [
        {
            "Name": "eta",
            "MaxValue": "0.5",
            "MinValue": "0",
            "ScalingType": "Auto"
        }
    ],
    "IntegerParameterRanges": [
        {
            "Name": "max_depth",
            "MaxValue": "10",
            "MinValue": "1",
            "ScalingType": "Auto"
        }
    ]
}
```
### Hyperparameter Scaling

For integer and continuous hyperparameter ranges, you can choose the scale you want hyperparameter tuning to use to search the range of values by specifying a value for the `ScalingType` field of the hyperparameter range. You can choose from the following scaling types:

**Auto**

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

**Linear**

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude), because uniformly searching values from the range will give you a reasonable exploration of the entire range.

**Logarithmic**

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have only values greater than 0.

Choose logarithmic scaling when you are searching a range that spans several orders of magnitude. For example, if you are tuning a Tune a linear learner model (p. 1872) model, and you specify a range of values between .0001 and 1.0 for the `learning_rate` hyperparameter, searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would, because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between .1 and 1.0, leaving only 10 percent of your training budget for the values between .0001 and .1.

**ReverseLogarithmic**

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Reverse logarithmic scaling works only for ranges that are entirely within the range $0 \leq x < 1.0$.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

For an example notebook that uses hyperparameter scaling, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

### Tune Multiple Algorithms with Hyperparameter Optimization to Find the Best Model

To create a new hyperparameter optimization (HPO) job with Amazon SageMaker that tunes multiple algorithms, you must provide job settings that apply to all of the algorithms to be tested and a training definition for each of these algorithms. You must also specify the resources you want to use for the tuning job.

- **The job settings** to configure include warm starting, early stopping, and the tuning strategy. Warm starting and early stopping are available only when tuning a single algorithm.

- **The training job definition** to specify the name, algorithm source, objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job. It
configures the channels for data inputs, data output locations, and any checkpoint storage locations for each training job. The definition also configures the resources to deploy for each training job, including instance types and counts, managed spot training, and stopping conditions.

- **The tuning job resources**: to deploy, including the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently and the maximum number of training jobs that the hyperparameter tuning job can run.

## Get Started

You can create a new hyperparameter tuning job, clone a job, add or edit tags to a job from the console. You can also use the search feature to find jobs by their name, creation time, or status. Alternatively, you can also hyperparameter tuning jobs with the SageMaker API.

- **In the console**: To create a new job, open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/, choose Hyperparameter tuning jobs from the Training, menu, and then choose Create hyperparameter tuning job. Then following the configuration steps to create a training job for each algorithm that you want to use. These steps are documented in the Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 2191) topic.

  **Note**
  When you start the configuration steps, note that the warm start and early stopping features are not available to use with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

- **With the API**: For instructions on using the SageMaker API to create a hyperparameter tuning job, see Example: Hyperparameter Tuning Job. When you call CreateHyperParameterTuningJob to tune multiple algorithms, you must provide a list of training definitions using TrainingJobDefinitions instead of specifying a single TrainingJobDefinition. You must choose just one of these definition types depending on the number of algorithms being tuned.

## Topics

- Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console) (p. 2191)
- Manage Hyperparameter Tuning and Training Jobs (p. 2195)

## Create a Hyperparameter Optimization Tuning Job for One or More Algorithms (Console)

To create a new hyperparameter optimization (HPO) tuning job for one or more algorithms, you need to define the settings for the tuning job, create training job definitions for each algorithm being tuned, and configure the resources for the tuning job.

## Topics

- Define job settings (p. 2191)
- Create Training Job Definitions (p. 2192)
- Configure Tuning Job Resources (p. 2194)
- Review and Create HPO Tuning Job (p. 2194)

## Define job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.
Warm Start

If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this new tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

Note
Warm start is compatible only with tuning jobs created after October 1, 2018. For more information, see Run a warm start job.

Early Stopping

To reduce compute time and avoid overfitting your model, training jobs can be stopped early when they are unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it’s disabled by default. For more information on how early stopping works, the algorithms that support it, and how to use it with your own algorithms, see Stop Training Jobs Early.

Tuning Strategy

Tuning strategy can be either random or Bayesian. It specifies how the automatic tuning searches over specified hyperparameter ranges. You specify the ranges in a later step. Random search chooses random combinations of values from the specified ranges and can be run concurrently. Bayesian search chooses values based on what is likely to get the best result given what is known about the history of previous selections. For more information search strategies, see How Hyperparameter Tuning Works.

Tags

You enter tags as key-value pairs to assign metadata to tuning jobs to help you manage them. Values are not required. You can use just the key. To see the keys associated with a job, choose the Tags tab on the details page for tuning job. For more information about using tags for tuning jobs, see Manage Hyperparameter Tuning and Training Jobs (p. 2195)

Create Training Job Definitions

To create a training job definition, you need to configure the algorithm and parameters, define the data input and output, and configure resources. You must provide at least one TrainingJobDefinition for each HPO tuning job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a job definition. Cloning a job can save time as it copies all of the job settings, including data channels, S3 storage locations for output artifacts. You can then edit the cloned job just for changes needed to configure the algorithm options.

Topics

- Configure algorithm and parameters (p. 2192)
- Define Data Input and Output (p. 2193)
- Configure Training Job Resources (p. 2194)
- Add or Clone a Training Job (p. 2194)

Configure algorithm and parameters

Each training job definition for a tuning job requires a name, permission to access services, and the specification of algorithm options, an objective metric, and the range of values, when required, to configure the set of hyperparameter values for each training job.

Name
Provide a unique name for the training definition.

Permissions

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let AWS create a role that has the AmazonSageMakerFullAccess IAM policy attached.

Optional Security Settings

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a private VPC.

Note
Inter-container encryption is only available when creating job definitions from the API.

Algorithm Options

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

- If you choose a built-in algorithm, it has the ECR image information prepopulated.
- If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe.
- If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

Metrics

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics. You can define up to 20 metrics for your tuning job to monitor, one of which must be chosen as the objective metric. For more information on how to define a metric for a tuning job, see Define Metrics (p. 2188).

Objective Metric

To find the best training job, set an objective metric and whether to maximize or minimize it. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

Hyperparameter Configuration

When you choose a built-in algorithm, the default values for its hyperparameters are set for you, using ranges that are optimized for the algorithm being tuned. You can change these values as you see fit. For example, instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to static. Each algorithm has different required and optional parameters. For more information, see Best Practices for Hyperparameter Tuning and Define Hyperparameter Ranges.

Define Data Input and Output

Each training job definition for a tuning job must configure the channels for data inputs, data output locations, and optionally any checkpoint storage locations for each training job.

Input Data Configuration

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the
algorithm you chose supports multiple input channels, you can specify those too. For example, when using the XGBoost churn prediction notebook, you could add two channels: train and validation.

Checkpoint Configuration

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs. For more information, see Use Checkpoints in Amazon SageMaker (p. 2376).

Output Data Configuration

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

Configure Training Job Resources

Each training job definition for a tuning job must configures the resources to deploy, including instance types and counts, managed spot training, and stopping conditions.

Resource Configuration

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

Managed spot training

You can save computer costs for jobs if you have flexibility in start and end times by allowing SageMaker to use spare capacity to run jobs. For more information, see Managed Spot Training in Amazon SageMaker (p. 2375).

Stopping condition

The stopping condition specifies the maximum duration allowed per training job.

Add or Clone a Training Job

Once you have created a training job definition for a tuning job, you are returned to the Training Job Definition(s) panel where you can create additional training job definitions to train additional algorithms. You can select the Add training job definition and work through the steps to define a training job again or choose Clone from the Action menu to replicate an existing training job definition and edit it for the new algorithm. The clone option can save time as it copies all of the job's settings, including the data channels, S3 storage locations. For more information on cloning, see Manage Hyperparameter Tuning and Training Jobs (p. 2195)

Configure Tuning Job Resources

Resource Limits

You can specify the maximum number of concurrent training jobs that a hyperparameter tuning job can run concurrently (10 at most) and the maximum number of training jobs that the hyperparameter tuning job can run (500 at most). The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

Review and Create HPO Tuning Job

Review the job settings, the training job definition(s), and resource limits. Then select Create hyperparameter tuning job.
Manage Hyperparameter Tuning and Training Jobs

A tuning job can contain many training jobs and creating and managing these jobs and their definitions can become a complex and onerous task. SageMaker provides tools to help facilitate the management of these jobs. Tuning jobs you have run can be accessed from the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/. Select Hyperparameter tuning job from the Training menu to see the list. This page is also where you start the procedure to create a new tuning job by selecting Create hyperparameter tuning job.

To see the training jobs run a part of a tuning job, select one of the hyperparameter tuning jobs from the list. The tabs on the tuning job page allow you to inspect the training jobs, their definitions, the tags and configuration used for the tuning job, and the best training job found during tuning. You can select the best training job or any of the other training jobs that belong to the tuning job to see all of their settings. From here you can create a model that uses the hyperparameter values found by a training job by selecting Create Model or you can clone the training job by selecting Clone.

Cloning

You can save time by cloning a training job that belongs to a hyperparameter tuning job. Cloning copies all of the job's settings, including data channels, S3 storage locations for output artifacts. You can do this for training jobs you have already run from the tuning job page, as just described, or when you are creating additional training job definitions while creating a hyperparameter tuning job, as described in Add or Clone a Training Job (p. 2194) step of that procedure.

Tagging

Automatic Model Tuning launches multiple training jobs within a single parent tuning job to discover the ideal weighting of model hyperparameters. Tags can be added to the parent tuning job as described in the Define job settings (p. 2191) section and these tags are then propagated to the individual training jobs underneath. Customers can use these tags for purposes such as cost allocation or access control. To add tags using the SageMaker SDK, use AddTags API. For more information about using tagging for AWS resources, see Tagging AWS resources.

Example: Hyperparameter Tuning Job

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm (p. 1956) to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level AWS SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

Prerequisites

To run the code in this example, you need

- An AWS account and an administrator user (p. 35)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance (p. 80)

Topics

- Create a Notebook (p. 2196)
• Get the Amazon SageMaker Boto 3 Client (p. 2196)
• Get the SageMaker Execution Role (p. 2197)
• Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 2197)
• Download, Prepare, and Upload Training Data (p. 2197)
• Configure and Launch a Hyperparameter Tuning Job (p. 2198)
• Monitor the Progress of a Hyperparameter Tuning Job (p. 2202)
• Clean up (p. 2205)

Create a Notebook

Create a Jupyter notebook that contains a pre-installed environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step

Get the Amazon SageMaker Boto 3 Client (p. 2196)

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np  # For performing matrix operations and numerical processing
import pandas as pd  # For manipulating tabular data
import os
region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```

The preceding code cell defines region and smclient objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.
Next Step

Get the SageMaker Execution Role (p. 2197)

Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

```python
from sagemaker import get_execution_role
role = get_execution_role()
print(role)
```

Next Step

Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 2197)

Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

To use a default S3 bucket

Use the following code to specify the default S3 bucket allocated for your SageMaker session. prefix is the path within the bucket where SageMaker stores the data for the current training job.

```python
sess = sagemaker.Session()
bucket = sess.default_bucket() # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

(Optional) To use a specific S3 bucket

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain sagemaker, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```python
bucket = "sagemaker-your-preferred-s3-bucket"
```

Note
The name of the bucket doesn't need to contain sagemaker if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the S3FullAccess permission.

Next Step

Download, Prepare, and Upload Training Data (p. 2197)

Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.
For more information about the dataset and the data transformation that the example performs, see the `hpo_xgboost_direct_marketing_sagemaker_APIs` notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

**Download and Explore the Training Dataset**

To download and explore the dataset, run the following code in your notebook:

```bash
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500) # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)
data
```

**Prepare and Upload Data**

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```python
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0) # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0) # Indicator for individuals not actively employed
model_data = pd.get_dummies(data) # Convert categorical variables to sets of indicators
model_data
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7*len(model_data)), int(0.9*len(model_data))])
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7*len(model_data)), int(0.9*len(model_data))])
pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)], axis=1).to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

**Next Step**

Configure and Launch a Hyperparameter Tuning Job (p. 2198)

**Configure and Launch a Hyperparameter Tuning Job**

To configure and launch a hyperparameter tuning job, complete the following steps.

**Topics**
- Specify the Hyperparameter Tuning Job Settings (p. 2199)
- Configure the Training Jobs (p. 2200)
Specify the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the HyperParameterTuningJobConfig parameter to CreateHyperParameterTuningJob when you create the tuning job.

In this JSON object, you specify:

- The ranges of hyperparameters that you want to tune. For more information, see Define Hyperparameter Ranges (p. 2189)
- The limits of the resource that the hyperparameter tuning job can consume.
- The objective metric for the hyperparameter tuning job. An objective metric is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

Note
To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see Define Metrics (p. 2188).

The hyperparameter tuning job defines ranges for the eta, alpha, min_child_weight, and max_depth hyperparameters of the XGBoost Algorithm (p. 1956) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the validation:auc metric that the algorithm sends to CloudWatch Logs.

```json
tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ],
        "ResourceLimits": {
            "MaxNumberOfTrainingJobs": 20,
            "MaxParallelTrainingJobs": 3
        },
        "Strategy": "Bayesian",
        "HyperParameterTuningJobObjective": {
```
Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the TrainingJobDefinition parameter of the CreateHyperParameterTuningJob call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit.

  **Note**
  
  Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see Define Metrics (p. 2188).

- The container image that specifies the training algorithm.
- The input configuration for your training and test data.
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- The values of algorithm hyperparameters that are not tuned in the tuning job.
- The type of instance to use for the training jobs.
- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the `eval_metric`, `num_round`, `objective`, `rate_drop`, and `tweedie_variance_power` parameters of the XGBoost Algorithm (p. 1956) built-in algorithm.

SageMaker Python SDK v1

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}/{}{}{}train'.format(bucket, prefix)
s3_input_validation = 's3://{}/{}{}{}validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }
    ],
    "HyperParameterTunings": [
        {
            "HyperParameterTuneConfig": {
                "Maximize": true,
                "MetricName": "validation:auc",
                "Type": "Maximize"
            }
        }
    ]
}
```
Example: Hyperparameter Tuning Job

```json
"DataSource": {
    "S3DataSource": {
        "S3DataDistributionType": "FullyReplicated",
        "S3DataType": "S3Prefix",
        "S3Uri": s3_input_validation
    }
}

"OutputDataConfig": {
    "S3OutputPath": "s3:///{}/{}\output".format(bucket, prefix)
},

"ResourceConfig": {
    "InstanceCount": 2,
    "InstanceType": "ml.c4.2xlarge",
    "VolumeSizeInGB": 10
},

"RoleArn": role,

"StaticHyperParameters": {
    "eval_metric": "auc",
    "num_round": "100",
    "objective": "binary:logistic",
    "rate_drop": "0.3",
    "tweedie_variance_power": "1.4"
},

"StoppingCondition": {
    "MaxRuntimeInSeconds": 43200
}
```

SageMaker Python SDK v2

```python
training_image = sagemaker.image_uris.retrieve('xgboost', region, '1.0-1')
s3_input_train = 's3:///{}/{}\train'.format(bucket, prefix)
s3_input_validation = 's3:///{}/{}\validation'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_train
                }
            }
        },
        {
            "ChannelName": "validation",
            "CompressionType": "None",
            "ContentType": "csv",
            "DataSource": {
                "S3DataSource": {
                    "S3DataDistributionType": "FullyReplicated",
                    "S3DataType": "S3Prefix",
                    "S3Uri": s3_input_validation
                }
            }
        }
    ]
}
```
Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the `CreateHyperParameterTuningJob` API. Pass `tuning_job_config`, and `training_job_definition` that you created in previous steps as the values of the parameters.

```
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name,
                                      HyperParameterTuningJobConfig = tuning_job_config,
                                      TrainingJobDefinition = training_job_definition)
```

Next Step

Monitor the Progress of a Hyperparameter Tuning Job (p. 2202)

Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics
- View the Status of the Hyperparameter Tuning Job (p. 2202)
- View the Status of the Training Jobs (p. 2204)
- View the Best Training Job (p. 2205)

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Hyperparameter tuning jobs.
Example: Hyperparameter Tuning Job

SageMaker Domain
- Studio
- RStudio
- Canvas

Images
- Ground Truth
- Notebook
- Processing
- Training
  - Algorithms
  - Training jobs
    - Hyperparameter tuning jobs
- Inference
- Edge Manager
- Augmented AI
- AWS Marketplace
3. In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

**View the Status of the Training Jobs**

**To view the status of the training jobs that the hyperparameter tuning job launched**

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

![Image of the Training job status counter](image)

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.

A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retryable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retryable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.
View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

Next Step

Clean up (p. 2205)

Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

**Note**

If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.

1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.
3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.
4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.
Stop Training Jobs Early

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto 3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the Amazon SageMaker Python SDK, set the `early_stopping_type` parameter of the `HyperParameterTuner` object to `Auto`.
- In the Amazon SageMaker console, in the Create hyperparameter tuning job workflow, under Early stopping, choose Auto.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the hpo_image_classification_early_stopping.ipynb notebook in the Hyperparameter Tuning section of the SageMaker Examples in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 250).

How Early Stopping Works

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

Algorithms That Support Early Stopping

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- Linear Learner Algorithm (p. 1872)—Supported only if you use `objective_loss` as the objective metric.
- XGBoost Algorithm (p. 1956)
- Image Classification Algorithm (p. 1829)
- Object Detection Algorithm (p. 1911)
- Sequence-to-Sequence Algorithm (p. 1943)
- IP Insights (p. 1840)

Note

This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a
metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow

Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see the `tf.keras.callbacks.ProgbarLogger API`.

MXNet

Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see the `mxnet.callback APIs`.

Chainer

Extend chainer by using the `extensions.Evaluator` class. For information, see the `chainer.training.extensions.Evaluator API`.

PyTorch and Spark

There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works (p. 2186). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

Note

Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons you might want to consider warm start include:

- You want to gradually increase the number of training jobs over several tuning jobs based on the results you see after each iteration.
- You get new data, and want to tune a model using the new data.
- You want to change the ranges of hyperparameters that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.

Topics

- Types of Warm Start Tuning Jobs (p. 2208)
- Warm Start Tuning Restrictions (p. 2208)
- Warm Start Tuning Sample Notebook (p. 2209)
Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

**IDENTICAL_DATA_AND_ALGORITHM**

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run a warm start tuning job of type **IDENTICAL_DATA_AND_ALGORITHM**, there is an additional field in the response to `DescribeHyperParameterTuningJob` named `OverallBestTrainingJob`. The value of this field is the `TrainingJobSummary` for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

**TRANSFER_LEARNING**

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.
- The number of total changes from tunable hyperparameters in the parent jobs to static hyperparameters in the new tuning job, plus the number of changes in the values of static hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible
values red and blue, you can change that hyperparameter to static in the new tuning job, that counts as 2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.

- Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly add it as a parent for MyTuningJob3.
- The training jobs launched by every parent job in a warm start tuning job count against the 500 maximum training jobs for a tuning job.
- Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Example Notebooks (p. 250). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook, click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK to create a warm start tuning job.

Topics
- Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3)) (p. 2209)
- Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 2210)

Create a Warm Start Tuning Job (Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker API for Python (Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:

```python
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
    {"HyperParameterTuningJobName" : 'MyParentTuningJob'},
    ],
    "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```

Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
```
Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a WarmStartConfig object.
- Pass the WarmStartConfig object as the value of the warm_start_config argument of a HyperparameterTuner object.
- Call the fit method of the HyperparameterTuner object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification Algorithm (p. 1829) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 2189).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                        'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a WarmStartConfig object.

```python
from sagemaker.tuner import WarmStartConfig, WarmStartTypes

parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(warm_start_type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM, parents={parent_tuning_job_name})
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, imageclassification is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                        image_shape='3,224,224',
                                        num_classes=257,
                                        num_training_samples=15420,
                                        mini_batch_size=128,
                                        epochs=30,
                                        optimizer='sgd',
                                        top_k='2',
                                        precision_dtype='float32',
                                        augmentation_type='crop')
```

Now create the HyperparameterTuner object and pass the WarmStartConfig object that you previously created as the warm_start_config argument.

```python
tuner_warm_start = HyperparameterTuner(imageclassification,
                                        'validation:accuracy',
                                        warm_start_config=warm_start_config)
```
Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```python
tuner_warm_start.fit(
    {'train': s3_input_train, 'validation': s3_input_validation},
    include_cls_metadata=False)
```

---

### Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

- Number of parallel (concurrent) hyperparameter tuning jobs: 100
- Number of hyperparameters that can be searched: 20
  - **Note**: Every possible value in a categorical hyperparameter counts against this limit.
- Number of metrics defined per hyperparameter tuning job: 20
- Number of parallel (concurrent) training jobs per hyperparameter tuning job: 10
  - **Note**: This can be increased to one hundred.
- [Bayesian search strategy] Number of training jobs per hyperparameter tuning job: 500
- [Random search strategy] Number of training jobs per hyperparameter tuning job: 500
  - **Note**: This can be increased up to ten thousand.
- Maximum run time for a hyperparameter tuning job: 30 days

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see [SageMaker Limits](#). Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one `ml.m4.xlarge` instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 500.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training `ml.m4.xlarge` instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
3. On the Case details panel, select SageMaker Automatic Model Tuning [Hyperparameter Optimization] for the Limit type
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.

5. In the Case description panel, provide a description of your use case.
6. In the Contact options panel, select your preferred Contact methods (Web, Chat or Phone) and then choose Submit.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.

Topics

- Choosing the Number of Hyperparameters (p. 2213)
- Choosing Hyperparameter Ranges (p. 2213)
- Using Logarithmic Scales for Hyperparameters (p. 2213)
- Choosing the Best Number of Concurrent Training Jobs (p. 2213)
Choosing the Number of Hyperparameters

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

Choosing Hyperparameter Ranges

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

Using Logarithmic Scales for Hyperparameters

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

Choosing the Best Number of Concurrent Training Jobs

When setting the resource limit MaxParallelTrainingJobs for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

Running Training Jobs on Multiple Instances

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.

Amazon SageMaker Distributed Training Libraries

SageMaker provides distributed training libraries for data parallelism and model parallelism. The libraries are optimized for the SageMaker training environment, help adapt your distributed training jobs to SageMaker, and improve training speed and throughput.

Get Started with Distributed Training

If you’re familiar with distributed training, follow one of the links to your preferred strategy or framework to get started. Otherwise, continue on to the next section to learn some distributed training concepts.

SageMaker distributed training libraries:

- SageMaker's Distributed Data Parallel Library (p. 2221)
- SageMaker's Distributed Model Parallel (p. 2250)

Note
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Basic Distributed Training Concepts

SageMaker's distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: \[ \text{global batch size} = (\text{the number of model replicas}) \times (\text{per-replica batch size}) \]. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker's distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an execution schedule defined by the library’s runtime.

Training

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the
global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.

- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model's ability to converge as well as the speed and optimality of convergence.

**Instances and GPUs**

- **Instances**: An AWS machine learning compute instance. These are also referred to as nodes.

- **Cluster size**: When using SageMaker's distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise, communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between AWS ML compute instances, leading to higher device utilization and faster training times.

**Distributed Training Solutions**

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as AWS ML Instances), and each processing node contains a replica of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple processing nodes (such as AWS ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

**Example**

The following example demonstrates how these terms might be used to describe a training job that uses hybrid model and data parallelism:

A 2-way data parallelism and 4-way model parallelism training job is launched with a global batch size of 64 images. This training job requires a total of 8 GPUs. Each of the two model replicas processes a per-replica batch of size 32. During the forward and backward pass, a per-replica batch is further divided up into micro-batches. These micro-batches are processed in an interleaved fashion using a pipelined execution schedule.

The training dataset includes 640 images, and so a single epoch takes 10 iterations.

**Advanced Concepts**

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better
accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well because they need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called mini-batches. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the most commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware subtracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, such as a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

**Strategies**

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you’re also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker’s distributed model parallel library includes automatic model splitting. The two
core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

**Train with Data Parallel and Model Parallel**

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model's hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.

Try gradient compression (FP16, INT8):

- On NVIDIA TensorCore-equipped hardware, using mixed precision training creates both speed-up and memory consumption reduction.
- SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:
  - Frameworks - PyTorch in the *NVIDIA Deep Learning Performance documentation*
  - Frameworks - TensorFlow in the *NVIDIA Deep Learning Performance documentation*
  - Automatic Mixed Precision for Deep Learning in the *NVIDIA Developer Docs*
  - Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the *PyTorch Blog*
  - TensorFlow mixed precision APIs in the *TensorFlow documentation*

Try reducing the input size:

- Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
- Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

- Your model does not fit on a single device.
- Due to your model size, you're facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

- SageMaker's Distributed Data Parallel Library (p. 2221)
Optimize Distributed Training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework’s distributed training documentation.

- Apache MXNet distributed training
- PyTorch distributed training
- TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

Tip

Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.

A number of techniques have been developed to maintain good model convergence when batch is increased.

Mini-Batch Size

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

- Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Goya et al.

- Accelerated Large Batch Optimization of BERT Pretraining in 54 minutes, Zheng et al.
- Deep Gradient Compression, Lin et al.

Scenarios

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.
Scaling from a Single GPU to Many GPUs

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer than you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

**Note**
The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.

Scaling from a Single Instance to Multiple Instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK's estimator function by setting your instance_count. For example, you can set instance_type = p3.16xlarge and instance_count = 2. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Availability Zones and Network Backplane

With multiple instances, it's important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an AllReduce operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

Optimized GPU, Network, and Storage

The p3dn.24xlarge instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as pipe mode. For HPC loads like distributed training, we recommend Amazon Fsx for your file storage.

Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker's container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker Built-In Distributed Training Features

The SageMaker built-in libraries of algorithms consists of 18 popular machine learning algorithms. Many of them were rewritten from scratch to be scalable and distributed out of the box. If you want to use distributed deep learning training code, we recommend Amazon SageMaker's distributed training libraries. SageMaker's distributed training libraries make it easier for you to write highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs.

SageMaker distributed training libraries offer both data parallel and model parallel training strategies. It combines software and hardware technologies to improve inter-GPU and inter-node communications. It extends SageMaker's training capabilities with built-in options that require only small code changes to your training scripts.

- SageMaker's Distributed Data Parallel Library (p. 2221)
- SageMaker's Distributed Model Parallel (p. 2250)

SageMaker's Distributed Data Parallel Library

The SageMaker distributed data parallel library extends SageMaker training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business
requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

To resolve such overhead problems, SageMaker offers two distributed training options: SageMaker model parallel and SageMaker data parallel. This guide focuses on how to train models using the SageMaker data parallel library.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

To track the latest updates of the library, see the SageMaker Distributed Data Parallel Release Notes in the SageMaker Python SDK documentation.

For more information about training with a model-parallel strategy, see SageMaker's Distributed Model Parallel (p. 2250).

Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker’s distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing AWS’s network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

Note

The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Training Benchmarks

PyTorch with SageMaker's data parallel library
Using instance type p3dn.24xlarge and on 2, 4, and 8 node clusters:

- **BERT**: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- **MaskRCNN**: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using ml.p3dn.24xlarge instances. You can find the training code on the SageMaker examples website. The examples website also has benchmark training code for these models using TensorFlow 2.3.

**Optimal Bandwidth Use with Balanced Fusion Buffer**

SageMaker’s distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing balanced fusion buffers. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers. Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient AllReduce Overlapping with a Backward Pass**

SageMaker’s distributed data parallel library achieves optimal overlapping of the AllReduce operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs AllReduce in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.
• **Leverages CPUs:** The library uses CPUs to AllReduce gradients, offloading this task from the GPUs.
• **Improved GPU usage:** The cluster’s GPUs focus on computing gradients, improving their utilization throughout training.

### SageMaker Distributed Data Parallel Architecture

The library supports larger compute instances that have 8 GPUs per node: `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge`. The high-level workflow of the SageMaker distributed data parallel library is as following:

1. The library assigns ranks to GPUs (workers).
2. At each iteration, the library divides each global batch by the total number of workers (world size) and assigns small batches (batch shards) to the workers.
   - The size of the global batch is \((\text{number of nodes in a cluster}) \times (\text{number of GPUs per node}) \times (\text{per batch shard})\).
   - A batch shard (small batch) is a subset of dataset assigned to each GPU (worker) per iteration.
3. The library launches a training script on each worker.
4. The library manages copies of model weights and gradients from the workers at the end of every iteration.
5. The library synchronizes model weights and gradients across the workers to aggregate a single trained model.

The following architecture diagram shows an example of how the library sets up data parallelism for a cluster of 3 nodes.
To start using the SageMaker distributed data parallel library, see Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2233) to set up a SageMaker estimator through Amazon SageMaker Python SDK, and Run a SageMaker Distributed Training Job with Data Parallelism (p. 2227) to adapt your training script using the SageMaker distributed data parallel library.

**Supported Frameworks, AWS Regions, and Instances Types**

Before using the SageMaker data parallel library, check what are the supported ML frameworks and instance types and if there are enough quotas in your AWS account and AWS Region.

**Supported Frameworks**

The SageMaker data parallel library supports the following deep learning frameworks and is available in AWS Deep Learning Containers (DLC) or downloadable as a binary file.

**PyTorch versions supported by SageMaker and the SageMaker distributed data parallel library**

<table>
<thead>
<tr>
<th>PyTorch version</th>
<th>SageMaker distributed data parallel library version</th>
<th>smdistributed-datatparallel integrated image URI</th>
<th>URL of the binary file**</th>
</tr>
</thead>
<tbody>
<tr>
<td>v1.10.2</td>

</tr>
</tbody>
</table>
**The SageMaker distributed data parallelism library v1.4.0 and later works as a backend of PyTorch distributed. In accordance with the change, the following smdistributed APIs for the PyTorch distributed package are deprecated.**

- `smdistributed.dataparallel.torch.distributed` is deprecated. Use the `torch.distributed` package instead.
- `smdistributed.dataparallel.torch.parallel.DistributedDataParallel` is deprecated. Use the `torch.nn.parallel.DistributedDataParallel` API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker distributed data parallel library documentation in the *SageMaker Python SDK documentation*.

**The URLs of the binary files are for installing the SageMaker distributed data parallelism library in custom containers. For more information, see *Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library* (p. 2236).**

Hugging Face Transformers versions supported by SageMaker and the SageMaker distributed data parallel library

The AWS Deep Learning Containers for Hugging Face use the SageMaker Training Containers for PyTorch and TensorFlow as their base images. To look up the Hugging Face Transformers library versions and paired PyTorch and TensorFlow versions, see the latest Hugging Face Containers and the Prior Hugging Face Container Versions.

AWS Regions

The SageMaker data parallel library is available in all of the AWS Regions where the AWS Deep Learning Containers for SageMaker are in service. For more information, see Available Deep Learning Containers Images.

Supported Instance Types

The SageMaker data parallel library requires one of the following ML instance types.

<table>
<thead>
<tr>
<th>Instance type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml.p3.16xlarge</td>
</tr>
<tr>
<td>ml.p3dn.24xlarge</td>
</tr>
<tr>
<td>ml.p4d.24xlarge</td>
</tr>
</tbody>
</table>

For specs of the instance types, see the Accelerated Computing section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge for training job usage' is 0 Instances, with current utilization of 0 Instances and a request delta of 1 Instances. Please contact AWS support to request an increase for this limit.
```

Run a SageMaker Distributed Training Job with Data Parallelism

SageMaker's distributed data parallel library APIs are designed for ease of use and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API** – In most cases, all you have to change in your training script is the data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- **Focus on your model training without infrastructure management** – When training a deep learning model with the library on SageMaker, you can focus on writing your training script and model training. You can run a training job using estimator classes provided by the SageMaker Python SDK. The estimator classes help prepare ML instances, load datasets from specified data resources, submit the training job using your training script, and shut down the instances after the training job is completed.

To begin, you need to adapt TensorFlow or PyTorch training scripts to use the library. The following topics provide instructions on how to modify your training script.

Topics
Step 1: Modify Your Own Training Script

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed data parallel library. To use the library-specific API functions and parameters, we recommend you use this documentation alongside the *SageMaker data parallel library APIs* in the *SageMaker Python SDK documentation*.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed data parallel library, see *Amazon SageMaker Distributed Training Notebook Examples*.

**Topics**
- Modify a TensorFlow Training Script
- Modify a PyTorch Training Script

Modify a TensorFlow Training Script

The following steps show you how to modify a TensorFlow training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. For additional details on each API that the library offers for TensorFlow, see the *SageMaker distributed data parallel TensorFlow API documentation*.

**Note**
SageMaker distributed data parallel is adaptable to TensorFlow training scripts composed of `tf` core modules except `tf.keras` modules. SageMaker distributed data parallel does not support TensorFlow with Keras implementation.

**Note**
SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to enable AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its `AllReduce` operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- **Frameworks - TensorFlow** in the *NVIDIA Deep Learning Performance documentation*
- **Automatic Mixed Precision for Deep Learning** in the *NVIDIA Developer Docs*
- **TensorFlow mixed precision APIs** in the *TensorFlow documentation*

1. Import the library's TensorFlow client and initialize it.

   ```python
   import smdistributed.dataparallel.tensorflow as sdp
   sdp.init()
   ```

2. Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the following code block as `sdp.local_rank()`. `set_memory_growth` is not directly related to SageMaker distributed, but must be set for distributed training with TensorFlow.
3. Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the following code block as `sdp.size()`.

   ```python
   learning_rate = learning_rate * sdp.size()
   ```

4. Use the library's `DistributedGradientTape` to optimize `AllReduce` operations during training. This wraps `tf.GradientTape`.

   ```python
   with tf.GradientTape() as tape:
       output = model(input)
       loss_value = loss(label, output)
   # SageMaker data parallel: Wrap tf.GradientTape with the library's
   DistributedGradientTape
   tape = sdp.DistributedGradientTape(tape)
   ```

5. Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. Use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the following code block as `sdp.broadcast_variables()`.

   ```python
   sdp.broadcast_variables(model.variables, root_rank=0)
   sdp.broadcast_variables(opt.variables(), root_rank=0)
   ```

6. Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

   ```python
   if sdp.rank() == 0:
       checkpoint.save(checkpoint_dir)
   ```

The following is an example TensorFlow training script for distributed training with the library.

```python
import tensorflow as tf
# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp
# SageMaker data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    # SageMaker data parallel: Pin GPUs to a single library process
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)
# Define Model
```
mnist_model = tf.keras.Sequential(...)  
loss = tf.losses.SparseCategoricalCrossentropy()  

# SageMaker data parallel: Scale Learning Rate  
# LR for 8 node run : 0.000125  
# LR for single node run : 0.001  
opt = tf.optimizers.Adam(0.000125 * sdp.size())  

@tf.function  
def training_step(images, labels, first_batch):  
    with tf.GradientTape() as tape:  
        probs = mnist_model(images, training=True)  
        loss_value = loss(labels, probs)  

        # SageMaker data parallel: Wrap tf.GradientTape with the library's  
        # DistributedGradientTape  
        tape = sdp.DistributedGradientTape(tape)  

        grads = tape.gradient(loss_value, mnist_model.trainable_variables)  
opt.apply_gradients(zip(grads, mnist_model.trainable_variables))  

        if first_batch:  
            # SageMaker data parallel: Broadcast model and optimizer variables  
            sdp.broadcast_variables(mnist_model.variables, root_rank=0)  
            sdp.broadcast_variables(opt.variables(), root_rank=0)  

        return loss_value  

...  

# SageMaker data parallel: Save checkpoints only from master node.  
if sdp.rank() == 0:  
    checkpoint.save(checkpoint_dir)

After you have completed adapting your training script, move on to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2233).

Modify a PyTorch Training Script

In the SageMaker data parallel library v1.4.0 and later, the library is available as a backend option for the PyTorch distributed package. You only need to import the library once at the top of your training script and set it as the PyTorch distributed backend during initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. To find the latest API documentation for the library, see the SageMaker distributed data parallel APIs for PyTorch in the SageMaker Python SDK documentation. To learn more about the PyTorch distributed package and backend options, see Distributed communication package - torch.distributed.

Important

Because the SageMaker distributed data parallelism library v1.4.0 and later works as a backend of PyTorch distributed, the following smdistributed APIs for the PyTorch distributed package are deprecated.

- smdistributed.dataparallel.torch.distributed is deprecated. Use the torch.distributed package instead.
- smdistributed.dataparallel.torch.parallel.DistributedDataParallel is deprecated. Use the torch.nn.parallel.DistributedDataParallel API instead.

If you need to use the previous versions of the library (v1.3.0 or before), see the archived SageMaker distributed data parallel library documentation in the SageMaker Python SDK documentation.
Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed

To use the SageMaker distributed data parallel library, the only thing you need to do is to import the SageMaker distributed data parallel library's PyTorch client (smdistributed.dataparallel.torch.torch_smddp). The client registers smddp as a backend for PyTorch. When you initialize the PyTorch distributed process group using the torch.distributed.init_process_group API, make sure you specify 'smddp' to the backend argument.

```python
import smdistributed.dataparallel.torch.torch_smddp
import torch.distributed as dist
dist.init_process_group(backend='smddp')
```

**Note**

The smddp backend currently does not support creating subprocess groups with the torch.distributed.new_group() API. You cannot use the smddp backend concurrently with other process group backends such as NCCL and Gloo.

If you already have a working PyTorch script and only need to add the backend specification, you can proceed to Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2234) in the Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2233) topic.

If you still need to modify your training script to properly use the PyTorch distributed package, follow the rest of the procedures on this page.

Preparing a PyTorch Training Script for Distributed Training

The following steps provide additional tips on how to prepare your training script to successfully run a distributed training job using PyTorch.

**Note**

In v1.4.0, the SageMaker distributed data parallel library supports the following collective primitive data types of the torch.distributed interface: all_reduce, broadcast, reduce, all_gather, and barrier.

1. Import the PyTorch distributed modules.

```python
import torch
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP
```

2. After parsing arguments and defining a batch size parameter (for example, batch_size=args.batch_size), add two lines of code to resize the batch size per worker (GPU). PyTorch's DataLoader operation does not automatically handle the batch resizing for distributed training.

```python
batch_size //= dist.get_world_size()
batch_size = max(batch_size, 1)
```

3. Pin each GPU to a single SageMaker data parallel library process with local_rank—this refers to the relative rank of the process within a given node.

You can retrieve the rank of the process from the LOCAL_RANK environment variable.

```python
import os
local_rank = os.enviren["LOCAL_RANK"]
torch.cuda.set_device(local_rank)
```
4. After defining a model, wrap it with the PyTorch `DistributedDataParallel` API.

```python
model = ...
# Wrap the model with the PyTorch DistributedDataParallel API
model = DDP(model)
```

5. When you call the `torch.utils.data.distributed.DistributedSampler` API, specify the total number of processes (GPUs) participating in training across all the nodes in the cluster. This is called `world_size`, and you can retrieve the number from the `torch.distributed.get_world_size()` API. Also, specify the rank of each process among all processes using the `torch.distributed.get_rank()` API.

```python
from torch.utils.data.distributed import DistributedSampler
train_sampler = DistributedSampler(  
    train_dataset,  
    num_replicas = dist.get_world_size(),  
    rank = dist.get_rank()  
)
```

6. Modify your script to save checkpoints only on the leader process (rank 0). The leader process has a synchronized model. This also avoids other processes overwriting the checkpoints.

```python
if dist.get_rank() == 0:
    torch.save(...)
```

The following example code shows the structure of a PyTorch training script with `smddp` as the backend.

```python
import os
import torch

# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.torch_smddp

# SageMaker data parallel: Import PyTorch’s distributed API
import torch.distributed as dist
from torch.nn.parallel import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the process group
dist.init_process_group(backend='smddp')

class Net(nn.Module):
    ...
    # Define model

def train(...):
    ...
    # Model training

def test(...):
    ...
    # Model evaluation

def main():
    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size()
    batch_size = max(batch_size, 1)
```
# Prepare dataset

```python
train_dataset = torchvision.datasets.MNIST(...)
```

# SageMaker data parallel: Set num_replicas and rank in DistributedSampler

```python
train_sampler = torch.utils.data.distributed.DistributedSampler(
    train_dataset,
    num_replicas=dist.get_world_size(),
    rank=dist.get_rank())
```

```python
train_loader = torch.utils.data.DataLoader(..)
```

# SageMaker data parallel: Wrap the PyTorch model with the library's DDP

```python
model = DDP(Net().to(device))
```

# SageMaker data parallel: Pin each GPU to a single library process.

```python
local_rank = os.environ['LOCAL_RANK']
torch.cuda.set_device(local_rank)
model.cuda(local_rank)
```

# Train

```python
optimizer = optim.Adadelta(...)
scheduler = StepLR(...)
for epoch in range(1, args.epochs + 1):
    train(...)
    if rank == 0:
        test(...)
    scheduler.step()
```

# SageMaker data parallel: Save model on master node.

```python
if dist.get_rank() == 0:
    torch.save(...)
```

```python
if __name__ == '__main__':
    main()
```

After you have completed adapting your training script, proceed to Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK (p. 2233).

## Step 2: Launch a SageMaker Distributed Training Job Using the SageMaker Python SDK

To run your adapted script in Step 1: Modify Your Own Training Script (p. 2228), start with creating a SageMaker framework or generic estimator object with the prepared training script and the distributed training configuration parameter. You can use the library in any kind of SageMaker environment and web IDEs, such as SageMaker notebook instance and SageMaker Studio.

Use the high-level SageMaker Python SDK to do one of the following:

- If you want to achieve a quick adoption of your distributed training job in SageMaker, configure a SageMaker PyTorch or TensorFlow framework estimator class. The framework estimator picks up your training script and automatically matches the right image URI of the pre-built PyTorch or TensorFlow Deep Learning Containers (DLC), given the value specified to the `framework_version` parameter.

- If you want to extend one of the pre-built containers or build a custom container to create your own ML environment with SageMaker, use the SageMaker generic `Estimator` class and specify the image URI of the custom Docker container hosted in your Amazon Elastic Container Registry (Amazon ECR).

Your training datasets should be stored in Amazon S3 or Amazon FSx for Lustre in the AWS Region in which you are launching your training job. If you use Jupyter notebooks, you should have a SageMaker notebook instance or a SageMaker Studio app running in the same AWS Region. For more information about storing your training data, see the SageMaker Python SDK data inputs documentation.
Tip
We highly recommend that you use Amazon FSx for Lustre instead of Amazon S3 to increase training performance. Amazon FSx has higher throughput and lower latency than Amazon S3.

Choose one of the following topics for instructions on how to run your TensorFlow or PyTorch training scripts. After you launch a training job, you can monitor system utilization and model performance using Amazon SageMaker Debugger (p. 2018) or Amazon CloudWatch.

While you follow instructions in the following topics to learn more about technical details, we also recommend that you try the Amazon SageMaker Distributed Training Notebook Examples (p. 2301) to get started.

Topics
- Using the SageMaker Framework Estimators For PyTorch and TensorFlow (p. 2234)
- Using the SageMaker Generic Estimator to Extend Prebuilt Containers (p. 2235)
- Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2236)

Using the SageMaker Framework Estimators For PyTorch and TensorFlow
You can activate the SageMaker distributed data parallel library by specifying it as the distribution strategy in the SageMaker framework estimator class.

Using the SageMaker PyTorch estimator

```python
from sagemaker.pytorch import PyTorch

pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    py_version="py38",
    framework_version="1.10.2",
    
    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,..8
    instance_count=2,
    
    # Instance types supported by the SageMaker data parallel library:
    # ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
    instance_type="ml.p3.16xlarge",
    
    # Training using the SageMaker data parallel distributed training strategy
    distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }
)

pt_estimator.fit("s3://bucket/path/to/training/data")
```

Using the SageMaker TensorFlow estimator

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="adapted-training-script.py",
    role="SageMakerRole",
    framework_version="2.6.3",
    py_version="py38",
    
    # For running a multi-node distributed training job, specify a value greater than 1
    # Example: 2,3,4,..8
    instance_count=2,
```

2234
# Instance types supported by the SageMaker data parallel library:
# ml.p4d.24xlarge, ml.p3dn.24xlarge, and ml.p3.16xlarge
instance_type="ml.p3.16xlarge",

# Training using the SageMaker data parallel distributed training strategy
distribution={ "smdistributed": { "dataparallel": { "enabled": True } } }

)  

tf_estimator.fit("s3://bucket/path/to/training/data")

The following two parameters of the SageMaker framework estimator are required to activate the SageMaker data parallelism.

**distribution** (dict): A dictionary with information on how to run distributed training (default: None).

- To use `smdistributed.dataparallel` as a distribution strategy, configure a dictionary as shown in the following code:

```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

- `custom_mpi_options` (str)(optional): Custom MPI options. The following is an example of how you can use this parameter when defining `distribution`. To learn more, see Custom MPI Options (p. 2245).

```python
distribution = {
    "smdistributed": {
        "dataparallel": {
            "enabled": True,
            "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"
        }
    }
}
```

**instance_type** (str): A type of Amazon EC2 instance to use.

- If using the `smdistributed` with `dataparallel` distribution strategy, you must use one of the following instance types: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, we recommend that you use an EFA-enabled instance, which are `ml.p3dn.24xlarge` and `ml.p4d.24xlarge`.

### Using the SageMaker Generic Estimator to Extend Prebuilt Containers

You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a prebuilt container or adapt your own container to use the library, you must use one of the images listed in Supported Frameworks (p. 2225).

**Important**

From TensorFlow 2.4.1 and PyTorch 1.8.1, the framework DLCs supports EFA-enabled instance types (`ml.p3dn.24xlarge`, `ml.p4d.24xlarge`). We recommend that you use the DLC images that contain TensorFlow 2.4.1 or later and PyTorch 1.8.1 or later.

For example, if you use PyTorch, your Dockerfile should contain a `FROM` statement similar to the following:
You can further customize your own Docker container to work with SageMaker using the SageMaker Training toolkit and the binary file of the SageMaker distributed data parallel library. To learn more, see the instructions in the following section.

Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library

To build your own Docker container for training and use the SageMaker data parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides instructions on how to create a complete Dockerfile with the minimum set of dependencies for distributed training in SageMaker using the data parallel library.

**Note**
This custom Docker option with the SageMaker data parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the data parallel library

1. Start with a Docker image from NVIDIA CUDA. Use the cuDNN developer versions that contain CUDA runtime and development tools (headers and libraries) to build from the PyTorch source code.

   ```
   FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04
   ```

   **Tip**
   The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. If you want to use the prebuilt DLC images as references while following the rest of the instructions, see the AWS Deep Learning Containers for PyTorch Dockerfiles.

2. Add the following arguments to specify versions of PyTorch and other packages. Also, indicate the Amazon S3 bucket paths to the SageMaker data parallel library and other software to use AWS resources, such as the Amazon S3 plug-in.

   To use versions of the third party libraries other than the ones provided in the following code example, we recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find versions that are tested, compatible, and suitable for your application.

   To find URLs for the `SMDATAPARALLEL_BINARY` argument, see the look up tables at Supported Frameworks (p. 2225).

   ```
   ARG PYTORCH_VERSION=1.10.2
   ARG PYTHONSHORT_VERSION=3.8
   ARG EFA_VERSION=1.14.1
   ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/
   ```

2236
3. Set the following environment variables to properly build SageMaker training components and run
the data parallel library. You use these variables for the components in the subsequent steps.

```bash
# Set ENV variables required to build PyTorch
ENV TORCH_CUDARCHLIST="7.0+PTX 8.0"
ENV TORCH_NVCCFLAGS="-Xfatbin -compress-all"
ENV NCCL_VERSION=2.10.3

# Add OpenMPI to the path.
ENV PATH /opt/amazon/openmpi/bin:$PATH

# Add Conda to path
ENV PATH $CONDA_PREFIX/bin:$PATH

# Set this environment variable for SageMaker to launch SMDDP correctly.
ENV SAGEMAKER_TRAINING_MODULE=sagemaker_pytorch_container.training:main

# Add environment variable for processes to be able to call fork()
ENV RDMAFORK_SAFE=1

# Indicate the container type
ENV DLC_CONTAINER_TYPE=training

# Add EFA and SMDDP to LD library path
ENV LD_LIBRARY_PATH="/opt/conda/lib/python$PYTHON_SHORT_VERSION/site-packages/
smdistributed/dataparallel/lib:$LD_LIBRARY_PATH"
ENV LD_LIBRARY_PATH=/opt/amazon/efa/lib/:$LD_LIBRARY_PATH
```

4. Install or update curl, wget, and git to download and build packages in the subsequent steps.

```bash
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt 
   apt-get update && apt-get install -y --no-install-recommends 
   curl 
   wget 
   git 
   && rm -rf /var/lib/apt/lists/*
```

5. Install Elastic Fabric Adapter (EFA) software for Amazon EC2 network communication.

```bash
RUN DEBIAN_FRONTEND=noninteractive apt-get update
RUN mkdir /tmp/efa 
   && cd /tmp/efa 
   && curl --silent -O https://efa-installer.amazonaws.com/aws-efa-installer-
   $#(EFA_VERSION).tar.gz 
   && tar -xf aws-efa-installer#$(EFA_VERSION).tar.gz 
   && cd aws-efa-installer 
   && ./efa_installer.sh -y --skip-kmod -g 
   && rm -rf /tmp/efa
```

6. Install Conda to handle package management.

```bash
RUN curl -fsSL -v -o ~/miniconda.sh -O https://repo.anaconda.com/miniconda/Miniconda3-
latest-Linux-x86_64.sh $&
   && chmod +x ~/miniconda.sh $&
   ~/miniconda.sh -b -p $CONDA_PREFIX $&
   rm ~/miniconda.sh $&
   $CONDA_PREFIX/bin/conda install -y python#$(PYTHON_SHORT_VERSION) conda-build pyyaml
   numpy ipython $&
```
$CONDA_PREFIX/bin/conda clean -ya

7. Get, build, and install PyTorch and its dependencies. We build PyTorch from the source code because we need to have control of the NCCL version to guarantee compatibility with the AWS OFI NCCL plugin.

a. Following the steps in the PyTorch official dockerfile, install build dependencies and set up ccache to speed up recompilation.

```bash
RUN DEBIAN_FRONTEND=noninteractive \
    apt-get install -y --no-install-recommends \
    build-essential \
    ca-certificates \
    ccache \
    git \
    libjpeg-dev \
    libpng-dev \
    && rm -rf /var/lib/apt/lists/*
# Setup ccache
RUN /usr/sbin/update-ccache-symlinks
RUN mkdir /opt/ccache && ccache --set-config=cache_dir=/opt/ccache
```

b. Install PyTorch's common and Linux dependencies.

```bash
# Common dependencies for PyTorch
RUN conda install astunparse numpy ninja pyyaml mkl mkl-include setuptools cmake cffi
# typing_extensions future six requests dataclasses
# Linux specific dependency for PyTorch
RUN conda install -c pytorch magma-cuda113
```

c. Clone the PyTorch GitHub repository.

```bash
RUN --mount=type=cache,target=/opt/ccache \
    cd / \
    && git clone --recursive https://github.com/pytorch/pytorch -b v${PYTORCH_VERSION}
```

d. Install and build a specific NCCL version. To do this, replace the content in the PyTorch's default NCCL folder (/pytorch/third_party/nccl) with the specific NCCL version from the NVIDIA repository. The NCCL version was set in the step 3 of this guide.

```bash
RUN cd /pytorch/third_party/nccl \
    && rm -rf nccl \
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \
    && cd nccl \
    && make -j64 src.build CUDA_HOME=/usr/local/cuda NVCC_GENCODE="-gencode=arch=compute_70,code=sm_70 -gencode=arch=compute_80,code=sm_80" \
    && make pkg.txz.build \
    && tar -xvf build/pkg/txz/nccl_*.txz -C $CONDA_PREFIX --strip-components=1
```

e. Build and install PyTorch. This process usually takes slightly more than one hour to complete. It is built using the NCCL version downloaded in a previous step.

```bash
RUN cd /pytorch \
    && CMAKE_PREFIX_PATH="$(dirname $(which conda))/../" \
    python setup.py install \
    && rm -rf /pytorch
```

8. Build and install AWS OFI NCCL plugin. This enables libfabric support for the SageMaker data parallel library.
RUN DEBIAN_FRONTEND=noninteractive apt-get update \
    && apt-get install -y --no-install-recommends \
    autoconf \
    automake \
    libtool
RUN mkdir /tmp/efa-ofi-nccl \
    && cd /tmp/efa-ofi-nccl \
    && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \
    && cd aws-ofi-nccl \
    && ./autogen.sh \
    && ./configure --with-libfabric=/opt/amazon/efa \
    --with-mpi=/opt/amazon/openmpi \
    --with-cuda=/usr/local/cuda \
    --with-nccl=$CONDA_PREFIX \
    && make \
    && make install \
    && rm -rf /tmp/efa-ofi-nccl

RUN pip install --no-cache-dir -U \n    packaging \n    mpi4py==3.0.3
RUN cd /tmp \n    && git clone https://github.com/pytorch/vision.git -b v0.9.1 \n    && cd vision \n    && BUILD_VERSION="0.9.1+cu111" python setup.py install \n    && cd /tmp \n    && rm -rf vision

10. Install and configure OpenSSH. OpenSSH is required for MPI to communicate between containers. Allow OpenSSH to talk to containers without asking for confirmation.

RUN apt-get update \
    && apt-get install -y --allow-downgrades --allow-change-held-packages --no-install-\n    recommends \
    && apt-get install -y --no-install-recommends openssh-client openssh-server \
    && mkdir -p /var/run/sshd \n    && cat /etc/ssh/ssh_config | grep -v StrictHostKeyChecking > /etc/ssh/ssh_config.new \n    && echo "    StrictHostKeyChecking no" >> /etc/ssh/ssh_config.new \n    && mv /etc/ssh/ssh_config.new /etc/ssh/ssh_config \n    && rm -rf /var/lib/apt/lists/*

# Configure OpenSSH so that nodes can communicate with each other
RUN mkdir -p /var/run/sshd && \
    sed 's@session\s*required\s*pam_loginuid.so@session optional pam_loginuid.so@g' -i /etc/\n    pam.d/sshd
RUN rm -rf /root/.ssh/ && \
    mkdir -p /root/.ssh/ && \
    ssh-keygen -q -t rsa -N '' -f /root/.ssh/id_rsa && \
    cp /root/.ssh/id_rsa.pub /root/.ssh/authorized_keys && \
    printf "Host *\n  StrictHostKeyChecking no\n" >> /root/.ssh/config

11. Install the PT S3 plug-in to efficiently access datasets in Amazon S3.

RUN pip install --no-cache-dir -U ${PT_S3_WHL_GPU}
RUN mkdir -p /etc/pki/tls/certs && cp /etc/ssl/certs/ca-certificates.crt /etc/pki/tls/\n    certs/ca-bundle.crt

12. Install the libboost library. This package is needed for networking the asynchronous IO functionality of the SageMaker data parallel library.
13. Install the following SageMaker tools for PyTorch training.

```
WORKDIR /root
RUN pip install --no-cache-dir -U
    smclarify
    "sagemaker>=2,<3"
    sagemaker-experiments==0.*
    sagemaker-pytorch-training
```

14. Finally, install the SageMaker data parallel binary and the remaining dependencies.

```
RUN --mount=type=cache,id=apt-final,target=/var/cache/apt
    apt-get update && apt-get install -y --no-install-recommends
    jq
    libhwloc-dev
    libnuma1
    libnuma-dev
    libssl1.1
    libtool
    hwloc
    && rm -rf /var/lib/apt/lists/*

RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}
```

15. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container, host it in Amazon ECR, and run a training job using the SageMaker Python SDK.

The following example code shows a complete Dockerfile after combining all the previous code blocks.

```
# This file creates a docker image with minimum dependencies to run SageMaker data parallel training
FROM nvidia/cuda:11.3.1-cudnn8-devel-ubuntu20.04

# Set appropriate versions and location for components
ARG PYTORCH_VERSION=1.10.2
ARG PYTHON_SHORT_VERSION=3.8
ARG EFA_VERSION=1.14.1
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/

```

**Tip**
For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

**Tip**
If you want to extend the custom Dockerfile to incorporate the SageMaker model parallel library, see Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 2274).

## SageMaker Distributed Data Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker's distributed data parallel library. This list includes tips that are applicable across frameworks.

**Topics**
- Data Preprocessing (p. 2244)
- Single Versus Multiple Nodes (p. 2244)
- Debug Scaling Efficiency with Debugger (p. 2244)
- Batch Size (p. 2245)
- Custom MPI Options (p. 2245)
- Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2245)

### Data Preprocessing

If you preprocess data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for `AllReduce` operations. You may be able to improve training time by moving preprocessing steps to a library that uses GPUs or by completing all preprocessing before training.

### Single Versus Multiple Nodes

We recommend that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs); however, when you use two or more nodes, the library's `AllReduce` operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node `AllReduce` efficiency.

### Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization and other metrics of interest during training. You can use Debugger built-in rules to monitor computational performance issues, such as `CPUBottleneck`, `LoadBalancing`, and `LowGPUUtilization`. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.
Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a **Linear Scaling Rule** where each time the mini-batch size is multiplied by $k$, the learning rate is also multiplied by $k$. To learn more about this technique, see the research paper, *Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour*, Sections 2 and 3.

Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the `mpirun` command to start jobs on the cluster nodes.

You can set custom MPI operations using the `custom_mpi_options` parameter in the `Estimator`. Any `mpirun` flags passed in this field are added to the `mpirun` command and executed by SageMaker for training. For example, you may define the `distribution` parameter of an `Estimator` using the following to use the `NCCL_DEBUG` variable to print the NCCL version at the start of the program:

```python
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-v NCCL_DEBUG=VERSION"}}}
```

Use Amazon FSx and set up an optimal storage and throughput capacity

When training a model on multiple nodes with distributed data parallelism, it is highly recommended to use FSx for Lustre. Amazon FSx is a scalable and high-performance storage service that supports shared file storage with a faster throughput. Using Amazon FSx storage at scale, you can achieve a faster data loading speed across the compute nodes.

Typically, with distributed data parallelism, you would expect that the total training throughput scales near-linearly with the number of GPUs. However, if you use suboptimal Amazon FSx storage, the training performance might slow down due to a low Amazon FSx throughput.

For example, if you use the **SCRATCH_2** deployment type of Amazon FSx file system with the minimum 1.2 TiB storage capacity, the I/O throughput capacity is 240 MB/s. Amazon FSx storage works in a way that you can assign physical storage devices, and the more devices assigned, the larger throughput you get. The smallest storage increment for the **SCRATCH_2** type is 1.2 TiB, and the corresponding throughput gain is 240 MB/s.

Assume that you have a model to train on a 4-node cluster over a 100 GB data set. With a given batch size that's optimized to the cluster, assume that the model can complete one epoch in about 30 seconds. In this case, the minimum required I/O speed is approximately 3 GB/s (100 GB / 30 s). This is apparently a much higher throughput requirement than 240 MB/s. With such a limited Amazon FSx capacity, scaling your distributed training job up to larger clusters might aggravate I/O bottleneck problems; model training throughput might improve in later epochs as cache builds up, but Amazon FSx throughput can still be a bottleneck.

To alleviate such I/O bottleneck problems, you should increase the Amazon FSx storage size to obtain a higher throughput capacity. Typically, to find an optimal I/O throughput, you may experiment with different Amazon FSx throughput capacities, assigning an equal to or slightly lower throughput than your estimate, until you find that it is sufficient to resolve the I/O bottleneck problems. In case of the aforementioned example, Amazon FSx storage with 2.4 GB/s throughput and 67 GB RAM cache would
be sufficient. If the file system has an optimal throughput, the model training throughput should reach maximum either immediately or after the first epoch as cache has built up.

To learn more about how to increase Amazon FSx storage and deployment types, see the following pages in the Amazon FSx for Lustre documentation:

- How to increase storage capacity
- Aggregate file system performance

**Amazon SageMaker Data Parallel Library FAQ**

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

**Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra C5s for jobs that use the library?**

The library uses the CPUs available with GPU instances. No additional C5 or CPU instances are launched; if your SageMaker training job is 8-node `ml.p3dn.24xlarge` clusters, only 8 `ml.p3dn.24xlarge` instances are used. No additional instances are provisioned.

**Q: I have a training job taking 5 days on a single `ml.p3.24xlarge` instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is using SageMaker's data parallelism library and a five-time bigger cluster enough to achieve an approximate five-time speedup? Or do I have to revisit its training hyperparameters after activating the library?**

The library changes the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

**Q: Does the library support Spot?**

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You save and restore checkpoints in their training script as mentioned in the last steps of the section called “TensorFlow” (p. 2228) and the section called “PyTorch” (p. 2230).

**Q: Is the library relevant in a single-host, multi-device setup?**

The library can be used in single-host multi-device training but the library offers performance improvements only in multi-host training.

**Q: Can the library be used with PyTorch Lightning?**

No. However, with the library's DDP for PyTorch, you can write custom DDP to achieve the functionality.

**Q: Where should the training dataset be stored?**

The training dataset can be stored in an Amazon S3 bucket or on an Amazon FSx drive. See this document for various supported input file systems for a training job.

**Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can Amazon EFS and Amazon S3 be used?**

We generally recommend you use Amazon FSx because of its lower latency and higher throughput. If you prefer, you can use Amazon EFS or Amazon S3.

**Q: Can the library be used with CPU nodes?**

No. The library supports `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge` instances at this time.
Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6.0 or later and TensorFlow v2.3.0 or later. It doesn't support TensorFlow 1.x. For more information about which version of the library is packaged within AWS deep learning containers, see Release Notes for Deep Learning Containers.

Q: Does the library support AMP?

Yes, SageMaker's distributed data parallelism library supports Automatic Mixed Precision (AMP) out of the box. No extra action is needed to use AMP other than the framework-level modifications to your training script. If gradients are in FP16, the SageMaker data parallelism library runs its AllReduce operation in FP16. For more information about implementing AMP APIs to your training script, see the following resources:

- Frameworks - PyTorch in the NVIDIA Deep Learning Performance documentation
- Frameworks - TensorFlow in the NVIDIA Deep Learning Performance documentation
- Automatic Mixed Precision for Deep Learning in the NVIDIA Developer Docs
- Introducing native PyTorch automatic mixed precision for faster training on NVIDIA GPUs in the PyTorch Blog
- TensorFlow mixed precision APIs in the TensorFlow documentation

Q: How do I identify if my distributed training job is slowed down due to I/O bottleneck?

With a larger cluster, the training job requires more I/O throughput, and therefore the training throughput might take longer (more epochs) to ramp up to the maximum performance. This indicates that I/O is being bottlenecked and cache is harder to build up as you scale nodes up (higher throughput requirement and more complex network topology). For more information about monitoring the Amazon FSx throughput on CloudWatch, see Monitoring FSx for Lustre in the FSx for Lustre User Guide.

Q: How do I resolve I/O bottlenecks when running a distributed training job with data parallelism?

We highly recommend that you use Amazon FSx as your data channel if you are using Amazon S3. If you are already using Amazon FSx but still having I/O bottleneck problems, you might have set up your Amazon FSx file system with a low I/O throughput and a small storage capacity. For more information about how to estimate and choose the right size of I/O throughput capacity, see Use Amazon FSx and set up an optimal storage and throughput capacity (p. 2245).

Q: (For the library v1.4.0 or later) How do I resolve the Invalid backend error while initializing process group.

If you encounter the error message ValueError: Invalid backend: 'smddp' when calling init_process_group, this is due to the breaking change in the library v1.4.0 and later. You must import the PyTorch client of the library, smdistributed.dataparallel.torch.torch_smddp, which registers smddp as a backend for PyTorch. To learn more, see Use the SageMaker Distributed Data Parallel Library as the Backend of torch.distributed (p. 2231).

Q: (For the library v1.4.0 or later) I would like to call the collective primitives of the torch.distributed interface. Which primitives does the smddp backend support?

In v1.4.0, the library supports all_reduce, broadcast, reduce, all_gather, and barrier.

Q: (For the library v1.4.0 or later) Does this new API work with other custom DDP classes or libraries like Apex DDP?

The SageMaker data parallel library is tested with other third-party distributed data parallel libraries and framework implementations that use the torch.distributed modules. Using the SageMaker data parallel library with custom DDP classes works as long as the collectives used by the custom DDP classes are supported by the library. See the preceding question for a list of supported collectives. If you have these use cases and need further support, reach out to the SageMaker team through the AWS Support Center or AWS Developer Forums for Amazon SageMaker.
Q: Does the library support the bring-your-own-container (BYOC) option? If so, how do I install the library and run a distributed training job by writing a custom Dockerfile?

If you want to integrate the SageMaker data parallel library and its minimum dependencies in your own Docker container, BYOC is the right approach. You can build your own container using the binary file of the library. The recommended process is to write a custom Dockerfile with the library and its dependencies, build the Docker container, host it in Amazon ECR, and use the ECR image URI to launch a training job using the SageMaker generic estimator class. For more instructions on how to prepare a custom Dockerfile for distributed training in SageMaker with the SageMaker data parallel library, see Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2236).

Data Parallel Troubleshooting

If you have problems in running a training job when you use the library, use the following list to try to troubleshoot. If you need further support, reach out to the SageMaker team through AWS Support Center or AWS Developer Forums for Amazon Amazon SageMaker.

Topics
- Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints (p. 2248)
- An Unexpected Prefix Attached to Model Parameter Keys (p. 2249)
- SageMaker Distributed Training Job Stalling During Initialization (p. 2249)
- SageMaker Distributed Training Job Stalling at the End of Training (p. 2250)
- Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks (p. 2250)
- SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings (p. 2250)

Using SageMaker Distributed Data Parallel with Amazon SageMaker Debugger and Checkpoints

To monitor system bottlenecks, profile framework operations, and debug model output tensors for training jobs with SageMaker distributed data parallel, use Amazon SageMaker Debugger.

However, when you use SageMaker Debugger, SageMaker distributed data parallel, and SageMaker checkpoints, you might see an error that looks like the following example.

```
SMDebug Does Not Currently Support Distributed Training Jobs With Checkpointing Enabled
```

This is due to an internal error between Debugger and checkpoints, which occurs when you enable SageMaker distributed data parallel.

- If you enable all three features, SageMaker Python SDK automatically turns off Debugger by passing `debugger_hook_config=False`, which is equivalent to the following framework estimator example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"
# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(...
  distribution={"smdistributed": {"dataparallel": { "enabled": True }},
  checkpoint_s3_uri=checkpoint_s3_bucket,
```

2248
checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)

• If you want to keep using both SageMaker distributed data parallel and SageMaker Debugger, a workaround is manually adding checkpointing functions to your training script instead of specifying the checkpoint_s3_uri and checkpoint_local_path parameters from the estimator. For more information about setting up manual checkpointing in a training script, see Saving Checkpoints (p. 2298).

An Unexpected Prefix Attached to Model Parameter Keys

For PyTorch distributed training jobs, an unexpected prefix (model for example) might be attached to state_dict keys (model parameters). The SageMaker data parallel library does not directly alter or prepend any model parameter names when PyTorch training jobs save model artifacts. The PyTorch's distributed training changes the names in the state_dict to go over the network, prepending the prefix. If you encounter any model failure problem due to different parameter names while you are using the SageMaker data parallel library and checkpointing for PyTorch training, adapt the following example code to remove the prefix at the step you load checkpoints in your training script.

```python
state_dict = {k.partition('model.')[2]:state_dict[k] for k in state_dict.keys()}
```

This takes each state_dict key as a string value, separates the string at the first occurrence of 'model.', and takes the third list item (with index 2) of the partitioned string.

For more information about the prefix issue, see a discussion thread at Prefix parameter names in saved model if trained by multi-GPU? in the PyTorch discussion forum.

For more information about the PyTorch methods for saving and loading models, see Saving & Loading Model Across Devices in the PyTorch documentation.

SageMaker Distributed Training Job Stalling During Initialization

If your SageMaker distributed data parallel training job stalls during initialization when using EFA-enabled instances (ml.p3dn.24xlarge and ml.p4d.24xlarge), this might be due to a misconfiguration in the security group of the VPC subnet that's used for the training job. EFA requires a proper security group configuration to enable traffic between the nodes.

To configure inbound and outbound rules for the security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Security Groups in the left navigation pane.
3. Select the security group that's tied to the VPC subnet you use for training.
4. In the Details section, copy the Security group ID.
6. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source, choose Custom, paste the security group ID into the search box, and select the security group that pops up.
7. Choose Save rules to finish configuring the inbound rule for the security group.
9. Repeat the step 6 and 7 to add the same rule as an outbound rule.
After you complete the preceding steps for configuring the security group with the inbound and outbound rules, rerun the training job and verify if the stalling issue is resolved.

For more information about configuring security groups for VPC and EFA, see Security groups for your VPC and Elastic Fabric Adapter.

**SageMaker Distributed Training Job Stalling at the End of Training**

One of the root causes of stalling issues at the end of training is a mismatch in the number of batches that are processed per epoch across different ranks. All workers (GPUs) synchronize their local gradients in the backward pass to ensure they all have the same copy of the model at the end of the batch iteration. If the batch sizes are unevenly assigned to different worker groups during the final epoch of training, the training job stalls. For example, while a group of workers (group A) finishes processing all batches and exits the training loop, another group of workers (group B) starts processing another batch and still expects communication from group A to synchronize the gradients. This causes group B to wait for group A, which already completed training and does not have any gradients to synchronize.

Therefore, when setting up your training dataset, it is important that each worker gets the same number of data samples so that each worker goes through the same number of batches while training. Make sure each rank gets the same number of batches to avoid this stalling issue.

**Observing Scaling Efficiency Degradation Due to Amazon FSx Throughput Bottlenecks**

One potential cause of lowered scaling efficiency is the FSx throughput limit. If you observe a sudden drop in scaling efficiency when you switch to a larger training cluster, try using a larger FSx for Lustre file system with a higher throughput limit. For more information, see Aggregate file system performance and Managing storage and throughput capacity in the Amazon FSx for Lustre User Guide.

**SageMaker Distributed Training Job with PyTorch Returns Deprecation Warnings**

Since v1.4.0, the SageMaker distributed data parallelism library works as a backend of PyTorch distributed. Because of the breaking change of using the library with PyTorch, you might encounter a warning message that the `smdistributed` APIs for the PyTorch distributed package are deprecated.

The warning message should be similar to the following:

```plaintext
smdistributed.dataparallel.torch.dist is deprecated in the SageMaker distributed data parallel library v1.4.0+.
Please use torch.distributed and specify 'smddp' as a backend when initializing process group as follows:
torch.distributed.init_process_group(backend='smddp')
For more information, see the library's API documentation at https://docs.aws.amazon.com/sagemaker/latest/dg/data-parallel-modify-sdp-pt.html
```

In v1.4.0 and later, the library only needs to be imported once at the top of your training script and set as the backend during the PyTorch distributed initialization. With the single line of backend specification, you can keep your PyTorch training script unchanged and directly use the PyTorch distributed modules. See Modify a PyTorch Training Script (p. 2230) to learn about the breaking changes and the new way to use the library with PyTorch.

**SageMaker's Distributed Model Parallel**

Use Amazon SageMaker's distributed model parallel library to train large deep learning (DL) models that are difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances. Using the library, you can achieve a target prediction accuracy faster by efficiently training larger DL models with billions or trillions of parameters.
You can use the library to automatically partition your own TensorFlow and PyTorch models across multiple GPUs and multiple nodes with minimal code changes. You can access the library's API through the SageMaker Python SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library's API documentation is located at Distributed Training APIs in the SageMaker Python SDK documentation.

To track the latest updates of the library, see the SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

Introduction to Model Parallelism

Model parallelism is the process of splitting a model up between multiple devices or nodes (such as GPU-equipped instances) and creating an efficient pipeline to train the model across these devices to maximize GPU utilization.

Use the sections on this page to learn more about model parallelism, including how it can be used to overcome issues that arise when training large ML models, and important considerations when integrating it into your ML training script.

What is Model Parallelism?

Increasing deep learning model size (layers and parameters) can result in better accuracy. However, there is a limit to the maximum model size you can fit in a single GPU. When training deep learning models, GPU memory limitations can be a bottleneck in the following ways:

- They can limit the size of the model you train. Given that larger models tend to achieve higher accuracy, this directly translates to trained model accuracy.
- They can limit the batch size you train with, leading to lower GPU utilization and slower training.

To overcome the limitations associated with training a model on a single GPU, you can use model parallelism to distribute and train your model on multiple computing devices.

Important Considerations when Using Model Parallelism

When you use model parallelism, you must consider the following:

- **How you split your model across devices**: The computational graph of your model, sizes of model parameters and activations, and your resource constraints (for example, time vs. memory) determine the best partitioning strategy.

To reduce the time and effort required to efficiently split your model, you can use automated model splitting features offered by Amazon SageMaker's distributed model parallel library.

- **Achieving parallelization**: Model training—that is, forward computations and backward propagation—is inherently sequential, where each operation must wait for its inputs to be computed by another
operation. For this reason, forward and backward pass stages of deep learning training are not easily parallelizable, and naively splitting a model across multiple GPUs may lead to poor device utilization. For example, a layer on GPU $i+1$ has to wait for the output from a layer on GPU $i$, and so GPU $i+1$ remains idle during this waiting period.

The model parallel library can achieve true parallelization by implementing pipelined execution by building an efficient computation schedule where different devices can work on forward and backward passes for different data samples at the same time.

To learn how you can use the library to efficiently split your model across devices and improve device utilization during training, see Core Features of the SageMaker Model Parallel Library (p. 2252).

Core Features of the SageMaker Model Parallel Library

Amazon SageMaker's model parallel library makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting algorithms can optimize for speed or memory consumption. The library also supports manual partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or TensorFlow estimators. Use the following sections to learn more about these core features of the library.

Note
The SageMaker distributed training libraries are available only through the AWS deep learning containers for the TensorFlow, PyTorch, and HuggingFace frameworks within the SageMaker training platform. To use the libraries, you must use the SageMaker Python SDK or the SageMaker APIs through SDK for Python (Boto3) or AWS Command Line Interface. Throughout the documentation, instructions and examples focus on how to use the distributed training libraries with the SageMaker Python SDK.

Automated Model Splitting

When you use SageMaker's model parallel library, you can take advantage of automated model splitting, also referred to as automated model partitioning. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

How It Works

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The follow section reviews the specifics of the design in each framework.
Automated Model Splitting with PyTorch

During the first training step, the model parallel library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameters`, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

Automated Model Splitting with TensorFlow

The model parallel library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
- Balancing the number of operations executed in each device

If you specify `speed` for `optimize` (in the model parallel parameters in the Python SDK), the library tries to balance the number of operations and `tf.Variable` objects in each device. Otherwise, it tries to balance the total size of `tf.Variables`.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same `tf.Variable` and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a `tf.Variable`, then all operations that are part of these layers are placed on a single device.

Comparison of Automated Model Splitting Between Frameworks

In TensorFlow, the fundamental unit of computation is a `tf.Operation`, and TensorFlow represents the model as a directed acyclic graph (DAG) of `tf.Operations`, and therefore model parallel library partitions this DAG so that each node goes to one device. Crucially, `tf.Operation` objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an `nn.Module`, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using `smp.partition` context managers.

To use this option, set `auto_partition` to `False`, and define a `default_partition` in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the `smp.partition` context manager is executed on the `default_partition`. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallel library creates a pipelined execution schedule automatically.
Pipeline Execution Schedule

A core feature of SageMaker's distributed model parallel library is pipelined execution, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A microbatch is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU $i$ might perform (forward or backward) computation on microbatch $b$ while GPU $i+1$ performs computation on microbatch $b+1$, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.

The library offers two different pipeline schedules, simple and interleaved, which can be configured using the pipeline parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

Interleaved Pipeline

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. Update represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

Simple Pipeline

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

Pipelining Execution in Specific Frameworks

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's distributed model parallel library makes for Tensorflow and PyTorch.
Pipeline Execution with TensorFlow

The following image is an example of a TensorFlow graph partitioned by the model parallel library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An SMPInput operation is inserted at each input of a subgraph, and an SMPOutput operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a SMPInput op is a SMPOutput op, and vice versa. This enables the gradients to flow backwards during back-propagation.

This GIF demonstrates an example interleaved pipeline execution schedule with B=2 microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As B grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue SMPInput operations to start executing.
Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallel library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

**Run a SageMaker Distributed Training Job with Model Parallelism**

Learn how to run a distributed model parallel training job using the SageMaker Python SDK with your own training script and SageMaker's distributed model parallel library.

There are three use-case scenarios for running a SageMaker training job:

1. You can use one of the prebuilt AWS Deep Learning Container for TensorFlow and PyTorch. This option is recommended if it is the first time for you to use the model parallel library. To find a tutorial for how to run a SageMaker model parallel training job, see MNIST with PyTorch 1.6 and Amazon SageMaker's distributed model parallel library.

2. You can extend the prebuilt containers to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To find an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

3. You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

For options 2 and 3 in the preceding list, refer to Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library (p. 2273) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your training job configuring a SageMaker TensorFlow or PyTorch estimator to initialize the library. To learn more, see the following topics.

**Topics**

- Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library (p. 2256)
- Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2269)

**Step 1: Modify Your Own Training Script Using SageMaker's Distributed Model Parallel Library**

Use this section to learn how to customize your training script to use the core features of the Amazon SageMaker distributed model parallel library. To use the library-specific API functions and parameters,
we recommend you use this documentation alongside the SageMaker model parallel library APIs in the SageMaker Python SDK documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end-to-end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed model parallel library, see Amazon SageMaker Distributed Training Notebook Examples (p. 2301).

**Topics**
- Modify a TensorFlow Training Script (p. 2257)
- Modify a PyTorch Training Script (p. 2263)

**Modify a TensorFlow Training Script**

In this section, you learn how to modify TensorFlow training scripts to configure the SageMaker distributed model parallel library for auto-partitioning and manual partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism.

**TensorFlow versions supported by SageMaker and the SageMaker distributed model parallel library**

To check the latest updates of the library, see the SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

Before you proceed to modify your TensorFlow training script, we recommend that you review Unsupported Framework Features (p. 2263).

The required modifications you must make to your training script to use the library are listed in TensorFlow (p. 2258).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 2259).

If you want to use manual partitioning, also review Manual partitioning with TensorFlow (p. 2261).

**Tip**
For end-to-end notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see TensorFlow Examples (p. 2302).

The following topics show examples of training scripts that you can use to configure SageMaker's model parallel library for auto-partitioning and manual partitioning TensorFlow models.
Note
Auto-partitioning is enabled by default. Unless otherwise specified, the example scripts use auto-partitioning.

Topics
- TensorFlow (p. 2258)
- TensorFlow with Horovod for Hybrid Model and Data Parallelism (p. 2259)
- Manual partitioning with TensorFlow (p. 2261)
- Unsupported Framework Features (p. 2263)

TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Define a Keras model by inheriting from `smp.DistributedModel` instead of the Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.
4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.
7. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

The following Python script is an example of a training script after the changes are made.

```python
import tensorflow as tf
# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
"MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0
# Add a channels dimension
x_train = x_train[..., tf.newaxis]
```
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = {
    tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
}

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

        def call(self, x, training=None):
            # define forward pass and return the model output

            model = MyModel()

            loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
            optimizer = tf.keras.optimizers.Adam()
            train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

            # smdistributed: Define smp.step. Return any tensors needed outside @smp.step
            def get_grads(images, labels):
                predictions = model(images, training=True)
                loss = loss_object(labels, predictions)

                grads = optimizer.get_gradients(loss, model.trainable_variables)
                return grads, loss, predictions

            @tf.function
            def train_step(images, labels):
                gradients, loss, predictions = get_grads(images, labels)

                # smdistributed: Accumulate the gradients across microbatches
                gradients = [g.accumulate() for g in gradients]
                optimizer.apply_gradients(zip(gradients, model.trainable_variables))

                # smdistributed: Merge predictions and average losses across microbatches
                train_accuracy(labels, predictions.merge())
                return loss.reduce_mean()

            for epoch in range(5):
                # Reset the metrics at the start of the next epoch
                train_accuracy.reset_states()
                for images, labels in train_ds:
                    loss = train_step(images, labels)
                    accuracy = train_accuracy.result()
In this step, we focus on how to modify your training script to adapt the SageMaker distributed model parallel library.

To properly set up your training script to pick up the hybrid parallelism configuration that you'll set in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2269), use the library's helper functions, `smp.dp_rank()` and `smp.mp_rank()`, which automatically detect the data parallel rank and model parallel rank respectively.

To find all MPI primitives the library supports, see MPI Basics in the SageMaker Python SDK documentation.

The required changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

**Note**

When you use Horovod, you must not directly call `hvd.init` in your training script. Instead, you'll have to set "horovod" to True in the SageMaker Python SDK modelparallel parameters in Step 2: Launch a Training Job Using the SageMaker Python SDK (p. 2269). This allows the library to internally initialize Horovod based on the device assignments of model partitions. Calling `hvd.init()` directly in your training script can cause problems.

**Note**

Using the `hvd.DistributedOptimizer` API directly in your training script might result in a poor training performance and speed, because the API implicitly places the AllReduce operation inside `smp.step`. We recommend you to use the model parallel library with Horovod by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as will be shown in the following example.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf
import horovod.tensorflow as hvd

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = np.expand_dims(x_train, axis=-1)
x_test = np.expand_dims(x_test, axis=-1)

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)
```
# smdistributed: Define `smp.DistributedModel` the same way as Keras sub-classing API

class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define `smp.step`. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: Allreduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()

    for batch, (images, labels) in enumerate(train_ds):
        loss = train_step(images, labels, tf.constant(batch == 0))

---

**Manual partitioning with TensorFlow**

Use `smp.partition` context managers to place operations in specific partition. Any operation not placed in any `smp.partition` contexts is placed in the `default_partition`. To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf

# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp
```
# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers

    def call(self, x):
        with smp.partition(0):
            x = self.layer0(x)
        with smp.partition(1):
            return self.layer1(x)

model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
loss = train_step(images, labels)
accuracy = train_accuracy.result()

Unsupported Framework Features

The following TensorFlow features are not supported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
- The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

Modify a PyTorch Training Script

In this section, you learn how to modify PyTorch training scripts to configure the SageMaker distributed model parallel library for auto-partitioning and manual partitioning.

* The SageMaker distributed model parallel library v1.6.0 and later provides extended features for PyTorch. For more information, see Extended Features of the SageMaker Model Parallel Library for PyTorch (p. 2275).

To check the latest updates of the library, see the SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

The following topics show examples of training scripts that you can use to configure SageMaker's model parallel library for auto-partitioning and manual partitioning PyTorch models. We recommend that you review the Important Considerations (p. 2267) and Unsupported Framework Features (p. 2269) before creating a training script.
The required modifications you must make to your training script to use the library are listed in PyTorch (p. 2264).

If you want to use manual partitioning, also review Manual Partitioning with PyTorch (p. 2266).

Tip
For end-to-end notebook examples that demonstrate how to use a PyTorch training script with the SageMaker distributed model parallel library, see PyTorch Examples (p. 2301).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following scripts use auto-partitioning.

Topics
- PyTorch (p. 2264)
- Manual Partitioning with PyTorch (p. 2266)
- Important Considerations (p. 2267)
- Unsupported Framework Features (p. 2269)

PyTorch

The following training script changes are required to run a PyTorch model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Wrap the model with `smp.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Wrap the optimizer with `smp.DistributedOptimizer`.
4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.
10. If there is an evaluation step, similarly place the forward logic inside an `smp.step-decorated function` and post-process the outputs using `StepOutput API`.
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
```
from torchvision import datasets

import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()  # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

    def train(model, device, train_loader, optimizer):
        model.train()
        for batch_idx, (data, target) in enumerate(train_loader):
            # smdistributed: Move input tensors to the GPU ID used by the current process,
            # Input tensors should be transferred to this device.
            data, target = data.to(device), target.to(device)
            optimizer.zero_grad()  # Return value, loss_mb is a StepOutput object
            _, loss_mb = train_step(model, data, target)
            # smdistributed: Average the loss across microbatches.
            loss = loss_mb.reduce_mean()
            optimizer.step()

        def train(model, device, train_loader, optimizer):
            model.train()
            for batch_idx, (data, target) in enumerate(train_loader):
                # smdistributed: Move input tensors to the GPU ID used by the current process,
                # based on the set_device call.
                data, target = data.to(device), target.to(device)
                optimizer.zero_grad()  # Return value, loss_mb is a StepOutput object
                _, loss_mb = train_step(model, data, target)
                # smdistributed: Average the loss across microbatches.
                loss = loss_mb.reduce_mean()
                optimizer.step()
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

## Manual Partitioning with PyTorch

Use smp.partition context managers to place modules in specific devices. Any module not placed in any smp.partition contexts is placed in the default_partition. The default_partition needs to be provided if auto_partition is set to False. The modules that are created within a specific smp.partition context are placed on the corresponding partition.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp
class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        with smp.partition(0):
            # define child modules on device 0
        with smp.partition(1):
            # define child modules on device 1

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)
        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

# smdistributed: initialize the backend
smp.init()
```
# smdistributed: Set the device to the GPU ID used by the current process.
torch.cuda.set_device(smp.local_rank())
device = torch.device("cuda")

# smdistributed: Download only on a single process per instance.
# When this is not present, the file is corrupted by multiple processes trying
# to download and extract at the same time
dataset = datasets.MNIST("../data", train=True, download=False)

# smdistributed: Shard the dataset based on data-parallel ranks
if smp.dp_size() > 1:
    partitions_dict = {'{}(i)'.format(i): 1 / smp.dp_size() for i in range(smp.dp_size())}
    dataset = SplitDataset(dataset, partitions=partitions_dict)
    dataset.select('{}(smp.dp_rank())'.format(i))

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

**Important Considerations**

When you configure a PyTorch training script using SageMaker’s distributed model parallel library, you should be aware of the following:

- If you are using an optimization technique that relies on global gradient norms, for example gradient norm from the entire model, such as some variants of LAMB optimizer or global gradient clipping, you need to gather all the norms across the model partitions for correctness. You can use the library’s communication basic data types to do this.

- All `torch.Tensor` arguments to the forward methods of the `nn.Module` objects in your model must be used in the computation of the module output. In other words, the library does not support the case where there is a `torch.Tensor` argument to a module on which the module output does not depend.

- The argument to the `smp.DistributedModel.backward()` call must depend on all model outputs. In other words, there cannot be an output from the `smp.DistributedModel.forward` call that is not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.

- If there are `torch.cuda.synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.

- Since the library places `nn.Module`s on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.

- You don’t need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don’t move the model to CPU.
and use it, as it won’t have correct parameters for modules not assigned to the partition held by
the process. If you want to retrain a model or use it for inference without the library after it was
trained using the model parallel library, the recommended way is to save the full model using our
checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with
  nn.Sequential can significantly improve performance.
- The weight update (optimizer.step()) needs to happen outside of smp.step because that is when
  the entire backward pass is done and gradients are ready. When using a hybrid model with model and
  data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.
- When using the library in combination with data parallelism, make sure that the number of batches
  on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not
  participating in the step.
- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the
data loader variable num_workers=0. For example, you may define your DataLoader as follows:

```python
dataloader = torch.utils.data.DataLoader(
    data,
    batch_size=batch_size,
    num_workers=0,
    pin_memory=True,
    drop_last=True,
    shuffle=shuffle,
)
```

- The inputs to smp.step must be the model inputs generated by DataLoader. This is because
  smp.step internally splits the input tensors along the batch dimension and pipelines them. This
  means that passing DataLoader itself to the smp.step function to generate the model inputs inside
  does not work.

For example, if you define a DataLoader as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by train_loader and pass those to an smp.step
decorated function. Do not pass train_loader directly to the smp.step function.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
    @smp.step
    def train_step(model, data, target):
        ...
        return output, loss
```

- The input tensors to smp.step must be moved to the current device using .to() API, which must
  take place after the torch.cuda.set_device(local_rank()) call.

For example, you may define the train function as follows. This function adds data and target to
the current device using .to() API before using those input tensors to call train_step.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
```
The input tensors to this `smp.set` decorated function have been moved to the current device in the `train` function above. The model does not need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```python
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker’s distributed model parallel library:

- If you use data parallelism with the native PyTorch DDP, the `torch.nn.parallel.DistributedDataParallel` wrapper module is not supported by the library. The library internally manages integrating with PyTorch DDP, including parameter broadcast and gradient AllReduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers that need to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `smp.get_dp_process_group()`.

- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `smp.amp.GradScaler` instead of the implementation in torch.

- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `smp.DistributedModel`.

- `apex`: `FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from `apex` are not supported. You can use the library implementations of these through `smp.optimizers` and `smp.nn` APIs instead.

Step 2: Launch a Training Job Using the SageMaker Python SDK

The SageMaker Python SDK supports managed training of models with ML frameworks such as TensorFlow and PyTorch. To launch a training job using one of these frameworks, you define a SageMaker `TensorFlow estimator`, a SageMaker `PyTorch estimator`, or a SageMaker generic `Estimator` to use the modified training script and model parallelism configuration.

Topics

- Using the SageMaker TensorFlow and PyTorch Estimators (p. 2270)
- How the Library Splits a Model Given the Configuration Parameters (p. 2272)
- Extend a Prebuilt Docker Container that Contains SageMaker’s Distributed Model Parallel Library (p. 2273)
- Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library (p. 2274)
Using the SageMaker TensorFlow and PyTorch Estimators

The TensorFlow and PyTorch estimator classes contain the `distribution` parameter, which you can use to specify configuration parameters for using distributed training frameworks. The SageMaker model parallel library internally uses MPI for hybrid data and model parallelism, so you must use the MPI option with the library.

The following template of a TensorFlow or PyTorch estimator shows how to configure the `distribution` parameter for using the SageMaker model parallel library with MPI.

Using the SageMaker TensorFlow estimator

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow

smp_options = {
    "enabled": True,               # Required
    "parameters": {
        "partitions": 2,         # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
        "horovod": True,          # Use this for hybrid model and data parallelism
    }
}

mpi_options = {
    "enabled": True,              # Required
    "processes_per_host": 8,      # Required
    # "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smd_mp_estimator = TensorFlow(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Using the SageMaker PyTorch estimator

```python
import sagemaker
from sagemaker.pytorch import PyTorch

smp_options = {
    "enabled": True,               # Required
    "parameters": {
        "pipeline_parallel_degree": 2, # Required
        "microbatches": 4,
        "placement_strategy": "spread",
        "pipeline": "interleaved",
        "optimize": "speed",
    }
}

smd_mp_estimator = PyTorch(
    entry_point="your_training_script.py", # Specify your train script
    source_dir="location_to_your_script",
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.p3.16xlarge',
    framework_version='2.6.3',
    py_version='py38',
    distribution={
        "modelparallel": smp_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```
To enable the library, you need to pass configuration dictionaries to the "smdistributed" and "mpi" keys through the distribution argument of the SageMaker estimator constructors.

Configuration parameters for SageMaker model parallelism

- For the "smdistributed" key, pass a dictionary with the "modelparallel" key and the following inner dictionaries.

  **Note**
  Using "modelparallel" and "dataparallel" in one training job is not supported.

  - "enabled" – Required. To enable model parallelism, set "enabled": True.
  - "parameters" – Required. Specify a set of parameters for SageMaker model parallelism.

  For a complete list of common parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

  For TensorFlow, see TensorFlow-specific Parameters.

  For PyTorch, see PyTorch-specific Parameters.

- "pipeline_parallel_degree" (or "partitions" in smdistributed-modelparallel<v1.6.0) – Required. Among the parameters for smdistributed, this parameter is required to specify how many model partitions you want to split into.

  **Important**
  There is a breaking change in the parameter name. The "pipeline_parallel_degree" parameter replaces the "partitions" since smdistributed-modelparallel v1.6.0. For more information, see Common Parameters for SageMaker model parallelism configuration and SageMaker Distributed Model Parallel Release Notes in the SageMaker Python SDK documentation.

- For the "mpi" key, pass a dictionary that contains the following:

  - "enabled" – Required. Set True to launch the distributed training job with MPI.
  - "processes_per_host" – Required. Specify the number of processes MPI should launch on each host. In SageMaker a host is a single Amazon EC2 ML instance. The SageMaker Python SDK
maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through torch.cuda.set_device(smp.local_rank()). To learn more, see PyTorch (p. 2264).

**Important**

process_per_host must not be greater than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

- "custom_mpi_options" (optional) – Use this key to pass any custom MPI options you might need. If you do not pass any MPI custom options to the key, the MPI option is set by default to the following flag.

```
--mca btl_vader_single_copy_mechanism none
```

**Note**

You do not need to explicitly specify this default flag to the key. If you explicitly specify it, your distributed model parallel training job might fail with the following error:

```
The following MCA parameter has been listed multiple times on the command line:
MCA param: btl_vader_single_copy_mechanism MCA parameters can only be listed once
on a command line to ensure there is no ambiguity as to its value.
Please correct the situation and try again.
```

**Tip**

If you launch a training job using an EFA-enabled instance type, such as ml.p4d.24xlarge and ml.p3dn.24xlarge, use the following flag for best performance:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa -x RDMAV_FORK_SAFE=1
```

To launch the training job using the estimator and your SageMaker model parallel configured training script, run the estimator.fit() function.

**How the Library Splits a Model Given the Configuration Parameters**

When you specify a value for the number of model partitions (pipeline_parallel_degree for PyTorch or partition for TensorFlow), the total number of GPUs (processes_per_host) must be divisible by the number of the model partitions. To set this up properly, you have to specify the right values to the pipeline_parallel_degree and processes_per_host parameters. The simple math is as follows:

\[(\text{pipeline_parallel_degree}) \times (\text{data_parallelism_degree}) = \text{processes_per_host}\]

The library takes care of calculating the number of model replicas (data_parallelism_degree) given the two input parameters you provide. For example, if you set pipeline_parallel_degree=4 and processes_per_host=8 to use an ML instance with eight GPU workers such as ml.p3.16xlarge, the library automatically sets up a two-way data parallelism (data_parallelism_degree=2).

The following image illustrates how a two-way data parallelism and four-way model parallelism is distributed across eight GPUs: the model is partitioned across four GPUs, and each partition is assigned to two GPUs.

Use the following resources to learn more about using the model parallelism features in the SageMaker Python SDK:

- Use TensorFlow with the SageMaker Python SDK
• **Use PyTorch with the SageMaker Python SDK**

• We recommend you use a SageMaker notebook instance if you are new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see [Amazon SageMaker Distributed Training Notebook Examples](p. 2301).

• You can also submit a distributed training job from your machine using AWS CLI. To set up AWS CLI on your machine, see [set up your AWS credentials and Region for development](p. 2301).

**Extend a Prebuilt Docker Container that Contains SageMaker's Distributed Model Parallel Library**

To extend a prebuilt container and use SageMaker’s distributed model parallel library, you must use one of the available AWS Deep Learning Containers (DLC) images for PyTorch or TensorFlow. The SageMaker distributed model parallel library is included in the TensorFlow (2.3.0 and later) and PyTorch (1.6.0 and later) DLC images with CUDA (c\*xyz). For a complete list of DLC images, see [Available Deep Learning Containers Images](https://github.com/aws-samples/sageMaker-dl-container) in the AWS Deep Learning Containers GitHub repository.

**Tip**

We recommend that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up-to-date version of the SageMaker distributed model parallel library.

For example, your Dockerfile should contain a FROM statement similar to the following:

```bash
# Use the SageMaker DLC image URI for TensorFlow or PyTorch
FROM aws-dlc-account-id.dkr.ecr.aws-region.amazonaws.com/framework-training:{framework-version-tag}

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the entry_point for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

**Tip**

You must push this Docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (image_uri) to define a SageMaker estimator for training. For more information, see [Extend a Prebuilt Container](p. 2301).

After you finish hosting the Docker container and retrieving the image URI of the container, create a SageMaker PyTorch estimator object as follows. This example assumes that you have already defined `smp_options` and `mpi_options`.

```python
smd_mp_estimator = Estimator(  
    entry_point="your_training_script.py",  
    role=sagemaker.get_execution_role(),  
    instance_type='ml.p3.16xlarge',  
    sagemaker_session=sagemaker_session,  
    image_uri='your_aws_account_id.dkr.ecr.region.amazonaws.com/name:tag'  
    instance_count=1,  
    distribution={  
        "smdistributed": smp_options,  
        "mpi": mpi_options
    })
```
Create Your Own Docker Container with the SageMaker Distributed Model Parallel Library

To build your own Docker container for training and use the SageMaker model parallel library, you must include the correct dependencies and the binary files of the SageMaker distributed parallel libraries in your Dockerfile. This section provides the minimum set of code blocks you must include to properly prepare a SageMaker training environment and the model parallel library in your own Docker container.

**Note**
This custom Docker option with the SageMaker model parallel library as a binary is available only for PyTorch.

To create a Dockerfile with the SageMaker training toolkit and the model parallel library

1. Start with one of the NVIDIA CUDA base images.

```
FROM <cuda-cudnn-base-image>
```

**Tip**
The official AWS Deep Learning Container (DLC) images are built from the NVIDIA CUDA base images. We recommend you look into the official Dockerfiles of AWS Deep Learning Container for PyTorch to find which versions of the libraries you need to install and how to configure them. The official Dockerfiles are complete, benchmark tested, and managed by the SageMaker and Deep Learning Container service teams. In the provided link, choose the PyTorch version you use, choose the CUDA (cuxyz) folder, and choose the Dockerfile ending with .gpu or .sagemaker_gpu.

2. To set up a distributed training environment, you need to install software for communication and network devices, such as Elastic Fabric Adapter (EFA), NVIDIA Collective Communications Library (NCCL), and Open MPI. Depending on the PyTorch and CUDA versions you choose, you must install compatible versions of the libraries.

**Important**
Because the SageMaker model parallel library requires the SageMaker data parallel library in the subsequent steps, we highly recommend that you follow the instructions at Create Your Own Docker Container with the SageMaker Distributed Data Parallel Library (p. 2236) to properly set up a SageMaker training environment for distributed training.

For more information about setting up EFA with NCCL and Open MPI, see Get started with EFA and MPI and Get started with EFA and NCCL.

3. Add the following arguments to specify the URLs of the SageMaker distributed training packages for PyTorch. The SageMaker model parallel library requires the SageMaker data parallel library to use the cross-node Remote Direct Memory Access (RDMA).

```
ARG SMDATAPARALLEL_BINARY=https://smdataparallel.s3.amazonaws.com/binary/pytorch/1.10.2/cu113/2022-02-18/smdistributed_dataparallel-1.4.0-cp38-cp38-linux_x86_64.whl
```

4. Install dependencies that the SageMaker model parallel library requires.

   a. Install the METIS library.

```
ARG METIS=metis-5.1.0
```
RUN rm /etc/apt/sources.list.d/* 
&& gunzip -f $(METIS).tar.gz 
&& tar -xvf $(METIS).tar 
&& cd $(METIS) 
&& apt-get update 
&& make config shared=1 
&& make install 
&& cd .. 
&& rm -rf $(METIS).tar* 
&& rm -rf $(METIS) 
&& rm -rf /var/lib/apt/lists/* 
&& apt-get clean

b. Install the RAPIDS Memory Manager library. This requires CMake 3.14 or later.

ARG RMM_VERSION=0.15.0
RUN wget -nv https://github.com/rapidsai/rmm/archive/v${RMM_VERSION}.tar.gz 
&& tar -xvf v${RMM_VERSION}.tar.gz 
&& cd rmm-${RMM_VERSION} 
&& INSTALL_PREFIX=/usr/local ./build.sh librmm 
&& cd .. 
&& rm -rf v${RMM_VERSION}.tar* 
&& rm -rf rmm-${RMM_VERSION}

5. Install the SageMaker model parallel library.

RUN pip install --no-cache-dir -U ${SMD_MODEL_PARALLEL_URL}

6. Install the SageMaker data parallel library.

RUN SMDATAPARALLEL_PT=1 pip install --no-cache-dir ${SMDATAPARALLEL_BINARY}

7. Install the sagemaker-training toolkit. The toolkit contains the common functionality that’s necessary to create a container compatible with the SageMaker training platform and the SageMaker Python SDK.

RUN pip install sagemaker-training

8. After you finish creating the Dockerfile, see Adapting Your Own Training Container to learn how to build the Docker container and host it in Amazon ECR.

Tip
For more general information about creating a custom Dockerfile for training in SageMaker, see Use Your Own Training Algorithms.

Extended Features of the SageMaker Model Parallel Library for PyTorch

In addition to its core features, the SageMaker distributed model parallel library offers memory-saving features for training deep learning models with PyTorch: tensor parallelism, optimizer state sharding, activation checkpointing, and activation offloading.

Note
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker distributed model parallel library v1.6.0 or later.
For each of the following features, you keep the same two-step workflow shown in the Run a SageMaker Distributed Training Job with Model Parallelism (p. 2256) section and add few additional parameters and code lines to the SageMaker PyTorch estimator and your training script.

To find an example of how to use the extended features, see Train GPT-2 with PyTorch 1.8.1 and Tensor Parallelism Using the SageMaker Model Parallelism Library.

Topics
- Tensor Parallelism (p. 2276)
- Optimizer State Sharding (p. 2286)
- Activation Checkpointing (p. 2287)
- Activation Offloading (p. 2289)
- Ranking Mechanism (p. 2290)

Tensor Parallelism

Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. In contrast to pipeline parallelism, which keeps individual weights intact but partitions the set of weights, tensor parallelism splits individual weights. This typically involves distributed computation of specific operations, modules, or layers of the model.

Tensor parallelism is required in cases in which a single parameter consumes most of the GPU memory (such as large embedding tables with a large vocabulary size or a large softmax layer with a large number of classes). In this case, treating this large tensor or operation as an atomic unit is inefficient and impedes balance of the memory load.

Tensor parallelism is also useful for extremely large models in which a pure pipelining is simply not enough. For example, with GPT-3-scale models that require partitioning over tens of instances, a pure microbatch pipelining is inefficient because the pipeline depth becomes too high and the overhead becomes prohibitively large.

Topics
- How Tensor Parallelism Works (p. 2276)
- Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism (p. 2278)
- Instructions for Checkpointing with Tensor Parallelism (p. 2283)
- Support for Hugging Face Transformer Models (p. 2285)

How Tensor Parallelism Works

Tensor parallelism takes place at the level of `nn.Modules`; it partitions specific modules in the model across tensor parallel ranks. This is in addition to the existing partition of the set of modules used in pipeline parallelism.

When a module is partitioned through tensor parallelism, its forward and backward propagation are distributed. The library handles the necessary communication across devices to implement the distributed execution of these modules; the modules are partitioned across multiple data parallel ranks. Contrary to the traditional distribution of workloads, each data parallel rank does not have the complete model replica when the library's tensor parallelism is used. Instead, each data parallel rank may have only a partition of the distributed modules, in addition to the entirety of the modules that are not distributed.

Example: Consider tensor parallelism across data parallel ranks, where the degree of data parallelism is 4 and the degree of tensor parallelism is 2. Assume that you have a data parallel group that holds the following module tree, after partitioning the set of modules.
### Tensor Parallel Training

Assume that tensor parallelism is supported for the modules B, G, and H. One possible outcome of tensor parallel partition of this model could be:

<table>
<thead>
<tr>
<th>dp_rank 0 (tensor parallel rank 0)</th>
<th>dp_rank 1 (tensor parallel rank 1)</th>
<th>dp_rank 2 (tensor parallel rank 0)</th>
<th>dp_rank 3 (tensor parallel rank 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A, B:0, C, D, G:0, H</td>
<td>A, B:1, C, D, G:1, H</td>
<td>A, B:0, C, D, G:0, H</td>
<td>A, B:1, C, D, G:1, H</td>
</tr>
</tbody>
</table>

Each line represents the set of modules stored in that dp_rank, and the notation X:y represents the yth fraction of the module X. Note the following:

1. Partitioning takes place across subsets of data parallel ranks, which we call TP_GROUP, not the entire DP_GROUP, so that the exact model partition is replicated across dp_rank 0 and dp_rank 2, and similarly across dp_rank 1 and dp_rank 3.
2. The modules E and F are no longer part of the model, since their parent module B is partitioned, and any execution that is normally a part of E and F takes place within the (partitioned) B module.
3. Even though H is supported for tensor parallelism, in this example it is not partitioned, which highlights that whether to partition a module depends on user input. The fact that a module is supported for tensor parallelism does not necessarily mean it is partitioned.

How the library adapts tensor parallelism to PyTorch's nn.Linear module

When tensor parallelism is performed over data parallel ranks, a subset of the parameters, gradients, and optimizer states are partitioned across the tensor parallel devices for the modules that are partitioned. For the rest of the modules, the tensor parallel devices operate in a regular data parallel manner. To execute the partitioned module, a device first collects the necessary parts of all data samples across peer devices in the same tensor parallelism group. The local fraction of the module is then executed on all these data samples, followed by another round of synchronization which both combines the parts of the output for each data sample and returns the combined data samples to the GPUs from which the data sample first originated. The following figure shows an example of this process over a partitioned nn.Linear module.
The first figure shows a small model with a large `nn.Linear` module with data parallelism over the two tensor parallelism ranks. The `nn.Linear` module is replicated into the two parallel ranks.

The second figure shows tensor parallelism applied on a larger model while splitting the `nn.Linear` module. Each `tp_rank` holds half the linear module, and the entirety of the rest of the operations. During the execution of the linear module, each `tp_rank` collects the relevant half of all data samples and passes it through their half of the `nn.Linear` module. The result needs to be reduce-scattered (with summation as the reduction operation) so that each rank has the final linear output for their own data samples. The rest of the model runs in the typical data parallel manner.

**Run a SageMaker Distributed Model Parallel Training Job with Tensor Parallelism**

In this section, you learn:

- How to configure a SageMaker PyTorch estimator and the SageMaker distributed model parallelism option to use tensor parallelism.
- How to adapt your training script using the extended `smdistributed.modelparallel` modules for tensor parallelism.

To learn more about the `smdistributed.modelparallel` modules, see the SageMaker distributed model parallel APIs in the SageMaker Python SDK documentation.

**Topics**

- Tensor parallelism alone (p. 2279)
- Tensor parallelism combined with pipeline parallelism (p. 2281)
Tensor parallelism alone

The following is an example of a distributed training option to activate tensor parallelism alone, without pipeline parallelism. Configure the mpi_options and smp_options dictionaries to specify distributed training options to the SageMaker PyTorch estimator.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker distributed model parallel library v1.6.0 or later.

**Configure a SageMaker PyTorch estimator**

```python
mpi_options = {
    "enabled": True,
    "processes_per_host": 8,  # 8 processes
    "custom_mpi_options": "--mca btl_vader_single_copy_mechanism none"
}

smp_options = {
    "enabled": True,
    "parameters": {
        "pipeline_parallel_degree": 1,  # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 4,  # tp over 4 devices
        "ddp": True
    }
}

smd_mp_estimator = PyTorch(
    entry_point='your_training_script.py',  # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.10.2',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

**Tip**
To find a complete list of parameters for distribution, see [Configuration Parameters for Model Parallelism](#) in the SageMaker Python SDK documentation.

**Adapt your PyTorch training script**

The following example training script shows how to adapt the SageMaker distributed model parallelism library to a training script. In this example, it is assumed that the script is named `your_training_script.py`.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets

import smdistributed.modelparallel.torch as smp
```

2279
class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target, reduction="mean")
        loss.backward()
        optimizer.step()

    # smdistributed: Initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    device = torch.device("cuda")
    torch.cuda.set_device(device)

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    if smp.local_rank() == 0:
        dataset = datasets.MNIST("../data", train=True, download=False)
        smp.barrier()

    # smdistributed: Shard the dataset based on data parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}")

    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64)

    # smdistributed: Enable tensor parallelism for all supported modules in the model
    # i.e., nn.Linear in this case. Alternatively, we can use
    # smp.set_tensor_parallelism(model.fc1, True)
    # to enable it only for model.fc1
    with smp.tensor_parallelism():
        model = Net()

    # smdistributed: Use the DistributedModel wrapper to distribute the
    # modules for which tensor parallelism is enabled
    model = smp.DistributedModel(model)
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

Tensor parallelism combined with pipeline parallelism

The following is an example of a distributed training option that enables tensor parallelism combined with pipeline parallelism. Set up the mpi_options and smp_options parameters to specify distributed model parallel options with tensor parallelism when you configure a SageMaker PyTorch estimator.

**Note**
Extended memory-saving features are available through Deep Learning Containers for PyTorch, which implements the SageMaker distributed model parallel library v1.6.0 or later.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8, # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2, # alias for "partitions"
        "placement_strategy": "cluster",
        "tensor_parallel_degree": 2, # tp over 2 devices
        "ddp": True
    }
}

smd_mp_estimator = PyTorch(
    entry_point='your_training_script.py', # Specify
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    framework_version='1.10.2',
    py_version='py36',
    instance_count=1,
    distribution={
        "smdistributed": {"modelparallel": smp_options},
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)

smd_mp_estimator.fit('s3://my_bucket/my_training_data/')
```

Adapt your PyTorch training script

The following example training script shows how to adapt the SageMaker distributed model parallelism library to a training script. Note that the training script now includes the smp.step decorator:

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import import SplitDataset
```
from torchvision import datasets

import smdistributed.modedistributed.torch as smp

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = F.relu(x)
        x = self.conv2(x)
        x = F.relu(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        x = self.fc1(x)
        x = F.relu(x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)

# smdistributed: Define smp.step. Return any tensors needed outside.
@smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by
        # the current process, based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()

    # smdistributed: Initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    # Input tensors should be transferred to this device.
    torch.cuda.set_device(smp.local_rank())
    device = torch.device("cuda")

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    if smp.local_rank() == 0:
        dataset = datasets.MNIST("../data", train=True, download=False)
    smp.barrier()

    # smdistributed: Shard the dataset based on data parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"i": 1 / smp.dp_size() for i in range(smp.dp_size())}
dataset = SplitDataset(dataset, partitions=partitions_dict)
dataset.select(f"{smp.dp_rank()}")

# smdistributed: Set drop_last=True to ensure that batch size is always divisible
# by the number of microbatches
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = Net()

# smdistributed: enable tensor parallelism only for model.fc1
smp.set_tensor_parallelism(model.fc1, True)

# smdistributed: Use the DistributedModel container to provide the model
# to be partitioned across different ranks. For the rest of the script,
# the returned DistributedModel object should be used in place of
# the model provided for DistributedModel class instantiation.
model = smp.DistributedModel(model)

optimizer = optim.AdaDelta(model.parameters(), lr=4.0)
optimizer = smp.DistributedOptimizer(optimizer)

train(model, device, train_loader, optimizer)

### Instructions for Checkpointing with Tensor Parallelism

The SageMaker model parallel library supports saving partial or full checkpoints with tensor parallelism. The following guide shows how to modify your script to save and load a checkpoint when you use tensor parallelism.

1. Prepare a model object and wrap it with the library's wrapper function `smp.DistributedModel()`. 

```python
model = MyModel(...)  
model = smp.DistributedModel(model)
```

2. Prepare an optimizer for the model. A set of model parameters is an iterable argument required by optimizer functions. To prepare a set of model parameters, you must process `model.parameters()` to assign unique IDs to individual model parameters.

   If there are parameters with duplicated IDs in the model parameter iterable, loading the checkpointed optimizer state fails. To create an iterable of model parameters with unique IDs for your optimizer, see the following:

   ```python
   unique_params = []
   unique_params_set = set()
   for p in model.parameters():
       if p not in unique_params_set:
           unique_params.append(p)
           unique_params_set.add(p)
   del unique_params_set
   optimizer = MyOpt(unique_params, ...)
   ```

3. Wrap the optimizer using the library's wrapper function `smp.DistributedOptimizer()`. 

```python
optimizer = smp.DistributedOptimizer(optimizer)
```

4. Save the model and the optimizer state using `smp.save()`. Depending on how you want to save checkpoints, choose one of the following two options:
   - **Option 1**: Save a partial model on each `mp_rank` for a single `MP_GROUP`.

     ```python
     model_dict = model.local_state_dict() # save a partial model
     ```

     ```python
     model.state_dict() = model_dict
     ```
opt_dict = optimizer.local_state_dict()  # save a partial optimizer state
# Save the dictionaries at rdp_rank 0 as a checkpoint
if smp.rdp_rank() == 0:
    smp.save(
        {"model_state_dict": model_dict, "optimizer_state_dict": opt_dict},
        f"/checkpoint.pt",
        partial=True,
    )

With tensor parallelism, the library saves checkpointed files named in the following format:
checkpoint.pt_{pp_rank}_{tp_rank}.

Note
With tensor parallelism, make sure you set the if statement as
if smp.rdp_rank() == 0 instead of if smp.dp_rank() == 0.
When the optimizer state is sharded with tensor parallelism, all reduced-data parallel ranks must save their own partition of the optimizer state. Using a wrong if statement for checkpointing might result in a stalling training job. For more information about using if smp.dp_rank() == 0 without tensor parallelism, see General Instruction for Saving and Loading in the SageMaker Python SDK documentation.

• Option 2: Save the full model.

if smp.rdp_rank() == 0:
    model_dict = model.state_dict(gather_to_rank0=True)  # save the full model
if smp.rank() == 0:
    smp.save(
        {"model_state_dict": model_dict},
        "/checkpoint.pt",
        partial=False,
    )

Note
Consider the following for full checkpointing:
- If you set gather_to_rank0=True, all ranks other than 0 return empty dictionaries.
- For full checkpointing, you can only checkpoint the model. Full checkpointing of optimizer states is currently not supported.
- The full model only needs to be saved at smp.rank() == 0.

5. Load the checkpoints using smp.load(). Depending on how you checkpointed in the previous step, choose one of the following two options:

• Option 1: Load the partial checkpoints.

checkpoint = smp.load("/checkpoint.pt", partial=True)
model.load_state_dict(checkpoint["model_state_dict"], same_partition_load=False)
optimizer.load_state_dict(checkpoint["optimizer_state_dict"])

You can set same_partition_load=True in model.load_state_dict() for a faster load, if you know that the partition will not change.

• Option 2: Load the full checkpoints.

if smp.rdp_rank() == 0:
    checkpoint = smp.load("/checkpoint.pt", partial=False)
    model.load_state_dict(checkpoint["model_state_dict"])

The if smp.rdp_rank() == 0 condition is not required, but it can help avoid redundant loading among different MP_GROUPS. Full checkpointing optimizer state dict is currently not supported with tensor parallelism.
Support for Hugging Face Transformer Models

The SageMaker model parallel library’s tensor parallelism offers out-of-the-box support for the following Hugging Face Transformer models:

- GPT-2, BERT, and RoBERTa (Available in the SageMaker model parallel library v1.7.0 and later)
- GPT-J (Available in the SageMaker model parallel library v1.8.0 and later)

**Note**
For any other Transformers models, you need to use the `smp.tp_register_with_module()` API to apply tensor parallelism.

**Note**
To use tensor parallelism for training Hugging Face Transformer models, you should add `transformers==4.4.2` to `requirements.txt` for installing the Transformers library in Deep Learning Container for PyTorch v1.8.1 and later.

If you use one of the Hugging Face Transformer models, you do not need to manually implement hooks to translate Transformer APIs to smdistributed transformer layers. You also do not need to manually register hooks for tensor parallelism using the `smp.tp_register` API. You can activate tensor parallelism by using the context manager `smp.tensor_parallelism()` and wrapping the model by `smp.DistributedModel()`. For example, see the following code:

```python
from transformers import AutoModelForCausalLM
with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)
    model = smp.DistributedModel(model)
```

Further, given a state_dict from the DistributedModel object, you can load the weights into the original HuggingFace GPT-2 model using the `translate_state_dict_to_hf_gpt2` API:

```python
from smdistributed.modelparallel.torch.nn.huggingface.gpt2 \import translate_state_dict_to_hf_gpt2
max_seq_len = 1024
with smp.tensor_parallelism():
    model = AutoModelForCausalLM.from_config(hf_gpt2_config)
    model = smp.DistributedModel(model)
# [...run training...]
if smp.rdp_rank() == 0:
    state_dict = dist_model.state_dict()
    hf_state_dict = translate_state_dict_to_hf_gpt2(state_dict, max_seq_len)
    # can now call model.load_state_dict(hf_state_dict) to the original HF model
```

Similarly, given a supported HuggingFace model state_dict, you can use `translate_hf_state_dict_to_smdistributed` API to convert it to a format readable by `smp.DistributedModel`. This can be useful in transfer learning use cases, where a pre-trained model is loaded into a `smp.DistributedModel` for model-parallel fine-tuning:

```python
from smdistributed.modelparallel.torch.nn.huggingface.roberta \import translate_state_dict_to_smdistributed
```
model = AutoModelForMaskedLM.from_config(roberta_config)
model = smp.DistributedModel(model)

pretrained_model = AutoModelForMaskedLM.from_pretrained("roberta-large")
translated_state_dict = translate_state_dict_to_smdistributed(pretrained_model.state_dict())

# load the translated pretrained weights into the smp.DistributedModel
model.load_state_dict(translated_state_dict)
# start fine-tuning...

The relevant `state_dict` translation functions between Hugging Face and `smp` can be accessed as follows.

- from smdistributed.modelparallel.torch.nn.huggingface.gpt2 import translate_state_dict_to_hf_gpt2
- from smdistributed.modelparallel.torch.nn.huggingface.gpt2 import translate_hf_state_dict_to_smdistributed
- from smdistributed.modelparallel.torch.nn.huggingface.bert import translate_state_dict_to_hf_bert
- from smdistributed.modelparallel.torch.nn.huggingface.bert import translate_hf_state_dict_to_smdistributed
- from smdistributed.modelparallel.torch.nn.huggingface.roberta import translate_state_dict_to_hf_roberta
- from smdistributed.modelparallel.torch.nn.huggingface.roberta import translate_hf_state_dict_to_smdistributed
- from smdistributed.modelparallel.torch.nn.huggingface.gptj import translate_hf_gptj_state_dict_to_smdistributed (Available in the SageMaker model parallel library v1.8.0 and later)
- from smdistributed.modelparallel.torch.nn.huggingface.gptj import translate_state_dict_to_hf_gptj (Available in the SageMaker model parallel library v1.8.0 and later)

### Optimizer State Sharding

**Optimizer state sharding** is a useful memory-saving technique that shards the optimizer state (the set of weights that describes the state of optimizer) across data parallel device groups. You can use optimizer state sharding whenever you use a stateful optimizer (such as Adam) or an FP16 optimizer (which stores both FP16 and FP32 copies of the parameters).

#### How to Use Optimizer State Sharding

**Optimizer state sharding** can be turned on by setting "shard_optimizer_state": True in the modelparallel configuration.

When this feature is turned on, the library partitions the set of model parameters based on the data parallelism degree. The gradients corresponding to the i'\textsuperscript{th} partition get reduced only at the i'\textsuperscript{th} data parallel rank. At the end of the first call to an `smp.step` decorator function, the optimizer wrapped by `smp.DistributedOptimizer` redefines its parameters to be only limited to those parameters corresponding to the partition of the current data parallel rank. The redefined parameters are called `virtual_parameters` and share underlying storage with the original parameters. During the first call to `optimizer.step`, the optimizer states are created based on these redefined parameters, which are sharded because of the original partition. After the optimizer update, an `allgather` operation (as part of the `optimizer.step` call) is performed across the data parallel ranks to achieve consistent parameter states.
Tip
Optimizer state sharding can be useful when the degree of data parallelism is greater than 1 and the model has more than a billion parameters.
The degree of data parallelism is calculated by \((\text{processes\_per\_host} \times \text{instance\_count} / \text{pipeline\_parallel\_degree})\), and the \text{smp.dp\_size()} function handles the sizing in the background.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled": True,
    "processes\_per\_host": 8,               # 8 processes
    "custom\_mpi\_options": "--mca btl_vader\_single\_copy\_mechanism none "
}

smp_options = {
    "enabled": True,
    "parameters": {
        "microbatches": 4,
        "pipeline\_parallel\_degree": 2,  # alias for "partitions"
        "placement\_strategy": "cluster",
        "tensor\_parallel\_degree": 2,  # tp over 2 devices
        "ddp": True,
        "shard\_optimizer\_state": True
    }
}
```

Adapt your PyTorch training script

See Adapt your PyTorch training script (p. 2281) in the Tensor parallelism combined with pipeline parallelism section. There’s no additional modification required for the script.

Activation Checkpointing

Activation checkpoining (or gradient checkpointing) is a technique to reduce memory usage by clearing activations of certain layers and recomputing them during a backward pass. Effectively, this trades extra computation time for reduced memory usage. If a module is checkpointed, at the end of a forward pass, the inputs to and outputs from the module stay in memory. Any intermediate tensors that would have been part of the computation inside that module are freed up during the forward pass. During the backward pass of checkpointed modules, these tensors are recomputed. At this point, the layers beyond this checkpointed module have finished their backward pass, so the peak memory usage with checkpointing can be lower.

How to Use Activation Checkpointing

With smdistributed.modelparallel, you can use activation checkpointing at the granularity of a module. For all torch.nn modules except torch.nn.Sequential, you can only checkpoint a module tree if it lies within one partition from the perspective of pipeline parallelism. In case of the torch.nn.Sequential module, each module tree inside the sequential module needs to completely lie within one partition for activation checkpointing to work. When you use manual partitioning, you need to be aware of these restrictions.

When you use automated model partitioning, you can find the partitioning assignment logs starting with Partition assignments: in the training job logs. If a module is partitioned across multiple ranks (for example, with one descendant on one rank and another descendant on a different rank), the library ignores the attempt to checkpoint the module and raises a warning message that the module won't be checkpointed.

Note
The SageMaker model parallel library supports both overlapping and non-overlapping allreduce in combination with checkpointing.
Note

PyTorch’s native checkpointing API is not compatible with smdistributed.modelparallel.

Example 1: The following sample code shows how to use activation checkpointing when you have a model definition in your script.

```python
import torch.nn as nn
import torch.nn.functional as F
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 32, 3, 1)
        self.conv2 = nn.Conv2d(32, 64, 3, 1)
        self.fc1 = nn.Linear(9216, 128)
        self.fc2 = nn.Linear(128, 10)

    def forward(self, x):
        x = self.conv1(x)
        x = self.conv2(x)
        x = F.max_pool2d(x, 2)
        x = torch.flatten(x, 1)
        # This call of fc1 will be checkpointed
        x = checkpoint(self.fc1, x)
        x = self.fc2(x)
        return F.log_softmax(x, 1)
```

Example 2: The following sample code shows how to use activation checkpointing when you have a sequential model in your script.

```python
import torch.nn as nn
from smdistributed.modelparallel.torch.patches.checkpoint import checkpoint_sequential

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.seq = nn.Sequential(
            nn.Conv2d(1,20,5),
            nn.ReLU(),
            nn.Conv2d(20,64,5),
            nn.ReLU()
        )

    def forward(self, x):
        # This call of self.seq will be checkpointed
        x = checkpoint_sequential(self.seq, x)
        return F.log_softmax(x, 1)
```

Example 3: The following sample code shows how to use activation checkpointing when you import a prebuilt model from a library, such as PyTorch and Hugging Face Transformers. Whether you checkpoint sequential modules or not, you need to do the following:

1. Wrap the model by smp.DistributedModel().
2. Define an object for sequential layers.
3. Wrap the sequential layer object by smp.set_activation_checkpointing().

```python
import smdistributed.modelparallel.torch as smp
```
Activation Offloading

When activation checkpointing and pipeline parallelism are turned on and the number of microbatches is greater than one, activation offloading is an additional feature that can further reduce memory usage. Activation offloading asynchronously moves the checkpointed activations corresponding to their microbatches that are not currently running in the CPU. Right before the GPU needs the activations for the microbatch’s backward pass, this functionality prefetches the offloaded activations back from the CPU.

How to Use Activation Offloading

Use activation offloading to reduce memory usage when the number of microbatches is greater than 1, and activation checkpointing is enabled (see Activation Checkpointing (p. 2287)). When the activation checkpointing is not used, activation offloading has no effect. When it is used with only one microbatch, it does not save memory.

To use activation offloading, set "offload_activations": True in the modelparallel configuration.

Activation offloading moves the checkpointed activations in nn.Sequential modules to CPU asynchronously. The data transfer over the PCIe link overlaps with GPU computation. The offloading happens immediately, as soon as the forward pass for a particular checkpointed layer is computed. The activations are loaded back to the GPU shortly before they are needed for the backward pass of a particular microbatch. The CPU-GPU transfer similarly overlaps with computation.

To adjust how early the activations are loaded back into the GPU, you can use the configuration parameter "activation_loading_horizon" (default is set to 4, must be int larger than 0). A larger activation loading horizon would cause the activations to be loaded back to the GPU earlier. If the horizon is too large, the memory-saving impact of activation offloading might be diminished. If the horizon is too small, the activations may not be loaded back in time, reducing the amount of overlap and degrading performance.

**Tip**

Activation offloading can be useful for large models with over a hundred billion parameters.

Configure a SageMaker PyTorch estimator

```python
mpi_options = {
    "enabled" : True,
    "processes_per_host" : 8,       # 8 processes
    "custom_mpi_options" : "--mca btl_vader_single_copy_mechanism none "
}

smp_options = {
    "enabled":True,
    "parameters": {
        "microbatches": 4,
        "pipeline_parallel_degree": 2,  # alias for "partitions"
        "placement_strategy": "cluster",
```
Amazon SageMaker Developer Guide
Model Parallel Training

```
"tensor_parallel_degree": 2,   # tp over 2 devices
"ddp": True,
"offload_activations": True,
"activation_loading_horizon": 4  # optional. default is 4.
}
```

## Ranking Mechanism

This section explains how the ranking mechanism of model parallelism works with tensor parallelism. This is extended from the [Ranking Basics for Core Features of the SageMaker Model Parallel Library](p. 2252). With tensor parallelism, the library introduces three types of ranking and process group APIs: `smp.tp_rank()` for tensor parallel rank, `smp.pp_rank()` for pipeline parallel rank, and `smp.rdp_rank()` for reduced-data parallel rank. The corresponding communication process groups are `tensor parallel group (TP_GROUP)`, `pipeline parallel group (PP_GROUP)`, and `reduced-data parallel group (RDP_GROUP)`. These groups are defined as follows:

- A tensor parallel group (`TP_GROUP`) is an evenly divisible subset of the data parallel group, over which tensor parallel distribution of modules takes place. When the degree of pipeline parallelism is 1, `TP_GROUP` is the same as `model parallel group (MP_GROUP)`.

- A pipeline parallel group (`PP_GROUP`) is the group of processes over which pipeline parallelism takes place. When the tensor parallelism degree is 1, `PP_GROUP` is the same as `MP_GROUP`.

- A reduced-data parallel group (`RDP_GROUP`) is a set of processes that hold both the same pipeline parallelism partitions, as well as the same tensor parallel partitions, and perform data parallelism among themselves. This is called the reduced data parallel group because it is a subset of the entire data parallelism group, `DP_GROUP`. For the model parameters that are distributed within the `TP_GROUP`, the gradient `allreduce` operation is performed only for reduced-data parallel group, while for the parameters that are not distributed, the gradient `allreduce` takes place over the entire `DP_GROUP`.

- A model parallel group (`MP_GROUP`) refers to a group of processes that collectively store the entire model. It consists of the union of the `PP_GROUPS` of all the ranks that are in the `TP_GROUP` of the current process. When the degree of tensor parallelism is 1, `MP_GROUP` is equivalent to `PP_GROUP`. It is also consistent with the existing definition of `MP_GROUP` from previous `smdistributed` releases. Note that the current `TP_GROUP` is a subset of both the current `DP_GROUP` and the current `MP_GROUP`.

To learn more about the communication process APIs in the SageMaker distributed model parallelism library, see the [Common API](https://docs.aws.amazon.com/sagemaker/latest/dg/pipelines-common-api.html) and the [PyTorch-specific APIs](https://docs.aws.amazon.com/sagemaker/latest/dg/pipelines-pytorch.html) in the [SageMaker Python SDK documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/python-sdk/index.html).

The following figure illustrates the ranking mechanism, parameter distribution, and associated `allreduce` operations.
The preceding figure illustrates process groups for a node with 8 GPUs, where the degree of tensor parallelism is 2, the degree of pipeline parallelism is 2, and the degree of data parallelism is 4. The first figure shows an example model with 4 layers. In the other figures, the 4-layer model is distributed across 4 GPUs using both pipeline parallelism and tensor parallelism, where tensor parallelism is used for the middle two layers. These figures are simple copies to illustrate different group boundary lines. The partitioned model is replicated for data parallelism across GPUs 0-3 and 4-7. The lower left figure shows the definitions of \texttt{MP\_GROUP}, \texttt{PP\_GROUP}, and \texttt{TP\_GROUP}. The lower right figure shows \texttt{RDP\_GROUP}, \texttt{DP\_GROUP}, and \texttt{WORLD} over the same set of GPUs. The gradients for the layers and layer slices that have the same color are \texttt{allreduce}d together for data parallelism. For example, the first layer (light blue) gets the \texttt{allreduce} operations across \texttt{DP\_GROUP}, whereas the dark orange slice in the second layer only gets the \texttt{allreduce} operations within the \texttt{RDP\_GROUP} of its process. The bold dark red arrows represent tensors with the batch of its entire \texttt{TP\_GROUP}.

In this example, pipeline parallelism occurs across the GPU pairs (0,1); (2,3); (4,5) and (6,7). In addition, we have data parallelism (\texttt{allreduce}) taking place across GPUs 0, 2, 4, 6, and independently over GPUs 1, 3, 5, 7. Tensor parallelism happens over subsets of \texttt{dp\_groups}, across the GPU pairs (0,2); (1,3); (4,6) and (5,7).
Note that under this type of tensor parallelism, \((\text{the degree of data parallelism}) \times (\text{the degree of pipeline parallelism}) = (\text{the number of GPUs})\).

### SageMaker Distributed Model Parallel Best Practices

Use the following guidelines when you run a distributed training job with the SageMaker model parallel library.

#### Setting Up the Right Configuration for a Given Model

When scaling up a model, we recommend you to go over the following list in order. Each list item discusses the advantage of using the library's techniques along with the tradeoffs that might arise.

**Tip**

If a model can fit well using a subset of the library's features, adding more model parallelism or memory saving features does not usually improve performance.

#### Using large GPU instance types

- In the realm of model parallelism, it is best to use powerful instances with large GPU memories to handle overhead from model parallelism operations such as partitioning models across multiple GPUs. We recommend using `ml.p4d` or `ml.p3dn` instances for training large DL models. These instances are also equipped with Elastic Fabric Adapter (EFA), which provides higher network bandwidth and enables large-scale training with model parallelism.

#### Sharding optimizer state

- The impact of sharding optimizer state depends on the number of data parallel ranks. Typically, a higher degree of data parallelism (proportional to the size of compute node) can improve the efficiency of memory usage.

  When you want to downsize a cluster, make sure you check the optimizer state sharding configuration. For example, a large DL model with optimizer state sharding that fits on a node with 16 GPUs won't fit on a node with 8 GPUs because there are simply not enough GPUs across which to shard the optimizer state.

  For more information, see Optimizer State Sharding (p. 2286).

#### Activation checkpointing

- Memory efficiency can be improved by using activation checkpointing for a group of modules. The more you group the modules, the more efficient the memory usage. When checkpointing sequential modules for layers, the `strategy` argument of the `smp.set_activation_checkpointing` function groups the layers together for checkpointing. For example, grouping two or more layers together for checkpointing is more memory efficient than checkpointing one layer at a time, and this trades extra computation time for reduced memory usage.

  For more information, see Activation Checkpointing (p. 2287).

#### Tensor parallelism

- The degree of tensor parallelism should be a power of two \((2, 4, 8, ..., 2^n)\), where the maximum degree must be equal to the number of GPUs per node. For example, if you use a node with 8 GPUs, possible numbers for the degree of tensor parallelism are 2, 4, and 8. We don't recommend arbitrary numbers (such as 3, 5, 6, and 7) for the degree of tensor parallelism. When you use multiple nodes, misconfiguring the degree of tensor parallelism might result in running tensor parallelism across the
nodes; this adds significant overhead from communication of activations across the nodes and can become computationally expensive.

For more information, see Tensor Parallelism (p. 2276).

Pipeline parallelism across nodes

• You can run pipeline parallelism both within a single node and across multiple nodes. When you use pipeline parallelism in combination with tensor parallelism, we recommend running pipeline parallelism across multiple nodes and keeping tensor parallelism within individual nodes.

• Pipeline parallelism comes with the following three knobs: microbatches, active_microbatches, and prescaled_batch.

  • When you use tensor parallelism with pipeline parallelism, we recommend activating prescaled_batch so that the batch size per model parallel group can be increased for efficient pipelining. With prescaled_batch activated, the batch size set in the training script becomes tp_size times the batch size set for each rank without prescaled_batch.

  • Increasing the number of microbatches helps achieve efficient pipelining and better performance. Note that the effective microbatch size is the batch size divided by number of microbatches. If you increase the number of microbatches while keeping batch size constant, each microbatch processes fewer samples.

  • The number of active_microbatches is the maximum number of microbatches that are simultaneously in process during pipelining. For each active microbatch in process, its activations and gradients take up GPU memory. Therefore, increasing active_microbatches takes up more GPU memory.

  • If both GPU and GPU memory are underutilized, increase active_microbatches for better parallelization during pipelining.

  • For more information about how to use tensor parallelism with pipeline parallelism, see Tensor parallelism combined with pipeline parallelism (p. 2281).

  • To find descriptions of the aforementioned parameters, see Parameters for smdistributed in the SageMaker Python SDK documentation.

Offloading activations to CPU

• Make sure that this is used in combination with activation checkpointing and pipeline parallelism. To ensure that the offloading and preloading happen in the background, specify a value greater than 1 to the microbatches parameter.

• When offloading activations, you might be able to increase active_microbatches and sometimes match with the total number of microbatches. This depends on which modules are checkpointed and how the model is partitioned.

For more information, see Activation Offloading (p. 2289).

Reference configurations

The SageMaker distributed model parallel training team provides the following reference points based on experiments with the GPT-2 model, the sequence length of 512, and the vocabulary size of 50,000.
You can extrapolate from the preceding configurations to estimate GPU memory usage for your model configuration. For example, if you increase the sequence length for a 10-billion-parameter model or increase the size of the model to 20 billion, you might want to lower batch size first. If the model still doesn’t fit, try increasing the degree of tensor parallelism.

Modifying Your Training Script

- Before you use the SageMaker model parallel library’s features in your training script, review SageMaker Distributed Model Parallel Configuration Tips and Pitfalls (p. 2295).
- To launch a training job faster, use the SageMaker local mode. This helps you quickly run a training job locally on a SageMaker notebook instance. Depending on the scale of the ML instance on which your SageMaker notebook instance is running, you might need to adjust the size of your model by changing the model configurations, such as the hidden width, number of transformer layers, and attention heads. Validate if the reduced model runs well on the notebook instance before using a large cluster for training the full model.

Monitoring and Logging a Training Job Using the SageMaker Console and Amazon CloudWatch

To monitor system-level metrics such as CPU memory utilization, GPU memory utilization, and GPU utilization, use visualization provided through the SageMaker console.

1. In the left navigation pane, choose Training.
2. Choose Training jobs.
3. In the main pane, choose the training job name for which you want to see more details.
4. Browse the main pane and find the Monitor section to see the automated visualization.
5. To see training job logs, choose View logs in the Monitor section. You can access the distributed training job logs of the training job in CloudWatch. If you launched multi-node distributed training, you should see multiple log streams with tags in the format of algo-n-1234567890. The algo-1 log stream tracks training logs from the main (0th) node.

For more information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 2383).
Permissions

To run a SageMaker training job with model parallelism or the SageMaker distributed training example notebooks, make sure you have the right permissions in your IAM role, such as the following:

- To use FSx for Lustre, add AmazonFSxFullAccess.
- To use Amazon S3 as a data channel, add AmazonS3FullAccess.
- To use Docker, build your own container, and push it to Amazon ECR, add AmazonEC2ContainerRegistryFullAccess.
- To have a full access to use the entire suite of SageMaker features, add AmazonSageMakerFullAccess.

SageMaker Distributed Model Parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker’s distributed model parallel library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow Training Script (p. 2257) and Modify a PyTorch Training Script (p. 2263), respectively.

Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can lower performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set drop_remainder=True in the tf.Dataset.batch() call (in TensorFlow), or set drop_last=True in DataLoader (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with smp.dp_rank(). If the dataset is being deterministically sharded across data
parallel devices, make sure that the shard is indexed by \texttt{smp.dp_rank()}. This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

**Returning Tensors from \texttt{smp.DistributedModel}**

- Any tensor that is returned from the \texttt{smp.DistributedModel.call} (for TensorFlow) or \texttt{smp.DistributedModel.forward} (for PyTorch) function is broadcast to all other ranks, from the rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

**The \texttt{smp.step} Decorator**

- If an \texttt{smp.step}-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the \texttt{non_split_inputs} list when calling \texttt{smp.step}. This prevents the library from attempting to split the tensor into microbatches. For more information see \texttt{smp.step} in the API documentation.

**Delaying Parameter Initialization**

For very large models over 100 billion parameters, weight initialization through the CPU memory might result in an out-of-memory error. To get around this, the library offers \texttt{smp.delay_param_initialization} context manager. This delays the physical allocation of parameters until they move to GPU during the first execution of a \texttt{smp.step}-decorated function. This avoids unnecessary memory usage of the CPU during the initialization of training. Use the context manager when you create a model object as shown in the following code.

```python
with smp.delay_param_initialization(enabled=True):
    model = MyModel()
```

**Tensor Parallelism for PyTorch**

- If you are using a seed for deterministic results, set the seed based on \texttt{smp.dp_rank()} (for example, \texttt{torch.manual_seed(42 + smp.dp_rank())}). If you do not do this, different partitions of an \texttt{nn.Parameter} are initialized in the same way, impacting convergence.
- SageMaker's model parallelism library uses NCCL to implement collectives needed for the distribution of the modules. Especially for smaller models, if too many NCCL calls are scheduled on the GPU at the same time, memory usage might increase because of additional space used by NCCL. To counteract this, \texttt{smp} throttles the NCCL calls so that the number of ongoing NCCL operations at any given time is less than or equal to a given limit. The default limit is 8, but this can be adjusted using the environment variable \texttt{SMP_NCCL_THROTTLE_LIMIT}. If you observe more memory usage than you expect while using tensor parallelism, you can try reducing this limit. However, choosing a limit that is too small might cause throughput loss. To disable throttling altogether, you can set \texttt{SMP_NCCL_THROTTLE_LIMIT=-1}.
- The following identity, which holds when the degree of tensor parallelism is 1, does not hold when the degree of tensor parallelism is greater than 1: \texttt{smp.mp_size() * smp.dp_size() == smp.size()}. This is because the tensor parallel group is part of both the model parallelism group and the data parallelism group. If your code has existing references to \texttt{mp_rank}, \texttt{mp_size}, \texttt{MP_GROUP}, and so on, and if you want to work with only the pipeline parallel group, you might need to replace the references with \texttt{smp.pp_size()}. The following identities are always true:
  - \texttt{smp.mp_size() * smp.rdp_size() == smp.size()}
  - \texttt{smp.pp_size() * smp.dp_size() == smp.size()}
  - \texttt{smp.pp_size() * smp.tp_size() * smp.rdp_size() == smp.size()}
• Since the `smp.DistributedModel` wrapper modifies the model parameters when tensor parallelism is enabled, the optimizer should be created after calling `smp.DistributedModel`, with the distributed parameters. For example, the following does not work:

```python
## WRONG
model = MyModel()
optimizer = SomeOptimizer(model.parameters())
model = smp.DistributedModel(model)  # optimizer now has outdated parameters!
```

Instead, the optimizer should be created with the parameters of the `smp.DistributedModel` as follows:

```python
## CORRECT
model = smp.DistributedModel(MyModel())
optimizer = SomeOptimizer(model.optimizers())
```

• When a module is replaced with its distributed counterpart through tensor parallelism, the distributed module does not inherit its weights from the original module, and initializes new weights. This means that, for instance, if the weights need to be initialized in a particular call (for example, through a `load_state_dict` call), this needs to happen after the `smp.DistributedModel` call, once the module distribution takes place.

• When accessing the parameters of distributed modules directly, note that the weight does not have the same shape as the original module. For instance,

```python
with smp.tensor_parallelism():
    linear = nn.Linear(60, 60)
    # will pass
    assert tuple(linear.weight.shape) == (60, 60)
distributed_linear = smp.DistributedModel(linear)
    # will fail. the number of input channels will have been divided by `smp.tp_size()`
    assert tuple(distributed_linear.module.weight.shape) == (60, 60)
```

• Using `torch.utils.data.distributed.DistributedSampler` is strongly recommended for tensor parallelism. This ensures that every data parallel rank receives the same number of data samples, which prevents hangs that might result from different `dp_ranks` taking a different number of steps.

• If you use the `join` API of PyTorch's `DistributedDataParallel` class to handle cases in which different data parallel ranks have different numbers of batches, you still need to make sure that ranks that are in the same `TP_GROUP` have the same number of batches; otherwise the communication collectives used in distributed execution of modules may hang. Ranks that are in different `TP_GROUPS` can have different numbers of batches, as long as `join` API is used.

• If you want to checkpoint your model and use tensor parallelism, consider the following:
  • To avoid stalling and race conditions while saving and loading models when you use tensor parallelism, make sure you call appropriate functions from the following model and optimizer states inside a reduced-data parallelism rank.
  • If you are transitioning an existing pipeline parallel script and enabling tensor parallel for the script, ensure that you modify any `if smp.dp_rank() == 0` block used for saving and loading with `if smp.rdp_rank() == 0` blocks. Otherwise, it might cause your training job to stall.
  • Full checkpointing of optimizer states is currently not supported with tensor parallelism. If you want to resume training from a checkpoint, use partial checkpointing instead.

For more information about checkpointing a model with tensor parallelism, see Instructions for Checkpointing with Tensor Parallelism (p. 2283).
Model Parallel Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

Topics
- Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel (p. 2298)
- Saving Checkpoints (p. 2298)
- Convergence Using Model Parallel and TensorFlow (p. 2300)
- Stalling or Crashing Distributed Training Jobs (p. 2300)
- NCCL error (p. 2301)

Considerations for Using SageMaker Debugger with SageMaker Distributed Model Parallel

SageMaker Debugger is not available for SageMaker distributed model parallel. Debugger is enabled by default for all SageMaker TensorFlow and PyTorch training jobs, and you might see an error that looks like the following:

```
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading
```

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating a framework `estimator` as shown in the following example.

```
bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"
# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}//{}//{}".format(bucket, base_job_name, checkpoint_in_bucket)
estimator = TensorFlow(
    ...
    distribution="smdistributed": { "modelparallel": { "enabled": True }},
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path="/opt/ml/checkpoints",
    debugger_hook_config=False
)
```

Saving Checkpoints

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker, use the following example to explicitly upload the checkpoints.

If you run into the preceding error, do not use `checkpoint_s3_uri` with the SageMaker `estimator` call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```
import os
```
def aws_s3_sync(source, destination):
    
    """aws s3 sync in quiet mode and time profile""
    import time, subprocess
    cmd = ['aws', 's3', 'sync', '--quiet', source, destination]
    print(f"Syncing files from {source} to {destination}")
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print(f"Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
    s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from local path to s3 ""

    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError("Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}"
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(local_path, s3_uri)
    return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
    s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """ sample function to sync checkpoints from s3 to local path ""

    import boto3
    #try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}"

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError("Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}"
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(s3_uri, local_path)
    return

Usage of helper functions:
Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and distributed model parallel, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Stalling or Crashing Distributed Training Jobs

If your training job has stalling, crashing, or not responding issues, read the following troubleshooting items to identify what's the cause of the issue. If you need any further support, reach out to the SageMaker distributed training team through AWS Support.

- If you see a distributed training job stalling at the NCCL initialization step, consider the following:
  - If you are using one of the EFA-enabled instances (ml.p4d or ml.p3dn instances) with a custom VPC and its subnet, ensure that the security group used has inbound and outbound connections for all ports to and from the same SG. You also generally need outbound connections to any IP as a separate rule (for internet access). To find instructions on how to add inbound and outbound rules for EFA communication, refer to SageMaker Distributed Training Job Stalling During Initialization (p. 2249).

- If you see a distributed training job stalling when checkpointing the full model, this might be because the state_dict() call on the model or optimizer was not made on all ranks with rdp_rank()==0 (when using tensor parallelism) or dp_rank()==0 (when using only pipeline parallelism). These ranks need to communicate to construct the checkpoint to be saved. Similar stalling issues can also happen when checkpointing partial optimizer if shard_optimizer_state is enabled.

For more information about checkpointing a model with model parallelism, see General Instruction for Saving and Loading and Instructions for Checkpointing with Tensor Parallelism (p. 2283).

- If the training job crashes with a CUDA Out of Memory error, this means that the distributed training configuration needs to be adjusted to fit the model on the GPU cluster. For more information and best practices, see Setting Up the Right Configuration for a Given Model (p. 2292).

- If the training job crashes with an uncorrectable ECC error, this means that one of the GPUs in the cluster has gone bad. If you need technical support, share the job ARN with the AWS team and restart your training job from a checkpoint if possible.

- In rare cases, a job configuration that worked previously but is close to the limits of GPU memory might fail later with a different cluster due to a CUDA Out of Memory error. This could be because some GPU has lower available memory than usual due to ECC errors.

- Network timeout crash might happen when running a multinode job which doesn’t use all GPUs in the node. To get around this, use all GPUs on the node by ensuring that the processes_per_host parameter is set to the number of GPUs in each instance. For example, this is processes_per_host=8 for ml.p3.16xlarge, ml.p3dn.24xlarge, and ml.p4d.24xlarge instances.
• If you find that your training job takes a long time during the data downloading stage, make sure the Amazon S3 path you provided to checkpoint_s3_uri for the SageMaker Estimator class is unique for the current training job. If this path is reused across multiple training jobs running simultaneously, all those checkpoints are uploaded and downloaded to the same Amazon S3 path and might significantly increase checkpoint loading time.
• Use FSx for Lustre when you deal with large data and models.
  • If your dataset is large and fetching it takes a long time, we recommend keeping your dataset in FSx for Lustre.
  • When training models are beyond 10 billion parameters, we recommend using FSx for Lustre for checkpointing.
  • After you create a file system, make sure to wait for the status to become available before starting a training job using it.

**NCCL error**

If you encountered the following error, it might be due to a process running out of GPU memory.

```
NCCL error in: ../torch/lib/c10d/ProcessGroupNCCL.cpp:825, unhandled system error, NCCL version 2.7.8
ncclSystemError: System call (socket, malloc, munmap, etc) failed.
```

You can resolve this by reducing the batch size or active_microbatches. If auto partitioning is not resulting in a well-balanced partitioning, you might have to consider manual partitioning. For more information, see [Pipeline parallelism across nodes](p. 2293).

**Amazon SageMaker Distributed Training Notebook Examples**

The following case studies and notebooks provide examples of implementing the SageMaker distributed training libraries for the supported deep learning frameworks (PyTorch, TensorFlow, and HuggingFace) and models, such as CNN and MaskRCNN for vision, and BERT for natural language processing.

These notebooks are provided in the SageMaker examples GitHub repository. You can also browse them on the SageMaker examples website.

The examples are set up to use p3.16xlarge instances for the worker nodes, but you may choose ml.p3dn.24xlarge or ml.p4d.24xlarge instance types for which the SageMaker distributed training libraries are optimized. You can test the notebooks using a cluster of a single node; however, to see a performance improvement as shown in the Training Benchmarks section, use a cluster of multiple nodes (two or more). The examples call out the section in which you modify this configuration.

**Blogs and Case Studies**

The following blogs discuss case studies about using the SageMaker distributed training libraries.

• Hyundai reduces ML model training time for autonomous driving models using Amazon SageMaker
• Distributed Training: Train BART/T5 for Summarization using Transformers and Amazon SageMaker in the [HuggingFace documentation](p. 2293)

**PyTorch Examples**

**SageMaker Distributed Data Parallel**

• CNN with PyTorch 1.6 and SageMaker Data Parallel
• MaskRCNN with PyTorch 1.6 and SageMaker Data Parallel
• BERT with PyTorch 1.6 and SageMaker Data Parallel

**SageMaker Distributed Model Parallel**
• Train GPT-2 with PyTorch 1.8.1 and Tensor Parallelism Using the SageMaker Model Parallelism Library
• BERT with PyTorch 1.6 and SageMaker Model Parallel

**TensorFlow Examples**

**SageMaker Distributed Data Parallel**
• CNN with TensorFlow 2.3.1 and SageMaker Data Parallel
• MaskRCNN with TensorFlow 2.3.1 and SageMaker Data Parallel
• BERT with TensorFlow 2.3.1 and SageMaker Data Parallel

**SageMaker Distributed Model Parallel**
• CNN with TensorFlow 2.3.1 and SageMaker Model Parallel

**HuggingFace Examples**

The following HuggingFace on SageMaker examples are available in the HuggingFace notebooks repository.

**SageMaker Distributed Data Parallel**
• HuggingFace Distributed Data Parallel Training in PyTorch on SageMaker - Distributed Question Answering
• HuggingFace Distributed Data Parallel Training in PyTorch on SageMaker - Distributed Text Summarization
• HuggingFace Distributed Data Parallel Training in TensorFlow on SageMaker

**SageMaker Distributed Model Parallel**
• HuggingFace with TensorFlow Distributed Model Parallel Training on SageMaker

**How to Access or Download the SageMaker Distributed Training Notebook Examples**

Follow instructions to access or download the SageMaker distributed training example notebooks.

**Option 1: Use a SageMaker notebook instance**

To use the aforementioned examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance runs Jupyter Notebook and JupyterServer apps on Amazon EC2 instances, which are optimized for machine learning. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 239) in the SageMaker developer guide to create one.

After you have created an instance, in the **Notebook instances** page of the SageMaker console, do the following:
1. Open JupyterLab.
2. Select the examples icon (🔍) in the left tray.
3. Browse the examples for Training and look for notebooks titled Distributed Data Parallel or Distributed Model Parallel.

Option 2: Clone the SageMaker example repository to SageMaker Studio or notebook instance

To download and use the aforementioned example notebooks, do the following to clone the example GitHub repositories:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   
   ```
   cd SageMaker
   ```
3. Clone the SageMaker examples GitHub repository.
   
   ```
   git clone https://github.com/aws/amazon-sagemaker-examples.git
   ```

   **Note**

   To download the HuggingFace example notebooks (p. 2302), clone the HuggingFace notebooks GitHub repository:
   
   ```
   git clone https://github.com/huggingface/notebooks huggingface-notebooks
   ```
4. In the JupyterLab interface, navigate into the `amazon-sagemaker-examples` folder.
5. In the `training/distributed_training` folder, there are folders for frameworks, and in each of these, there are folders for `data_parallel` and `model_parallel`. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

Amazon SageMaker Training Compiler

Use Amazon SageMaker Training Compiler to train deep learning (DL) models faster on scalable GPU instances managed by SageMaker.

**What Is SageMaker Training Compiler?**

State-of-the-art deep learning (DL) models consist of complex multi-layered neural networks with billions of parameters that can take thousands of GPU hours to train. Optimizing such models on training infrastructure requires extensive knowledge of DL and systems engineering; this is challenging even for narrow use cases. Although there are open-source implementations of compilers that optimize the DL training process, they can lack the flexibility to integrate DL frameworks with some hardware such as GPU instances.

SageMaker Training Compiler is a capability of SageMaker that makes these hard-to-implement optimizations to reduce training time on GPU instances. The compiler optimizes DL models to accelerate training by more efficiently using SageMaker machine learning (ML) GPU instances. SageMaker Training Compiler is available at no additional charge within SageMaker and can help reduce total billable time as it accelerates training.
SageMaker Training Compiler is integrated into the AWS Deep Learning Containers (DLCs). Using the SageMaker Training Compiler–enabled AWS DLCs, you can compile and optimize training jobs on GPU instances with minimal changes to your code. Bring your deep learning models to SageMaker and enable SageMaker Training Compiler to accelerate the speed of your training job on SageMaker ML instances for accelerated computing.

How It Works

SageMaker Training Compiler converts DL models from their high-level language representation to hardware-optimized instructions. Specifically, SageMaker Training Compiler applies graph-level optimization, dataflow-level optimizations, and backend optimizations to produce an optimized model that efficiently uses hardware resources. As a result, you can train your models faster than when you train them without compilation.

It is a two-step process to activate SageMaker Training Compiler for your training job:

1. Use the SageMaker Python SDK or SageMaker API to construct a SageMaker estimator.
   a. Enable SageMaker Training Compiler by adding
      
      ```
      compiler_config=TrainingCompilerConfig()
      ```
      as a parameter. To learn more, see Enable SageMaker Training Compiler (p. 2309).

   b. Adjust hyperparameters (`batch_size` and `learning_rate`) to maximize the benefit that SageMaker Training Compiler provides through its optimization and efficient usage of the GPU memory.

2. Bring your own DL script and pass it to the SageMaker estimator. To learn more, see Bring Your Own Deep Learning Model (p. 2314).

   By running the `estimator.fit()` class method, SageMaker compiles your model and starts training.

SageMaker Training Compiler does not alter the final trained model, while allowing you to accelerate the training job by more efficiently using the GPU memory and fitting a larger batch size per iteration. The final trained model from the compiler-accelerated training job is identical to the one from the ordinary training job.

Tip

SageMaker Training Compiler only compiles DL models for training on ML GPU instances managed by SageMaker. To compile your model for inference and deploy it to run anywhere in the cloud and at the edge, use SageMaker Neo compiler.

Topics

- Supported Frameworks, AWS Regions, Tested Instances, and Tested Models (p. 2305)
- Enable SageMaker Training Compiler (p. 2309)
Supported Frameworks, AWS Regions, Tested Instances, and Tested Models

Before using SageMaker Training Compiler, check if your framework of choice is supported, the instance types are available in your AWS account, and your AWS account is in one of the supported AWS Regions.

Note
SageMaker Training Compiler is available in the SageMaker Python SDK v2.70.0 or later.

Supported Frameworks

SageMaker Training Compiler supports the following deep learning frameworks and is available through AWS Deep Learning Containers.

<table>
<thead>
<tr>

</tbody>
</table>

For specs of the instance types, see the **Accelerated Computing** section in the Amazon EC2 Instance Types page. For information about instance pricing, see Amazon SageMaker Pricing.

If you encountered an error message similar to the following, follow the instructions at Request a service quota increase for SageMaker resources.

```
ResourceLimitExceeded: An error occurred (ResourceLimitExceeded) when calling
the CreateTrainingJob operation: The account-level service limit 'ml.p3dn.24xlarge
for training job usage' is 0 Instances, with current utilization of 0 Instances
and a request delta of 1 Instances.
Please contact AWS support to request an increase for this limit.
```

Tested Models

The following table includes a list of the models that have been tested with SageMaker Training Compiler. For reference, the largest batch size that is able to fit into memory is also included alongside other training parameters. SageMaker Training Compiler can change the memory footprint of the model training process; as a result, a larger batch size can often be used during the training process, further decreasing total training time. You must retune your model with the compiler enabled to find this increased batch size. To save time, use the reference table to pick up the largest batch sizes that can be used with the tested models.

**Note**
The batch sizes are local batch size that fit into each individual GPU of an instance type. You should also adjust the learning rate when changing the batch size.

Enable SageMaker Training Compiler

SageMaker Training Compiler is built into the SageMaker Python SDK and AWS Deep Learning Containers so that you don't need to change your workflows to enable Training Compiler. You can use any of the SageMaker interfaces: Amazon SageMaker Studio, Amazon SageMaker notebook instances, AWS SDK for Python (Boto3), and AWS Command Line Interface, to run training jobs in the same way as you already do.

Topics
- Enable SageMaker Training Compiler Using the SageMaker Python SDK (p. 2309)
- Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation (p. 2314)

Enable SageMaker Training Compiler Using the SageMaker Python SDK

To enable SageMaker Training Compiler, add the compiler_config parameter to the HuggingFace estimator. Import the TrainingCompilerConfig class and pass an instance to the parameter. The following code shows the basic structure of a SageMaker estimator class with SageMaker Training Compiler enabled.

Tip
To get started, try using the batch sizes provided in the reference table at Tested Models (p. 2306).

Note
SageMaker Training Compiler is currently available only through the SageMaker HuggingFace estimator.

For information that fits your use case, see one of the following options.

For single GPU training

Hugging Face Estimator for TensorFlow

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update the global learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
)```
After you finish setting up the estimator, see the following pages to prepare your training script:

- **For single GPU training (p. 2315)** of a TensorFlow Keras model with Hugging Face Transformers
- **For single GPU training (p. 2316)** of a TensorFlow model with Hugging Face Transformers

### Hugging Face Estimator for PyTorch

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# the original max batch size that can fit into GPU memory without compiler
batch_size_native=12
learning_rate_native=float('5e-5')

# an updated max batch size that can fit into GPU memory with compiler
batch_size=64

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size

hyperparameters={
    "n_gpus": 1,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    transformers_version='4.17.0',
    pytorch_version='1.10.2',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

After you finish setting up the estimator, see the following pages to prepare your training script:

- **For single GPU training (p. 2317)** of a PyTorch model using Hugging Face Transformers' Trainer API
- **For single GPU training (p. 2318)** of a PyTorch model without Hugging Face Transformers' Trainer API

To find end-to-end examples, see the following notebooks:

- Compile and Train a Hugging Face Transformers Trainer Model for Question and Answering with the SQuAD dataset
Enable Training Compiler

- Compile and Train a Hugging Face Transformer BERT Model with the SST Dataset using SageMaker Training Compiler
- Compile and Train a Binary Classification Trainer Model with the SST2 Dataset for Single-Node Single-GPU Training

For distributed training

Hugging Face Estimator for TensorFlow

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate
}

tensorflow_huggingface_estimator=HuggingFace(
    entry_point='train.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.17.0',
    tensorflow_version='2.6.3',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

tensorflow_huggingface_estimator.fit()
```

Tip
After you finish setting up the estimator, see the following pages to prepare your training script:

- For distributed training (p. 2315) of a TensorFlow Keras model with Hugging Face Transformers
- For distributed training (p. 2316) of a TensorFlow model with Hugging Face Transformers

Hugging Face Estimator for PyTorch

For PyTorch, SageMaker Training Compiler uses an alternate mechanism for distributed training, and you don't need to specify the distribution parameter. The compiler requires you to pass a
SageMaker distributed training launcher script to the entry point and pass your training script to the hyperparameters argument.

```python
from sagemaker.huggingface import HuggingFace, TrainingCompilerConfig

# choose an instance type, specify the number of instances you want to use, # and set the num_gpus variable the number of GPUs per instance.
instance_count=1
instance_type='ml.p3.8xlarge'
num_gpus=4

# the original max batch size that can fit to GPU memory without compiler
batch_size_native=16
learning_rate_native=float('5e-5')

# an updated max batch size that can fit to GPU memory with compiler
batch_size=26

# update learning rate
learning_rate=learning_rate_native/batch_size_native*batch_size*num_gpus*instance_count

training_script="your_training_script.py"

hyperparameters={
    "n_gpus": num_gpus,
    "batch_size": batch_size,
    "learning_rate": learning_rate,
    "training_script": training_script
}

pytorch_huggingface_estimator=HuggingFace(
    entry_point='distributed_training_launcher.py',
    instance_count=instance_count,
    instance_type=instance_type,
    transformers_version='4.17.0',
    pytorch_version='1.10.2',
    hyperparameters=hyperparameters,
    compiler_config=TrainingCompilerConfig(),
    disable_profiler=True,
    debugger_hook_config=False
)

pytorch_huggingface_estimator.fit()
```

The launcher script wraps your training script and sets up the distributed training environment depending on the size of the training instance of your choice. The launcher script should look like the following:

```python
#!/bin/python

import subprocess
import sys

if __name__ == "__main__":
    arguments_command = " ".join([arg for arg in sys.argv[1:]])
    
    The following line takes care of setting up an inter-node communication as well as managing intra-node workers for each GPU.
    " ",
    subprocess.check_call("python -m torch_xla.distributed.sm_dist " + arguments_command, shell=True)
```
After you finish setting up the estimator, see the following pages to prepare your training script:

- For distributed training (p. 2317) of a PyTorch model using Hugging Face Transformers' Trainer API
- For distributed training (p. 2319) of a PyTorch model without Hugging Face Transformers' Trainer API

**Tip**
To find end-to-end examples, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

**Important**
You must specify the `transformers_version`, `pytorch_version` or `tensorflow_version`, `hyperparameters`, and `compiler_config` parameters to enable SageMaker Training Compiler. You cannot use `image_uri` to choose the Training Compiler integrated Deep Learning Containers that are listed at Supported Frameworks (p. 2305).

The following list is the minimal set of parameters required to run a SageMaker training job with the compiler.

- `entry_point` (str) – Required. Specify the filename of your training script.
  
**Note**
To run a PyTorch distributed training job with SageMaker Training Compiler, specify the filename of a launcher script that wraps your training script and configures the distributed training job properly. For more information, see the following notebooks:

- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Single-Node Multi-GPU Training
- Compile and Train the GPT2 Model using the Transformers Trainer API with the SST2 Dataset for Multi-Node Multi-GPU Training

- `instance_count` (int) – Required. Specify the number of instances.
- `instance_type` (str) – Required. Specify the instance type.
- `transformers_version` (str) – Required. Specify the Hugging Face Transformers library version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2305).
- `pytorch_version` or `tensorflow_version` (str) – Required. Specify the PyTorch or TensorFlow version supported by SageMaker Training Compiler. To find available versions, see Supported Frameworks (p. 2305).
- `hyperparameters` (dict) – Optional. Specify hyperparameters for the training job, such as `n_gpus`, `batch_size`, and `learning_rate`. When you enable SageMaker Training Compiler, try larger batch sizes and adjust the learning rate accordingly. To find examples, see SageMaker Training Compiler Example Notebooks and Blogs (p. 2320).
  
**Note**
To run a PyTorch distributed training job with SageMaker Training Compiler, you need to add an additional parameter, "training_script", to specify your training script. For example:

```
"training_script": "<your_dl_training_script.py>
```

- `compiler_config` (TrainingCompilerConfig object) – Required. Include this parameter to enable SageMaker Training Compiler. The following are parameters for the TrainingCompilerConfig class.
• **enabled (bool)** – Optional. Specify `True` or `False` to enable or disable SageMaker Training Compiler. The default value is `True`.

• **debug (bool)** – Optional. To receive more detailed training logs from your compiler-accelerated training jobs, change it to `True`. However, the additional logging might add overhead and slow down the compiled training job. The default value is `False`.

**Warning**

If you turn on SageMaker Debugger, it might impact the performance of SageMaker Training Compiler. We recommend that you turn off Debugger when running SageMaker Training Compiler to make sure there's no impact on performance. To turn the Debugger functionalities off, add the following two arguments to the estimator:

```python
disable_profiler=True,
debugger_hook_config=False
```

If the training job with the compiler is launched successfully, you receive the following logs during the job initialization phase:

- With `TrainingCompilerConfig(debug=False)`

  ```plaintext
  Found configuration for Training Compiler
  Configuring SM Training Compiler...
  ```

- With `TrainingCompilerConfig(debug=True)`

  ```plaintext
  Found configuration for Training Compiler
  Configuring SM Training Compiler...
  Training Compiler set to debug mode
  ```

**Enable SageMaker Training Compiler Using the SageMaker CreateTrainingJob API Operation**

SageMaker Training Compiler configuration options must be specified through the `AlgorithmSpecification` and `HyperParameters` field in the request syntax for the `CreateTrainingJob` API operation.

```
"AlgorithmSpecification": {
  "TrainingImage": "<sagemaker-training-compiler-enabled-dlc-image>"
},

HyperParameters": {
  "sagemaker_training_compiler_enabled": "true",
  "sagemaker_training_compiler_debug_mode": "false"
}
```

To find a complete list of deep learning container image URIs that have SageMaker Training Compiler implemented, see [Supported Frameworks](p. 2305).

**Bring Your Own Deep Learning Model**

This guide walks you through how to adapt your training script for a compiler-accelerated training job. The preparation of your training script depends on the following:

- Training settings such as single-core or distributed training.
• Frameworks and libraries that you use to create the training script.

Choose one of the following topics depending on the framework you use.

Topics
• TensorFlow Models (p. 2315)
• PyTorch Models (p. 2317)

**Note**
After you finish preparing your training script, you can run a SageMaker training job using the SageMaker framework estimator classes. For more information, see the previous topic at Enable SageMaker Training Compiler Using the SageMaker Python SDK (p. 2309).

**TensorFlow Models**

Bring your own TensorFlow model to SageMaker, and run the training job with SageMaker Training Compiler.

**TensorFlow Models with Hugging Face Transformers**

TensorFlow models with Hugging Face Transformers are based on TensorFlow's `tf.keras.Model` API. Hugging Face Transformers also provides pretrained model classes for TensorFlow to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Enable SageMaker Training Compiler (p. 2309).

SageMaker Training Compiler automatically optimizes model training workloads that are built on top of the native TensorFlow API or the high-level Keras API, such as the TensorFlow transformer models.

**Topics**
• Using Keras (p. 2315)
• Without Keras (p. 2316)

**Using Keras**

For the best compiler acceleration, we recommend using models that are subclasses of TensorFlow Keras (`tf.keras.Model`). As noted in the Quick tour page in the Hugging Face Transformers documentation, you can use the models as regular TensorFlow Keras models.

**For single GPU training**

There's no additional change you need to make in the training script.

**For distributed training**

SageMaker Training Compiler acceleration works transparently for multi-GPU workloads when the model is constructed and trained using Keras APIs within the scope of `tf.distribute.Strategy.scope()` call.

1. Choose the right distributed training strategy.
   a. For single-node multi-GPU, use `tf.distribute.MirroredStrategy` to set the strategy.

```python
strategy = tf.distribute.MirroredStrategy()
```
b. For multi-node multi-GPU, add the following code to properly set the TensorFlow distributed training configuration before creating the strategy.

```python
def set_sm_dist_config():
    DEFAULT_PORT = '8890'
    DEFAULT_CONFIG_FILE = '/opt/ml/input/config/resourceconfig.json'
    with open(DEFAULT_CONFIG_FILE) as f:
        config = json.loads(f.read())
    current_host = config['current_host']
    tf_config = {
        'cluster': {
            'worker': []
        },
        'task': {'type': 'worker', 'index': -1}
    }
    for i, host in enumerate(config['hosts']):
        tf_config['cluster']['worker'].append('%s:%s' % (host, DEFAULT_PORT))
        if current_host == host:
            tf_config['task']['index'] = i
    os.environ['TF_CONFIG'] = json.dumps(tf_config)
set_sm_dist_config()
```

Use `tf.distribute.MultiWorkerMirroredStrategy` to set the strategy.

```python
strategy = tf.distribute.MultiWorkerMirroredStrategy()
```

2. Using the strategy of your choice, wrap the model.

```python
with strategy.scope():
    # create a model and do fit
```

Without Keras

If you want to bring custom models with custom training loops using TensorFlow without Keras, you should wrap the model and the training loop with the TensorFlow function decorator (`@tf.function`) to leverage compiler acceleration.

SageMaker Training Compiler performs a graph-level optimization, and uses the decorator to make sure your TensorFlow functions are set to run in graph mode.

For single GPU training

TensorFlow 2.0 or later has the eager execution on by default, so you should add the `@tf.function` decorator in front of every function that you use for constructing a TensorFlow model.

For distributed training

In addition to the changes needed for Using Keras for distributed training, you need to ensure that functions to be run on each GPU are annotated with `@tf.function`, while cross-GPU communication functions are not annotated. An example training code should look like the following:

```python
@tf.function()
def compiled_step(inputs, outputs):
    with tf.GradientTape() as tape:
        pred=model(inputs, training=True)
        total_loss=loss_object(outputs, pred)/args.batch_size
        gradients=tape.gradient(total_loss, model.trainable_variables)
    return total_loss, pred, gradients
```
def train_step(inputs, outputs):
    total_loss, pred, gradients = compiled_step(inputs, outputs)
    if args.weight_decay > 0.:
        gradients = [g+v*args.weight_decay for g,v in zip(gradients, model.trainable_variables)]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))
    train_loss.update_state(total_loss)
    train_accuracy.update_state(outputs, pred)

@tf.function()
def train_step_dist(inputs, outputs):
    strategy.run(train_step, args=(inputs, outputs))

Note that this instruction can be used for both single-node multi-GPU and multi-node multi-GPU.

**PyTorch Models**

Bring your own PyTorch model to SageMaker, and run the training job with SageMaker Training Compiler.

**PyTorch Models with Hugging Face Transformers**

PyTorch models with Hugging Face Transformers are based on PyTorch's `torch.nn.Module` API. Hugging Face Transformers also provides Trainer and pretrained model classes for PyTorch to help reduce the effort for configuring natural language processing (NLP) models. After creating your own training script using the Transformers library, you can run the training script using the SageMaker HuggingFace estimator with the SageMaker Training Compiler configuration class as shown in the previous topic at Enable SageMaker Training Compiler (p. 2309).

**Topics**

- Using Hugging Face Trainer API (p. 2317)
- Using PyTorch without Hugging Face Trainer API (p. 2318)
- Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2320)

**Using Hugging Face Trainer API**

If you use the transformers library's Trainer class, you don't need to make any additional changes to your training script. SageMaker Training Compiler automatically compiles your Trainer model if you enable it through the estimator class. The following code shows the basic form of a PyTorch training script with Hugging Face Trainer API.

```python
from transformers import Trainer, TrainingArguments

training_args = TrainingArguments(**kwargs)
trainer = Trainer(args=training_args, **kwargs)
```

**For single GPU training**

You don't need to change your code when you use the Transformers Trainer API.

**For distributed training**

SageMaker Training Compiler uses an alternate mechanism for distributed training, and you don't need to specify the `distribution` parameter. The compiler requires you to pass a SageMaker distributed training launcher script to the entry point and pass your training script to the `hyperparameters`
argument. For more information, choose For distributed training and the Hugging Face Estimator for PyTorch tab in the Enable SageMaker Training Compiler Using the SageMaker Python SDK (p. 2309) page.

Using PyTorch without Hugging Face Trainer API

If you have a training script that uses PyTorch directly, you need to make additional changes to your PyTorch training script. For example, you need to modify the script using PyTorch/XLA as shown in the following code examples:

Topics

- For single GPU training (p. 2318)
- For distributed training (p. 2319)

For single GPU training

1. Import the optimization libraries.

   ```python
   import torch_xla
   import torch_xla.core.xla_model as xm
   ```

2. Change the target device to be XLA instead of torch.device("cuda")

   ```python
device=xm.xla_device()
   ```

3. If you're using PyTorch's Automatic Mixed Precision (AMP), do the following:
   a. Replace torch.cuda.amp with the following:

      ```python
      import torch_xla.amp
      ```

   b. Replace torch.optim.SGD and torch.optim.Adam with the following:

      ```python
      import torch_xla.amp.syncfree.Adam as adam
      import torch_xla.amp.syncfree.SGD as SGD
      ```

   c. Replace torch.cuda.amp.GradScaler with the following:

      ```python
      import torch_xla.amp.GradScaler as grad_scaler
      ```

4. If you're not using AMP, replace optimizer.step() with the following:

   ```python
   xm.optimizer_step(optimizer)
   ```

5. If you're using a distributed dataloader, wrap your dataloader in the PyTorch/XLA's ParallelLoader class:

   ```python
   import torch_xla.distributed.parallel_loader as pl
   parallel_loader=pl.ParallelLoader(dataloader, [device]).per_device_loader(device)
   ```

6. Add mark_step at the end of the training loop when you're not using parallel_loader:

   ```python
   xm.mark_step()
   ```

7. To checkpoint your training, use the PyTorch/XLA's model checkpoint method:

   ```python
   xm.save(model.state_dict(), path_to_save)
   ```
For distributed training

In addition to the changes listed in the previous For single GPU training (p. 2318) section, add the following changes to properly distribute workload across GPUs.

1. If you’re using AMP, add all_reduce after scaler.scale(loss).backward():

```python
gradients=xm._fetch_gradients(optimizer)
xm.all_reduce('sum', gradients, scale=1.0/xm.xrt_world_size())
```

2. If you need to set variables for local_ranks and world_size, use similar code to the following:

```python
local_rank=xm.get_local_ordinal()
world_size=xm.xrt_world_size()
```

3. For any world_size (num_gpus_per_node*num_nodes) greater than 1, you must define a train sampler which should look similar to the following:

```python
import torch_xla.core.xla_model as xm
if xm.xrt_world_size() > 1:
    train_sampler=torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=xm.xrt_world_size(),
        rank=xm.get_ordinal(),
        shuffle=True
    )
train_loader=torch.utils.data.DataLoader(
    train_dataset,
    batch_size=args.batch_size,
    sampler=train_sampler,
    drop_last=args.drop_last,
    shuffle=False if train_sampler else True,
    num_workers=args.num_workers
)
```

4. Make the following changes to make sure you use the parallel_loader provided by the torch_xla distributed module.

```python
import torch_xla.distributed.parallel_loader as pl
train_device_loader=pl.MpDeviceLoader(train_loader, device)
```

The train_device_loader functions like a regular PyTorch loader as follows:

```python
for step, (data, target) in enumerate(train_device_loader):
    optimizer.zero_grad()
    output=model(data)
    loss=torch.nn.NLLLoss(output, target)
    loss.backward()
```

With all of these changes, you should be able to launch distributed training with any PyTorch model without the Transformer Trainer API. Note that these instructions can be used for both single-node multi-GPU and multi-node multi-GPU.
Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API

If you want to leverage the SageMaker Training Compiler on your native PyTorch training script, you may want to first get familiar with PyTorch on XLA devices. The following sections list some best practices to enable XLA for PyTorch.

**Note**
This guide assumes that you use the following Python modules:

```python
import torch_xla.core.xla_model as xm
import torch_xla.distributed.parallel_loader as pl
```

Understand the lazy mode in PyTorch/XLA

One significant difference between PyTorch/XLA and native PyTorch is that the PyTorch/XLA system runs in lazy mode while the native PyTorch runs in eager mode. Tensors in lazy mode are placeholders for building the computational graph until they are materialized after the compilation and evaluation are complete. The PyTorch/XLA system builds the computational graph on the fly when you call PyTorch APIs to build the computation using tensors and operators. The computational graph gets compiled and executed when `xm.mark_step()` is called explicitly or implicitly by `pl.MpDeviceLoader/pl.ParallelLoader`, or when you explicitly request the value of a tensor such as by calling `loss.item()` or `print(loss)`.

Minimize the number of compilation-and-executions using `pl.MpDeviceLoader/pl.ParallelLoader` and `xm.step_closure`

For best performance, you should keep in mind the possible ways to initiate compilation-and-executions as described in Understand the lazy mode in PyTorch/XLA (p. 2320) and should try to minimize the number of compilation-and-executions. Ideally, only one compilation-and-execution is necessary per training iteration and is initiated automatically by `pl.MpDeviceLoader/pl.ParallelLoader`. The `MpDeviceLoader` is optimized for XLA and should always be used if possible for best performance. During training, you might want to examine some intermediate results such as loss values. In such case, the printing of lazy tensors should be wrapped using `xm.add_step_closure()` to avoid unnecessary compilation-and-executions.

Use AMP and syncfree optimizers

Training in Automatic Mixed Precision (AMP) mode significantly accelerates your training speed by leveraging the Tensor cores of NVIDIA GPUs. SageMaker Training Compiler provides `syncfree` optimizers that are optimized for XLA to improve AMP performance. Currently, the following three `syncfree` optimizers are available and should be used if possible for best performance.

```python
torch_xla.amp.syncfree.SGD
torch_xla.amp.syncfree.Adam
torch_xla.amp.syncfree.AdamW
```

These `syncfree` optimizers should be paired with `torch_xla.amp.GradScaler` for gradient scaling/unscaling.

SageMaker Training Compiler Example Notebooks and Blogs

The following blogs, case studies, and notebooks provide examples of how to implement SageMaker Training Compiler.

Example notebooks are provided in the SageMaker examples GitHub repository, and you can also browse them on the SageMaker examples website.
Blogs and Case Studies
The following blogs discuss case studies about using SageMaker Training Compiler.

- New – Introducing SageMaker Training Compiler
- Hugging Face Transformers BERT fine-tuning using Amazon SageMaker Training Compiler
- Speed up Hugging Face Training Jobs on AWS by Up to 50% with SageMaker Training Compiler

Examples Notebooks
To find examples of using SageMaker Training Compiler, see the Training Compiler page in the Amazon SageMaker Example Read the Docs website.

SageMaker Training Compiler Best Practices
Review the following tips and pitfalls when using SageMaker Training Compiler.

- If you are not getting any performance improvement after enabling SageMaker Training Compiler, make sure you chose the right instance type, batch size, and learning rate for your training job. SageMaker Training Compiler is only tested on GPU instances (the ml.p3 instances and ml.p4 instances). For more information, see Tested Models (p. 2306).
- If you bring a PyTorch model, make sure you use PyTorch/XLA's model save function to properly checkpoint your model. For more information about the function, see torch_xla.core.xla_model.save in the PyTorch on XLA Devices documentation.

To learn how to add the modifications to your PyTorch script, see Using PyTorch without Hugging Face Trainer API (p. 2318).

For more information about the actual application of using the model save function, see Checkpoint Writing and Loading in the Hugging Face on PyTorch/XLA TPUs: Faster and cheaper training blog.
- To debug the compiler-accelerated training job, enable the debug flag in the compiler_config parameter. This enables SageMaker to put the debugging logs into SageMaker training job logs.

```python
huggingface_estimator=HuggingFace(
    ...
    compiler_config=TrainingCompilerConfig(debug=True)
)
```

Note that if you enable the full debugging of the training job with the compiler, this might add some overhead.

SageMaker Training Compiler FAQ
Use the following FAQ items to find answers to commonly asked questions about SageMaker Training Compiler.

Q. How do I know SageMaker Training Compiler is working?
If you successfully launched your training job with SageMaker Training Compiler, you receive the following log messages:

- With TrainingCompilerConfig(debug=False)

  Found configuration for Training Compiler
Q. Which models does SageMaker Training Compiler accelerate?

SageMaker Training Compiler supports the most popular deep learning models from the Hugging Face transformers library. With most of the operators that the compiler supports, these models can be trained faster with SageMaker Training Compiler. Compilable models include but are not limited to the following: `bert-base-cased`, `bert-base-chinese`, `bert-base-uncased`, `distilbert-base-uncased`, `distilbert-base-uncased-finetuned-sst-2-english`, `gpt2`, `roberta-base`, `roberta-large`, `t5-base`, and `xlm-roberta-base`. The compiler works with most DL operators and data structures and can accelerate many other DL models beyond those that have been tested.

Q. What happens if I enable SageMaker Training Compiler with a model that isn't tested?

For an untested model, you might need to first modify the training script to be compatible with SageMaker Training Compiler. For more information, see Bring Your Own Deep Learning Model (p. 2314) and follow the instructions describing how to prepare your training script.

Once you have updated your training script, you can start the training job. The compiler proceeds to compile the model. However, training speed may not increase and might even decrease relative to the baseline with an untested model. You might need to retune training parameters such as `batch_size` and `learning_rate` to achieve any speedup benefits.

If compilation of the untested model fails, the compiler returns an error. See SageMaker Training Compiler Troubleshooting (p. 2323) for detailed information about the failure types and error messages.

Q. Will I always get a faster training job with SageMaker Training Compiler?

No, not necessarily. First, SageMaker Training Compiler adds some compilation overhead before the ongoing training process can be accelerated. The optimized training job must run sufficiently long to amortize and make up for this incremental compilation overhead at the beginning of the training job.

Additionally, as with any model training process, training with suboptimal parameters can increase training time. SageMaker Training Compiler can change the characteristics of the training job by, for example, changing the memory footprint of the job. Because of these differences, you might need to retune your training job parameters to speed up training. A reference table specifying the best performing parameters for training jobs with different instance types and models can be found at Tested Models (p. 2306).

Finally, some code in a training script might add additional overhead or disrupt the compiled computation graph and slow training. If working with a customized or untested model, see the instructions at Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2320).

Q. Can I always use a larger batch size with SageMaker Training Compiler?

Batch size increases in most, but not all, cases. The optimizations made by SageMaker Training Compiler can change the characteristics of your training job, such as the memory footprint. Typically, a Training Compiler job occupies less memory than an uncompiled training job with the native framework, which allows for a larger batch size during training. A larger batch size, and a corresponding adjustment to the learning rate, increases training throughput and can decrease total training time.
However, there could be cases where SageMaker Training Compiler might actually increase memory footprint based on its optimization scheme. The compiler uses an analytical cost model to predict the execution schedule with the lowest cost of execution for any compute-intensive operator. This model could find an optimal schedule that increases memory use. In this case, you won’t be able to increase batch sizes, but your sample throughput is still higher.

Q. Does SageMaker Training Compiler work with other SageMaker training features, such as the SageMaker distributed training libraries and SageMaker Debugger?

SageMaker Training Compiler is currently not compatible with SageMaker’s distributed training libraries.

SageMaker Training Compiler is compatible with SageMaker Debugger, but Debugger might degrade computational performance by adding overhead.

Q. Does SageMaker Training Compiler support custom containers (bring your own container)?

No, SageMaker Training Compiler is provided through AWS Deep Learning Containers with Training Compiler implemented. For more information, see Supported Frameworks (p. 2305). If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

SageMaker Training Compiler Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If you need further support, reach out to the SageMaker team through AWS Support or AWS Developer Forums for Amazon SageMaker.

Training Job Fails Due to Missing XLA Configuration

If a training job fails with the Missing XLA configuration error message, it might be due to a misconfiguration in the number of GPUs per instance that you use.

XLA requires additional environment variables to compile the training job. The most common missing environment variable is `GPU_NUM_DEVICES`. For the compiler to work properly, you must set this environment variable equal to the number of GPUs per instance.

There are three approaches to set the `GPU_NUM_DEVICES` environment variable:

- **Approach 1** – Use the environment argument of the SageMaker estimator class. For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:

```python
# Using the SageMaker Python SDK's HuggingFace estimator
hf_estimator=HuggingFace(
    ...
    instance_type="ml.p3.8xlarge",
    hyperparameters={...},
    environment={
        "GPU_NUM_DEVICES": "4" # corresponds to number of GPUs on the specified instance
    },
)
```

- **Approach 2** – Use the hyperparameters argument of the SageMaker estimator class and parse it in your training script.
  1. To specify the number of GPUs, add a key-value pair to the hyperparameters argument.

    For example, if you use an `ml.p3.8xlarge` instance that has four GPUs, do the following:
# Using the SageMaker Python SDK's HuggingFace estimator

```python
hf_estimator=HuggingFace(
    ...
    entry_point = "train.py",
    instance_type= "ml.p3.8xlarge",
    hyperparameters = {
        ...
        "n_gpus": 4  # corresponds to number of GPUs on specified instance
    }
)
```

hf_estimator.fit()

2. In your training script, parse the `n_gpus` hyperparameter and specify it as an input for the `GPU_NUM_DEVICES` environment variable.

```python
# train.py
import os, argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()

    # Data, model, and output directories
    parser.add_argument('--output_data_dir', type=str, default=os.environ['SM_OUTPUT_DATA_DIR'])
    parser.add_argument('--model_dir', type=str, default=os.environ['SM_MODEL_DIR'])
    parser.add_argument('--training_dir', type=str, default=os.environ['SM_CHANNEL_TRAIN'])

    # Approach 3 – Hard-code the `GPU_NUM_DEVICES` environment variable in your training script. For example, add the following to your script if you use an instance that has four GPUs.
    parser.add_argument('--n_gpus', type=str, default=os.environ['SM_NUM_GPUS'])

    args, _ = parser.parse_known_args()

    os.environ['GPU_NUM_DEVICES'] = args.n_gpus
```

**Tip**

To find the number of GPU devices on machine learning instances that you want to use, see Accelerated Computing in the Amazon EC2 Instance Types page.

Incorrect API Uses for PyTorch without Hugging Face Trainer API

PyTorch/XLA defines a set of APIs to replace some of the existing PyTorch training APIs. Failing to use them properly leads PyTorch training to fail.

- One of the most typical errors when compiling a PyTorch model is due to a wrong device type for operators and tensors. To properly compile a PyTorch model, make sure you use XLA devices (`xm.xla_device()`) instead of using CUDA or mixing CUDA devices and XLA devices.
- `mark_step()` is a barrier just for XLA. Failing to set it correctly causes a training job to stall.
- PyTorch/XLA provides additional distributed training APIs. Failing to program the APIs properly causes gradients to be collected incorrectly, which causes a training convergence failure.
To properly set up your PyTorch script and avoid the aforementioned incorrect API uses, see Using PyTorch without Hugging Face Trainer API (p. 2318) and Best Practices to Enable SageMaker Training Compiler for PyTorch without the Hugging Face Trainer API (p. 2320).

Amazon SageMaker Training Compiler Release Notes

See the following release notes to track the latest updates for Amazon SageMaker Training Compiler.

SageMaker Training Compiler Release Notes: April 26, 2022

Improvements

• Added support for all of the AWS Regions where AWS Deep Learning Containers are in service except the China regions.

SageMaker Training Compiler Release Notes: April 12, 2022

Currency Updates

• Added support for Hugging Face Transformers v4.17.0 with TensorFlow v2.6.3 and PyTorch v1.10.2.

SageMaker Training Compiler Release Notes: February 21, 2022

Improvements

• Completed benchmark test and confirmed training speed-ups on the ml.g4dn instance types. To find a complete list of tested ml instances, see Tested Instance Types (p. 2306).

SageMaker Training Compiler Release Notes: December 01, 2021

New Features

• Launched Amazon SageMaker Training Compiler at AWS re:Invent 2021.

Migration to AWS Deep Learning Containers

• Amazon SageMaker Training Compiler passed benchmark testing and is migrated to AWS Deep Learning Containers. To find a complete list of pre-built containers with Amazon SageMaker Training Compiler, see Supported Frameworks, AWS Regions, Tested Instances, and Tested Models (p. 2305).

Amazon SageMaker Clarify Bias Detection and Model Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided.
Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection and model explainability:

- Amazon SageMaker Clarify Processing – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Topics

- Prerequisites (p. 2326)
- How SageMaker Clarify Processing Jobs Work (p. 2326)
- Get Started with a SageMaker Clarify Container (p. 2327)
- Configure a SageMaker Clarify Processing Job Container's Input and Output Parameters (p. 2329)
- Configure the Analysis (p. 2329)
- Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 2336)
- Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify (p. 2340)
- Amazon SageMaker Clarify Model Explainability (p. 2359)
- Troubleshoot SageMaker Clarify Processing Jobs (p. 2367)

Prerequisites

Before you begin, you need to meet the following prerequisites:

- You need to provide an input dataset as tabular files in CSV or JSON Lines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.
- You need to provide a model artifact that supports either the CSV or JSON Lines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.
- When creating processing jobs with the SageMaker container image, you need the following:
  - Network isolation must be disabled for the processing job.
  - If the model is in a VPC, the processing job must be in the same VPC as the model.
  - The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the "arn:aws:iam::aws:policy/AmazonSageMakerFullAccess" managed policy.

How SageMaker Clarify Processing Jobs Work

A SageMaker processing job uses the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

- pretraining bias metrics
- posttraining bias metrics
- SHAP values for explainability
• Partial dependence plots (PDP)

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the `ProcessingOutput` parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a shadow endpoint. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.

**Get Started with a SageMaker Clarify Container**

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process Data (p. 918) in your account.

The image URIs for the containers are in the following form:

```<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0```

For example:

```205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0```

The following table lists the addresses by AWS Region.

### Docker Images for Clarify Processing Jobs

Configure a SageMaker Clarify Processing Job
Container's Input and Output Parameters

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as Amazon S3 object or prefix, and an analysis configuration file with input name "analysis_config" as an Amazon S3 object. The job also requires an output parameter: the output location as an Amazon S3 prefix.

You can create and run a processing job with SageMaker CreateProcessingJob API using the AWS SDK or CLI or SageMaker Python SDK.

Using SageMaker Python SDK, create a Processor using the SageMaker Clarify container image URI:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
instance_count=1,
instance_type='ml.c5.xlarge',
max_runtime_in_seconds=1200,
volume_size_in_gb=100)
```

After you finish creating the Clarify processor, you need to set up the input and output object for the processor.

**Note**
If you provide the "dataset_uri" through the "analysis_config.json" (see the following topic at Configure the Analysis (p. 2329)), you don't need to create the dataset_input object.

```python
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
    input_name="analysis_config",
    source=analysis_config_path,
    destination="/opt/ml/processing/input/config",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None"
)

dataset_input = ProcessingInput(
    input_name="dataset",
    source=dataset_path,
    destination="/opt/ml/processing/input/data",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None"
)

analysis_result_output = ProcessingOutput(
    source="/opt/ml/processing/output",
    destination=analysis_result_path,
    output_name="analysis_result",
    s3_upload_mode="EndOfJob"
)
```

Configure the Analysis

The inputs for the analysis are configured by the parameters of the ProcessingInput API. The "analysis_config" value of the input_name specifies the JSON file named analysis_config.json that contains the configuration values. The path to the JSON file is provided in the source parameter of ProcessingInput. Examples of analysis configuration JSON files are provided for JSON files for CSV, JSON Lines, image, and text datasets following the parameter descriptions.
Parameters for JSON configuration files

In the JSON configuration file, you can specify the following parameters.

- "version" – (Optional) Schema version of the configuration file. If not provided, the latest supported version is used.
- "dataset_type" – (Required) Format of the dataset. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable computer vision explainability.
- "dataset_uri" – (Optional) Dataset S3 prefix/object URI (if not given as ProcessingInput). If it is a prefix, the processing job recursively collects all S3 files under the prefix. For computer vision, the URI is required and it can either be a path to the image manifest file, or to the bucket of images to be explained.
- "headers" – (Optional) A list of column names in the dataset. If the dataset_type is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
- "label" – (Optional) Target attribute for the model to be used for bias metrics. Specified as a column name, or as index if the dataset format is CSV, or as JSONPath if the dataset format is JSON Lines.
- "probability_threshold" – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. This parameter is used in object detection to filter out objects detected with confidence scores lower than the probability_threshold value. The default value is 0.5.
- "features" – (Optional) JSONPath for locating the feature columns for bias metrics, if the dataset format is JSON Lines.
- "label_values_or_threshold" – (Optional) List of label values or threshold. Indicates positive outcome used for bias metrics.
- "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets. Facets are used for bias metrics in the form of pairs, and include the following:
  - "name_or_index" – Facet column name or index.
  - "value_or_threshold" – (Optional) List of values or threshold that the facet column can take. Indicates the sensitive group, such as the group that is used to measure bias against. If not provided, bias metrics are computed as one group for every unique value (rather than all values). If the facet column is numeric, this threshold value is applied as the lower bound to select the sensitive group.
- "group_variable" – (Optional) A column name or index to indicate the group variable to be used for the bias metric Conditional Demographic Disparity.
- "joinsource_name_or_index" – (Optional) The name or index of the column in the dataset that acts as an identifier column, for example, while performing a join. This column is only used as an identifier, and not used for any other computations. This is an optional field in all cases except when the dataset contains more than one file, and "save_local_shap_values" is set to true.
- "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted, then it is not computed.
  - "pre_training_bias" – (Optional) Section on pretraining bias metrics.
    - "methods" – A list of pretraining metrics to be computed.
  - "post_training_bias" – (Optional) Section on posttraining bias metrics.
    - "methods" – A list of posttraining metrics to be computed.
  - "shap" – (Optional) Section on SHAP value computation.
    - "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
• "mean_abs" – Mean of absolute SHAP values for all instances.
• "median" – Median of SHAP values for all instances.
• "mean_sq" – Mean of squared SHAP values for all instances.
• "baseline" – (Optional) A list of rows (at least one), or an S3 object URI. To be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns (or values) and omit any column that must be excluded before being sent to the model. This includes label column, joinsource column, and columns included in the "exclude_column" field.
• For Computer Vision, a path to the baseline image that is used to mask out features from the input image. Default: RGB Noise mask.
• For natural language processing (NLP) of text columns, the baseline value should be the value used to replace the unit of text specified by the granularity in the "text_config". Valid values for the unit of text are token, sentence, and paragraph.
• "num_clusters" – (Optional) If "baseline" is not provided, Clarify attempts to compute a baseline by clustering the dataset. The "num_clusters" determines the number of clusters that the dataset is clustered into. Each cluster contributes to a baseline, so the number of clusters directly affects the runtime of SHAP explanations.
• "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
• "seed" – (Optional) Seed value for the random number generator to obtain a deterministic SHAP result.
• "text_config" – (Required) The configuration that specifies the natural language processing (NLP) features. If this config is provided, text features are treated as text and explanations are provided for individual units of text. The unit of text is specified by the "granularity".
• "granularity" – (Required) For NLP, determines the unit of granularity for the analysis of text features. Valid values are "token", "sentence", or "paragraph". Each of these units is considered a feature, and shap values are computed for the feature specified.
• "use_logit" – (Optional) Boolean value to indicate if the logit function is to be applied to the model predictions. If "use_logit" is true, then the SHAP values have log-odds units. The default value is false.
• "image_config" – (Optional) Section for configuring SHAP configuration parameters for computer vision explainability.
• "model_type" – Either an object detection model or an image classification model.
• "num_segments" – (Optional) Determines the approximate number of segments to be labeled in the input image. The default is 20.
• "segment_compactness" – (Optional) Determines the shape and size of the image segments generated by SKLearn's slic method. For more details, see scikit-image slic documentation. The default is 5.
• "max_objects" – (Optional) Used to filter objects detected by the computer vision model by top confidence score. The default is 3.

Amazon SageMaker Developer Guide
Configure the Analysis
• "iou_threshold" – (Optional) Minimum intersection over union (IOU) metric for evaluating predictions against the original detections. Used because detection boxes will shift during masking. The default value is 0.5.

• "context" – (Optional) Masks the area around the bounding box of the detected object when running SHAP. Valid values are 0 to mask everything, or 1 to mask nothing. The default value is 1.

• "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Use true to save them; false to not save them. The default is false.

• "pdp" – (Optional) Section for configuring partial dependence plots (PDP). Shows the dependence of the target response on a set of input features of interest. Marginalizes over the values of all other input features.

• "features": ["pdp_feature_1", "pdp_feature_2"...] – (Optional) The list of feature names or indices for which partial dependence plots are to be computed and plotted. If SHAP is not requested, the features must be provided.

• "grid_resolution" – (Required) Used for numerical features. Represents that number of buckets into which the range of numerical values is divided. This specifies the granularity of the grid for the PDP plot.

• "top_k_features" – (Optional) If the features parameter is not provided, and shap is provided, Clarify chooses the top k features based on SHAP attributions. You can set this value to specify how many of the top features must be used for PDP plots. The default is 10.

• "predictor" – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.

• "model_name" – Model name created by CreateModel API, with container mode as SingleModel.

• "instance_type" – Instance type for the shadow endpoint.

• "initial_instance_count" – Instance count for the shadow endpoint.

• "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as the dataset_type format.

• "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV, "application/jsonlines" for JSON Lines, application/x-parquet for Apache Parquet, and application/x-image to enable Computer Vision explainability. The default value is the same as content_type.

• "accelerator_type" – (Optional) The type of Elastic Inference (EI) accelerator to attach to the instance. Example: ml.eia1.medium. For more information, see Use Amazon SageMaker Elastic Inference (EI) (p. 2732).

• "custom_attributes" – (Optional) Provides additional information about a request for an inference that is submitted to a model hosted on an Amazon SageMaker endpoint. The information is an opaque value that is forwarded verbatim. You can use this value, for example, to provide an ID that tracks a request. You can also use this value to provide metadata that a service endpoint was programmed to process. The value must consist of no more than 1024 visible US-ASCII characters, as specified in Section 3.3.6. Field Value Components of the Hypertext Transfer Protocol (HTTP/1.1).

• "label" – (Optional) Index or JSONPath location in the model output for the target attribute that is used by the bias metrics. If the label is not provided in the CSV accept_type case, then Clarify assumes that the model output is a single numeric value corresponding to the score or probability.

• "probability" – (Optional) Index or JSONPath location in the model output for probabilities or scores to be used for explainability. If the model output is JSON Lines with a list of labels and probabilities, for example, then the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.
Configure the Analysis

• "endpoint_name-prefix" – (Optional) Provides a custom prefix to the name of the temporary endpoint.

• "endpoint_name" – (Optional) Specifies an existing endpoint to use for getting predictions. Using an existing endpoint reduces the bootstrap time, but can cause a significant load increase for existing endpoints. Be cautious when specifying an existing production endpoint.

• "target_model" – (Optional) Sets the target model name when using a multi-model endpoint. For more information about multi-model endpoints, see Request Syntax.

• "label_headers" – (Optional) A list of values that the "label" takes in the dataset. Associates the scores returned by the model endpoint with their corresponding label values. Used to extract the label value with the highest score as the predicted label.

• "content_template" – (Optional) A template string used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have only one placeholder, $features, which is replaced by the features list at runtime. For example, given "content_template" : "{"myfeatures":$features}'" if an instance (no label) is 1, 2, 3, then model input becomes JSON Line '{"myfeatures":[1,2,3]}'.

• "report" – (Optional) Section on report parameters. A report is generated if this section is present.

• "name" – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".

• "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".

Example JSON configuration files

Here are examples of analysis configuration JSON files for CSV, JSON Lines, image, and text datasets.

Topics

• Analysis configuration JSON file for a CSV dataset (p. 2333)
• Analysis configuration JSON file for a JSON Lines dataset (p. 2335)
• Analysis configuration JSON file for an image dataset (p. 2336)
• NLP analysis configuration JSON file for a text dataset (p. 2336)

Analysis configuration JSON file for a CSV dataset

The following code sample shows how to configure an analysis for a CSV dataset.

```json
{
    "dataset_type": "text/csv",
    "headers": [
        "feature_0",
        "feature_1",
        "feature_2",
        "feature_3",
        "target"
    ],
    "label": "target",
    "label_values_or_threshold": [1],
    "probability_threshold" : 0.7,
    "facet": [
        {
            "name_or_index" : "feature_1",
            "value_or_threshold": [1]
        },
        {
            "name_or_index" : "feature_2",
```
"value_or_threshold": [0.7]
},
"group_variable": "feature_3",
"joinsource_name_or_index": 'column_name',
"methods": {
  "shap": {
    "baseline": [
      ["yes", 3, 0.9, 1]
    ],
    "num_samples": 1000,
    "agg_method": "mean",
    "use_logit": true,
    "save_local_shap_values": true,
    "num_clusters": 5,
    "seed": 1234
  },
  "pre_training_bias": {
    "methods": "all"
  },
  "post_training_bias": {
    "methods": "all"
  },
  "report": {
    "name": "report",
    "title": "Analysis Report"
  }
},
"predictor": {
  "model_name": "my_model",
  "instance_type": "ml.m5.xlarge",
  "initial_instance_count": 1,
  "content_type": "text/csv",
  "accept_type": "text/csv",
  "accelerator_type": "ml.eia1.medium",
  "custom_attributes": "c000b4f9-df62-4c85-a0bf-7c525f9104a4",
  "label": 0,
  "probability": 1,
  "endpoint_name_prefix": "myendpointsuffix",
  "target_model": ""
}

Model output as CSV is as follows:

```
Current,"[0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]
```

Corresponding predictor configuration is as follows:

```
"predictor": {
  ...
  "accept_type": "text/csv",
  "label": 0,
  "probability": 1,
  ...
}
```
Analysis configuration JSON file for a JSON Lines dataset

The following code sample shows how to configure an analysis for a JSON Lines dataset.

```json
{
    "dataset_type": "application/jsonlines",
    "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
    "headers": ["Label", "Feature1", "Feature2"],
    "label": "data.label",
    "features": "data.features.values",
    "facet": [
        {
            "name_or_index": "Feature1",
            "value_or_threshold": [1, 5]
        },
        {
            "name_or_index": "Feature2",
            "value_or_threshold": [2, 6]
        }
    ],
    "methods": {
        "shap": {
            "baseline": [
                {"data": {"features": [9, 10], "label": 0}},
                {"data": {"features": [11, 12], "label": 1}}
            ]
        }
    },
    "predictor": {
        "model_name": "my_jsonl_model",
        "instance_type": "ml.m5.xlarge",
        "initial_instance_count": 1
    }
}
```

Dataset as S3 prefix is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSON Lines is as follows:

```
{"predicted_label": "Current", "score": [0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.028957107016444206, 0.0290389321744442, 0.02905467338860035]}
```

Corresponding predictor configuration is as follows:

```
"predictor": {
    ...
    "accept_type": "application/jsonlines",
    "label": "predicted_label",
    "probability": "score",
    ...
}
```
Analysis configuration JSON file for an image dataset

The following code sample shows how to configure an analysis for object detection with Computer Vision.

```json
"dataset_type": "application/x-image",
"dataset_uri": "s3://<BUCKET/KEY>",
"probability_threshold": 0.7,
"methods": {
    "shap": {
        "num_samples": 500,
        "baseline": "s3://path/to/baseline/image/noise_rgb.png",
        "image_config": {
            "model_type": "{OBJECT_DETECTION|IMAGE_CLASSIFICATION}"
        },
        "num_segments": 20,
        "segment_compactness": (5|10|100),
        "max_objects": 3,
        "overlap": 0.5,
        "context": 1.0
    }
},

"predictor": {
    "endpoint_name": "sagemaker-endpoint-name",
    "content_type": "(image/jpeg | image/png | application/x-npy)",
    "label_headers": [...] # Required for CV
}
```

NLP analysis configuration JSON file for a text dataset

The following code sample shows how to configure an analysis for natural language processing.

```json
{
    "dataset_type": ...,
    "methods": {
        "shap": {
            "baseline": "...",
            "num_samples": 100,
            "text_config": {
                "granularity": "(token|sentence|paragraph)",
                "language": "...",
            }
        }
    }
}
```

Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 735). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias...
(for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

**Topics**

- Compute Resources Required for SageMaker Clarify Processing Jobs (p. 2337)
- Run the Clarify Processing Job (p. 2337)
- Run the Clarify Processing Job with Spark (p. 2338)
- Get the Analysis Results (p. 2339)

**Compute Resources Required for SageMaker Clarify Processing Jobs**

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:

- Processing jobs can take several minutes or more to complete.
- Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
- Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see Amazon SageMaker Pricing.

**Run the Clarify Processing Job**

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role,
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a DataConfig object, specify information about your trained model with ModelConfig, and provide information about the formats of your predictions with ModelPredictedLabelConfig.

```python
bias_report_output_path = 's3://{}/classify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=bias_report_output_path,
    label='Target',
    headers=training_data.columns.to_list(),
)```
dataset_type='text/csv')

model_config = clarify.ModelConfig(
    model_name=model_name,
    instance_type='ml.c5.xlarge',
    instance_count=1,
    accept_type='text/csv')

predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)

Use BiasConfig to provide information on which columns contain the facets (sensitive groups, Sex), what the sensitive features (facet_values_or_threshold) might be, and what the desirable outcomes are (label_values_or_threshold).

bias_config = clarify.BiasConfig(
    label_values_or_threshold=[1],
    facet_name='Sex',
    facet_values_or_threshold=[0])

You can run both the pretraining and posttraining analysis in the processing job at the same time with run_bias().

clarify_processor.run_bias(
    data_config=bias_data_config,
    bias_config=bias_config,
    model_config=model_config,
    model_predicted_label_config=predictions_config,
    pre_training_methods='all',
    post_training_methods='all')

View the results in Studio or download them from the bias_report_output_path S3 bucket.

Run the Clarify Processing Job with Spark

Apache Spark is a unified analytics engine for large-scale data processing. When working with large datasets, you can use the Spark processing capabilities of SageMaker Clarify to enable your Clarify processing jobs to run faster. To use Spark processing for Clarify jobs, set the instance count to a number greater than one. Clarify uses Spark distributed computing when there is more than once instance per Clarify processor.

The following example shows how to use SageMakerClarityProcessor to create a Clarify processor with 5 instances.

Clarify runs any jobs associated with this processor using Spark distributed processing.

from sagemaker import clarify
clarify_processor = clarify.SageMakerClarityProcessor(
    role=role,
    instance_count=5,
    instance_type='ml.c5.xlarge',
    max_runtime_in_seconds=1200,
    volume_size_in_gb=100)

If you configure a Clarify job to save local SHAP values in the SHAPConfig class, Spark saves the local SHAP value as multiple part files in parallel.

If you add more instances, we recommend that you also increase the number of instances in the model configuration ModelConfig for the shadow endpoint. This is to prevent the processing instances from being bottlenecked by the shadow endpoint. Specifically, we recommend that you use a one-to-one ratio of endpoint to processing instances.
Get the Analysis Results

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:

- **analysis.json** – Bias metrics and SHAP values in JSON format.
- **report.ipynb** – Static notebook to visualize the bias metrics and SHAP values.
- **explanations_shap/out.csv** – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.

In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```json
{
  "explanations": { . . . }
  "pre_training_bias_metrics": { . . . }
  "post_training_bias_metrics": { . . . }
}
```

SHAP values are in the “explanations” section. Values correspond to the global SHAP value for each feature column.

```json
"explanations": {
  "kernel_shap": {
    "label": "target",
    "global_shap_values": {
      "feature_0": 0.022486410860333206,
      "feature_1": 0.007381025261958729,
      "feature_2": 0.006843906804137847
    },
    "expected_value": 0.508233428001
  }
}
```

The bias metrics are in the pretraining and posttraining bias metrics sections.

```json
{
  "post_training_bias_metrics": {
    "label": "target",
    "label_value_or_threshold": "1",
    "facets": {
      "feature_2": [
        "value_or_threshold": "1",
        "metrics": [
          "name": "DI",
          "description": "Disparate Impact (DI)",
          "value": 0.711340206185567
        ],
        { "name": "DCR",
          "description": "Difference in Conditional Rejections (DCR)",
          "value": -0.34782608695652184
        }
      ]
    }
  }
}

Detect Posttraining Data and Model Bias with Amazon SageMaker Clarify

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.

There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet, experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 724).

For additional information about posttraining bias metrics, see Fairness Measures for Machine Learning in Finance.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSON Lines data formats, bringing your own container, and running processing jobs with Spark.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample...
space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multicategory classification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet $a$ and for a disfavored facet $d$. These labels $y$ are referred to as observed labels to distinguish them from the predicted labels $y'$ that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- **labels:**
  - $y$ represents the $n$ observed labels for event outcomes in a training dataset.
  - $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.

- **outcomes:**
  - A positive outcome (with value 1) for a sample, such as an application acceptance.
    - $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
    - $n^{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
  - A negative outcome (with value 0) for a sample, such as an application rejection.
    - $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
    - $n^{(0)}$ is the number of predicted labels for negative outcomes (rejections).

- **facet values:**
  - facet $a$ – The feature value that defines a demographic that bias favors.
    - $n_a$ is the number of observed labels for the favored facet value: $n_a = n_a^{(1)} + n_a^{(0)}$ the sum of the positive and negative observed labels for the value facet $a$.
    - $n'_a$ is the number of predicted labels for the favored facet value: $n'_a = n'_a^{(1)} + n'_a^{(0)}$ the sum of the positive and negative predicted outcome labels for the facet value $a$. Note that $n'_a = n_a$.
  - facet $d$ – The feature value that defines a demographic that bias disfavors.
    - $n_d$ is the number of observed labels for the disfavored facet value: $n_d = n_d^{(1)} + n_d^{(0)}$ the sum of the positive and negative observed labels for the facet value $d$.
    - $n'_d$ is the number of predicted labels for the disfavored facet value: $n'_d = n'_d^{(1)} + n'_d^{(0)}$ the sum of the positive and negative predicted labels for the facet value $d$. Note that $n'_d = n_d$.

- **probability distributions for outcomes of the labeled facet data outcomes:**
  - $P_a(y)$ is the probability distribution of the observed labels for facet $a$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $a$ labeled with positive outcomes to the total number, $P_a(y^1) = n_a^{(1)}/n_a$, and the ratio of the number of samples with negative outcomes to the total number, $P_a(y^0) = n_a^{(0)}/n_a$.
  - $P_d(y)$ is the probability distribution of the observed labels for facet $d$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $d$ labeled with positive outcomes to the total number, $P_d(y^1) = n_d^{(1)}/n_d$, and the ratio of the number of samples with negative outcomes to the total number, $P_d(y^0) = n_d^{(0)}/n_d$.

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

</table>

For additional information about posttraining bias metrics, see A Family of Fairness Measures for Machine Learning in Finance.
Difference in Positive Proportions in Predicted Labels (DPPL)

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions ($y' = 1$) for facet $a$ and the proportion of positive predictions ($y' = 1$) for facet $d$. For example, if the model predictions grant loans to 60% of a middle-aged group (facet $a$) and 50% other age groups (facet $d$), it might be biased against facet $d$. In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

$$DPPL = q'_a - q'_d$$

Where:

- $q'_a = n'_a(1)/n_a$ is the predicted proportion of facet $a$ who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here $n'_a(1)$ represents the number of members of facet $a$ who get a positive predicted outcome of value 1 and $n_a$ the is number of members of facet $a$.
- $q'_d = n'_d(1)/n_d$ is the predicted proportion of facet $d$ who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here $n'_d(1)$ represents the number of members of facet $d$ who get a positive predicted outcome and $n_d$ the is number of members of facet $d$.

If DPPL is close enough to 0, it means that posttraining demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval [-1, 1]. For continuous labels, the values vary over the interval (-∞, +∞).

- Positive DPPL values indicate that facet $a$ has a higher proportion of predicted positive outcomes when compared with facet $d$.
  
  This is referred to as positive bias.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets $a$ and $d$ and a value of zero indicates perfect demographic parity.

- Negative DPPL values indicate that facet $d$ has a higher proportion of predicted positive outcomes when compared with facet $a$. This is referred to as negative bias.
Disparate Impact (DI)

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 2349). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions \( (y' = 1) \) for facet \( d \) over the proportion of positive predictions \( (y' = 1) \) for facet \( a \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), then \( DI = .5/0.6 = 0.8 \), which indicates a positive bias and an adverse impact on the other aged group represented by facet \( d \).

The formula for the ratio of proportions of the predicted labels:

\[
DI = \frac{q'_d}{q'_a}
\]

Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a positive predicted outcome and \( n_a \) the is number of members of facet \( a \).
- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) a who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

For binary, multicategory facet, and continuous labels, the DI values range over the interval \([0, \infty)\).

- Values less than 1 indicate that facet \( a \) has a higher proportion of predicted positive outcomes than facet \( d \). This is referred to as positive bias.
- A value of 1 indicates demographic parity.
- Values greater than 1 indicate that facet \( d \) has a higher proportion of predicted positive outcomes than facet \( a \). This is referred to as negative bias.

Difference in Conditional Acceptance (DCAcc)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels \( y' \)) for a certain facet as compared to what was observed in the training dataset (labels \( y \)). For example, if there were more acceptances (a positive outcome) observed in the training dataset for loan applications for a middle-aged group (facet \( a \)) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet \( d \)), this might indicate potential bias in the way loans were approved favoring the middle-aged group.

The formula for the difference in conditional acceptance:

\[
DCAcc = c_a - c_d
\]

Where:

- \( c_a = \frac{n_a(1)}{n'_a(1)} \) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet \( a \) to the predicted number of positive outcome (acceptances) for facet \( a \).
Detect Posttraining Data and Model Bias

- \( c_d = \frac{n_d^{(1)}}{n_d^{(1)}} \) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet \( d \) to the predicted number of predicted positive outcomes (acceptances) for facet \( d \).

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have a dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet \( d \) be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet \( a \) and 20 from facet \( d \) were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested \((70/60 = 1.17)\) and granted loans to 33% more from other age groups than the observed labels suggested \((20/30 = 0.67)\). The calculation of the DCAcc value gives the following:

\[
DCAcc = \frac{70}{60} - \frac{20}{30} = \frac{1}{2}
\]

The positive value indicates that there is a potential bias against the middle-aged facet \( a \) with a lower acceptance rate as compared with the other facet \( d \) than the observed data (taken as unbiased) indicate is the case.

**Example 2: Negative bias**

Suppose we have a dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet \( d \) be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet \( a \) and 40 from facet \( d \) were granted loans. In other words, the model granted loans to 17% fewer from the middle aged facet than the observed labels in the training data suggested \((50/60 = 0.83)\), and granted loans to 33% more from other age groups than the observed labels suggested \((40/30 = 1.33)\). The calculation of the DCAcc value gives the following:

\[
DCAcc = \frac{50}{60} - \frac{40}{30} = -\frac{1}{2}
\]

The negative value indicates that there is a potential bias against facet \( d \) with a lower acceptance rate as compared with the middle-aged facet \( a \) than the observed data (taken as unbiased) indicate is the case.

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions \( y' \) by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of \( y' \). The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multicategory facet, and continuous labels is \((-\infty, +\infty)\).

- Positive values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is higher than the same ratio for facet \( d \). These values indicate a possible bias against the qualified applicants from facet \( a \). The larger the difference of the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is similar to the ratio for facet \( d \). These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- Negative values occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet \( a \) is less than that ratio for facet \( d \). These values indicate a possible bias against the qualified applicants from facet \( d \). The more negative the difference in the ratios, the more extreme the apparent bias.
Difference in Conditional Rejection (DCR)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels \( y' \)) to a certain facet as compared to what was suggested by the labels in the training dataset (observed labels \( y \)). For example, if there were more observed rejections (a negative outcome) for loan applications for a middle-aged group (facet \( a \)) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet \( d \)), this might indicate potential bias in the way loans were rejected that favored the middle-aged group over other groups.

The formula for the difference in conditional acceptance:

\[
DCR = r_d - r_a
\]

Where:
- \( r_d = \frac{n_d^{(0)}}{n_d^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet \( d \) to the predicted number of negative outcome (rejections) for facet \( d \).
- \( r_a = \frac{n_a^{(0)}}{n_a^{(0)}} \) is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet \( a \) to the predicted number of negative outcome of value 0 (rejections) for facet \( a \).

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet \( d \) be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet \( a \) and 40 from facet \( d \) were rejected. In other words, the model rejected 17% more loans from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and rejected 33% fewer loans from other age groups than the observed labels suggested (40/30 = 1.33). The DCR value quantifies this difference in the ratio of observed to predicted rejection rates between the facets. The positive value indicates that there is a potential bias favoring the middle aged group with lower rejection rates as compared with other groups than the observed data (taken as unbiased) indicate is the case.

\[
DCR = 40/30 - 50/60 = 1/2
\]

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet \( a \)) and 50 people from other age groups (facet \( d \)) who applied for loans, where the model recommended that 60 from facet \( a \) and 30 from facet \( d \) be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet \( a \) and 20 from facet \( d \) were rejected. In other words, the model rejected 17% fewer loans from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17), and rejected 33% more loans from other age groups than the observed labels suggested (20/30 = 0.67). The negative value indicates that there is a potential bias favoring facet \( a \) with lower rejection rates as compared with the middle-aged facet \( a \) than the observed data (taken as unbiased) indicate is the case.

\[
DCR = 20/30 - 70/60 = -1/2
\]

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is \((-\infty, +\infty)\).

- Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet \( d \) is greater than that ratio for facet \( a \). These values indicate a possible bias against
Detect Posttraining Data and Model Bias

the qualified applicants from facet $a$. The larger the value of DCR metric, the more extreme the apparent bias.

- Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet $a$ is similar to the ratio for facet $d$. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.
- Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet $d$ is less than that ratio for facet $a$. These values indicate a possible bias against the qualified applicants from facet $d$. The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

Recall Difference (RD)

The recall difference (RD) metric is the difference in recall of the model between the favored facet $a$ and disfavored facet $d$. Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the $y=1$ cases are correctly predicted as $y'=1$ for that facet. Recall is greater when the model minimizes false negatives known as the Type II error.

For example, how many of the people in two different groups (facets $a$ and $d$) that should qualify for loans are detected correctly by the model? If the recall rate is high for lending to facet $a$, but low for lending to facet $d$, the difference provides a measure of this bias against the group belonging to facet $d$.

The formula for difference in the recall rates for facets $a$ and $d$:

$$RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FN_a$ are the false negatives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FN_d$ are the false negatives predicted for facet $d$.
- $TPR_a = \frac{TP_a}{TP_a + FN_a}$ is the recall for facet $a$ or its true positive rate.
- $TPR_d = \frac{TP_d}{TP_d + FN_d}$ is the recall for facet $d$ or its true positive rate.

For example, consider the following confusion matrices for facets $a$ and $d$.

**Confusion Matrix for the Favored Facet $a$**

<table>
<thead>
<tr>
<th>Class $a$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

**Confusion Matrix for the Disfavored Facet $d$**

<table>
<thead>
<tr>
<th>Class $d$ predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
</tbody>
</table>
The value of the recall difference is \( RD = \frac{65}{70} - \frac{20}{27} = 0.93 - 0.74 = 0.19 \) which indicates a bias against facet \( d \).

The range of values for the recall difference between facets \( a \) and \( d \) for binary and multicategory classification is \([-1, +1]\). This metric is not available for the case of continuous labels.

- Positive values are obtained when there is higher recall for facet \( a \) than for facet \( d \). This suggests that the model finds more of the true positives for facet \( a \) than for facet \( d \), which is a form of bias.
- Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.
- Negative values are obtained when there is higher recall for facet \( d \) than for facet \( a \). This suggests that the model finds more of the true positives for facet \( d \) than for facet \( a \), which is a form of bias.

**Difference in Acceptance Rates (DAR)**

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets \( a \) and \( d \). This metric measures the difference in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets \( a \) and \( d \):

\[
DAR = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}
\]

Where:

- \( TP_a \) are the true positives predicted for facet \( a \).
- \( FP_a \) are the false positives predicted for facet \( a \).
- \( TP_d \) are the true positives predicted for facet \( d \).
- \( FP_d \) are the false positives predicted for facet \( d \).

For example, suppose the model accepts 70 middle-aged applicants (facet \( a \)) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet \( d \)) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then DAR = \( \frac{35}{70} - \frac{40}{100} = 0.10 \), which indicates a potential bias against qualified people from the second age group (facet \( d \)).

The range of values for DAR for binary, multicategory facet, and continuous labels is \([-1, +1]\).

- Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet \( a \) is larger than the same ratio for facet \( d \). These values indicate a possible bias against the disfavored facet \( d \) caused by the occurrence of relatively more false positives in facet \( d \). The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets \( a \) and \( d \) have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet \( d \) is larger than the ratio facet \( a \). These values indicate a
possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$
\text{DRR} = \frac{\text{TN}_d}{\text{TN}_d + \text{FN}_d} - \frac{\text{TN}_a}{\text{TN}_a + \text{FN}_a}
$$

Where:
- $\text{TN}_d$ are the true negatives predicted for facet $d$.
- $\text{FN}_d$ are the false negatives predicted for facet $d$.
- $\text{TP}_a$ are the true negatives predicted for facet $a$.
- $\text{FN}_a$ are the false negatives predicted for facet $a$.

For example, suppose the model rejects 100 middle-aged applicants (facet $a$) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model rejects 50 applicants from other age demographics (facet $d$) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then DRR = 40/50 - 80/100 = 0, so no bias is indicated.

The range of values for DRR for binary, multicategory facet, and continuous labels is [-1, +1].

- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $d$ is larger than the same ratio for facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false negatives in facet $a$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets $a$ and $d$ have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $a$ is larger than the ratio facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Accuracy Difference (AD)**

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet $a$) than for another age-based demographic (facet $d$), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that
group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet $a$, $\text{ACC}_a$, minus that for facet $d$, $\text{ACC}_d$:

$$\text{AD} = \text{ACC}_a - \text{ACC}_d$$

Where:

- $\text{ACC}_a = (\text{TP}_a + \text{TN}_a)/(\text{TP}_a + \text{TN}_a + \text{FP}_a + \text{FN}_a)$
- $\text{TP}_a$ are the true positives predicted for facet $a$
- $\text{TN}_a$ are the true negatives predicted for facet $a$
- $\text{FP}_a$ are the false positives predicted for facet $a$
- $\text{FN}_a$ are the false negatives predicted for facet $a$
- $\text{ACC}_d = (\text{TP}_d + \text{TN}_d)/(\text{TP}_d + \text{TN}_d + \text{FP}_d + \text{FN}_d)$
- $\text{TP}_d$ are the true positives predicted for facet $d$
- $\text{TN}_d$ are the true negatives predicted for facet $d$
- $\text{FP}_d$ are the false positives predicted for facet $d$
- $\text{FN}_d$ are the false negatives predicted for facet $d$

For example, suppose a model approves loans to 70 applicants from facet $a$ of 100 and rejected the other 30. 10 should not have been offered the loan (FP$_a$) and 60 were approved that should have been (TP$_a$). 20 of the rejections should have been approved (FN$_a$) and 10 were correctly rejected (TN$_a$). The accuracy for facet $a$ is as follows:

$$\text{ACC}_a = (60 + 10)/(60 + 10 + 20 + 10) = 0.7$$

Next, suppose a model approves loans to 50 applicants from facet $d$ of 100 and rejected the other 50. 10 should not have been offered the loan (FP$_d$) and 40 were approved that should have been (TP$_d$). 40 of the rejections should have been approved (FN$_d$) and 10 were correctly rejected (TN$_d$). The accuracy for facet $a$ is determined as follows:

$$\text{ACC}_d = (40 + 10)/(40 + 10 + 40 + 10) = 0.5$$

The accuracy difference is thus $\text{AD} = \text{ACC}_a - \text{ACC}_d = 0.7 - 0.5 = 0.2$. This indicates there is a bias against facet $d$ as the metric is positive.

The range of values for AD for binary and multicategory facet labels is $[-1, +1]$.

- Positive values occur when the prediction accuracy for facet $a$ is greater than that for facet $d$. It means that facet $d$ suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet $d$.
- Values near zero occur when the prediction accuracy for facet $a$ is similar to that for facet $d$.
- Negative values occur when the prediction accuracy for facet $d$ is greater than that for facet $a$. It means that facet $a$ suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means the is a bias against the favored facet $a$.

**Treatment Equality (TE)**

The treatment equality (TE) is the difference in the ratio of false positives to false negatives between facets $a$ and $d$. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the
total of false positives and false negatives, but the breakdown of these two maybe very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

\[
\text{TE} = \frac{\text{FP}_a}{\text{FN}_a} - \frac{\text{FP}_d}{\text{FN}_d}
\]

Where:

- FP<sub>a</sub> are the false positives predicted for facet <i>a</i>.
- FN<sub>a</sub> are the false negatives predicted for facet <i>a</i>.
- FP<sub>d</sub> are the false positives predicted for facet <i>d</i>.
- FN<sub>d</sub> are the false negatives predicted for facet <i>d</i>.

Note the metric becomes unbounded if FN<sub>a</sub> or FN<sub>d</sub> is zero.

For example, suppose that there are 100 loan applicants from facet <i>a</i> and 50 from facet <i>d</i>. For facet <i>a</i>, 8 were wrongly denied a loan (FN<sub>a</sub>) and another 6 were wrongly approved (FP<sub>a</sub>). The remaining predictions were true, so TP<sub>a</sub> + TN<sub>a</sub> = 86. For facet <i>d</i>, 5 were wrongly denied (FN<sub>d</sub>) and 2 were wrongly approved (FP<sub>d</sub>). The remaining predictions were true, so TP<sub>d</sub> + TN<sub>d</sub> = 43. The ratio of false positives to false negatives equals 6/8 = 0.75 for facet <i>a</i> and 2/5 = 0.40 for facet <i>d</i>. Hence TE = 0.75 - 0.40 = 0.35, even though both facets have the same accuracy:

\[
\text{ACC}_a = \frac{86}{86 + 8 + 6} = 0.86
\]
\[
\text{ACC}_d = \frac{43}{43 + 5 + 2} = 0.86
\]

The range of values for differences in conditional rejection for binary and multicategory facet labels is (-∞, +∞). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

- Positive values occur when the ratio of false positives to false negatives for facet <i>a</i> is greater than that for facet <i>d</i>.
- Values near zero occur when the ratio of false positives to false negatives for facet <i>a</i> is similar to that for facet <i>d</i>.
- Negative values occur when the ratio of false positives to false negatives for facet <i>a</i> is less than that for facet <i>d</i>.

**Conditional Demographic Disparity in Predicted Labels (CDDPL)**

The demographic disparity metric (DDPL) determines whether facet <i>d</i> has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range (-1, +1).

The formula for the demographic disparity predictions for labels of facet <i>d</i> is as follows:

\[
\text{DDPL}_d = \frac{n'^{(0)}_d}{n'^{(0)}_d + n'^{(1)}_d} - \frac{n'^{(1)}_d}{n'^{(0)}_d + n'^{(1)}_d} = P_d^R(y^0) - P_d^A(y^1)
\]

Where:

- \(n'^{(0)}_d = n'^{(0)}_a + n'^{(0)}_d\) is the number of predicted rejected labels for facets <i>a</i> and <i>d</i>.
- \(n'^{(1)}_d = n'^{(1)}_a + n'^{(1)}_d\) is the number of predicted accepted labels for facets <i>a</i> and <i>d</i>.
- \(P_d^R(y^0)\) is the proportion of predicted rejected labels (value 0) in facet <i>d</i>. 

2357
• $P_d^A(y'^1)$ is the proportion of predicted accepted labels (value 1) in facet $d$.

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson's paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.

The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of the dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

$$CDDPL = \frac{1}{n} \sum_i n_i \cdot DDPL_i$$

Where:

• $\sum_i n_i = n$ is the total number of observations and $n_i$ is the number of observations for each subgroup.
• $DDPL_i = n_i^{(0)/n^{(0)}} - n_i^{(1)/n^{(1)}} = P_i^R(y'^0) - P_i^A(y'^1)$ is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is $[-1,+1]$.

• +1: when there are no predicted rejection labels for facet $a$ or subgroup and no predicted acceptances for facet $d$ or subgroup.
• Positive values indicate there is a demographic disparity in predicted labels as facet $d$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
• Values near zero indicate there is no demographic disparity on average.
• Negative values indicate there is a demographic disparity in predicted labels as facet $a$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
• -1: when there are no predicted rejection labels for facet $d$ or subgroup and no predicted acceptances for facet $a$ or subgroup.

**Counterfactual Flipped Test (FT)**

The flip test is an approach that looks at each member of facet $d$ and assesses whether similar members of facet $a$ have different model predictions. The members of facet $a$ are chosen to be $k$-nearest neighbors of the observation from facet $d$. We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual flip test is the difference in the cardinality of two sets divided by the number of members of facet $d$:

$$FT = (F^+ - F^-)/n_d$$
Where:

- \( F^+ \) is the number of disfavored facet \( d \) members with an unfavorable outcome whose nearest neighbors in favored facet \( a \) received a favorable outcome.
- \( F^- \) is the number of disfavored facet \( d \) members with a favorable outcome whose nearest neighbors in favored facet \( a \) received an unfavorable outcome.
- \( n_d \) is the sample size of facet \( d \).

The range of values for the counterfactual flittest for binary and multicategory facet labels is \([-1, +1]\). For continuous labels, we set a threshold to collapse the labels to binary.

- Positive values occur when the number of unfavorable counterfactual flittest decisions for the disfavored facet \( d \) exceeds the favorable ones.
- Values near zero occur when the number of unfavorable and favorable counterfactual flittest decisions balance out.
- Negative values occur when the number of unfavorable counterfactual flittest decisions for the disfavored facet \( d \) is less than the favorable ones.

Amazon SageMaker Clarify Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators. They need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach. You can use this to understand why a model made a prediction after training, and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP. This is based on the concept of a Shapley value, from the field of cooperative game theory, that assigns each feature an importance value for a particular prediction.

Clarify produces partial dependence plots (PDPs) that show the marginal effect features have on the predicted outcome of a machine learning model. Partial dependence helps explain target response given a set of input features. It also supports both computer vision (CV) and natural language processing (NLP) explainability using the same Shapley Values (SHAP) algorithm as used for tabular data explanations.

What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- Why did the model predict a negative outcome such as a loan rejection for a given applicant?
- How does the model make predictions?
- Why did the model make an incorrect prediction?
- Which features have the largest influence on the behavior of the model?

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different
explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, for example in the case of ML modeling of images, the baseline might be implicit, where an image whose pixels are all the same color can serve as a baseline.

**Sample Notebooks**

Amazon SageMaker Clarify provides the following sample notebook for model explainability:

- **Amazon SageMaker Clarify Processing** – Use SageMaker Clarify to create a processing job for detecting bias and explaining model predictions with feature attributions. Examples include using CSV and JSONLines data formats, bringing your own container, and running processing jobs with Spark.
- **Explaining Image Classification with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models classify images.
- **Explaining object detection models with SageMaker Clarify** – SageMaker Clarify provides you with insights into how your computer vision models detect objects.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). If you’re prompted to choose a kernel, choose Python 3 (Data Science).

**Topics**

- Feature Attributions that Use Shapley Values (p. 2360)
- SHAP Baselines for Explainability (p. 2361)
- Partial Dependence Plots: Analysis Configuration and Output (p. 2361)
- SageMaker Clarify Computer Vision (p. 2364)
- Create Feature Attribute Baselines and Explainability Reports (p. 2365)
- Explainability Reports for NLP Models (p. 2365)

**Feature Attributions that Use Shapley Values**

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model’s predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the game and the features included in the model as the players. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either dropping that feature from the model or dropping all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature.
Given \( d \) features, there are \( 2^d \) such possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature \( f \), consider the marginal contribution of including \( f \) in all feature combinations (and associated models) that do not contain \( f \), and take the average. It can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of \( d \), say 50 features, it is computationally prohibitive and impractical to train \( 2^d \) possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see A Unified Approach to Interpreting Model Predictions.

**SHAP Baselines for Explainability**

As noted earlier, explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines so your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either uninformative or informative. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptance based on an average applicant. If not provided, a baseline is calculated automatically by SageMaker Clarify using K-means or K-prototypes in the input dataset.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can't act on to the same value as in the given instance.

**Partial Dependence Plots: Analysis Configuration and Output**

Partial dependence plots (PDP) show the dependence of the predicted target response on a set of input features of interest. These are marginalized over the values of all other input features and are referred to as the complement features. Intuitively, you can interpret the partial dependence as the target response, which is expected as a function of each input feature of interest.

**Topics**

- Partial dependence plots analysis configuration (p. 2361)
- Partial dependence plots analysis output (p. 2362)

**Partial dependence plots analysis configuration**

To create a partial dependence plot (PDP), Amazon SageMaker Clarify initially looks for the feature columns specified in a JSON array of the `analysis_config.json`. The other parameters that
configure the analysis of a processing job must be provided in this JSON file. For more information about configuring PDPs and other aspects of an analysis, see Configure the Analysis (p. 2329).

The following code contains an example of a JSON "pdp" object in the "methods" object of an analysis_config.json configuration file.

```
{
  "dataset_type": ...
  "baseline": [[..]]
  "methods": {
    "shap": {
      "baseline": "..",
      "num_samples": 100
    },
    "pdp": {
      "features": ["Age", "MaturityMonths"] // The features for which we need to plot PDP,
      "grid_resolution": 20, //Required for numerical columns only.
      //The number of buckets into which the range of values is divided.
      "top_k_features": 10, //Specifies how many of the top features must be used for PDP plots. The default is 10.
    },
    ...
  }
}
```

**Note**

If "features" is not mentioned in the "pdp" object but "shap" config is provided, SageMaker Clarify takes top ten features from the global SHAP results to plot the PDP visualizations.

### Partial dependence plots analysis output

The following code shows an example of the partial dependence plot (PDP) schema returned in the analysis.json result file. The "pdp" section in this analysis output file contains the information required to generate the PDP plots. Each dictionary in the list contains the specification for the PDP of the feature specified by the feature_name.

The data_type indicates whether the data is numerical or categorical. The feature_values field contains the values present in the feature. If the data_type inferred by Clarify is categorical, feature_values contain all the unique values that the feature could assume. If the data_type inferred by Clarify is numerical, it contains a list of the central values of each of the grid_resolution number of buckets generated by Clarify.

If the partial dependence plots are computed for a particular feature, the feature_values, model_predictions, and data_distributions fields are replaced by the error field which contains an error message.

```
{
  "version": "1.0",
  "explanations":{
    "kernel_shap":{
      ...
    }
  }
}
```
This PDP schema generates the following partial dependence plot for the Age feature. The PDP plots the `feature_values` along the x-axis. The y-axis contains the values in `model_predictions` field. Each list in the `model_predictions` field corresponds to one class in the output from the model.
You can view the plot in the report.pdf file in the analysis output path that you provided.

**SageMaker Clarify Computer Vision**

Amazon SageMaker Clarify generates heat maps for images that highlight features under analysis. In particular, the heat maps provide insights into how your computer vision models classify the images and how they detect objects in those images.

**Topics**
- Explain Image Classification with Amazon SageMaker Clarify (p. 2364)
- Explain Object Detection with Amazon SageMaker Clarify (p. 2364)

**Explain Image Classification with Amazon SageMaker Clarify**

SageMaker Clarify processing jobs provides support for explaining images using the KernelSHAP algorithm. This algorithm treats the image as a collection of super pixels. Given a dataset consisting of images, the processing job outputs a dataset of images where each image shows the heatmap of the relevant super pixels.

For a sample notebook that uses SageMaker Clarify to classify images and explain its classification, see Explaining Image Classification with SageMaker Clarify.

**Explain Object Detection with Amazon SageMaker Clarify**

Amazon SageMaker Clarify can detect and classify objects in an image and then provide an explanation for the detection predicted. The objects are first categorized into one of the classes in a specified
collection. SageMaker Clarify produces a confidence score for each object that it belongs to the class and the coordinates of a bounding box that delimits the object. For each detected object identified with sufficient probability, SageMaker Clarify extracts features using the Simple Linear Iterative Clustering (SLIC) method from scikit-learn library for image segmentation.

SageMaker Clarify can then provide an explanation for the detection of an object in the image scene. It uses Shapley values to determine the contribution that each feature has made to a model prediction. It produces a heat map that shows how important each of the features in the image scene were for its detection of the object. The context of an object is often very important for the correct identification of an object, so it is important not to just use the cropped image for classification.

For a sample notebook that uses SageMaker Clarify to detect objects in an image and explain its predictions, see Explaining object detection models with Amazon SageMaker Clarify.

Create Feature Attribute Baselines and Explainability Reports

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use SHAPConfig to create the baseline. In this example, the mean_abs is the mean of absolute SHAP values for all instances, specified as the baseline. You use DataConfig to configure the target variable, data input and output paths, and their formats.

```python
shap_config = clarify.SHAPConfig(baseline=test_features.iloc[0].values.tolist(),
                                num_samples=15,
                                agg_method='mean_abs')

explainability_output_path = 's3://{}/{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                                s3_output_path=explainability_output_path,
                                                label='Target',
                                                headers=training_data.columns.to_list(),
                                                dataset_type='text/csv')
```

**Note**

Kernel SHAP in SageMaker Clarify supports omitting the “baseline” parameter. In this case, a baseline based on clustering the input dataset is generated automatically.

Then run the explainability job.

```python
clarify_processor.run_explainability(data_config=explainability_data_config,
                                     model_config=model_config,
                                     explainability_config=shap_config)
```

View the results in Studio or download them from the explainability_output_path S3 bucket.

**Explainability Reports for NLP Models**

Amazon SageMaker Clarify supports explanations for natural language processing (NLP) models. NLP models help you understand which sections of text are most important for the predictions made by
Your model. This functionality can be used to explain either an individual local prediction or the model's expected predictions for overall global explanations. You can define the length of the text segment (tokens, phrases, sentences, paragraphs) to understand and visualize a model's behavior at multiple levels of granularity.

SageMaker Clarify NLP explainability is compatible with classification and regression models. You can also use Clarify to explain your model's behavior on multi-modal datasets that contain text, categorical, or numerical features. NLP explainability for multi-modal datasets can help you understand how important each feature is to the model's output. SageMaker Clarify supports 62 languages and can handle text which includes multiple languages.

To obtain feature importance for parts of an input text, create a TextConfig specifying the granularity of the parts of the text and the language. Clarify then breaks the text down into tokens, sentences, or paragraphs depending on your choice of granularity. It replaces subsets of these parts with the values from the baseline. The baseline defaults to empty strings, meaning SageMaker Clarify drops parts of the input text. SageMaker Clarify then replaces tokens (sentences and paragraphs, respectively) to determine how these replacements affect the model's prediction, in order to assess their importance.

```python
from sagemaker import clarify
text_config = clarify.TextConfig(
    # Specify the language of your text or use "xx" for multi-language.
    language="en",
    # Choose the granularity of your explanations as tokens, sentences or paragraphs.
    granularity="token"
)
shap_config = clarify.SHAPConfig(
    # For now, we don't support global aggregation,
    # so make sure you retrieve local explanations.
    save_local_shap_values=True,
    text_config=text_config,
    # Determine with what to replace tokens/sentences/paragraphs (based on your choice of granularity) with.
    baseline=["<UNK>"],
    # You can further specify num_samples and agg_method.
)
```

The remainder of the explainability job is coded as usual.

```python
explainability_output_path = 's3://{}/{}/clarify-explainability'.format(bucket, prefix)
explainability_data_config = clarify.DataConfig(
    s3_data_input_path=train_uri,
    s3_output_path=explainability_output_path,
    # With text data sometimes detection of headers fails,
    # so we recommend explicitly setting it in the config.
    headers="text",
    dataset_type="text/csv")
model_config = clarify.ModelConfig(
    model_name=model_name,
    # Specialized hardware is well-suited for NLP models.
    instance_type="ml.p2.xlarge",
    instance_count=1
)
clarify_processor = clarify.SageMakerClarifyProcessor(
    role=role, instance_count=1, instance_type="ml.m5.xlarge", sagemaker_session=session
)
clarify_processor.run_explainability(
    data_config=explainability_data_config,
    model_config=model_config,
)```
explainability_config=shap_config)

View the local explanations in the `explainability_output_path` S3 bucket. SageMaker Clarify does not aggregate the importance of individual tokens/sentences/paragraphs.

Extensions:

- **Multi-modal data** - If your data contains more than text, such as categorical or numeric features, you can add more columns in your header and baseline to accommodate those features.
- **JSON** - If the model input or output data is in JSON Lines format, specify the `dataset_type` in the `DataConfig` or the `accept_type` and `content_type` in the `ModelConfig`.
- **Multi-class model output** - If your model does multi-class or multi-label predictions, SageMaker Clarify computes the importance for each class.
- **Model output** - Some model outputs contain more than a single score. A prediction of three examples returns a matrix of shape `[3, 1]` such as `[[0.1], [-1.1], [10.2], [0.0], [3.2]]`. You can specify `model_scores` in `run_explainability`. For example, if your model predicts probabilities of five classes and additionally outputs the winning class, `"c1", [0.1, 0.4, 0.3, 0.2]`, then you can set `model_scores=1`.

Tips for fast results:

- During the development phase, work with a small subset of examples for quick iterations.
- To scale up for deployment, increase the `instance_count` for the processing job and the predictor. This instructs SageMaker Clarify to partition the data and work with multiple machines in parallel. For parallel processing, we recommend using the parquet data format because Spark can struggle with special characters in CSV files.
- Choose an appropriate `instance_type` for your model. GPU instances are often suitable for NLP models.
- To save unnecessary computation, consider truncating your text. Many models work with a maximum text length. By applying the truncation in a preprocessing step, SageMaker Clarify does not waste resources determining the feature importance for the parts of text that are disregarded by the model.

## Troubleshoot SageMaker Clarify Processing Jobs

If you encounter failures with SageMaker Clarify processing jobs, consult the following scenarios to help identify the issue.

**Note**

The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

**Topics**

- Processing job fails to finish (p. 2368)
- Processing job finishes without results and you get a CloudWatch warning message (p. 2368)
- Error message for invalid analysis configuration (p. 2368)
- Bias metric computation fails for several or all metrics (p. 2368)
- Mismatch between analysis config and dataset/model input/output (p. 2369)
- Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error (p. 2369)
• Execution role is invalid (p. 2369)
• Failed to download data (p. 2369)
• Could not connect to SageMaker (p. 2369)

Processing job fails to finish

If the processing job fails to finish, you can try the following:

• Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
• Inspect the job logs in CloudWatch.
• Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:

  ```python
  clarify_processor.jobs[-1].describe()
  ```
• Execute the following AWS CLI command to describe the processing job and look for the failure reason and exit message:

  ```bash
  aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

Processing job finishes without results and you get a CloudWatch warning message

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says "Signal 15 received, cleaning up", this is an indication that the job was stopped either due to a customer request that called the `StopProcessingJob` API or that the job ran out of time allotted for its completion. In the later case, check the maximum runtime in the job configuration (`max_runtime_in_seconds`) and increase it as needed.

Error message for invalid analysis configuration

• If you get the error message "Unable to load analysis configuration as JSON.", this means that the analysis configuration input file for the processing job does not contain a valid JSON object. Check the validity of the JSON object using a JSON linter.
• If you get the error message "Analysis configuration schema validation error.", this means that the analysis configuration input file for the processing job contains unknown fields or invalid types for some field values. Review the configuration parameters in the file and cross-check them with the parameters listed in the configuration specification file.

Bias metric computation fails for several or all metrics

If you receive one of the following error messages "No Label values are present in the predicted Label Column, Positive Predicted Index Series contains all False values." or "Predicted Label Column series datatype is not the same as Label Column series.", try the following:

• Check that the correct dataset is being used.
• Check whether the dataset size is too small; whether, for example, it contains only a few rows. This may cause the model outputs to have the same value or the data type is inferred incorrectly.
• Check if the label or facet is treated as continuous or categorical. SageMaker Clarify uses heuristics to determine the `DataType`. For post-training bias metrics, the data type returned by the model may not match what is in the dataset or SageMaker Clarify may not be able to transform it correctly.
In the bias report, you should see a single value for categorical columns or an interval for continuous columns.

For example, if a column has values 0.0 and 1.0 as floats, it will be treated as continuous even if there are too few unique values.

Mismatch between analysis config and dataset/model input/output

• Check that the baseline format in the analysis config is the same as dataset format.
• If you receive the error message "Could not convert string to float.", check that the format is correctly specified. It could also indicate that the model predictions have a different format than the label column or it could indicate that the configuration for the label or probabilities is incorrect.
• If you receive the error message "Unable to locate the facet." or "Headers must contain label." or "Headers in config do not match with the number of columns in the dataset." or "Feature names not found.", check that the headers match the columns.
• If you receive the error message "Data must contain features.", check the content template for JSON Lines and compare it with the dataset sample if available.

Model returns 500 Internal Server Error or container falls back to per-record predictions due to model error

If you receive the error message "Fallback to per-record prediction because of model error.", this could indicate that model cannot handle the batch size, or be throttled, or just does not accept the input passed by the container due to serialization problems. You should review the CloudWatch logs for the SageMaker endpoint and look for error messages or tracebacks. For model throttling cases, it may help to use a different instance type or increasing the number of instances for the endpoint.

Execution role is invalid

This indicates that the role provided is incorrect or missing required permissions. Check the role and its permissions that were used to configure the processing job and verify the permission and trust policy for the role.

Failed to download data

This indicates that job inputs could not be downloaded for the job to start. Check the bucket name and permissions for the dataset and the configuration inputs.

Could not connect to SageMaker

This indicates that the job could not reach SageMaker service endpoints. Check the network configuration settings for the processing job and verify VPC configuration.

Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.
Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don’t need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see Train a Model with Amazon SageMaker (p. 9).

You can train incrementally using the SageMaker console or the Amazon SageMaker Python SDK.

Important
Only three built-in algorithms currently support incremental training: Object Detection Algorithm (p. 1911), Image Classification Algorithm (p. 1829), and Semantic Segmentation Algorithm (p. 1934).

Topics
- Perform Incremental Training (Console) (p. 2370)
- Perform Incremental Training (API) (p. 2372)

Perform Incremental Training (Console)

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
- The Amazon Elastic Container Registry path where the training code is stored. For more information, see Docker Registry Paths and Example Code (p. 989).
- The URL of the S3 bucket where you've stored the model artifacts that you want to use in incremental training. To find the URL for the model artifacts, see the details page of the training job used to create the model. To find the details page, in the SageMaker console, choose Inference, choose Models, and then choose the model.

To restart a stopped training job, use the URL to the model artifacts that are stored in the details page as you would with a model or a completed training job.

To perform incremental training (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 982).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, *ml.m4.xlarge* is sufficient.

b. For **Instance count**, use the default, 1.

c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.

7. Provide information about the input data for the training dataset.

a. For **Channel name**, either leave the default (*train*) or enter a more meaningful name for the training dataset, such as *expanded-training-dataset*.

b. For **InputMode**, choose **File**. For incremental training, you need to use file input mode.

c. For **S3 data distribution type**, choose **FullyReplicated**. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.

d. If the expanded dataset is uncompressed, set the **Compression type** to **None**. If the expanded dataset is compressed using Gzip, set it to **Gzip**.

e. (Optional) If you are using File input mode, leave **Content type** empty. For Pipe input mode, specify the appropriate MIME type. **Content type** is the multipurpose internet mail extension (MIME) type of the data.

f. For **Record wrapper**, if the dataset is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO formatted file, choose **None**.

g. For **S3 data type**, if the dataset is stored as a single file, choose **S3Prefix**. If the dataset is stored as several files in a folder, choose **Manifest**.

h. For **S3 location**, provide the URL to the path where you stored the expanded dataset.

i. Choose **Done**.

8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.

a. For **Input data configuration**, choose **Add channel**.

b. For **Channel name**, enter **model** to identify this channel as the source of the model artifacts.

c. For **InputMode**, choose **File**. Model artifacts are stored as files.

d. For **S3 data distribution type**, choose **FullyReplicated**. This indicates that each ML compute instance should use all of the model artifacts for training.

e. For **Compression type**, choose **None** because we are using a model for the channel.

f. Leave **Content type** empty. Content type is the multipurpose internet mail extension (MIME) type of the data. For model artifacts, we leave it empty.

g. Set **Record wrapper** to **None** because model artifacts are not stored in RecordIO format.

h. For **S3 data type**, if you are using a built-in algorithm or an algorithm that stores the model as a single file, choose **S3Prefix**. If you are using an algorithm that stores the model as several files, choose **Manifest**.

i. For **S3 location**, provide the URL to the path where you stored the model artifacts. Typically, the model is stored with the name **model.tar.gz**. To find the URL for the model artifacts, in the navigation pane, choose **Inference**, then choose **Models**. From the list of models, choose a model to display its details page. The URL for the model artifacts is listed under **Primary container**.

j. Choose **Done**.

9. For **Output data configuration**, provide the following information:

a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

b. (Optional) For **Encryption key**, you can add your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. Provide the key ID or its Amazon Resource Number (ARN). For more information, see [KMS-Managed Encryption Keys](#).
10. (Optional) For **Tags**, add one or more tags to the training job. A *tag* is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value referring to a project that is related to the training job, such as **Home value forecasts**.

11. Choose **Create training job**. SageMaker creates and runs training job.

After the training job has completed, the newly trained model artifacts are stored under the **S3 output path** that you provided in the **Output data configuration** field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 90).

**Perform Incremental Training (API)**

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the Caltech 256 Image Dataset; then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the incremental training sample notebook for more details on using incremental training.

**Note**
In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the **data_channels** variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role
role = get_execution_role()
print(role)

sess = sagemaker.Session()
bucket=sess.default_bucket()
print(bucket)
prefix = 'ic-incr-training'
```

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(sess.boto_region_name, 'image-classification',
repo_version="latest")
#Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split("/")[0]
    if not os.path.exists(filename):
```
urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}{}train/'.format(bucket, prefix)
s3validation = 's3://{}{}validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet

Define the training hyperparameters:

# Define hyperparameters for the estimator
hyperparams = { "num_layers": "18",
"resize": "32",
"num_training_samples": "50000",
"num_classes": "10",
"image_shape": "3,28,28",
"mini_batch_size": "128",
"epochs": "3",
"learning_rate": "0.1",
"lr_scheduler_step": "2,3",
"lr_scheduler_factor": "0.1",
"augmentation_type": "crop_color",
"optimizer": "sgd",
"momentum": "0.9",
"weight_decay": "0.0001",
"beta_1": "0.9",
"beta_2": "0.999",
"gamma": "0.9",
"eps": "1e-8",
"top_k": "5",
"checkpoint_frequency": "1",
"use_pretrained_model": "0",
"model_prefix": "" }

Create an estimator object and train the first model using the training and validation datasets:

# Fit the base estimator
s3_output_location = 's3://{}{}output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
role,
instance_count=1,
instance_type='ml.p2.xlarge',
volume_size=50,
max_run=360000,
input_mode='File',
output_path=s3_output_location,
sagemaker_session=sess,
hyperparameters=hyperparams)

train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
content_type='application/x-recordio',
s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
distribution='FullyReplicated',
content_type='application/x-recordio',
s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}

ic.fit(inputs=data_channels, logs=True)

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (ic.model_data, in this example) for the model_uri input argument:

```python
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
            role,
            instance_count=1,
            instance_type='ml.p2.xlarge',
            volume_size=50,
            max_run=360000,
            input_mode='File',
            output_path=s3_output_location,
            sagemaker_session=sess,
            hyperparameters=hyperparams,
            model_uri=ic.model_data) # This parameter will
            ingest the previous job's model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in Output_path. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 90).

### Access Training Data

When you create a training job, you specify the location of the training dataset and the input mode for accessing that data. For data location, Amazon SageMaker supports Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre, dependent on the input mode. The input mode determines whether the data is streamed or downloaded at the start of the training job.

#### Input modes

- **File** mode presents a file system view of the dataset to the training container. Data sources can be Amazon S3 or Amazon EFS and Amazon FSx remote file systems.

  - **File** mode downloads the training data from the storage location to a local directory in the Docker container. Training starts after the full dataset has been downloaded.

- **Pipe** mode streams data directly from an Amazon S3 data source. Streaming can provide faster start times and better throughput than File mode.

  When you stream the data directly, you can reduce the size of the Amazon EBS volumes used by the training instance. Pipe mode needs only enough disk space to store the final model artifacts.

- **FastFile** mode provides file system access to an Amazon S3 data source while leveraging the performance advantage of Pipe mode. At the start of training, FastFile mode identifies the data files but does not download them. Training can start without waiting for the entire dataset to download. The start-up time is lower when there are fewer files in the Amazon S3 prefix provided.

  In contrast to Pipe mode, FastFile mode works with random access to the data. However, it works best when data is read sequentially. FastFile mode doesn't support augmented manifest files.

For more information, see How Amazon SageMaker Provides Training Information (p. 2777), the CreateTrainingJob API, and the TrainingInputMode in AlgorithmSpecification.
Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 2376).

Note
Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

Topics
- Using Managed Spot Training (p. 2375)
- Managed Spot Training Lifecycle (p. 2375)

Using Managed Spot Training

To use managed spot training, create a training job. Set EnableManagedSpotTraining to True and specify the MaxWaitTimeInSeconds. MaxWaitTimeInSeconds must be larger than MaxRuntimeInSeconds. For more information about creating a training job, see DescribeTrainingJob.

You can calculate the savings from using managed spot training using the formula \((1 - \frac{BillableTimeInSeconds}{TrainingTimeInSeconds}) \times 100\). For example, if BillableTimeInSeconds is 100 and TrainingTimeInSeconds is 500, the savings is 80%.

To learn how to run training jobs on Amazon SageMaker spot instances and how managed spot training works and reduces the billable time, see the following example notebooks:
- Managed Spot Training with TensorFlow
- Managed Spot Training with XGBoost
- Managed Spot Training with MXNet
- Amazon SageMaker Managed Spot Training Examples GitHub repository

Managed Spot Training Lifecycle

You can monitor a training job using TrainingJobStatus and SecondaryStatus returned by DescribeTrainingJob. The list below shows how TrainingJobStatus and SecondaryStatus values change depending on the training scenario:
Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by the callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers. SageMaker provides functionality to copy the checkpoints from the local path to Amazon S3. Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Managed Spot Training in Amazon SageMaker (p. 2375).

Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.
Enable Checkpointing

SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path `/opt/ml/checkpoints` and copies them to Amazon S3.

- **Deep Learning Containers**: TensorFlow, PyTorch, MXNet, and HuggingFace
  
  **Note**
  
  If you are using the HuggingFace framework estimator, you need to specify a checkpoint output path through hyperparameters. For more information, see Run training on Amazon SageMaker in the HuggingFace documentation.

- **Built-in algorithms**: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)
  
  **Note**
  
  If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.

For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`/opt/ml/checkpoints`) and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see
Docker Registry Paths and Example Code (p. 989). You can also replace estimator and Estimator with other SageMaker frameworks' estimator parent classes and estimator classes, such as TensorFlow, PyTorch, MXNet, HuggingFace and XGBoost.

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
bucket_name='sagemaker-checkpoint-test'
checkpoint_bucket='checkpoints'
checkpoint_s3_bucket= 's3://{}/{}'.format(bucket, base_job_name, checkpoint_in_bucket)
checkpoint_local_path= '/opt/ml/checkpoints'

estimator = Estimator(
    image_uri='<ecr_path>/<algorithm-name>:<tag>',  # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path
)
```

The following two parameters specify paths for checkpointing:

- **checkpoint_local_path** – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to '/opt/ml/checkpoints'. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to '/opt/ml/checkpoints'.

  **Note**
  We recommend specifying the local paths as '/opt/ml/checkpoints' to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the checkpoint_local_path parameter of the SageMaker estimators.

- **checkpoint_s3_uri** – The URI to an S3 bucket where the checkpoints are stored in real time.

To find a complete list of SageMaker estimator parameters, see the Estimator API in the Amazon SageMaker Python SDK documentation.

**Browse Checkpoint Files**

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

**To find the checkpoint files programmatically**

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```python
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.
To find the checkpoint files from the Amazon S3 console

2. In the left navigation pane, choose Training jobs.
3. Choose the link to the training job with checkpointing enabled to open Job settings.
4. On the Job settings page of the training job, locate the Checkpoint configuration section.

<table>
<thead>
<tr>
<th>Checkpoint configuration</th>
<th>S3 output path</th>
<th>Local path</th>
</tr>
</thead>
<tbody>
<tr>
<td>s3://path-to-your-checkpoint</td>
<td>/opt/ml/checkpoints/</td>
<td></td>
</tr>
</tbody>
</table>

5. Use the link to the S3 bucket to access the checkpoint files.

Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same checkpoint_s3_uri that you created in the Enable Checkpointing (p. 2377) section. Once the training has resumed, the checkpoints from this S3 bucket are restored to checkpoint_local_path in each instance of the new training job. Ensure that the S3 bucket is in the same Region as that of the current SageMaker session.

Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using the framework's model save functions or checkpoint callbacks.
- If you use SageMaker checkpoints with SageMaker Debugger and SageMaker distributed and are facing issues, see the following pages for troubleshooting and considerations.
  - Considerations for Amazon SageMaker Debugger (p. 2182)
  - Data Parallel Troubleshooting (p. 2248)
Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3), and you must configure your training job to use the dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.

During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ["line", "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.

If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], the following example shows a valid augmented manifest file:

```
{"image-ref": "s3://my-bucket/my-image.jpg", "is-a-cat": true}
```
In case of the first JSON line of this manifest file, SageMaker retrieves the image1.jpg file from s3://mybucket/sample01/ and the string representation of the is-a-cat attribute "1" for image classification.

Tip
To create an augmented manifest file, use Amazon SageMaker Ground Truth and create a labeling job. For more information about the output from a labeling job, see Output Data (p. 546).

Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a "-ref" suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.

Using the ["image-ref", "is-a-cat"] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding is-a-cat attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as S3DataDistributionType. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

Use an Augmented Manifest File (Console)

To complete this procedure, you need:

- The URL of the S3 bucket where you’ve stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

To use an augmented manifest file in a training job (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Training**, then choose **Training jobs**.

3. Choose **Create training job**.

4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and . : + = @ % - (hyphen).

5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see [*Use Amazon SageMaker Built-in Algorithms*](<p. 982>). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.

6. (Optional) For **Resource configuration**, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For **Instance type**, choose the ML compute instance type that you want to use. In most cases, `ml.m4.xlarge` is sufficient.
   b. For **Instance count**, use the default, 1.
   c. (Optional) For **Additional volume per instance (GB)**, choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.

7. Provide information about the input data for the training dataset.
   a. For **Channel name**, either accept the default (train) or enter a more meaningful name, such as `training-augmented-manifest-file`.
   b. For **InputMode**, choose Pipe.
   c. For **S3 data distribution type**, choose FullyReplicated. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as **Neural Topic Model (NTM) Algorithm** (p. 1889), choose ShardedByS3Key.
   d. If the data specified in the augmented manifest file is uncompressed, set the **Compression type** to None. If the data is compressed using gzip, set it to Gzip.
   e. (Optional) For **Content type**, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.
   f. For **Record wrapper**, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose RecordIO. If your dataset is not saved as a RecordIO-formatted file, choose None.
   g. For **S3 data type**, choose AugmentedManifestFile.
   h. For **S3 location**, provide the path to the bucket where you stored the augmented manifest file.
   i. For **AugmentedManifestFile attribute names**, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.
   j. (Optional) To add more attribute names, choose Add row and specify another attribute name for each attribute.
   k. (Optional) To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.
   l. Choose Done.

8. For **Output data configuration**, provide the following information:
   a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.
   b. (Optional) You can use your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. For Encryption key, provide the key ID or its Amazon Resource Number (ARN). For more information, see [*KMS-Managed Encryption Keys*](<p.>).

9. (Optional) For **Tags**, add one or more tags to the training job. A tag is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with...
Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
import sagemaker

# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(
    training_image,
    role,
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode = 'Pipe',
    output_path=s3_output_location,
    sagemaker_session=session
)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute names.
train_data = sagemaker.inputs.TrainingInput(
    your_augmented_manifest_file,
    distribution='FullyReplicated',
    content_type='application/x-recordio',
    s3_data_type='AugmentedManifestFile',
    attribute_names=['source-ref', 'annotations'],
    input_mode='Pipe',
    record_wrapping='RecordIO'
)

data_channels = {'train': train_data}

# Train a model.
model.fit(inputs=data_channels, logs=True)
```

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for S3 output path in the Output data configuration field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 90).

Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm
writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the `DescribeTrainingJob` operation.

**Note**
Amazon CloudWatch supports high-resolution custom metrics, and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the Amazon CloudWatch API Reference.

**Tip**
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

**Topics**
- Defining Training Metrics (p. 2384)
- Monitoring Training Job Metrics (CloudWatch Console) (p. 2387)
- Monitoring Training Job Metrics (SageMaker Console) (p. 2387)
- Example: Viewing a Training and Validation Curve (p. 2389)

**Defining Training Metrics**

SageMaker automatically parses training job logs and sends training metrics to CloudWatch. By default, SageMaker sends system resource utilization metrics listed in SageMaker Jobs and Endpoint Metrics. If you want SageMaker to parse logs and send custom metrics from a training job of your own algorithm to CloudWatch, you need to specify metrics definitions by passing the name of metrics and regular expressions when you configure a SageMaker training job request.

You can specify the metrics that you want to track using the SageMaker console, the SageMaker Python SDK, or the low-level SageMaker API.

If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs.
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch.

For example, suppose your algorithm emits the following metrics for training error and validation error:

```
Train_error=0.138318;  Valid_error=0.324557;
```

If you want to monitor both of those metrics in CloudWatch, the dictionary for the metric definitions should look like the following example:

```
[
  ["Train_error", "0.138318"],
  ["Valid_error", "0.324557"]
]```
Defining Training Metrics

```json
{
    "Name": "train:error",
    "Regex": "Train_error=(.*?);"
},
{
    "Name": "validation:error",
    "Regex": "Valid_error=(.*?);"
}
```

In the regex for the `train:error` metric defined in the preceding example, the first part of the regex finds the exact text "Train_error=", and the expression `(.*?);` captures any characters until the first semicolon character appears. In this expression, the parenthesis tell the regex to capture what is inside them, `.` means any character, `*` means zero or more, and `?` means capture only until the first instance of the `;` character.

**Define Metrics Using the SageMaker Python SDK**

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following example:

```python
import sagemaker
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri="your-own-image-uri",
    role=sagemaker.get_execution_role(),
    sagemaker_session=sagemaker.Session(),
    instance_count=1,
    instance_type='ml.c4.xlarge',
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)
```

For more information about training by using Amazon SageMaker Python SDK estimators, see [Sagemaker Python SDK on GitHub](https://github.com/aws/sagemaker-python-sdk).

**Define Metrics Using the SageMaker Console**

If you choose the **Your own algorithm container in ECR** option as your algorithm source in the SageMaker console when you create a training job, add the metric definitions in the `Metrics` section. The following screenshot shows how it should look after you add the example metric names and the corresponding regular expressions.
Define Metrics Using the Low-level SageMaker API

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the MetricDefinitions field of the AlgorithmSpecification input parameter that you pass to the `CreateTrainingJob` operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your AlgorithmSpecification would look like the following example:

```json
"AlgorithmSpecification": {
  "TrainingImage": "your-own-image-uri",
  "TrainingInputMode": "File",
  "MetricDefinitions": [
    { "Name": "train:error", "Regex": "Train_error=(.*?);" },
    { "Name": "validation:error", "Regex": "Valid_error=(.*?);" }
  ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see `CreateTrainingJob`.
Monitoring Training Job Metrics (CloudWatch Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

To monitor training job metrics (CloudWatch console)
2. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
3. Choose TrainingJobName.
4. On the All metrics tab, choose the names of the training metrics that you want to monitor.
5. On the Graphed metrics tab, configure the graph options. For more information about using CloudWatch graphs, see Graph Metrics in the Amazon CloudWatch User Guide.

Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

To monitor training job metrics (SageMaker console)
2. Choose Training jobs, then choose the training job whose metrics you want to see.
3. Choose TrainingJobName.
4. In the Monitor section, you can review the graphs of instance utilization and algorithm metrics.
Example: Viewing a Training and Validation Curve

Typically, you split the data on which you train your model into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the Image-classification-full-training example in the Example notebooks section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 80). If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

2. Choose Notebooks, and then choose Notebook instances.
3. Choose the notebook instance that you want to use, and then choose Open.
4. On the dashboard for your notebook instance, choose SageMaker Examples.
5. Expand the Introduction to Amazon Algorithms section, and then choose Use next to Image-classification-fulltraining.ipynb.
7. Run all of the cells in the notebook up to the Inference section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch.
9. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
10. Choose TrainingJobName.
11. On the All metrics tab, choose the train:accuracy and validation:accuracy metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following example.
Example: Viewing a Training and Validation Curve
Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

- To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an example of how to deploy a model to the SageMaker hosting service, see Create your endpoint and deploy your model (p. 2414).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

- To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see Use Batch Transform (p. 2565).

For an example of how to deploy a model with batch transform, see (Optional) Make Prediction with Batch Transform (p. 91).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

Prerequisites

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the Get Started with Amazon SageMaker (p. 34) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models (p. 977).

What do you want to do?

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

- To manage data processing and real-time predictions or to process batch transforms in a pipeline, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2446).

- If you want to deploy a model on inf1 instances, see Optimize model performance using Neo (p. 2666).

- To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see Optimize model performance using Neo (p. 2666).

- To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don’t need a persistent endpoint, see Use Batch Transform (p. 2565).

- To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see Use Amazon SageMaker Elastic Inference (EI) (p. 2732).

- To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatically Scale Amazon SageMaker Models (p. 2460).

- To create an endpoint that can host multiple models using a shared serving container, see Host multiple models in one container behind one endpoint (p. 2424).
Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

- For tools that can be used to monitor model deployments, see Monitor Amazon SageMaker (p. 3190).
- For troubleshooting model deployments, see Troubleshoot Amazon SageMaker model deployments (p. 2485).
- For model deployment best practices, see Best practices (p. 2483).
- For information about the size of storage volumes provided for different sizes of hosting instances, see Host instance storage volumes (p. 2475).

Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

- To run your own inference code hosting services, see Use Your Own Inference Code with Hosting Services (p. 2783).
- To run your own inference code for batch transforms, see Use Your Own Inference Code with Batch Transform (p. 2788).

Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender is a new capability of Amazon SageMaker that reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker ML instances. You can use Inference Recommender to deploy your model to a real-time inference endpoint that delivers the best performance at the lowest cost. Inference Recommender helps you select the best instance type and configuration (such as instance count, container parameters, and model optimizations) for your ML models and workloads.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you must first register a model to SageMaker model registry with your model artifact and container, use AWS SDK for Python (Boto3) to benchmark different SageMaker endpoint configurations, collect metrics, and visualize metrics across performance and resource utilization to help you decide on which instance type to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites (p. 2393) section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
2. Read through the Recommendation jobs (p. 2399) section to launch your first Inference Recommender recommendation jobs.
3. Explore the Amazon SageMaker Inference Recommender Jupyter notebook example.

Prerequisites

To use Amazon SageMaker Inference Recommender, first make sure you have met the prerequisites listed below. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs.

Note

- The following code examples use Python. Remove the `!` prefix character if you run any of the following code samples in your terminal or AWS CLI.
- This example uses the `conda_pytorch_p36_latest` kernel within a Amazon SageMaker Notebook instance. This kernel is provided by SageMaker and uses Python 3.6 and PyTorch 1.7.1. For more information about SageMaker Notebooks, see Use Amazon SageMaker Notebook Instances (p. 237).

1. Create an IAM role for Amazon SageMaker.

Create an IAM Role for Amazon SageMaker that has the `AmazonSageMakerFullAccess` IAM managed policy attached.

2. (Optional) Review existing models benchmarked by Inference Recommender.

Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

Use `ListModelMetaData` to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

```python
import boto3
aws_region="<INSERT>"
sagemaker_client = boto3.client("sagemaker", aws_region)
list_model_metadata_response=sagemaker_client.list_model_metadata()
```

The output includes model summaries (`ModelMetadataSummaries`) and response metadata (`ResponseMetadata`) similar to the following:

```json
{
    "ModelMetadataSummaries": [{
        "Domain": "NATURAL_LANGUAGE_PROCESSING",
        "Framework": "PYTORCH:1.6.0",
        "Model": "bert-base-cased",
        "Task": "FILL_MASK"
    },
    {
        "Domain": "NATURAL_LANGUAGE_PROCESSING",
        "Framework": "PYTORCH:1.6.0",
        "Model": "bert-base-uncased",
        "Task": "FILL_MASK"
    },
    {
        "Domain": "COMPUTER_VISION",
        "Framework": "MXNET:1.8.0",
```
For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```python
# ML framework details
framework = 'PYTORCH'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

### 3. Upload your machine learning model to Amazon S3.

Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```python
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets

# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)

# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is required for Inferentia compilation.
model.eval()

# Save your traced model
model_trace.save('model.pth')
```

Download a sample inference script `inference.py`. Create a `code` directory and move the inference script to the `code` directory.

```bash
# Download the inference script
```
# move it into a code/ directory
!mkdir code
!mv inference.py code/

Amazon SageMaker requires pre-trained machine learning models be packaged as a compressed TAR file (*.tar.gz). Compress your model to satisfy this requirement:

```
!tar -czf test.tar.gz model.pth resnet18.py
```

When your endpoint is provisioned, the files in the archive are extracted to /opt/ml/model/ on the endpoint.

After you compress your model and model artifacts as a .tar.gz file, upload them to your Amazon S3 bucket. The following demonstrates how to upload your model to Amazon S3 using the AWS CLI:

```
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#).

If none of the existing SageMaker containers meet your needs and you don’t have an existing container of your own, create a new Docker image. See [Use Your Own Inference Code](#) for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```python
from sagemaker import image_uris

aws_region="<aws_region>"

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework, 
    region=aws_region, 
    version=framework_version, 
    py_version='py3', 
    instance_type=instance_type, 
    image_scope='inference')
```

For a list of available SageMaker Instances, see [Amazon SageMaker Pricing](#).

5. **Create a sample payload archive.**

Create an archive that contains individual files that the load testing tool can send to your SageMaker endpoints. Your inference code must be able to read the file formats from the sample payload.

The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.
Compress the sample payload as a tarball:

```bash
!tar -cvzf payload.tar.gz flowers-5841251_1280.jpg
```

Upload the sample payload to Amazon S3 and note the Amazon S3 URI:

```bash
!aws s3 cp payload.tar.gz s3://{bucket}/models/
```

You need the Amazon S3 URI in a later step, so store it in a variable:

```python
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
payload_s3_key = f'{bucket_prefix}/payload.tar.gz'
sample_payload_url= f's3://{bucket}/{payload_s3_key}'
```

6. **Register your model in the model registry**

With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the AWS SDK for Python (Boto3) or with Amazon SageMaker Studio. To create a versioned model package programmatically, first create a model package group with the `CreateModelPackageGroup` API. Next, create a model package using the `CreateModelPackage` API. Calling this method makes a versioned model package.

See Create a Model Group (p. 2593) and Register a Model Version (p. 2597) for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the AWS SDK for Python (Boto3) and Amazon SageMaker Studio.

The following code sample demonstrates how to create a versioned model package using the AWS SDK for Python (Boto3).

**Note**

Note: You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the `CreateModelPackageGroup` API. Provide a name to the model package group for the `ModelPackageGroupName` and optionally provide a description of the model package in the `ModelPackageGroupNameDescription` field.

```python
model_package_group_name = '<INSERT>'
model_package_group_description = '<INSERT>'
```
See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateModelPackageGroup.

Create a Model Package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for InferenceSpecification. InferenceSpecification should contain information about inference jobs that can be run with models based on this Model Package, including the following:

- The Amazon ECR paths of images that run your inference code.
- (Optional) The instance types that the Model Package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the Model Package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- **Domain**: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- **Task**: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification.
- **SamplePayloadUrl**: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single gzip compressed tar archive (.tar.gz suffix).
- **Framework**: The machine learning framework of the model package container image.
- **FrameworkVersion**: The framework version of the Model Package Container Image.

If you provide an allow list of instance types to use to generate inferences in real-time for the SupportedRealtimeInferencelInstanceTypes, Inference Recommender will limit the search space for instance types during a Default job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called **models**. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called **image_uri**. We use those variables in the following code sample where we define a dictionary used as input to the CreateModelPackage API.

```python

model_package_group_input_dict = {
    "ModelPackageName": model_package_group_name,
    "ModelPackageGroupDescription": model_package_group_description,
}

model_package_group_response =
    sagemaker_client.create_model_package_group(**model_package_group_input_dict)

# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f'{bucket_prefix}/test.tar.gz'
model_url= f's3://{bucket}/{model_s3_key}'

# Similar open source model to the packaged model
# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'
```
# The supported MIME types for input and output data. In this example, we are using images as input.
input_content_type='image/jpeg'

# Optional - provide a description of your model.
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version in a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating a model package group
model_package_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageDescription" : model_package_description,
    "Domain": ml_domain,
    "Task": ml_task,
    "SamplePayloadUrl": sample_payload_url,
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": image_uri,
                "ModelDataUrl": model_url,
                "Framework": framework.upper(),
                "FrameworkVersion": framework_version,
                "NearestModelName": nearest_model_name,
                "ModelInput": {
                    "DataInputConfig": data_input_configuration
                }
            }
        ],
        "SupportedContentTypes": [input_content_type]
    }
}

b. **Create a Model Package**

Use the CreateModelPackage API to create a Model Package. Pass the input dictionary defined in the previous step:

```python
model_package_response =
sagemaker_client.create_model_package(**model_package_input_dict)
```

You need the model package ARN to use Amazon SageMaker Inference Recommender. Note the ARN of the model package or store it in a variable:

```python
model_package_arn = model_package_response['ModelPackageArn']
print('ModelPackage Version ARN : {}' .format(model_package_arn))
```
Recommendation jobs

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. Instance recommendations *(default job type)* run a set of load tests on recommended instance types. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Instance recommendation jobs complete within 45 minutes.

2. Endpoint recommendations *(advanced job type)* are based on a custom load test where you select ML instances, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of instance configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Endpoint recommendations also provide an initial instance count which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, specify *Default* to create preliminary endpoint recommendations and *Advanced* for custom load testing and endpoint recommendations.

**Note**
- You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of each other.

**Topics**
- Get an instance recommendation (p. 2399)
- Run a custom load test (p. 2406)

Get an instance recommendation

Instance recommendation jobs run a set of load tests on recommended instance types. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

**Note**
- Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites (p. 2393).

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an instance recommendation based on your model type using the AWS SDK for Python (Boto3), AWS CLI, and Amazon SageMaker Studio.

Create an instance recommendation

Create an instance recommendation programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. Specify a job name for your instance recommendation, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry.

**AWS SDK for Python (Boto3)**

Use the `CreateInferenceRecommendationsJob` API to get an instance endpoint recommendation. Set the `JobType` field to `'Default'` for instance endpoint recommendation jobs. In addition, provide the following:
• The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.

• The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.

• Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

Import the AWS SDK for Python (Boto3) package and create a SageMaker client object using the client class. If you followed the steps in the Prerequisites section, the model package group ARN was stored in a variable named `model_package_arn`.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = 'arn:aws:iam::<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

**AWS CLI**

Use the `create-inference-recommendations-job` API to get an instance endpoint recommendation. Set the `job-type` field to `Default` for instance endpoint recommendation jobs. In addition, provide the following:

• The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.

• The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.

• Provide a name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the AWS Region and within your AWS account.

```bash
aws sagemaker create-inference-recommendations-job
```
Create an instance recommendation job in Studio.

1. In the left sidebar of Amazon SageMaker, choose the Components and registries icon.
2. Select Model Registry from the dropdown list to display models you have registered with the model registry.

   The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
3. Select the name of your model group. When you select your model group, the right pane of Studio displays column heads such as Versions and Setting.

   If you have one or more model packages within your model group, you will see a list of those model packages within the Versions column.
4. Choose the Inference recommender column.
5. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the AmazonSageMakerFullAccess IAM managed policy to accomplish this. Or you can let Studio create a role for you.
6. Choose Get recommendations.

   The instance recommendation can take up to 45 minutes.

   Warning
   Do not close this tab. If you close this tab, you cancel the instance recommendation job.

Get Your Instance Recommendation Job Results

Collect the results of your instance recommendation job programmatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

AWS SDK for Python (Boto3)

   Once an instance recommendation is complete, you can use DescribeInferenceRecommendationsJob to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

   ```python
   job_name='<INSERT>'
   response = sagemaker_client.describe_inference_recommendations_job(
               job_name=job_name)
   ```

   Print the response object. The previous code sample stored the response in a variable name response.

   ```python
   print(response['Status'])
   ```

   This returns a JSON response similar to the following:

   ```json
   {
   ```
'JobName': 'job-name',
'JobDescription': 'job-description',
'JobType': 'Default',
'Status': 'COMPLETED',
'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000, tzinfo=tzlocal()),
'InputConfig': {
'JobDurationInSeconds': 0
},
'InferenceRecommendations': [{
'Metrics': {
'CostPerHour': 0.20399999618530273,
'CostPerInference': 5.246913588052848e-06,
'MaximumInvocations': 648,
'ModelLatency': 263596
},
'EndpointConfiguration': {

'Compiled': False,
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

AWS CLI

Once an instance recommendation is complete, you can use `describe-inference-recommendations-job` to get the job details and recommended instance types. Provide the job name that you used when you created the instance recommendation job.

```bash
aws sagemaker describe-inference-recommendations-job
  --job-name <job-name>
  --region <aws-region>
```

The JSON response similar should resemble the following:

```json
{
  'JobName': 'job-name',
  'JobDescription': 'job-description',
  'Status': 'COMPLETED',
  'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000, tzinfo=tzlocal()),
  'InputConfig': {}
}
```
'JobDurationInSeconds': 0,
}
,'InferenceRecommendations': [{

}
The first few lines provide information about the instance recommendation job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

Amazon SageMaker Studio

The instance recommendations populate in a new **Inference recommendations** tab within Studio. It can take up to 45 minutes for the results to show up. This tab contains **Results** and **Details** column headings.

The **Details** column provides information about the instance recommendation job, such as the name of the instance recommendation, when the job was created (**Creation time**), and more. It also provides **Settings** information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides a **Deployment goals** and **SageMaker recommendations** window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

**Stop Your Instance Endpoint Recommendation**

Stop your Inference Recommender instance recommendation jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio.

**AWS SDK for Python (Boto3)**

Specify the name of the instance recommendation job for the `JobName` field:
Recommendation jobs

AWS CLI

Specify the job name of the instance recommendation job for the `--job-name` flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio

Close the tab in which you initiated the instance recommendation to stop your Inference Recommender instance recommendation.

Run a custom load test

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programmatically using AWS SDK for Python (Boto3) and the AWS CLI, and interactively using Amazon SageMaker Studio.

Create a Load Test Job

Create a load test programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using Studio. As with Inference Recommender instance recommendations, specify a job name for your load test, an AWS IAM role ARN, an input configuration, and your model package ARN when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

AWS SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`JobName`). The job name must be unique within your AWS Region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- A traffic pattern of the load test (`TrafficPattern`).
- An endpoint configuration dictionary (`InputConfig`) where you specify an AWS instance type against which to run benchmarks.

```python
# Create a low-level SageMaker service client.
import boto3
aws_region=<INSERT>
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name="<INSERT>"

# Provide the name of the sagemaker instance type
instance_type="<INSERT>"

# Provide the IAM Role that gives SageMaker permission to access AWS services
```
role_arn='arn:aws:iam::<account>:role/*'

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn='arn:aws:sagemaker:<region>:<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName=load_test_job_name,
    JobType="Advanced",
    RoleArn=role_arn,
    InputConfig={
        'ModelPackageVersionArn': model_package_arn,
        "JobDurationInSeconds": 7200,
        'TrafficPattern': {  
            'TrafficType': 'PHASES',
            'Phases': [
                {
                    'InitialNumberOfUsers': 1,
                    'SpawnRate': 60,
                    'DurationInSeconds': 300
                },
                {
                    'InitialNumberOfUsers': 5,
                    'SpawnRate': 1,
                    'DurationInSeconds': 300
                }
            ]
        },
        'ResourceLimits': {
            'MaxNumberOfTests': 10,
            'MaxParallelOfTests': 3
        },
        "EndpointConfigurations": [{
            'InstanceType': 'ml.c5.xlarge'
        },
        {
            'InstanceType': 'ml.m5.xlarge'
        },
        {
            'InstanceType': 'ml.r5.xlarge'
        }]
    },
    StoppingConditions={
        'MaxInvocations': 1000,
        'ModelLatencyThresholds':{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
        }
    }
)

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to CreateInferenceRecommendationsJob.

AWS CLI

Use the create-inference-recommendations-job API to create an Inference Recommender load test. Specify Advanced for the JobType field and provide:

- A job name for your load test (job-name). The job name must be unique within your AWS region and within your AWS account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the role-arn field.
- A traffic pattern of the load test (TrafficPattern).
• An endpoint configuration dictionary (input-config) where you specify an AWS instance type for running benchmarks against.

```
aws sagemaker create-inference-recommendations-job
  --region <region>
  --job-name <job-name>
  --job-type ADVANCED
  --role-arn arn:aws:iam::<account>:role/*
  --input-config "{
    "JobDurationInSeconds": 7200,
    "TrafficPattern": {
      "TrafficType": "PHASES",
      "Phases": [
        {
          "InitialNumberOfUsers": 1,
          "SpawnRate": 60,
          "DurationInSeconds": 300
        }
      ],
      "ResourceLimit": {
        "MaxNumberOfTests": 10,
        "MaxParallelOfTests": 3
      },
      "EndpointConfigurations": [
        {
          "InstanceType": "ml.c5.xlarge"
        },
        {
          "InstanceType": "ml.m5.xlarge"
        },
        { 'InstanceType': 'ml.r5.xlarge' }
      ]
    }" --stopping-conditions "{
    "MaxInvocations": 1000,
    "ModelLatencyThresholds": [
      { "Percentile": "P95",
        "ValueInMilliseconds": 100
      }
    ]
  }"
```

Amazon SageMaker Studio

Create a load test with Studio.

1. In the left sidebar of Studio, choose the Components and registries icon.
2. Select Inference Recommender Jobs from the dropdown list. A new tab titled Create inference recommender job opens in the right pane.
3. Select the name of your model group from the dropdown Model group field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio.
4. Select a model version from the dropdown Model version field.
5. Choose Continue.
6. Provide a name for the job in the Name field.
7. (Optional) Provide a description of your job in the **Description** field.

8. Choose an IAM role that grants Inference Recommender permission to access AWS services. You can create a role and attach the `AmazonSageMakerFullAccess` IAM managed policy to accomplish this, or you can let Studio create a role for you.

9. Choose **Stopping Conditions** to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.
   a. Specify the maximum number of requests per minute expected for the endpoint in the **Max Invocations Per Minute** field.
   b. Specify the model latency threshold in microseconds in the **Model Latency Threshold** field. The **Model Latency Threshold** depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

10. Choose **Traffic Pattern** to expand the available input fields.
   a. Set the initial number of virtual users by specifying an integer in the **Initial Number of Users** field.
   b. Provide an integer number for the **Spawn Rate** field. The spawn rate sets the number of users created per second.
   c. Set the duration for the phase in seconds by specifying an integer in the **Duration** field.
   d. (Optional) Add additional traffic patterns. To do so, choose **Add**.

11. Choose the **Additional** setting to reveal the **Max test duration** field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.

12. Choose **Continue**.

13. Choose **Selected Instances**.

14. In the **Instances for benchmarking** field, choose **Add instances to test**. Select up to 10 instances for Inference Recommender to use for load testing.

15. Choose **Additional settings**.
   a. Provide an integer that sets an upper limit on the number of tests a job can make for the **Max number of tests** field. Note that each endpoint configuration results in a new load test.
   b. Provide an integer for the **Max parallel** test field. This setting defines an upper limit on the number of load tests that can run in parallel.

16. Choose **Submit**.

The load test can take up to 2 hours.

**Warning**
Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

### Get Your Load Test Results

You can collect metrics across all load tests once the load tests are done programatically with AWS SDK for Python (Boto3), the AWS CLI, or Studio.

**AWS SDK for Python (Boto3)**

Collect metrics with the `DescribeInferenceRecommendationsJob` API. Specify the job name of the load test for the **JobName** field:
load_test_response = sagemaker_client.describe_inference_recommendations_job(
    job_name=load_test_job_name
)

Print the response object.

load_test_response['Status']

This returns a JSON response similar to the following:

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES '
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
        }]
    },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
        }],
        'InferenceRecommendations': [{
            'Metrics': {
                'CostPerHour': 0.6899999976158142,
                'CostPerInference': 1.0332434612791985e-05,
                'MaximumInvocations': 1113,
                'ModelLatency': 100000
            },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
                'InstanceType': 'ml.c5d.xlarge',
                'InitialInstanceCount': 3
            },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
            }
        }],
        'ResponseMetadata': {
            'RequestId': 'request-id',
            'HTTPStatusCode': 200
        }
    }]
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The InferenceRecommendations dictionary contains a list of Inference Recommender instance recommendations.

The EndpointConfiguration nested dictionary contains the instance type (InstanceType) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190) for more information.

The Metrics nested dictionary contains information about the estimated cost per hour (CostPerHour) for your real-time endpoint in US dollars, the estimated cost per inference (CostPerInference) for your real-time endpoint, the maximum number of InvokeEndpoint requests sent to the endpoint, and the model latency (ModelLatency), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

AWS CLI

Collect metrics with the describe-inference-recommendations-job API. Specify the job name of the load test for the job-name flag:

```
aws sagemaker describe-inference-recommendations-job --job-name <job-name>
```

This returns a response similar to the following:

```python
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000, tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000, tzinfo=tzlocal()),
    'InputConfig': {
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
        },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
            'MaxParallelOfTests': 100
        },
        'EndpointConfigurations': [
            {
                'InstanceType': 'ml.c5d.xlarge'
            }
        ]
    }
}
```
The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender instance recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed AWS machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190) for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

Amazon SageMaker Studio

The recommendations populate in a new tab called `Inference recommendations` within Studio. It can take up to 2 hours for the results to show up. This tab contains Results and Details columns.
The **Details** column provides information about the load test job, such as the name given to the load test job, when the job was created (**Creation time**), and more. It also contains **Settings** information, such as the maximum number of invocation that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides **Deployment goals** and **SageMaker recommendations** windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances.

In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

### Stop Your Load Test

Stop your load test jobs programmatically with the **StopInferenceRecommendationsJob** API or with Studio.

**AWS SDK for Python (Boto3)**

Specify the job name of the load test for the **JobName** field:

```python
sagemaker_client.stop_inference_recommendations_job(
    job_name='<INSERT>
)
```

**AWS CLI**

Specify the job name of the load test for the **job-name** flag:

```bash
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

**Amazon SageMaker Studio**

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

---

**Real-time inference**

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker hosting services and get an endpoint that can be used for inference. These endpoints are fully managed and support autoscaling (see [Automatically Scale Amazon SageMaker Models](p. 2460)).

**Topics**

- Hosting options (p. 2414)
- Automatically Scale Amazon SageMaker Models (p. 2460)
Hosting options

The following topics describe available SageMaker realtime hosting options along with how to set up, invoke, and delete each hosting option.

Topics
- Host a single model (p. 2414)
- Host multiple models in one container behind one endpoint (p. 2424)
- Host multiple models which use different containers behind one endpoint (p. 2439)
- Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2446)

Host a single model

Create, update, and delete real-time inference endpoints that host a single model with the AWS SDK for Python (Boto3), the SageMaker Python SDK, the SageMaker console, or the AWS CLI.

Create, update, and delete real-time inference endpoints that host a single model with the AWS SDK for Python (Boto3), the SageMaker Python SDK, the SageMaker console, or the AWS CLI.

Topics
- Create your endpoint and deploy your model (p. 2414)
- Delete Endpoints and Resources (p. 2420)

Create your endpoint and deploy your model

There are several options to deploy a model using SageMaker hosting services. You can programmatically deploy a model using an AWS SDK (for example, the SDK for Python (Boto3)), the SageMaker Python SDK, the AWS CLI, or you can interactively deploy a model with the SageMaker console. The AWS SDK is a low-level API and supports Java, C++, Go, JavaScript, Node.js, PHP, Ruby, and Python whereas the SageMaker Python SDK is a high-level Python API. The following documentation demonstrates how to deploy a model using the AWS SDK for Python (Boto3) and the SageMaker Python SDK.

Deploying a model using SageMaker hosting services is a three-step process if you use AWS SDK for Python (Boto3), the AWS CLI, or the SageMaker console:

2. Create an endpoint configuration for an HTTPS endpoint.
3. Create an HTTPS endpoint.

Deploying a model using the SageMaker Python SDK does not require that you create an endpoint configuration. It is therefore a two-step process:

1. Create a model object from the Model Class that can be deployed to an HTTPS endpoint.
2. Create an HTTPS endpoint with the Model object's pre-built `deploy()` method.

To use the proceeding code snippets, replace the *italicized placeholder text* in the example code with your own information.

**Note**

- SageMaker supports running (a) multiple models, (b) multiple variants of a model, or (c) combinations of models and variants on the same endpoint. Model variants can reference the same model inference container (i.e. run the same algorithm), but use different model artifacts (e.g., different model weight values based on other hyper-parameter configurations). In contrast, two different models may use the same algorithm, but focus on different business problems or underlying goals and may operate on different data sets.

- When you create an endpoint, SageMaker attaches an Amazon EBS storage volume to each ML compute instance that hosts the endpoint. The size of the storage volume depends on the instance type. For a list of instance types that SageMaker hosting service supports, see AWS Service Limits. For a list of the sizes of the storage volumes that SageMaker attaches to each instance, see Host instance storage volumes (p. 2475).

- Endpoints are scoped to an individual AWS account, and are not public. The URL does not contain the account ID, but SageMaker determines the account ID from the authentication token that is supplied by the caller.

For an example of how to use Amazon API Gateway and AWS Lambda to set up and deploy a web service that you can call from a client application that is not within the scope of your account, see Call a SageMaker model endpoint using Amazon API Gateway and AWS Lambda in the AWS Machine Learning Blog.

**Before you begin**

Before you create and deploy a SageMaker model, locate and make note of the:

- AWS region where your Amazon S3 bucket is located
- Amazon S3 URI path where the model artifacts are stored
- IAM role for SageMaker
- Docker Amazon ECR URI registry path for the custome image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by AWS.

For a list of AWS Services available in each AWS Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

**Important**

The Amazon S3 bucket where the model artifacts are stored must be in the same region as the model that you are creating.

The following demonstrates how to define the aforementioned parameters programmatically.

**AWS SDK for Python (Boto3)**

Import `Boto3`. Define your AWS region. Next, initialize a low-level SageMaker service client object using the `Client` class. This will make it easy to send and receive requests to AWS services. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
import boto3
```
# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>::<account>::role/*"

The first few lines define:

- **sagemaker_client**: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- **sagemaker_role**: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- **aws_region**: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (`framework` field) along with the version of the framework or algorithm (`version` field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use Your Own Inference Code (p. 2782).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework='<framework>'
#framework='xgboost' # Example

# Version of the framework or algorithm
version = '<version-number>'
#version = '0.90-1' # Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region,
                               framework=framework,
                               version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK `Model` object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/{model_filename}'

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```
Amazon SageMaker Developer Guide
Hosting options

SageMaker Python SDK

Define your AWS region. In addition, define the AWS role that gives SageMaker permission to access AWS services on your behalf:

```python
# Specify your AWS Region
aws_region = '<aws_region>'

# Role to give SageMaker permission to access AWS services.
sagemaker_role = 'arn:aws:iam::<region>:<account>:role/*'
```

The first few lines define:

- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

Import the `image_uris` module from the SageMaker Python SDK. Use the `retrieve()` function to retrieve the Amazon ECR URI for the Docker image matching the given arguments. Provide both the name of the framework or algorithm (`framework` field) along with the version of the framework or algorithm (`version` field). For a list of built-in Docker images provided by AWS, see Available Deep Learning Containers Images. For more information on how to bring your own image, see Use Your Own Inference Code (p. 2782).

```python
from sagemaker import image_uris

# Name of the framework or algorithm
framework = '<framework>'  # Example

# Version of the framework or algorithm
version = '<version-number>'  # Example

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework=framework, version=version)
```

Next, provide the Amazon S3 URI of the pre-trained model. This model will be used to create a SageMaker Python SDK Model.model object in the next step. In this example, the full Amazon S3 URI is stored in a string variable `model_url`:

```python
# Create a variable w/ the model S3 URI
# First, provide the name of your S3 bucket
s3_bucket = '<your-bucket-name>'

# Specify what directory within your S3 bucket your model is stored in
bucket_prefix = '<directory-name>'

# Replace with the name of your model artifact
model_filename = '<model-name>.tar.gz'

# Relative S3 path
model_s3_key = f'{bucket_prefix}/{model_filename}

# Combine bucket name, model file name, and relate S3 path to create S3 model URI
model_url = f's3://{s3_bucket}/{model_s3_key}'
```
Create a Model

By creating a model, you tell SageMaker where it can find the model components.

AWS SDK for Python (Boto3)

Create a model in SageMaker with `create_model`. Specify the following:

- `ModelName`: A name for your model (in this example it is stored as a string variable called `model_name`).
- `ExecutionRoleArn`: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- `PrimaryContainer`: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

For the primary container, specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

```python
model_name = '<The_name_of_the_model>'

# Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })
```

SageMaker Python SDK

Create a model object from the SageMaker Python SDK `Model` class. You will use this object to deploy your model to an endpoint in a later step.

```python
from sagemaker.model import Model

model = Model(image_uri=container,
               model_data=model_url,
               role=sagemaker_role)
```

Create an Endpoint Configuration

Create an endpoint configuration for an HTTPS endpoint. Specify the name of one or more models in production (variants) and the ML compute instances that you want SageMaker to launch to host each production variant.

**Note**

Skip this section if you are exclusively using the SageMaker Python SDK.

When hosting models in production, you can configure the endpoint to elastically scale the deployed ML compute instances. For each production variant, you specify the number of ML compute instances that you want to deploy. When you specify two or more instances, SageMaker launches them in multiple Availability Zones. This ensures continuous availability. SageMaker manages deploying the instances.
AWS SDK for Python (Boto3)

Create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker to provision.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date 
# so it we can search endpoints based on creation time.
endpoint_config_name = '<endpoint-config-name>'

# The name of the model that you want to host. This is the name that you specified when 
# creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a 
    # CreateEndpoint request. 
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant. 
            "ModelName": model_name, 
            "InstanceType": instance_type, # Specify the compute instance type. 
            "InitialInstanceCount": 1 # Number of instances to launch initially. 
        }
    ]
)

print(f"Created EndpointConfig: {endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for the `ProductionVariants` field:

- **VariantName**: The name of the production variant.
- **ModelName**: The name of the model that you want to host. This is the name that you specified when creating the model.
- **InstanceType**: The compute instance type. See the `InstanceType` field in [https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html](https://docs.aws.amazon.com/sagemaker/latest/APIReference/API_ProductionVariant.html) and SageMaker Pricing for a list of supported compute instance types and pricing for each instance type.

**SageMaker Python SDK**

You do not need to define an endpoint configuration for real-time endpoints if you use the SageMaker Python SDK `Model` Class.

**Deploy your model**

Deploy your model and create an HTTPS endpoint.
AWS SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(  
    EndpointName=endpoint_name,  
    EndpointConfigName=endpoint_config_name)
```

For more information, see the `CreateEndpoint` API.

SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker will create a unique name for you:

```python
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"  
print("EndpointName =", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object’s built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```python
initial_instance_count=<integer>  
# initial_instance_count=1 # Example

instance_type='<instance-type>'  
# instance_type='ml.m4.xlarge' # Example

model.deploy(  
    initial_instance_count=initial_instance_count,  
    instance_type=instance_type,  
    endpoint_name=endpoint_name
)
```

Delete Endpoints and Resources

Delete endpoints to stop incurring charges.

Delete Endpoint

Delete your endpoint programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console.
SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting an endpoint will not delete the endpoint configuration or the SageMaker model. See Delete Endpoint Configuration (p. 2421) and Delete Model (p. 2423) for information on how to delete your endpoint configuration and SageMaker model.

AWS SDK for Python (Boto3)

Use the DeleteEndpoint API to delete your endpoint. Specify the name of your endpoint for the EndpointName field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint
sagemaker_client.delete_endpoint(EndpointName=endpoint_name)
```

AWS CLI

Use the delete-endpoint command to delete your endpoint. Specify the name of your endpoint for the endpoint-name flag.

```
aws sagemaker delete-endpoint --endpoint-name <endpoint-name>
```

SageMaker Console

Delete your endpoint interactively with the SageMaker console.

2. Choose Endpoints from the drop down menu. A list of endpoints created in your AWS account will appear by name, Amazon Resource Name (ARN), creation time, status, and a time stamp of when the endpoint was last updated.
3. Select the endpoint you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Delete Endpoint Configuration

Delete your endpoint configuration programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting an endpoint configuration does not delete endpoints created using this configuration. See Delete Endpoint (p. 2420) for information on how to delete your endpoint.

Do not delete an endpoint configuration in use by an endpoint that is live or while the endpoint is being updated or created. You might lose visibility into the instance type the endpoint is using if you delete the endpoint configuration of an endpoint that is active or being created or updated.

AWS SDK for Python (Boto3)

Use the DeleteEndpointConfig API to delete your endpoint. Specify the name of your endpoint configuration for the EndpointConfigName field.
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
endpoint_config_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

You can optionally use the DescribeEndpointConfig API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the EndpointConfigName field.

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
endpoint_config_name = response['ProductionVariants'][0]['EndpointConfigName']

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)

For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

AWS CLI

Use the delete-endpoint-config command to delete your endpoint configuration. Specify the name of your endpoint configuration for the endpoint-config-name flag.

aws sagemaker delete-endpoint-config \
    --endpoint-config-name <endpoint-config-name>

You can optionally use the describe-endpoint-config command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the endpoint-config-name flag.

aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the endpoint configuration name associated with that endpoint.
### SageMaker Console

Delete your endpoint configuration interactively with the SageMaker console.

1. In the SageMaker console at [https://console.aws.amazon.com/sagemaker/](https://console.aws.amazon.com/sagemaker/) navigation menu, choose **Inference**.
2. Choose **Endpoint configurations** from the dropdown menu. A list of endpoint configurations created in your AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the endpoint configuration you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

### Delete Model

Delete your SageMaker model programmatically using AWS SDK for Python (Boto3), with the AWS CLI, or interactively using the SageMaker console. Deleting a SageMaker model only deletes the model entry that was created in SageMaker. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

**AWS SDK for Python (Boto3)**

Use the **DeleteModel** API to delete your SageMaker model. Specify the name of your model for the **ModelName** field.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
model_name='<model_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete model
sagemaker_client.delete_model(ModelName=model_name)
```

You can optionally use the **DescribeEndpointConfig** API to return information about the name of your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the **EndpointConfigName** field.

```python
# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the next step.
response = sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
model_name = response['ProductionVariants'][0]['ModelName']
sagemaker_client.delete_model(ModelName=model_name)
```
For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

AWS CLI

Use the `delete-model` command to delete your SageMaker model. Specify the name of your model for the `model-name` flag.

```bash
aws sagemaker delete-model \
   --model-name <model-name>
```

You can optionally use the `describe-endpoint-config` command to return information about the name of your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```bash
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the name of the model associated with that endpoint.

SageMaker Console

Delete your SageMaker model interactively with the SageMaker console.

2. Choose Models from the dropdown menu. A list of models created in you AWS account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the model you want to delete.
4. Select the Actions dropdown button in the top right corner.
5. Choose Delete.

Host multiple models in one container behind one endpoint

To create an endpoint that can host multiple models, use multi-model endpoints. Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use a shared serving container that is enabled to host multiple models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to them.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints. Multi-model endpoints are also well suited to scenarios that can tolerate occasional cold-start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support A/B testing. They work with Auto Scaling and AWS PrivateLink. You can use multi-model-enabled containers with serial inference pipelines, but only one multi-model-enabled container can be included in an inference pipeline. You can't use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. You can use multi-model endpoints with custom-built containers by integrating the Multi Model Server library.
Supported Algorithms and Frameworks

The inference containers for the following algorithms and frameworks support multi-model endpoints:

- XGBoost Algorithm (p. 1956)
- K-Nearest Neighbors (k-NN) Algorithm (p. 1858)
- Linear Learner Algorithm (p. 1872)
- Random Cut Forest (RCF) Algorithm (p. 1926)
- Use TensorFlow with Amazon SageMaker (p. 30)
- Use Scikit-learn with Amazon SageMaker (p. 29)
- Use Apache MXNet with Amazon SageMaker (p. 14)
- Use PyTorch with Amazon SageMaker (p. 26)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container with Multi Model Server (p. 2433).

Sample Notebooks for Multi-Model Endpoints

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see the Multi-Model Endpoint XGBoost Sample Notebook. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After you've created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. The Multi-Model Endpoint notebook is located in the ADVANCED FUNCTIONALITY section. To open a notebook, choose its Use tab and choose Create copy.

How Multi-Model Endpoints Work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container’s memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory on that instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

When you update a multi-model endpoint, invocation requests on the endpoint might experience higher latencies as traffic is directed to the instances in the updated endpoint.

**Setting SageMaker Multi-Model Endpoint Model Caching Behavior**

By default, multi-model endpoints cache frequently used models in memory and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. The concurrency is a factor of the number of vCPUs of the container instance.

For guidelines on choosing a SageMaker ML instance type for a multi-model endpoint, see [Instance Recommendations for Multi-Model Endpoint Deployments](#) (p. 2426).

**Instance Recommendations for Multi-Model Endpoint Deployments**

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint. Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served. Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see [Host instance storage volumes](#) (p. 2475). For a container configured to run in `MultiModel` mode, the storage volume...
provisioned for its instances has more memory. This allows more models to be cached on the instance storage volume.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are not supported on GPU instance types.
- The traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance):
  - Think of the amount of memory on an instance as the cache space for models to be loaded. Think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
  - A higher amount of instance memory enables you to have more models loaded and ready to serve inference requests. You don’t need to waste time loading the model.
  - A higher amount of vCPUs enables you to invoke more unique models concurrently (again assuming that inference is bound to CPU).
  - Have some “slack” memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

In some cases, you might opt to reduce costs by choosing an instance type that can’t hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you are going to pay a price with the dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for proper performance testing and analysis will pay great dividends in successful production deployments.

You can use the Average statistic of the ModelCacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the ModelUnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

SageMaker multi-model endpoints fully supports Auto Scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances by considering all of the above and also set up auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event is based on the aggregate set of predictions across the full set of models served by the endpoint.

Create a Multi-Model Endpoint

You can use AWS SDK for Python (Boto) or Amazon SageMaker to create a multi-model endpoint.

Topics

- Create a Multi-Model Endpoint (Console) (p. 2428)
• Create a Multi-Model Endpoint AWS SDK for Python (Boto3) (p. 2430)

Create a Multi-Model Endpoint (Console)

To create a multi-model endpoint (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy attached.
5. In the Container definition section, for Provide model artifacts and inference image options choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location of your inference code. See Deploying a Model on Amazon SageMaker Hosting Services.

**Model settings**

Model name

```
mml-test-model
```

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

IAM role

Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let Amazon SageMaker create a role that has the `AmazonSageMakerFullAccess` IAM policy attached.

`AmazonSageMaker-ExecutionRole-XXXXXXXXXXXXXXXXX`

**Container definition 1**

**Container input options**

Provide model artifacts and inference image location

Provide model artifacts and inference image options

- [ ] Use a single model
  
  Use this to host a single model in this container.

- [x] Use multiple models
  
  Use this to host multiple models in this container.

Location of inference code image

Type the registry path where the inference code image is stored in Amazon ECR.

```
123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag
```

Location of model artifacts

Type the URL where model artifacts are stored in S3.

```
s3://my-bucket/path/to/artifacts/
```

The path must point to the prefix in S3 where the model artifacts are located.
6. Choose **Create model**.

7. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see *Deploy the Model to SageMaker Hosting Services* (p. 90).

### Create a Multi-Model Endpoint AWS SDK for Python (Boto3)

You create a multi-model endpoint using the Amazon SageMaker `create_model`, `create_endpoint_config`, and `create_endpoint` APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see *Multi-Model Endpoint XGBoost Sample Notebook*.

The following procedure outlines the key steps used in that sample to create a multi-model endpoint.

**To deploy the model (AWS SDK for Python (Boto 3))**

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see *Supported Algorithms and Frameworks* (p. 2425). For this example, we use the K-Nearest Neighbors (k-NN) Algorithm (p. 1858) built-in algorithm. We call the SageMaker Python SDK utility function `image_uris.retrieve()` to get the address for the K-Nearest Neighbors built-in algorithm image.

```python
import sagemaker
region = sagemaker_session.boto_region_name
image = sagemaker.image_uris.retrieve("knn", region=region)
container = {
    'Image': image,
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
}
```

2. Get a Boto 3 SageMaker client and create the model that uses this container.

```python
import boto3
sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.create_model(
    ModelName        = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers       = [container])
```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:

```python
preprocessor_container = {
    'Image':
    '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
}

multi_model_container = {
    'Image':
    '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
    'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
    'Mode': 'MultiModel'
}
```
response = sagemaker_client.create_model(
    ModelName = '<MODEL_NAME>',
    ExecutionRoleArn = role,
    Containers = [preprocessor_container, multi_model_container]
)

4. (Optional) If your use case does not benefit from model caching, set the value of the ModelCacheSetting field of the MultiModelConfig parameter to Disabled, and include it in the Container argument of the call to create_model. The value of the ModelCacheSetting field is Enabled by default.

    container = {
        'Image': image,
        'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
        'Mode': 'MultiModel'
        'MultiModelConfig': {
            // Default value is 'Enabled'
            'ModelCacheSetting': 'Disabled'
        }
    }

    response = sagemaker_client.create_model(
        ModelName = '<MODEL_NAME>',
        ExecutionRoleArn = role,
        Containers = [container]
    )

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker to provide a highly available set of predictions across multiple Availability Zones for the models.

    response = sagemaker_client.create_endpoint_config(
        EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
        ProductionVariants=[
            {
                'InstanceType': 'ml.m4.xlarge',
                'InitialInstanceCount': 2,
                'InitialVariantWeight': 1,
                'ModelName': '<MODEL_NAME>',
                'VariantName': 'AllTraffic'
            }
        ]
    )

    Note
    You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the EndpointName and EndpointConfigName parameters.

    response = sagemaker_client.create_endpoint(
        EndpointName = '<ENDPOINT_NAME>',
        EndpointConfigName = '<ENDPOINT_CONFIG_NAME>'
    )

Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new TargetModel parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by
combining the prefix that is provided as part of the CreateModel API call with the relative path of the model.

AWS SDK for Python (Boto 3)

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName = "<ENDPOINT_NAME>",
    ContentType  = "text/csv",
    TargetModel  = "<MODEL_FILENAME>.tar.gz",
    Body         = body)
```

AWS CLI

The following example shows how to make a CSV request with two rows using the AWS Command Line Interface (AWS CLI):

```bash
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name "<ENDPOINT_NAME>" \ 
  --body "1.0,2.0,5.0$'n'"2.0,3.0,4.0" \ 
  --content-type "text/csv" \ 
  --target-model "<MODEL_NAME>.tar.gz" \ 
  output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the AWS CLI, see Making predictions with the AWS CLI in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. (This is called a cold start.) Subsequent calls finish faster because there's no additional overhead after the model has loaded.

Retry Requests on ModelNotReadyException Errors

The first time you call invoke_endpoint for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to invoke_endpoint within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to invoke_endpoint returns with the error code ModelNotReadyException, and the model continues to download and load into the inference container for up to 360 seconds. If you get a ModelNotReadyException error code for an invoke_endpoint request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using Legacy retry mode) and Java retry invoke_endpoint requests that result in ModelNotReadyException errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for Boto 3, see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to invoke_endpoint for up to 180 seconds.

```python
import boto3
from botocore.config import Config
```
# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for up to 180 seconds: 1 original request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2  # This value can be adjusted to 5 to go up to the 360s max
timeout
    }
)
runtime_sagemaker_client = boto3.client('sagemaker-runtime', config=config)

## Add or Remove Models

Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```python
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

**Important**

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```python
response = runtime_sagemaker_client.invoke_endpoint(
    EndpointName='<ENDPOINT_NAME>',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

## Build Your Own Container with Multi Model Server

Build Your Own Container with Multi Model Server

Custom Elastic Container Registry (ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 2783) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```Dockerfile
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```
SageMaker also injects an environment variable into the container

SAGEMAKER_MULTI_MODEL=true

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 2450).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.

- **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

### Use the SageMaker Inference Toolkit

Currently, the only pre-built containers that support multi-model endpoints are the MXNet inference container and the PyTorch inference container. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the [SageMaker Inference Toolkit](https://github.com/aws/sagemaker-inference) to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the [Multi-Model Endpoint BYOC Sample Notebook](https://github.com/aws/sagemaker-inference).

**Note**

The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see [Contract for Custom Containers to Serve Multiple Models](https://github.com/aws/sagemaker-inference).

### To extend a container by using the SageMaker inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see `model_handler.py` from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)
```

---

2434
@retry(stop_max_delay=1000 * 50,
    retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through
    # the
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

        # prevent docker exit
        subprocess.call(['tail', '-f', '/dev/null'])

main()

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from
   the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile
   used in the sample notebook:

   # Copy the default custom service file to handle incoming data and inference requests
   COPY model_handler.py /home/model-server/model_handler.py

   # Define an entrypoint script for the docker image
   ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]

4. Build and register your container. The following shell script from the sample notebook builds the
   container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

   ```bash
   # The name of our algorithm
   algorithm_name=demo-sagemaker-multimodel

   cd container

   account=$(aws sts get-caller-identity --query Account --output text)

   # Get the region defined in the current configuration (default to us-west-2 if none
   # defined)
   region=$(aws configure get region)
   region=${region:-us-west-2}

   fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

   # If the repository doesn't exist in ECR, create it.
   aws ecr describe-repositories --repository-names "$\{algorithm_name\}" > /dev/null 2>&1
   if [ $? -ne 0 ]
   then
     aws ecr create-repository --repository-name "$\{algorithm_name\}" > /dev/null
   fi

   # Get the login command from ECR and execute it directly
   $(aws ecr get-login --region $\{region\} --no-include-email)

   # Build the docker image locally with the image name and then push it to ECR
   # with the full name.
   ```
You can now use this container to deploy multi-model endpoints in SageMaker.

Topics

- Contract for Custom Containers to Serve Multiple Models (p. 2436)

Contract for Custom Containers to Serve Multiple Models

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The model_name is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using model_name as the mapping key. Also, the model_name is an opaque identifier and is not necessarily the value of the TargetModel parameter passed into the InvokeEndpoint API. The original TargetModel value in the InvokeEndpoint request is passed to container in the APIs as a X-Amzn-SageMaker-Target-Model header that can be used for logging purposes.

Topics

- Load Model API (p. 2436)
- List Model API (p. 2436)
- Get Model API (p. 2437)
- Unload Model API (p. 2437)
- Invoke Model API (p. 2438)

Load Model API

Instructs the container to load a particular model present in the url field of the body into the memory of the customer container and to keep track of it with the assigned model_name. After a model is loaded, the container should be ready to serve inference requests using this model_name.

```json
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{  
  "model_name" : "{model_name}"
  
  "url" : "/opt/ml/models/{model_name}/model",
}
```

Note

If model_name is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

List Model API

Returns the list of models loaded into the memory of the customer container.

```
GET /models HTTP/1.1
Accept: application/json
```
Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}

This API also supports pagination.

GET /models HTTP/1.1
Accept: application/json
Response =
{
    "models": [
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}

SageMaker can initially call the List Models API without providing a value for next_page_token. If a nextPageToken field is returned as part of the response, it will be provided as the value for next_page_token in a subsequent List Models call. If a nextPageToken is not returned, it means that there are no more models to return.

Get Model API

This is a simple read API on the model_name entity.

GET /models/{model_name} HTTP/1.1
Accept: application/json
{
    "modelName" : "{model_name}",
    "modelUrl" : "/opt/ml/models/{model_name}/model",
}

Note
If model_name is not loaded, this API should return 404.

Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process.
of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```plaintext
DELETE /models/{model_name}
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

```plaintext
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: ContentType
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the `CreateModel` operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict `InvokeEndpoint` access to a limited set of models in S3, you can do one of the following:

- Restrict `InvokeEndpoint` calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key. For example, the following policy allows `InvokeEndpoint` requests only when the value of the `TargetModel` field matches one of the specified regular expressions:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "sagemaker:InvokeEndpoint"
         ],
         "Effect": "Allow",
         "Resource":
         "arn:aws:sagemaker:region:account-id:endpoint/endpoint_name",
         "Condition": {
            "StringLike": {
               "sagemaker:TargetModel": ["company_a/*", "common/*"]
            }
         }
      }
   ]
}
```
Hosting options

For information about SageMaker condition keys, see Condition Keys for Amazon SageMaker in the AWS Identity and Access Management User Guide.

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see SageMaker Roles (p. 3097). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded, and the model wait times for loading, downloading, and uploading at a multi-model endpoint. For information, see Multi-Model Endpoint Model Loading Metrics and Multi-Model Endpoint Model Instance Metrics in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190). Per-model metrics aren't supported.

Host multiple models which use different containers behind one endpoint

SageMaker multi-container endpoints enable customers to deploy multiple containers, that use different models or frameworks, on a single SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2446).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 2440)

Topics

- Create a multi-container endpoint (Boto 3) (p. 2439)
- Update a multi-container endpoint (p. 2440)
- Delete a multi-container endpoint (p. 2440)
- Use a multi-container endpoint with direct invocation (p. 2440)

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.
Note
Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and InferenceExecutionConfig with direct invocation.

```python
container1 = {'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage1:mytag',
              'ContainerHostname': 'firstContainer'}
container2 = {'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage2:mytag',
              'ContainerHostname': 'secondContainer'}
inferenceExecutionConfig = {'Mode': 'Direct'}
```

2. Create the model with the container elements and set the InferenceExecutionConfig field.

```python
import boto3
sm_client = boto3.Session().client('sagemaker')
response = sm_client.create_model(
    ModelName = 'my-direct-mode-model-name',
    InferenceExecutionConfig = inferenceExecutionConfig,
    ExecutionRoleArn = role,
    Containers = [container1, container2])
```

To create an endpoint, you would then call `create_endpoint_config` and `create_endpoint` as you would to create any other endpoint.

**Update a multi-container endpoint**

To update a multi-container endpoint, complete the following steps.

1. Call `create_model` to create a new model with a new value for the `Mode` parameter in the InferenceExecutionConfig field.
2. Call `create_endpoint_config` to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call `update_endpoint` to update the endpoint with the new endpoint config you created in the previous step.

**Delete a multi-container endpoint**

To delete an endpoint, call `delete_endpoint`, and provide the name of the endpoint you want to delete as the `EndpointName` parameter.

**Use a multi-container endpoint with direct invocation**

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

**Topics**
- Invoke a multi-container endpoint with direct invocation (p. 2441)
Hosting options

- Security with multi-container endpoints with direct invocation (p. 2441)
- Metrics for multi-container endpoints with direct invocation (p. 2442)
- Autoscale multi-container endpoints (p. 2445)
- Troubleshoot multi-container endpoints (p. 2445)

Invoke a multi-container endpoint with direct invocation

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```python
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(
    EndpointName='my-endpoint',
    ContentType='text/csv',
    TargetContainerHostname='secondContainer',
    Body=body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
```
The following policy denies `invoke_endpoint` requests when the value of the `TargetContainerHostname` field matches one of the specified regular expressions in the Deny statement.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["customIps*", "common*""]
        }
      }
    },
    {
      "Action": [
        "sagemaker:InvokeEndpoint"
      ],
      "Effect": "Deny",
      "Condition": {
        "StringLike": {
          "sagemaker:TargetContainerHostname": ["special*"]
        }
      }
    }
  ]
}
```

For information about SageMaker condition keys, see Condition Keys for SageMaker in the AWS Identity and Access Management User Guide.

**Metrics for multi-container endpoints with direct invocation**

In addition to the endpoint metrics that are listed in Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: AWS/SageMaker and aws/sagemaker/Endpoints. The AWS/SageMaker namespace includes invocation-related metrics, and the aws/sagemaker/Endpoints namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [EndpointName, VariantName, ContainerName] dimension, which filters
metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level [EndpointName, VariantName, ContainerName].

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Invocations</strong></td>
<td>The number of InvokeEndpoint requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>Invocation4XX Errors</strong></td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>Invocation5XX Errors</strong></td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
<tr>
<td><strong>ContainerLatency</strong></td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td>EndpointName, VariantName, ContainerName</td>
<td>AWS/SageMaker</td>
</tr>
</tbody>
</table>
### OverheadLatency

The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus the ModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, `Sample Count`

### CPUUtilization

The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>EndpointName, VariantName, ContainerName</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead.</td>
<td></td>
<td>Microseconds</td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by each container running on an instance.</td>
<td></td>
<td>Percent</td>
</tr>
</tbody>
</table>
MemoryUtilization | The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent
---|---
EndpointName, VariantName, ContainerName | aws/sagemaker/Endpoints

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table expect ContainerLatency.

**Autoscale multi-container endpoints**

If you want to configure automatic scaling for a multi-container endpoint using the InvocationsPerInstance metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a high CPU utilization model to a low CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see [Automatically Scale Amazon SageMaker Models](p. 2460).

**Troubleshoot multi-container endpoints**

The following sections can help you troubleshoot errors with multi-container endpoints.

**Ping Health Check Errors**

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

**Missing accept-bind-to-port=true Docker label**

The containers in a multi-container endpoints listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn’t present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, You will see an error message such as Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).
If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format `XXXX-YYYY`, where `XXXX` and `YYYY` are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

**Host models along with pre-processing logic as serial inference pipeline behind one endpoint**

An *inference pipeline* is a Amazon SageMaker model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one PrimaryContainer, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker model registry, see Register and Deploy Models with Model Registry (p. 2592).

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

**Topics**

- Sample Notebooks for Inference Pipelines (p. 2446)
- Feature Processing with Spark ML and Scikit-learn (p. 2447)
- Create a Pipeline Model (p. 2447)
- Run Real-time Predictions with an Inference Pipeline (p. 2450)
- Run Batch Transforms with Inference Pipelines (p. 2452)
- Inference Pipeline Logs and Metrics (p. 2453)
- Troubleshoot Inference Pipelines (p. 2458)

**Sample Notebooks for Inference Pipelines**

For an example that shows how to create and deploy inference pipelines, see the Training using SparkML on EMR and hosting on SageMaker sample notebook. For instructions on creating and accessing Jupyter
notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create copy.

**Feature Processing with Spark ML and Scikit-learn**

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

**Feature Processing with Spark ML**

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to AWS Glue.

*Note*

To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

**Feature Processing with Scikit-Learn**

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher's Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.

**Create a Pipeline Model**

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the CreateModel operation.

**To create an inference pipeline (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Models, and then choose Create models from the Inference group.
3. On the Create model page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.
4. To add information about the containers in the inference pipeline, choose Add container, then choose Next.

5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the Container input options, Location of inference code image, and, optionally, Location of model artifacts, Container host name, and Environmental variables fields.
The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the **Environment variables** field.

### Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.
MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format "XXXX-YYYY", where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**

To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2458).

Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}{}{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-{}{}'.format(timestamp_prefix, timestamp_prefix)
endpoint_name = 'serial-inference-ep-{}{}'.format(timestamp_prefix, timestamp_prefix)
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge', endpoint_name=endpoint_name)
```

Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, Predictor

payload = {
    "input": [
        {
            "name": "Pclass",
            "type": "float",
            "val": "1.0"
        },
        {
            "name": "Embarked",
            "type": "string",
```
"val": "Q"
},
{
  "name": "Age",
  "type": "double",
  "val": "48.0"
},
{
  "name": "Fare",
  "type": "double",
  "val": "100.67"
},
{
  "name": "SibSp",
  "type": "double",
  "val": "1.0"
},
{
  "name": "Sex",
  "type": "string",
  "val": "male"
},
  "output": {
    "name": "features",
    "type": "double",
    "struct": "vector"
  }
}]
predictor = Predictor(endpoint=endpoint_name, sagemaker_session=sagemaker.Session(),
serializer=json_serializer, content_type='text/csv', accept='application/json'
print(predictor.predict(payload))

The response you get from predictor.predict(payload) is the model's inference result.

**Realtime inference pipeline example**

You can run this [example notebook using the SKLearn predictor](https://aws.amazon.com/sagemaker/) that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see "Section 2 - Preprocess the raw housing data using Scikit Learn" of the Amazon SageMaker Multi-Model Endpoints using Linear Learner sample notebook. For information about Amazon SageMaker batch transforms, see Use Batch Transform (p. 2565).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2458).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, model_name is the inference pipeline that combines SparkML and XGBoost models
import sagemaker
input_data_path = 's3://{}/{}/*'.format(default_bucket, 'key', 'file_name')
output_data_path = 's3://{}/{}'.format(default_bucket, 'key')
transform_job = sagemaker.transformer.Transformer(
    model_name = model_name,
    instance_count = 1,
    instance_type = 'ml.m4.xlarge',
    strategy = 'SingleRecord',
    assemble_with = 'Line',
    output_path = output_data_path,
    base_transform_job_name='inference-pipelines-batch',
    sagemaker_session=sagemaker.Session(),
    accept = CONTENT_TYPE_CSV)
transform_job.transform(data = input_data_path,
    content_type = CONTENT_TYPE_CSV,
    split_type = 'Line')

Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor Amazon SageMaker (p. 3190).

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A dimension is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190).

Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to InvokeEndpoint. Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Invocations5XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1.                                                                                          Units: None                                                                                                                                   Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocations</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint.                                                                                                                                                                                                                                                                     Units: None                                                                                                                                   Valid statistics: Sum, Sample Count</td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of endpoint invocations sent to a model, normalized by <code>InstanceCount</code> in each <code>ProductionVariant</code>. SageMaker sends 1/<code>numberOfInstances</code> as the value for each request, where <code>numberOfInstances</code> is the number of active instances for the <code>ProductionVariant</code> at the endpoint at the time of the request. Units: None                                                                 Valid statistics: Sum</td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. <code>ModelLatency</code> is the total time taken by all containers in an inference pipeline. Units: Microseconds                                                                                                                                 Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. <code>OverheadLatency</code> is measured from the time that SageMaker receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds                                                                 Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for an Inference Pipelines container to respond as viewed from SageMaker. <code>ContainerLatency</code> includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds                                                                 Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

**Dimensions for Endpoint Invocation Metrics**

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows. The **ContainerLatency** metric appears only for inferences pipelines.

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

### Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>

</tbody>
</table>
| **MemoryUtilization** | The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%.  
For training jobs, MemoryUtilization is the memory used by the algorithm container running on the instance.  
For batch transform jobs, MemoryUtilization is the memory used by the transform container running on the instance.  
For multi-container models, MemoryUtilization is the sum of memory used by all containers running on the instance.  
For endpoint variants, MemoryUtilization is the sum of memory used by all of the containers running on the instance.  
Units: Percent  |
| **GPUUtilization** | The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%.  
For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance.  
For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance.  
For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance.  
For endpoint variants, GPUUtilization is the sum of the GPU used by all of the containers running on the instance.  
Units: Percent  |
| **GPUMemoryUtilization** | The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%.  
For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance.  
For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance.  
For multi-container models, GPUMemoryUtilization is the sum of GPU memory used by all containers running on the instance.  
For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance.  
Units: Percent  |
Hosting options

Metric | Description
--- | ---
DiskUtilization | The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs.

For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance.

For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance.

Units: Percent

Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace.</td>
</tr>
</tbody>
</table>

For batch transform jobs, Host has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace.

For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id]. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace.

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

Use Logs to Monitor an Inference Pipeline

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch.

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Amazon SageMaker Developer Guide
Hosting options

Log Group Name | Log Stream Name
----------------|-----------------------------------------------
[production-variant-name]/[instance-id]/[container-name provided in the SageMaker model] (For Inference Pipelines) | For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.
/aws/sagemaker/NotebookInstances | [notebook-instance-name]/[LifecycleConfigHook]
/aws/sagemaker/TransformJobs | [transform-job-name]/[instance-id]-[epoch_timestamp]
 | [transform-job-name]/[instance-id]-[epoch_timestamp]/data-log
 | [transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.

Note
SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 243).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201).

Troubleshoot Inference Pipelines

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

Topics
- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 2458)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 2459)
- Use Error Messages to Troubleshoot Inference Pipelines  (p. 2460)

Troubleshoot Amazon ECR Permissions for Inference Pipelines

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
    "Version": "2008-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            }
        }
    ]
}
```
Hosting options

Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container:

/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}

For example, logs for this endpoint are published to the following log groups and streams:

| EndpointName: MyInferencePipelinesEndpoint |
| Variant: MyInferencePipelinesVariant |
| InstanceId: i-0179208609ff7e488 |
| ContainerHostname: MyContainerName1 and MyContainerName2 |

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

To see the log groups and streams:

2. In the navigation page, choose Logs.
3. In Log Groups, filter on MyInferencePipelinesEndpoint:

To see the log streams, on the CloudWatch Log Groups page, choose MyInferencePipelinesEndpoint, and then Search Log Group.
For a list of the logs that SageMaker publishes, see Inference Pipeline Logs and Metrics (p. 2453).

**Use Error Messages to Troubleshoot Inference Pipelines**

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker is invoking an endpoint, the service returns a `ModelError` (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker provides a detailed error message, such as:

```
Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum limit of 5 MB.
```

If a container fails the ping health check while SageMaker is creating an endpoint, it returns a `ClientError` and indicates all of the containers that failed the ping check in the last health check.

**Automatically Scale Amazon SageMaker Models**

Amazon SageMaker supports automatic scaling (autoscaling) for your hosted models. **Autoscaling** dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using.

**Topics**
- Prerequisites (p. 2460)
- Configure model autoscaling with the console (p. 2463)
- Register a model (p. 2464)
- Define a scaling policy (p. 2465)
- Apply a scaling policy (p. 2467)
- Edit a scaling policy (p. 2468)
- Delete a scaling policy (p. 2470)
- Query Endpoint Autoscaling History (p. 2471)
- Update or delete endpoints that use automatic scaling (p. 2472)
- Load testing your autoscaling configuration (p. 2474)
- Use AWS CloudFormation to update autoscaling policies (p. 2475)

**Prerequisites**

Before you can use autoscaling, must have already created a Amazon SageMaker model deployment. Deployed models are referred to as a production variant. This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see Deploy the Model to SageMaker Hosting Services (p. 90).

To enable autoscaling for a model, you can use the console, the AWS CLI, or the Application Auto Scaling API. It is recommended to try to Configure model autoscaling with the console (p. 2463) to get familiar with the requirements and to test your first autoscaling configuration. When using the AWS CLI or
Application Auto Scaling the flow is to register the model, define the scaling policy, then apply it. The following overview provides further details on the prerequisites and components used with autoscaling.

**Autoscaling policy overview**

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.

You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Alternatively, you can use either the AWS Command Line Interface (AWS CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your autoscaling configuration. You configure the target-tracking scaling policy by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see [Target Tracking Scaling Policies](#).

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see [Step Scaling Policies](#).

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. SageMaker automatic scaling automatically generates this role, `AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint`, for you.

**Target metric for autoscaling**

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined `InvocationsPerInstance` metric with a target value of 70 can keep `InvocationsPerInstance` at, or close to 70.

**Minimum and maximum capacity**

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.
You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your autoscaling configuration with the expected rate of traffic to your model.

**Important**
Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

**Cooldown period**

Tune the responsiveness of your scaling policy by adding a cooldown period. A cooldown period controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn't launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don’t specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

**Permissions**

The SagemakerFullAccessPolicy IAM policy has all of the IAM permissions required to perform autoscaling. For more information about SageMaker IAM permissions, see SageMaker Roles (p. 3097).

If you are using a custom permission policy, you must include the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "sagemaker:DescribeEndpoint",
        "sagemaker:DescribeEndpointConfig",
        "sagemaker:UpdateEndpointWeightsAndCapacities"
    ],
    "Resource": "*
}
Service-linked role

Autoscaling uses the AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint service-linked role; it created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other AWS services on your behalf. For more information, see Service-Linked Roles.

Configure model autoscaling with the console

To configure autoscaling for a model using the console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Endpoints.
3. Choose the endpoint that you want to configure.
4. For Endpoint runtime settings, choose the model variant that you want to configure.
5. For Endpoint runtime settings, choose Configure autoscaling.

The Configure variant automatic scaling page appears.

6. For Minimum capacity, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For Maximum capacity, type the maximum number of instances that you want the scaling policy to maintain.
8. For the target value, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing (p. 2474).

Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.
9. For **Scale-in cool down (seconds)** and **Scale-out cool down (seconds)**, type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.

10. Select **Disable scale in** to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, disable scale-in activities.

    Scale-out activities are always enabled so that the scaling policy can create endpoint instances as needed.

11. Choose **Save**.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

**Note**

SageMaker doesn't support autoscaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see Amazon EC2 Instance Types.

### Register a model

You can add autoscaling for a model with the AWS CLI or the Application Auto Scaling API. You first must register the model, then you must define an autoscaling policy.

#### Register a model with the AWS CLI

With the AWS CLI, you can configure autoscaling based on either a predefined or a custom metric.

To register your endpoint, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace`—Set this value to `sagemaker`.
- `--resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--min-capacity`—The minimum number of instances that for this model. Set `min-capacity` to at least 1. It must be equal to or less than the value specified for `max-capacity`.
- `--max-capacity`—The maximum number of instances that Application Auto Scaling should manage. Set `max-capacity` to a minimum of 1, It must be equal to or greater than the value specified for `min-capacity`.

**Example**

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have one to eight instances:

```
aws application-autoscaling register-scalable-target \
    --service-namespace sagemaker \
```
Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the production variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant, for example `endpoint/MyEndPoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **MinCapacity**—The minimum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or less than the value specified for `MaxCapacity`.
- **MaxCapacity**—The maximum number of instances to be managed by Application Auto Scaling. This value must be set to at least 1 and must be equal to or greater than the value specified for `MinCapacity`.

**Example**

The following example shows how to register a SageMaker production variant that is dynamically scaled to use one to eight instances:

```plaintext
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration.
Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.

Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the SageMakerVariantInvocationsPerInstance predefined metric to adjust the number of variant instances so that each instance has an InvocationsPerInstance metric of 70.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  }
}
```

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

Important

Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named my-variant, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```json
{
  "TargetValue": 50,
  "CustomizedMetricSpecification":
  {
    "MetricName": "CPUUtilization",
    "Namespace": "/aws/sagemaker/Endpoints",
    "Dimensions": [
      {"Name": "EndpointName", "Value": "my-endpoint" },
      {"Name": "VariantName","Value": "my-variant"}
    ],
    "Statistic": "Average",
  }
}
```
Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

Example

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification": {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  },
  "ScaleInCooldown": 600,
  "ScaleOutCooldown": 300
}
```

Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the AWS CLI or the Application Auto Scaling API.

Apply a scaling policy (AWS CLI)

To apply a scaling policy to your model, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to `TargetTrackingScaling`.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`. 
aws application-autoscaling put-scaling-policy
   --policy-name myscalablepolicy
   --policy-type TargetTrackingScaling
   --resource-id endpoint/MyEndpoint/variant/MyVariant
   --service-namespace sagemaker
   --scalable-dimension sagemaker:variant:DesiredInstanceCount
   --target-tracking-scaling-policy-configuration file://config.json

**Apply a scaling policy (Application Auto Scaling API)**

To apply a scaling policy to a variant with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:

- **PolicyName**—The name of the scaling policy.
- **ServiceNamespace**—Set this value to `sagemaker`.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- **ScalableDimension**—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- **PolicyType**—Set this value to `TargetTrackingScaling`.
- **TargetTrackingScalingPolicyConfiguration**—The target-tracking scaling policy configuration to use for the variant.

**Example**

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a variant named `myscalablevariant`. It uses a policy configuration based on the `SageMakerVariantInvocationsPerInstance predefined metric`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "myscalablepolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 70.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
        }
    }
}
```

**Edit a scaling policy**

You can edit an autoscaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.
Scale-in

Scaling-in occurs when there is no traffic: if a variant’s traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

Disable scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your variant by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

To enable or disable scale-in activity for your model, specify a Boolean value for DisableScaleIn. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

Example

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the SageMakerVariantInvocationsPerInstance predefined metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also disables scale-in activity for the scaling policy.

```
{
   "TargetValue": 70.0,
   "PredefinedMetricSpecification":
   {
      "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
   },
   "DisableScaleIn": true
}
```

Scale-out

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the --min-capacity argument, or use the Application Auto Scaling API's MinCapacity parameter.

Disable scale-out activity

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the --max-capacity argument, or use the Application Auto Scaling API's MaxCapacity parameter.

Edit a scaling policy (Console)

To edit a scaling policy with the AWS Management Console, use the same procedure that you used to Configure model autoscaling with the console (p. 2463).

Edit a scaling policy (AWS CLI or Application Auto Scaling API)

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the AWS CLI, specify the name of the policy that you want to edit in the --policy-name parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the PolicyName parameter. Specify new values for the parameters that you want to change.
For more information, see Apply a scaling policy (p. 2467).

Delete a scaling policy

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

Delete a scaling policy (Console)

To delete an automatic scaling policy (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Endpoints.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For Endpoint runtime settings, choose the variant that you want to configure.
5. Choose Configure auto scaling.
6. Choose Deregister auto scaling.

Delete a scaling policy (AWS CLI or Application Auto Scaling API)

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

Delete a scaling policy (AWS CLI)

To delete a scaling policy from a variant, use the delete-scaling-policy AWS CLI command with the following parameters:

- --policy-name—The name of the scaling policy.
- --resource-id—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- --service-namespace—Set this value to sagemaker.
- --scalable-dimension—Set this value to sagemaker:variant: DesiredInstanceCount.

Example

The following example deletes a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```
aws application-autoscaling delete-scaling-policy
  --policy-name myscalablepolicy
  --resource-id endpoint/MyEndpoint/variant/MyVariant
  --service-namespace sagemaker
  --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy from your variant, use the DeleteScalingPolicy Application Auto Scaling API action with the following parameters:

- PolicyName—The name of the scaling policy.
Automatically scale models

- **ServiceNamespace**—Set this value to sagemaker.
- **ResourceId**—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
- **ScalableDimension**—Set this value to sagemaker:variant:DesiredInstanceCount.

**Example**

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named myscalablepolicy from a variant named myscalablevariant.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS
{
  "PolicyName": "myscalablepolicy",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount"
}
```

**Query Endpoint Autoscaling History**

You can view the status of scaling activities from your endpoint using `DescribeScalingActivities`. `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

**How To Query Endpoint Autoscaling Actions**

Query your autoscaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNameSpace` parameter. `ServiceNameSpace` is the name of the AWS service that provides the resource.

Valid service name values include the following:

- ecs | elasticmapreduce | ec2 | appstream | dynamodb | rds | sagemaker | custom-resource | comprehend | lambda | cassandra

In this situation you need to set `ServiceNameSpace` to sagemaker.

Use the following AWS CLI command to view details about all of your sagemaker endpoints that have a scaling policy:

```bash
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```bash
aws application-autoscaling describe-scaling-activities \
  --resource-id <ResourceId>
```
Automatically scale models

When you run this command, it returns the following output:

```bash
--service-namespace sagemaker
--resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

How to Identify Blocked AutoScaling Due to Instance Quotas

When you scale out or add more instances, you might reach your account-level instance quota. You can use `DescribeScalingActivities` to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the AWS CLI command as shown in the proceeding example where you specified the `ResourceId`

```bash
aws application-autoscaling describe-scaling-activities
   --service-namespace sagemaker
   --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

Within the return syntax, check the `StatusCode` and `StatusMessage` keys and their associated values. `StatusCode` returns `Failed`. Within `StatusMessage` there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```
{  "ActivityId": "activity-id",  "ServiceNamespace": "sagemaker",  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>"",  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",  "Description": "string",  "Cause": "string",  "StartTime": timestamp,  "EndTime": timestamp,  "StatusCode": "string",  "StatusMessage": "string"}
```

Update or delete endpoints that use automatic scaling

Topics

- Update endpoints that use automatic scaling (p. 2473)
• Delete endpoints configured for automatic scaling (p. 2474)

Update endpoints that use automatic scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the AWS Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by calling the UpdateEndpoint API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the DeleteScalingPolicy Application Auto Scaling API action, then call DeregisterScalableTarget to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn't typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn't significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

To update an endpoint that has automatic scaling applied

1. Deregister the endpoint as a scalable target by calling DeregisterScalableTarget.
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling UpdateEndpointWeightsAndCapacities.
3. Call DescribeEndpoint repeatedly until the value of the EndpointStatus field of the response is InService.
4. Call DescribeEndpointConfig to get the values of the current endpoint config.
5. Create a new endpoint config by calling CreateEndpointConfig. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to DescribeEndpointConfig in the previous step. For all other values, use the values that you got as the response when you called DescribeEndpointConfig in the previous step.
6. Update the endpoint by calling UpdateEndpoint. Specify the endpoint config you created in the previous step as the EndpointConfig field. If you want to retain the variant properties like instance count or weight, set the value of the RetainAllVariantProperties parameter to True. This specifies that production variants with the same name will are updated with the most recent DesiredInstanceCount from the response from the call to DescribeEndpoint, regardless of the values of the InitialInstanceCount field in the new EndpointConfig.
7. (Optional) Re-enable automatic scaling by calling RegisterScalableTarget.

Note
Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

• Changing the instance type for a production variant that has automatic scaling configured
• Removing a production variant that has automatic scaling configured.
Delete endpoints configured for automatic scaling

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn't provide permission for the `DeleteScalingPolicy` and `DeregisterScalableTarget` actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.

**Note**
You, as an IAM user, might not have sufficient permission to delete an endpoint if another IAM user configured automatic scaling for a variant on that endpoint.

Load testing your autoscaling configuration

Perform load tests to choose an automatic scaling configuration that works the way you want.

For an example of load testing to optimize automatic scaling for an Amazon SageMaker endpoint, see [Load test and optimize an Amazon SageMaker endpoint using automatic scaling](#).

The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric `SageMakerVariantInvocationsPerInstance`.

**Topics**
- Determine the performance characteristics (p. 2474)
- Calculate the target load (p. 2474)

Determine the performance characteristics

Perform load testing to find the peak `InvocationsPerInstance` that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

**To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests**

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see [Deploy the Model to SageMaker Hosting Services (p. 90)](#).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

**Note**
You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate `SageMakerVariantInvocationsPerInstance` shown below.

When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum
value. Use the following equation in combination with load testing to determine the correct value for the SageMakerVariantInvocationsPerInstance target metric in your automatic scaling configuration.

\[
\text{SageMakerVariantInvocationsPerInstance} = (\text{MAX}\_\text{RPS} \times \text{SAFETY}\_\text{FACTOR}) \times 60
\]

Where \(\text{MAX}\_\text{RPS}\) is the maximum RPS that you determined previously, and \(\text{SAFETY}\_\text{FACTOR}\) is the safety factor that you chose to ensure that your clients don’t exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker uses to implement automatic scaling (you don’t need to do this if you measured requests-per-minute instead of requests-per-second).

**Note**
SageMaker recommends that you start testing with a \(\text{SAFETY}\_\text{FACTOR}\) of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

### Use AWS CloudFormation to update autoscaling policies

The following is an example for how to enable autoscaling on an endpoint using AWS CloudFormation.

```
Endpoint:
  Type: "AWS::SageMaker::Endpoint"
  Properties:
    EndpointName: yourEndpointName
    EndpointConfigName: yourEndpointConfigName

ScalingTarget:
  Type: "AWS::ApplicationAutoScaling::ScalableTarget"
  Properties:
    MaxCapacity: 10
    MinCapacity: 2
    ResourceId: endpoint/MyEndPoint/variant/MyVariant
    RoleARN: arn
    ScalableDimension: sagemaker:variant:DesiredInstanceCount
    ServiceNamespace: sagemaker

ScalingPolicy:
  Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
  Properties:
    PolicyName: myscalablepolicy
    PolicyType: TargetTrackingScaling
    ScalingTargetId: Ref: ScalingTarget
    TargetTrackingScalingPolicyConfiguration:
      TargetValue: 75.0
      ScaleInCooldown: 600
      ScaleOutCooldown: 30
      PredefinedMetricSpecification:
        PredefinedMetricType: SageMakerVariantInvocationsPerInstance
```

For more details, refer to AWS CloudFormation’s AutoScalingPlans API reference.

### Host instance storage volumes

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.
For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see Host Instance Storage Volumes Table

**Note**
Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances only when you create Asyncoous inference (p. 2550) or Real-time inference (p. 2413) endpoint types.

**Safely update models in production**

In production ML workflows, data scientists and engineers frequently try to improve their models in various ways, such as by performing Perform Automatic Model Tuning with SageMaker (p. 2186), training on additional or more-recent data, and improving feature selection. Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously-existing version, replace the old version of the model with the new version in production.

Amazon SageMaker enables you to test multiple models or model versions behind the same endpoint using production variants. Each production variant identifies a machine learning (ML) model and the resources deployed for hosting the model. By using production variants, you can test ML models that have been trained using different datasets, trained using different algorithms and ML frameworks, or are deployed to different instance type, or any combination of all of these. You can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

**Topics**

- Test models by specifying traffic distribution (p. 2476)
- Test models by invoking specific variants (p. 2477)
- Model A/B test example (p. 2478)

**Test models by specifying traffic distribution**

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see CreateEndpointConfig. The following diagram shows how this works in more detail.
Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the TargetVariant parameter when you call InvokeEndpoint. SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the TargetVariant parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.
Model A/B test example

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production.

Step 1: Create and deploy models

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```python
model_url = f"s3://{{path_to_model_1}}"
model_url2 = f"s3://{{path_to_model_2}}"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri

model_name = f"DEMO-xgb-churn-pred-{{datetime.now():%Y-%m-%d-%H-%M-%S}}"
model_name2 = f"DEMO-xgb-churn-pred2-{{datetime.now():%Y-%m-%d-%H-%M-%S}}"
image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')
```
image_uri2 = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-2')

sm_session.create_model(name=model_name, role=role, container_defs={
    'Image': image_uri,
    'ModelDataUrl': model_url
})

sm_session.create_model(name=model_name2, role=role, container_defs={
    'Image': image_uri2,
    'ModelDataUrl': model_url2
})

We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial_weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

from sagemaker.session import production_variant

variant1 = production_variant(model_name=model_name,
    instance_type="ml.m5.xlarge",
    initial_instance_count=1,
    variant_name='Variant1',
    initial_weight=1)

variant2 = production_variant(model_name=model_name2,
    instance_type="ml.m5.xlarge",
    initial_instance_count=1,
    variant_name='Variant2',
    initial_weight=1)

Finally we're ready to deploy these production variants on a SageMaker endpoint.

endpoint_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}" 
print(f"EndpointName={endpoint_name}" )

sm_session.endpoint_from_production_variants( 
    name=endpoint_name, 
    production_variants=[variant1, variant2] 
)

Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.

# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/test_sample_tail_input_cols.csv
print(f"Sending test traffic to the endpoint {endpoint_name}. Please wait..."
)
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
for row in f:
    print(".", end="", flush=True)
    payload = row.rstrip('\n')
    sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
        ContentType="text/csv",
        Body=payload)
    time.sleep(0.5)

print("Done!")

SageMaker emits metrics such as **Latency** and **Invocations** for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see [Monitor Amazon SageMaker with Amazon CloudWatch](p. 3190). Let's query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
</tbody>
</table>

Now let's invoke a specific version of the model by specifying **Variant1** as the **TargetVariant** in the call to `invoke_endpoint`.

```python
print(f"Sending test traffic to the endpoint {endpoint_name}. 
Please wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print(".", end="", flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
            ContentType="text/csv",
            Body=payload,
            *TargetVariant="Variant1"*)  # Notice the new parameter
time.sleep(0.5)
```

To confirm that all new invocations were processed by **Variant1**, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by **Variant1**, as we had specified. There were no invocations made for **Variant2**.
Step 3: Evaluate model performance

To see which model version performs better, let’s evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let’s look at these metrics for Variant1:

Accuracy: 0.9583333333333334  
Precision: 0.9411764705882353  
Recall: 0.8  
F1 Score: 0.8648648648648648  
AUC is 0.895

Now let’s look at the metrics for Variant2:
For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

Step 4: Increase traffic to the best model

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use TargetVariant to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling `UpdateEndpointWeightsAndCapacities`. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

Now we shift 75% of the traffic to Variant2 by assigning new weights to each variant using `UpdateEndpointWeightsAndCapacities`. SageMaker now sends 75% of the inference requests to Variant2 and remaining 25% of requests to Variant1.

```python
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```
The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

![Graph showing CloudWatch metrics for total invocations for each variant]

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `UpdateEndpointWeightsAndCapacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```python
sm.update_endpoint_weights_and_capacities(  
    EndpointName=endpoint_name,  
    DesiredWeightsAndCapacities=[  
        {  
            "DesiredWeight": 0,  
            "VariantName": variant1["VariantName"]  
        },  
        {  
            "DesiredWeight": 1,  
            "VariantName": variant2["VariantName"]  
        }  
    ]  
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

![Graph showing CloudWatch metrics for total invocations for each variant]

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.

**Best practices**

This topic provides guidance on best practices for deploying machine learning models in Amazon SageMaker.
Topics

- Best practices for deploying models on SageMaker Hosting Services (p. 2484)
- Troubleshoot Amazon SageMaker model deployments (p. 2485)

Best practices for deploying models on SageMaker Hosting Services

When hosting models using SageMaker hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.

- You can deploy a model trained with SageMaker to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training (p. 1784).

- You can deploy multiple variants of a model to the same SageMaker HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you've deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the `ProductionVariant` in your request to the `CreateEndPointConfig`. For more information, see `ProductionVariant`.

- You can configure a `ProductionVariant` to use Application Auto Scaling. For information about configuring automatic scaling, see Automatically Scale Amazon SageMaker Models (p. 2460).

- You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker implements the changes without any downtime. For more information see, `UpdateEndpoint` and `UpdateEndpointWeightsAndCapacities`.

- Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.

- If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Use Batch Transform (p. 2565)

Deploy Multiple Instances Across Availability Zones

Create robust endpoints when hosting your model. SageMaker endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommended that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two Subnets, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.
Troubleshoot Amazon SageMaker model deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

Topics

- Detection Errors in the Active CPU Count (p. 2485)

Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux taskset commands or control groups (cgroups). SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn’t limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the `-XX:-UseContainerSupport` parameter when starting Java applications. For example, run the `java` command to start your JVM as follows:

```
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
```
Check whether the JVM used in your container supports the `-XX:UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker containers. For example, when using a JVM to support SparkML Scala. The `-XX:UseContainerSupport` parameter also affects the output returned by the `Java Runtime.getRuntime().availableProcessors()` API.

**Monitor models for data and model quality, bias, and explainability**

Amazon SageMaker Model Monitor continuously monitors the quality of Amazon SageMaker machine learning models in production. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

- **Monitor data quality (p. 2488)** - Monitor drift in data quality.
- **Monitor model quality (p. 2493)** - Monitor drift in model quality metrics, such as accuracy.
- **Monitor Bias Drift for Models in Production (p. 2499)** - Monitor bias in your model's predictions.
- **Monitor Feature Attribution Drift for Models in Production (p. 2503)** - Monitor drift in feature attribution.

**How Model Monitor Works**

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works.
To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- Enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.

Notes

- Model Monitor currently supports only tabular data.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see Host multiple models in one container behind one endpoint (p. 2424).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see VPC endpoints in the Amazon Virtual Private Cloud User Guide. For information about launching SageMaker Studio in a custom VPC, see Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3159).
Model Monitor Sample Notebooks

For a sample notebook that takes you through the full end-to-end workflow for Model Monitor, see the Introduction to Amazon SageMaker Model Monitor.

For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the Model Monitor Visualization.

For instructions that show you how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose the notebook's Use tab and choose Create copy.

Monitor data quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

• Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture data (p. 2507).

• Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see Create a Baseline (p. 2488).

• Define and schedule data quality monitoring jobs. For more information, see Schedule monitoring jobs (p. 2509).

• View data quality metrics. For more information, see Schema for Statistics (statistics.json file) (p. 2490).

• Integrate data quality monitoring with Amazon CloudWatch. For more information, see CloudWatch Metrics (p. 2491).

• Interpret the results of a monitoring job. For more information, see Interpret results (p. 2512).

• Use SageMaker Studio to enable data quality monitoring and visualize results. For more information, see Visualize results in Amazon SageMaker Studio (p. 2514).

Note

Amazon SageMaker Model Monitor currently supports only tabular data.

Topics

• Create a Baseline (p. 2488)

• Schema for Statistics (statistics.json file) (p. 2490)

• CloudWatch Metrics (p. 2491)

• Schema for Violations (constraint_violations.json file) (p. 2492)

Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This sagemaker-model-monitor-analyzer container also provides you with a range of model monitoring capabilities, including
constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with Deequ. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to trained the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

To Create a baseline from a training dataset

When you have your training data ready and stored in Amazon S3, start a baseline processing job with DefaultModelMonitor.suggest_baseline(,,) using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor prebuilt container (p. 2510) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the output_s3_uri location that you specify.

```python
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)
```

Note

If you provide the feature/column names in the training dataset as the first row and set the header=True option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the statistics.json file and the suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri.

Output Files for Tabular Dataset Statistics and Constraints

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see Schema for Statistics (statistics.json file) (p. 2525).</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. For more information about the schema for this file, see Schema for Constraints (constraints.json file) (p. 2527).</td>
</tr>
</tbody>
</table>
Monitor models for data and model quality, bias, and explainability

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the `Environment` map as shown in the following example:

```
"Environment": {
  "dataset_format": "{"csv": { "header": true}},
  "dataset_source": "/opt/ml/processing/sm_input",
  "output_path": "/opt/ml/processing/sm_output",
  "publish_cloudwatch_metrics": "Disabled",
}
```

**Schema for Statistics (statistics.json file)**

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",
            "numerical_statistics": {
                "common": {
                    "num_present": number,
                    "num_missing": number
                },
                "mean": number,
                "sum": number,
                "std_dev": number,
                "min": number,
                "max": number,
                "distribution": {
                    "kll": {
                        "buckets": [
                            {
                                "lower_bound": number,
                                "upper_bound": number,
                                "count": number
                            }
                        ],
                    },
                    "sketch": {
                        "parameters": {
                            "c": number,
                            "k": number
                        },
                        "data": [
                            [num, num, num, num],
                            [num, num]
                        ]
                    }
                }
            }
        }
    ]
}
```
Note the following:

- The prebuilt containers compute KLL sketch, which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

**CloudWatch Metrics**

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the emit_metrics option is Enabled in the baseline constraints file, SageMaker emits these metrics for each feature/column observed in the dataset in the /aws/sagemaker/Endpoints/data-metric namespace with EndpointName and ScheduleName dimensions.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for MetricName: `feature_data_{feature_name}`, Stat: Max
- Metric: Min → query for MetricName: `feature_data_{feature_name}`, Stat: Min
- Metric: Sum → query for MetricName: `feature_data_{feature_name}`, Stat: Sum
- Metric: SampleCount → query for MetricName: `feature_data_{feature_name}`, Stat: SampleCount
- Metric: Average → query for MetricName: `feature_data_{feature_name}`, Stat: Average

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for MetricName: `feature_non_null_{feature_name}`, Stat: Sum
• Metric: Baseline Drift → query for MetricName: feature_baseline_drift_{feature_name}, Stat: Sum

Schema for Violations (constraint_violations.json file)

The violations file is generated as the output of a MonitoringExecution, which lists the results of evaluating the constraints (specified in the constraints.json file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```json
{
    "violations": [{
        "feature_name": "string",
        "constraint_check_type": "data_type_check",
        "description": "string"
    }]
}
```

Types of Violations Monitored

<table>
<thead>
<tr>
<th>Violation Check Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_type_check</td>
<td>If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged. During the baseline step, the generated constraints suggest the inferred data type for each column. The monitoring_config.datatype_check_threshold parameter can be tuned to adjust the threshold on when it is flagged as a violation.</td>
</tr>
<tr>

Monitor model quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual ground truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model Quality Metrics (p. 2496).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint. To monitor model quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture data (p. 2507).
- Create a baseline. In this step, you run a baseline job that compares predictions from the model with ground truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see Create a Model Quality Baseline (p. 2494).
- Define and schedule model quality monitoring jobs. For more information, see Schedule Model Quality Monitoring Jobs (p. 2495).
- Ingest ground truth labels that model monitor merges with captured prediction data from real-time inference endpoint. For more information, see Ingest Ground Truth Labels and Merge Them With Predictions (p. 2495).
- Integrate model quality monitoring with Amazon CloudWatch. For more information, see Model Quality CloudWatch Metrics (p. 2499).
- Interpret the results of a monitoring job. For more information, see Interpret results (p. 2512).
- Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see Visualize results in Amazon SageMaker Studio (p. 2514).

Topics

- Create a Model Quality Baseline (p. 2494)
- Schedule Model Quality Monitoring Jobs (p. 2495)
- Ingest Ground Truth Labels and Merge Them With Predictions (p. 2495)
- Model Quality Metrics (p. 2496)
- Model Quality CloudWatch Metrics (p. 2499)
Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the ground truth for your data.

To create a baseline job use the ModelQualityMonitor class provided by the SageMaker Python SDK, and complete the following steps.

To create a model quality baseline job

1. First, create an instance of the ModelQualityMonitor class. The following code snippet shows how to do this.

   ```python
   from sagemaker import get_execution_role, session, Session
   from sagemaker.model_monitor import ModelQualityMonitor
   
   role = get_execution_role()
   session = Session()
   
   model_quality_monitor = ModelQualityMonitor(
       role=role,
       instance_count=1,
       instance_type='ml.m5.xlarge',
       volume_size_in_gb=20,
       max_runtime_in_seconds=1800,
       sagemaker_session=session
   )
   ```

2. Now call the suggest_baseline method of the ModelQualityMonitor object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

   ```python
   baseline_job_name = "MyBaseLineJob"
   job = model_quality_monitor.suggest_baseline(
       job_name=baseline_job_name,
       baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
       dataset_format=DatasetFormat.csv(header=True),
       output_s3_uri = baseline_results_uri, # The S3 location to store the results.
       problem_type='BinaryClassification',
       inference_attribute= "prediction", # The column in the dataset that contains predictions.
       probability_attribute= "probability", # The column in the dataset that contains probabilities.
       ground_truth_attribute= "label" # The column in the dataset that contains ground truth labels.
   )
   job.wait(logs=False)
   ```

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the latest_baselining_job method of the ModelQualityMonitor object.

   ```python
   baseline_job = model_quality_monitor.latest_baselining_job
   ```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To
view the constraints that the baseline job generated, call the `suggested_constraints` method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```python
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"]).T
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

5. When you are satisfied with the constraints, pass them as the `constraints` parameter when you create a monitoring schedule. For more information, see Schedule Model Quality Monitoring Jobs (p. 2495).

The suggested baseline constraints are contained in the `constraints.json` file in the location you specify with `output_s3_uri`. For information about the schema for this file in the Schema for Constraints (constraints.json file) (p. 2527).

### Schedule Model Quality Monitoring Jobs

For general information about scheduling monitoring jobs, see the section called “Schedule monitoring jobs” (p. 2509). For model quality monitoring, you also have to consider the fact that the availability of ground truth labels might be delayed.

To address this, use offsets. Model quality jobs include `StartOffset` and `EndOffset`, which are fields of the `ModelQualityJobInput` parameter of the `create_model_quality_job_definition` method that work as follows:

- `StartOffset` - If specified, jobs subtract this time from the start time.
- `EndOffset` - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, `-P7H`, where `7H` is 7 hours. You can use `-P#H` or `-P#D`, where `H=hours, D=days, and M=minutes, and # is the number.

For example, if your ground truth starts coming in after 1 day, but is not complete for a week, set `StartOffset` to `-P8D` and `EndOffset` to `-P1D`. Then, if you schedule a job to run at `2020-01-09T13:00`, it analyzes data from between `2020-01-01T13:00` and `2020-01-08T13:00`.

**Important**

The schedule cadence should be such that one execution finishes before the next execution starts, which allows the ground truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of `MaxRuntimeInSeconds` specified as part of `StoppingCondition` should be no more than 1800.

### Ingest Ground Truth Labels and Merge Them With Predictions

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint and upload it to Amazon S3.

To match ground truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```json
{
}
```
Monitor models for data and model quality, bias, and explainability

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with ground truth records. You are responsible for making sure that the `inferenceId` in the ground truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a ground truth record.

You must upload ground truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

```
s3://bucket/prefixyyyy/mm/dd/hh
```

The date in this path is the date when the ground truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the ground truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using AWS SDK for Python (Boto3), do this by specifying the location of ground truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the ground truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.

**Model Quality Metrics**

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

**Note**

Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.

**Regression Metrics**

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```
"regression_metrics" : {
    "mae" : {
        "value" : 0.3711832061068702,
        "standard_deviation" : 0.0037566388129940394
    },
    "mse" : {
```

Model Quality CloudWatch Metrics

If you set the value of the enable_cloudwatch_metrics to True when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the aws/sagemaker/Endpoints/model-metrics namespace. For a list of the metrics that are emitted, see Model Quality Metrics (p. 2496).

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see Create a CloudWatch Alarm Based on a Static Threshold in the Amazon CloudWatch User Guide.

Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications.
if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates. With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=(a_{\text{min}},a_{\text{max}})$, for instance an interval of $(-0.1, 0.1)$, that DPPL should belong to during deployment. Any deviation from this range should raise a bias detected alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example, $D_{\text{win}}$ is the data that the model processed during last 2-day window. An alert is issued if the DPPL value $b_{\text{win}}$ computed on $D_{\text{win}}$ falls outside of an allowed range $A$. This approach to checking if $b_{\text{win}}$ is outside of $A$ can be somewhat noisy. $D_{\text{win}}$ might consist of very few samples and might not be representative of the live data distribution. The small sample size means that the value of bias $b_{\text{win}}$ computed over $D_{\text{win}}$ might not be a very robust estimate. In fact, very high (or low) values of $b_{\text{win}}$ may be observed purely due to chance. To ensure that the conclusions drawn from the observed data $D_{\text{win}}$ are statistically significant, SageMaker Clarify makes use of confidence intervals. Specifically, it uses the Normal Bootstrap Interval method to construct an interval $C=(c_{\text{min}},c_{\text{max}})$ such that SageMaker Clarify is confident that the true bias value computed over the full live data is contained in C with high probability. Now, if the confidence interval C overlaps with the allowed range $A$, SageMaker Clarify interprets it as “it is likely that the bias metric value of the live data distribution falls within the allowed range”. If C and A are disjoint, SageMaker Clarify is confident that the bias metric does not lie in A and raises an alert.

Model Monitor Sample Notebook

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics

- Create a Bias Drift Baseline (p. 2501)
- Schedule Bias Drift Monitoring Jobs (p. 2502)
- Inspect Reports for Data Bias Drift (p. 2502)
Create a Bias Drift Baseline

After you have configured your application to capture real-time inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.

```python
model_bias_monitor = ModelBiasMonitor(  
    role=role,  
    sagemaker_session=sagemaker_session,  
    max_runtime_in_seconds=1800,  
)
```

DataConfig stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSONLines), headers (if any) and label.

```python
model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"
model_bias_data_config = DataConfig(  
    s3_data_input_path=validation_dataset,  
    s3_output_path=model_bias_baselining_job_result_uri,  
    label=label_header,  
    headers=all_headers,  
    dataset_type=dataset_type,  
)
```

BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the facet. For posttraining bias, you should also take the positive label into account.

```python
model_bias_config = BiasConfig(  
    label_values_or_threshold=[1],  
    facet_name="Account Length",  
    facet_values_or_threshold=[100],  
)
```

ModelPredictedLabelConfig specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JSONPath to locate predicted label in endpoint response payload.

```python
model_predicted_label_config = ModelPredictedLabelConfig(  
    probability_threshold=0.8,  
)
```

ModelConfig is the configuration related to the model to be used for inferencing. In order to compute posttraining bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as shadow endpoint). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

```python
model_config = ModelConfig(  
)
```
Now you can start the baselining job.

```python
model_bias_monitor.suggest_baseline(
    model_config=model_config,
    data_config=model_bias_data_config,
    bias_config=model_bias_config,
    model_predicted_label_config=model_predicted_label_config,
)
print(f"ModelBiasMonitor baselining job: {model_bias_monitor.latest_baselining_job_name}"
)
```

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

### Schedule Bias Drift Monitoring Jobs

Now that you have a baseline, you can call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.

```python
model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )
model_bias_monitor.create_monitoring_schedule(
    analysis_config=model_bias_analysis_config,
    output_s3_uri=s3_report_path,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT1H",
        end_time_offset="-PT0H",
        probability_threshold_attribute=0.8,
    ),
    ground_truth_input=ground_truth_upload_path,
    schedule_cron_expression=schedule_expression,
)
print(f"Model bias monitoring schedule: {model_bias_monitor.monitoring_schedule_name}"
)
```

### Inspect Reports for Data Bias Drift

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

```python
schedule_desc = model_bias_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[-1]
```

2502
Monitor models for data and model quality, bias, and explainability

```python
last_model_bias_monitor_execution_report_uri = last_model_bias_monitor_execution.output.destination
print(f'Report URI: {last_model_bias_monitor_execution_report_uri}')
last_model_bias_monitor_execution_report_files = sorted(S3Downloader.list(last_model_bias_monitor_execution_report_uri))
print(f'Found Report Files: 
\n'.join(last_model_bias_monitor_execution_report_files))
else:
    last_model_bias_monitor_execution = None
    print('====STOP==== 
No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.')
```

If there are violations compared to the baseline, they are listed here:

```python
if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraint_violations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

**Monitor Feature Attribution Drift for Models in Production**

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:

**College Admission Hypothetical Scenario**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Attribution in training data</th>
<th>Attribution in live data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAT score</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>GPA</td>
<td>0.50</td>
<td>0.20</td>
</tr>
<tr>
<td>Class rank</td>
<td>0.05</td>
<td>0.70</td>
</tr>
</tbody>
</table>

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive to the raw attribution score of the features. For instance, given two features that fall in the ranking by the same number of positions going from training to live data, we want to be more sensitive to the feature that had a higher attribution score in the training data. With these properties in mind, we use the Normalized Discounted Cumulative Gain (NDCG) score for comparing the feature attributions rankings of training and live data.
Specifically, assume we have the following:

- \( F = [f_1, \ldots, f_m] \) is the list of features sorted with respect to their attribution scores in the training data where \( m \) is the total number of features. For instance, in our case, \( F = [\text{SAT Score}, \text{GPA}, \text{Class Rank}] \).
- \( a(f) \) is a function that returns the feature attribution score on the training data given a feature \( f \). For example, \( a(\text{SAT Score}) = 0.70 \).
- \( F' = [f'_1, \ldots, f'_m] \) is the list of features sorted with respect to their attribution scores in the live data. For example, \( F' = [\text{Class Rank}, \text{GPA}, \text{SAT Score}] \).

Then, we can compute the NDCG as:

\[
\text{NDCG} = \frac{\text{DCG}}{\text{iDCG}}
\]

with

- \( \text{DCG} = \sum_{1}^{m} a(f_i)/\log_2(i+1) \)
- \( \text{iDCG} = \sum_{1}^{m} a(f_i)/\log_2(i+1) \)

The quantity DCG measures whether features with high attribution in the training data are also ranked higher in the feature attribution computed on the live data. The quantity iDCG measures the ideal score and it's just a normalizing factor to ensure that the final quantity resides in the range \([0, 1]\), with 1 being the best possible value. A NDCG value of 1 means that the feature attribution ranking in the live data is the same as the one in the training data. In this particular example, because the ranking changed by quite a bit, the NDCG value is 0.69.

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.

**Model Monitor Example Notebook**

SageMaker Clarify provides the following example notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in SageMaker Studio only. If you need instructions on how to open a notebook in SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131). If you’re prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

**Topics**

- Create a SHAP Baseline for Models in Production (p. 2504)
- Schedule Feature Attribute Drift Monitoring Jobs (p. 2506)
- Inspect Reports for Feature Attribute Drift in Production Models (p. 2506)

**Create a SHAP Baseline for Models in Production**

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see SHAP Baselines for Explainability (p. 2361).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its
features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- **mean_abs** – Mean of absolute SHAP values for all instances.
- **median** – Median of SHAP values for all instances.
- **mean_sq** – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can explain the predictions of a deployed model that's producing inferences and detect feature attribution drift on a regular basis.

```python
code
model_explainability_monitor = ModelExplainabilityMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it uses the same `DataConfig`, and the only difference is the job output URI.

```python
code
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/
model_explainability"
model_explainability_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_explainability_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)
```

Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the explainability config is SHAPConfig, including the following:

- **baseline** – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values.
- **num_samples** – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
- **agg_method** – Aggregation method for global SHAP values. Following are valid values:
  - **mean_abs** – Mean of absolute SHAP values for all instances.
  - **median** – Median of SHAP values for all instances.
  - **mean_sq** – Mean of squared SHAP values for all instances.
  - **use_logit** – Indicator of whether the logit function is to be applied to the model predictions. Default is False. If use_logit is True, the SHAP values will have log-odds units.
  - **save_local_shap_values** (bool) – Indicator of whether to save the local SHAP values in the output location. Default is False.

# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]

shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)

Start a baselining job. The same model_config is required because the explainability baselining job needs to create a shadow endpoint to get predictions for the generated synthetic dataset.

model_explainability_monitor.suggest_baseline(
    data_config=model_explainability_data_config,
    model_config=model_config,
    explainability_config=shap_config,
)

print(f"ModelExplainabilityMonitor baselining job:
    {model_explainability_monitor.latest_baselining_job_name}"
)

Schedule Feature Attribute Drift Monitoring Jobs

Model explainability monitoring helps you understand and interpret the predictions made by your ML models. When Model Monitor is configured to monitor model explainability, SageMaker automatically detects any drift in relative importance of features and creates reports explaining feature attributions.

Call the create_monitoring_schedule() method to schedule an hourly monitor to analyze the data with a monitoring schedule. If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. ModelConfig is required by ExplainabilityAnalysisConfig for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude ground truth labeling.

Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for the its first execution to start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

schedule_desc = model_explainability_monitor.describe_schedule()
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary")
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_explainability_monitor_execution =
    model_explainability_monitor.list_executions()[-1]
    last_model_explainability_monitor_execution_report_uri =
    last_model_explainability_monitor_execution.output.destination
    print(f'Report URI: {last_model_explainability_monitor_execution_report_uri}')
    last_model_explainability_monitor_execution_report_files =
    sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print("\n ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("****STOP**** \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
If there are any violations compared to the baseline, they are listed here:

```python
if last_model_explainability_monitor_execution:
    model_explainability_violations =
    last_model_explainability_monitor_execution.constraint_violations()
if model_explainability_violations:
    print(model_explainability_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

**Capture data**

To use Model Monitor, configure your real-time inference endpoint to capture data from requests and responses and store the captured data in Amazon S3. Model monitor compares metrics from this data with a baseline that you create for the model. For information about creating a baseline, see Create a Baseline (p. 2488).

**Note**

To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

**To set up data capture**

1. First, configure the Amazon S3 buckets Model Monitor uses to store the captured data.

```python
import boto3
import re
import json
from sagemaker import get_execution_role, session
region= boto3.Session().region_name
role = get_execution_role()
print("RoleArn: ".format(role))
# You can use a different bucket, but make sure the role you chose for this notebook
# has s3:PutObject permissions. This is the bucket into which the data is captured
bucket = session.Session(boto3.Session()).default_bucket()
print("Demo Bucket: ".format(bucket))
prefix = 'sagemaker/DEMO-ModelMonitor'
data_capture_prefix = '{}/datacapture'.format(prefix)
s3_capture_upload_path = 's3://{}/{}'.format(bucket, data_capture_prefix)
reports_prefix = '{}/reports'.format(prefix)
s3_report_path = 's3://{}/{}'.format(bucket,reports_prefix)
code_prefix = '{}/code'.format(prefix)
s3_code_preprocessor_uri = 's3://{}/{}preprocessor.py'.format(bucket,code_prefix)
s3_code_postprocessor_uri = 's3://{}/{}postprocessor.py'.format(bucket,code_prefix)
print("Capture path: ".format(s3_capture_upload_path))
print("Report path: ".format(s3_report_path))
print("Preproc Code path: ".format(s3_code_preprocessor_uri))
print("Postproc Code path: ".format(s3_code_postprocessor_uri))
```

2. Next, upload the pre-trained model to Amazon S3.

```python
model_file = open("model/your-prediction-model.tar.gz", 'rb')
```
s3_key = os.path.join(prefix, 'your-prediction-model.tar.gz')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(model_file)

3. Configure the data you want to capture by configuring the data you want to capture in a `DataCaptureConfig` structure. You can capture the request payload, the response payload, or both with this configuration.

```python
from sagemaker.model_monitor import DataCaptureConfig

endpoint_name = 'your-pred-model-monitor-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}").format(endpoint_name)

data_capture_config=DataCaptureConfig(
    enable_capture = True,
    sampling_percentage=100,
    destination_s3_uri=s3_capture_upload_path)
```

4. Enable data capture by passing the configuration you created in the previous step when you deploy the model.

```python
predictor = model.deploy(initial_instance_count=1,
     instance_type='ml.m4.xlarge',
     endpoint_name=endpoint_name,
     data_capture_config=data_capture_config)
```

5. Invoke the endpoint to send data to the endpoint to get inferences in real time. Because you enabled the data capture in the previous steps, the request and response payload, along with some additional metadata, is saved in the Amazon S3 location that you specified in `DataCaptureConfig`.

```python
from sagemaker.predictor import Predictor
from sagemaker.serializers import CSVSerializer
from sagemaker.deserializers import JSONDeserializer
import time

predictor = Predictor(endpoint=endpoint_name,
     serializer=CSVSerializer(),
     deserializer=JSONDeserializer())

# get a subset of test data for a quick test
!head -120 test_data/test-dataset-input-cols.csv > test_data/test_sample.csv
print("Sending test traffic to the endpoint {}. Please wait...").format(endpoint_name)

with open('test_data/test_sample.csv', 'r') as f:
    for row in f:
        payload = row.rstrip('
')
        response = predictor.predict(data=payload)
        time.sleep(0.5)

print("Done!")
```

6. The delivery of captured data to Amazon S3 can require a couple of minutes. You can optionally run the following to check if data has been captured:

```python
from sagemaker.s3 import S3Downloader
print("Waiting for captures to show up", end="")
for _ in range(120):
    capture_files = sorted(S3Downloader.list(f"{s3_capture_upload_path}/
    {endpoint_name}"))
    if capture_files:
        capture_file = S3Downloader.read_file(capture_files[-1]).split("\n")
        capture_record = json.loads(capture_file[0])
```

2508
if "inferenceId" in capture_record["eventMetadata"]:
    break
print(".", end="", flush=True)
sleep(1)
print()
print("Found Capture Files:")
print("\n ".join(capture_files[-3:]))

Schedule monitoring jobs

Amazon SageMaker Model Monitor provides you the ability to continuously monitor the data collected from the endpoints on a schedule. You can create a monitoring schedule with the CreateMonitoringSchedule API with a predefined periodic interval. For example, every \(x\) hours (\(x\) can range from 1 to 23).

With a monitoring schedule, SageMaker can kick off processing jobs at a specified frequency to analyze the data collected during a given period. SageMaker provides a prebuilt container for performing analysis on tabular datasets. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics, constraints provided and generate a violations report. In addition, CloudWatch metrics are emitted for each feature under analysis. Alternatively, you could choose to bring your own container as outlined in the Bring Your Own Containers (p. 2523) topic.

You can create a model monitoring schedule for the endpoint created earlier. Use the baseline resources (constraints and statistics) to compare against the real-time traffic. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already have it in Amazon S3, you can point to it directly.

```python
# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'
baseline_data_uri = 's3://{}/{}'.format(bucket, baseline_data_prefix)
baseline_results_uri = 's3://{}/{}'.format(bucket, baseline_results_prefix)
print('Baseline data uri: {}'.format(baseline_data_uri))
print('Baseline results uri: {}'.format(baseline_results_uri))
```

```python
training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
s3_key = os.path.join(baseline_prefix, 'data', 'training-dataset-with-header.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(training_data_file)
```

Create a model monitoring schedule for the endpoint using the baseline constraints and statistics to compare against real-time traffic.

```python
from sagemaker.model_monitor import CronExpressionGenerator
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule- ' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    endpoint_input=predictor.endpoint,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
)```
Monitor models for data and model quality, bias, and explainability

```python
enable_cloudwatch_metrics=True,
)
```

Describe and inspect the schedule: After you describe it, observe that the `MonitoringScheduleStatus` in `MonitoringScheduleSummary` returned by the `ListMonitoringSchedules` API changes to Scheduled.

```python
desc_schedule_result = my_default_monitor.describe_schedule()
print('Schedule status: {}'.format(desc_schedule_result['MonitoringScheduleStatus']))
```

## The cron expression for monitoring schedule

To provide details for the monitoring schedule, use `ScheduleConfig`, which is a cron expression that describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following cron expressions:
- To set the job to start every hour, use the following:
  ```
  Hourly: cron(0 * ? * *)
  ```
- To run the job daily, use the following:
  ```
  cron(0 [00-23] ? * *)
  ```

For example, the following are valid cron expressions:
- Daily at 12 PM UTC: `cron(0 12 ? * *)`
- Daily at 12 AM UTC: `cron(0 0 ? * *)`

To support running every 6, 12 hours, Model Monitor supports the following expression:

```
cron(0 [00-23]/[01-24] ? * *)
```

For example, the following are valid cron expressions:
- Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * *)`
- Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * *)`

### Notes
- Although the cron expression is set to start at 5 PM UTC, note that there could be a delay of 0-20 minutes from the actual requested time to run the execution.
- If you want to run on a daily schedule, don't provide this parameter. SageMaker picks a time to run every day.
- Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.

## Amazon SageMaker Model Monitor prebuilt container

SageMaker provides a built-in image called `sagemaker-model-monitor-analyzer` that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This image is based on Spark and is built with Deequ.
Note
You can not pull the built-in sagemaker-model-monitor-analyzer image directly. You can use the sagemaker-model-monitor-analyzer image when you submit a baseline processing or monitoring job using one of the AWS SDKs.

Use the SageMaker Python SDK (see image_uris.retrieve in the SageMaker Python SDK reference guide) to generate the ECR image URI for you, or specify the ECR image URI directly. The prebuilt image for SageMaker Model Monitor can be accessed as follows:

<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer

For example: 159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer

If you are in an AWS region in China, the prebuilt images for SageMaker Model Monitor can be accessed as follows:

<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com.cn/sagemaker-model-monitor-analyzer

The following table lists the supported values for account IDs and corresponding AWS Region names.

To write your own analysis container, see the container contract described in Customize monitoring (p. 2520).

Interpret results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see Visualize results in Amazon SageMaker Studio (p. 2514).

List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```python
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus 0 - 20 min buffer:\nWe will have to wait till we hit the hour..."
while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()
```

Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
- **Failed** – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the FailureReason and ExitMessage.

```python
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and so on..
time.sleep(60)
```
latest_execution.wait(logs=False)

print("Latest execution status: {}".format(latest_execution.describe() ['ProcessingJobStatus']))
print("Latest execution result: {}".format(latest_execution.describe() ['ExitMessage']))

latest_job = latest_execution.describe()
if (latest_job ['ProcessingJobStatus'] != 'Completed'):
    print("====STOP==== \n No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")

report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))

List Generated Reports

List the generated reportsUse the following code to list the generated reports.

from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/')
print('Report bucket: {}'.format(report_bucket))
print('Report key: {}'.format(report_key))

s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get("Key") for report_file in result.get('Contents')]
print("Found Report Files:")
print("\n ".join(report_files))

Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

violations = my_default_monitor.latest_monitoring_constraint_violations()
pd.set_option('display.max_colwidth', -1)
constraints_df = pd.io.json.json_normalize(violations.body_dict['violations'])
constraints_df.head(10)

This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic.</td>
</tr>
<tr>
<td>constraintsViolations.json</td>
<td>Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file.</td>
</tr>
</tbody>
</table>
Monitor models for data and model quality, bias, and explainability

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>specified in the baseline_constraints and baseline_statistics paths.</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Model Monitor prebuilt container (p. 2510) saves a set of Amazon CloudWatch metrics for each feature by default.

The container code can emit CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

**Visualize results in Amazon SageMaker Studio**

You can also visualize the results of monitoring in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

**To view the detailed results of a monitoring job**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Components and registries icon (🔍).
3. Choose Endpoints in the drop-down menu.
4. On the endpoint tab, choose the monitoring type for which you want to see job details.
5. Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.

6. The MONITORING JOB DETAILS tab opens with a detailed report of the monitoring job.
You can create a chart that displays the baseline and captured metrics for a time period.

**To create a chart in SageMaker Studio to visualize monitoring results**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. Choose **Endpoints** in the drop-down menu.
4. On the **Endpoint** tab, choose the monitoring type you want to create a chart for. This example shows a chart for the **Model quality** monitoring type.

5. Choose **Add chart**.
6. On the **CHART PROPERTIES** tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a **Timeline** of 1 week, the **Average Statistic** of, and the **F1 Metric**.
7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.
Advanced topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use AWS CloudFormation to create a monitoring schedule.

Topics
- Customize monitoring (p. 2520)
- Create a Monitoring Schedule with an AWS CloudFormation Custom Resource (p. 2530)

Customize monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

Topics
- Preprocessing and Postprocessing (p. 2520)
- Bring Your Own Containers (p. 2523)

Preprocessing and Postprocessing

In addition to using the built-in mechanisms, you can extend the code with the preprocessing and postprocessing scripts.

Topics
- Postprocessing Script (p. 2520)
- Preprocessing Script (p. 2521)

Postprocessing Script

You can extend the code with the postprocessing script by following this contract:

```python
def postprocess_handler():
```
print("Hello from post-proc script!")

Specify it as a path in Amazon Simple Storage Service (Amazon S3) in the CreateMonitoringSchedule request, as shown following:

Preprocessing Script

The Amazon SageMaker Model Monitor container works only with tabular or flattened JSON structures. We provide a pre-record preprocessor for some small changes required to transform the dataset. For example, if your output is an array [1.0, 2.1], you need to convert this into a flattened JSON, like {"prediction0": 1.0, "prediction1": 2.1}. A sample implementation might look like the following:

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.datarstrip("\n")
    data = output_data + "," + input_data
    return { str(i).zfill(20) : d for i, d in enumerate(data.split(",")) }
```

Specify it as a path in Amazon S3 in the CreateMonitoringSchedule request:

The structure of the inference_record is defined as follows:

```json
"captureData": {
    "endpointInput": {
        "observedContentType": "text/csv",
        "mode": "INPUT",
        "data": "132,25,113.2,96,269.9,107,,0,0,0,0,0,0,1,0,1,0,0,1",
        "encoding": "CSV"
    },
    "endpointOutput": {
        "observedContentType": "text/csv; charset=utf-8",
        "mode": "OUTPUT",
        "data": "0.01076381653547287",
        "encoding": "CSV"
    }
},
"eventMetadata": {
    "eventId": "feca1ab1-8025-47e3-8f6a-99e3fdd7b8d9",
    "inferenceTime": "2019-11-20T23:33:12Z"
}
```
Monitor models for data and model quality, bias, and explainability

```python
"eventVersion": "0"
}
"

class EventConfig:
    def __init__(self, endpoint, variant, start_time, end_time):

```

2522
Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a `MonitoringSchedule`, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the `Build Your Own Processing Container (Advanced Scenario)` topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the `Container Contract Inputs`.

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can chose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in `Container Contract Outputs`. If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.

You also emit CloudWatch metrics from the container by following the instructions in `CloudWatch Metrics for Bring Your Own Containers`.

Topics
- `Container Contract Inputs`
- `Container Contract Outputs`
- `CloudWatch Metrics for Bring Your Own Containers`

Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you chose to write your own container code, the following environment variables are available for your container code. In this context, you can analyze the current dataset or evaluate the constraints if you chose to and emit metrics, if applicable.

```
"Environment": {
  "dataset_format": "{"sagemakerCaptureJson": {"captureIndexNames": ["endpointInput", "endpointOutput"]}},
  "dataset_source": "/opt/ml/processing/endpointdata",
  "end_time": "2019-12-01T16:20:00Z",
  "output_path": "/opt/ml/processing/resultdata",
  "publish_cloudwatch_metrics": "Disabled",

Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataset_format</td>
<td>For a job started from a <code>MonitoringSchedule</code> backed by an <code>Endpoint</code>, this is</td>
</tr>
</tbody>
</table>
### Monitor models for data and model quality, bias, and explainability

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sagemakerCaptureJson</code></td>
<td>with the capture indices <code>endpointInput</code>, or <code>endpointOutput</code>, or both.</td>
</tr>
<tr>
<td><code>dataset_source</code></td>
<td>The local path in which the data corresponding to the monitoring period, as specified by <code>start_time</code> and <code>end_time</code>, are available. At this path, the data is available in <code>{endpoint-name}/{variant-name}/yyyy/mm/dd/hh</code>. We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.</td>
</tr>
<tr>
<td><code>output_path</code></td>
<td>The local path to write output reports and other files. You specify this parameter in the CreateMonitoringSchedule request as <code>MonitoringOutputConfig.MonitoringOutput[0].LocalPath</code>. It is uploaded to the <code>S3Uri</code> path specified in <code>MonitoringOutputConfig.MonitoringOutput[0].S3Uri</code>.</td>
</tr>
<tr>
<td><code>publish_cloudwatch_metrics</code></td>
<td>For a job launched by CreateMonitoringSchedule, this parameter is set to <code>Enabled</code>. The container can choose to write the Amazon CloudWatch output file at <code>[filepath]</code>.</td>
</tr>
<tr>
<td><code>sagemaker_endpoint_name</code></td>
<td>The name of the Endpoint that this scheduled job was launched for.</td>
</tr>
<tr>
<td><code>sagemaker_monitoring_schedule_name</code></td>
<td>The name of the MonitoringSchedule that launched this job.</td>
</tr>
<tr>
<td><code>sagemaker_endpoint_datacapture_prefix</code></td>
<td>The prefix specified in the DataCaptureConfig parameter of the Endpoint. The container can use this if it needs to directly access more data than already downloaded by SageMaker at the <code>dataset_source</code> path.</td>
</tr>
<tr>
<td><code>start_time, end_time</code></td>
<td>The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, <code>start_time</code> is 2020-02-19T06:00:00Z and <code>end_time</code> is 2020-02-20T05:00:00Z.</td>
</tr>
<tr>
<td><code>baseline_constraints:</code></td>
<td>The local path of the baseline constraint file specified in <code>BaselineConfig.ConstraintResource.S3Uri</code>. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
</tbody>
</table>
**Parameter Name** | **Description**
---|---
baseline_statistics | The local path to the baseline statistics file specified in BaselineConfig.StatisticsResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.

**Container Contract Outputs**

The container can analyze the data available in the *dataset_source* path and write reports to the path in *output_path*. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API. This applies only to tabular datasets.

**Output Files for Tabular Datasets**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics path.</td>
</tr>
</tbody>
</table>

In addition, if the publish_cloudwatch_metrics value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: /opt/ml/output/metrics/cloudwatch. The schema for these files is described in the following sections.

**Topics**

- Schema for Statistics (statistics.json file) (p. 2525)
- Schema for Constraints (constraints.json file) (p. 2527)

**Schema for Statistics (statistics.json file)**

The schema defined in the statistics.json file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by KLL, a very compact quantiles sketch with lazy compaction scheme.

```json
{
   "version": 0,
   # dataset level stats
   "dataset": {
      "item_count": number
   },
   # feature level stats
```

2525
"features": [
    {
      "name": "feature-name",
      "inferred_type": "Fractional" | "Integral",
      "numerical_statistics": {
        "common": {
          "num_present": number,
          "num_missing": number
        },
        "mean": number,
        "sum": number,
        "std_dev": number,
        "min": number,
        "max": number,
        "distribution": {
          "kll": {
            "buckets": [
              {

              "data": [
                [num, num, num, num],
                [num, num]
              ]
            }
          }
        }
      }
    },
    {
      "name": "feature-name",
      "inferred_type": "String",
      "string_statistics": {
        "common": {
          "num_present": number,
          "num_missing": number
        },
        "distinct_count": number,
        "distribution": {
          "categorical": {
            "buckets": [
              {"value": "string",
                "count": number
              }
            ]
          }
        }
      }
    }
]
Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- KLL sketch is the recognized sketch. Custom containers can write their own representation, but it won’t be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can’t change this.

Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```json
{
  "version": 0,
  "features": [
    {
      "name": "string",
      "inferred_type": "Integral" | "Fractional" | "String" | "Unknown",
      "completeness": number, # denotes observed non-null value percentage
      "num_constraints": {
        "is_non_negative": boolean,
      },
      "string_constraints": {
        "domains": [
          "list of",
          "observed values",
          "for small cardinality"
        ],
      },
      "monitoringConfigOverrides": {
        "evaluate_constraints": "Enabled",
        "emit_metrics": "Enabled",
        "datatype_check_threshold": 0.1,
        "domain_content_threshold": 0.1,
        "distribution_constraints": {
          "perform_comparison": "Enabled",
          "comparison_threshold": 0.1,
          "comparison_method": "Simple"||"Robust"
        }
      }
    }
  ]
}
```

# options to control monitoring for this feature with monitoring jobs
# See the following table for notes on what each constraint is doing,
## Monitoring Constraints

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluate_constraints</td>
<td>When Enabled, evaluates whether the current dataset being analyzed satisfies the constraints specified in the constraints.json file taken as a baseline.</td>
</tr>
<tr>
<td></td>
<td>Valid values: Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>Default: Enabled</td>
</tr>
<tr>
<td>emit_metrics</td>
<td>When Enabled, emits CloudWatch metrics for the data contained in the file.</td>
</tr>
<tr>
<td></td>
<td>Valid values: Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>Default: Enabled</td>
</tr>
<tr>
<td>datatype_check_threshold</td>
<td>If the threshold is above the value of the specified datatype_check_threshold, this causes a failure that is treated as a violation in the violation report. If the data types in the current execution are not the same as in the baseline dataset, this threshold is used to evaluate if it needs to be flagged as a violation.</td>
</tr>
<tr>
<td></td>
<td>During the baseline step, the generated constraints suggest the inferred data type for each column. The datatype_check_threshold parameter can be tuned to adjust the threshold on when it is flagged as a violation.</td>
</tr>
<tr>
<td></td>
<td>Valid values: float</td>
</tr>
<tr>
<td></td>
<td>Default: 0.1</td>
</tr>
<tr>
<td>domain_content_threshold</td>
<td>If there are more unknown values for a String field in the current dataset than in the baseline dataset, this threshold can be used to dictate if it needs to be flagged as a violation.</td>
</tr>
<tr>
<td></td>
<td>Valid values: float</td>
</tr>
<tr>
<td></td>
<td>Default: 0.1</td>
</tr>
<tr>
<td>distribution_constraints</td>
<td>perform_comparison</td>
</tr>
<tr>
<td></td>
<td>When Enabled, this flag instructs the code to perform a distribution comparison between the baseline distribution and the distribution observed for the current dataset.</td>
</tr>
<tr>
<td></td>
<td>Valid values: Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>Default: Enabled</td>
</tr>
<tr>
<td>Constraint</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>comparison_threshold</td>
<td>If the threshold is above the value set for the <code>comparison_threshold</code>, this causes a failure that is treated as a violation in the violation report. The distance is calculated by getting the maximum absolute difference between the cumulative distribution functions of two distributions. Validation values: float. Default: 0.1</td>
</tr>
<tr>
<td>comparison_method</td>
<td>Whether to calculate <code>linf_simple</code> or <code>linf_robust</code>. The <code>linf_simple</code> is based on the maximum absolute difference between the cumulative distribution functions of two distributions. Calculating <code>linf_robust</code> is based on <code>linf_simple</code>, but is used when there are not enough samples. The <code>linf_robust</code> formula is based on the Two-sample Kolmogorov–Smirnov test. Validation values: <code>linf_simple</code> or <code>linf_robust</code>.</td>
</tr>
</tbody>
</table>

**CloudWatch Metrics for Bring Your Own Containers**

If the `publish_cloudwatch_metrics` value is `Enabled` in the `Environment` map in the `/opt/ml/processing/processingjobconfig.json` file, the container code emits Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`.

The schema for this file is closely based on the CloudWatch `PutMetrics` API. The namespace is not specified here. It defaults to `/aws/sagemaker/Endpoint/data-metrics`. However, you can specify dimensions. We recommend that you add the `Endpoint` and `MonitoringSchedule` dimensions at a minimum.

```json
{
    "MetricName": "", # Required
    "Timestamp": "2019-11-26T03:00:00Z", # Required
    "Dimensions": [{"Name": "Endpoint", "Value": "endpoint_0"},
                    {"Name": "MonitoringSchedule", "Value": "schedule_0"}],
    "Value": Float,
    # Either the Value or the StatisticValues field can be populated and not both.
    "StatisticValues": {
        "SampleCount": Float,
        "Sum": Float,
        "Minimum": Float,
        "Maximum": Float
    },
    "Unit": "Count", # Optional
}
```
Create a Monitoring Schedule with an AWS CloudFormation Custom Resource

To use AWS CloudFormation to create a monitoring schedule, use an AWS CloudFormation custom resource. The custom resource is in Python. To deploy it, see Python Lambda deployment.

Custom Resource

Start by adding a custom resource to your AWS CloudFormation template. This points to a AWS Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule. You can add or remove more parameters by modifying the AWS CloudFormation resource and the Lambda function in the following example resource.

```json
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MonitoringSchedule": {
         "Type": "Custom::MonitoringSchedule",
         "Version": "1.0",
         "Properties": {
            "ScheduleName": "YourScheduleName",
            "EndpointName": "YourEndpointName",
            "BaselineConstraintsUri": "s3://your-baseline-constraints/constraints.json",
            "BaselineStatisticsUri": "s3://your-baseline-stats/statistics.json",
            "PostAnalyticsProcessorSourceUri": "s3://your-post-processor/postprocessor.py",
            "RecordPreprocessorSourceUri": "s3://your-preprocessor/preprocessor.py",
            "InputLocalPath": "/opt/ml/processing/endpointdata",
            "OutputLocalPath": "/opt/ml/processing/localpath",
            "OutputS3URI": "s3://your-output-uri",
            "ImageURI": "111111111111.dkr.ecr.us-west-2.amazonaws.com/your-image",
            "ScheduleExpression": "cron(0 * * * *)",
            "PassRoleArn": "arn:aws:iam::111111111111:role/AmazonSageMaker-ExecutionRole"
         }
      }
   }
}
```

Lambda Custom Resource Code

This AWS CloudFormation custom resource uses the Custom Resource Helper AWS library, which you can install with pip using pip install crhelper.

This Lambda function is invoked by AWS CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```python
import boto3
import botocore
import logging
from crhelper import CfnResource
from botocore.exceptions import ClientError

logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')
```
# cfnhelper makes it easier to implement a CloudFormation custom resource

```python
helper = CfnResource()
```

### CFN Handlers

```python
def handler(event, context):
    helper(event, context)
```

```python
@helper.create
def create_handler(event, context):
    """
    Called when CloudFormation custom resource sends the create event
    """
    create_monitoring_schedule(event)
```

```python
@helper.delete
def delete_handler(event, context):
    """
    Called when CloudFormation custom resource sends the delete event
    """
    schedule_name = get_schedule_name(event)
    delete_monitoring_schedule(schedule_name)
```

```python
@helper.poll_create
def poll_create(event, context):
    """
    Return true if the resource has been created and false otherwise so
    CloudFormation polls again.
    """
    schedule_name = get_schedule_name(event)
    logger.info('Polling for creation of schedule: %s', schedule_name)
    return is_schedule_ready(schedule_name)
```

```python
@helper.update
def noop():
    """
    Not currently implemented but crhelper will throw an error if it isn't added
    """
    pass
```

### Helper Functions

```python
def get_schedule_name(event):
    return event['ResourceProperties']['ScheduleName']
```

```python
def create_monitoring_schedule(event):
    schedule_name = get_schedule_name(event)
    monitoring_schedule_config = create_monitoring_schedule_config(event)

    logger.info('Creating monitoring schedule with name: %s', schedule_name)
    sm.create_monitoring_schedule(MonitoringScheduleName=schedule_name,
        MonitoringScheduleConfig=monitoring_schedule_config)
```

```python
def is_schedule_ready(schedule_name):
    is_ready = False

    schedule = sm.describe_monitoring_schedule(MonitoringScheduleName=schedule_name)
    status = schedule['MonitoringScheduleStatus']

    if status == 'Scheduled':
        logger.info('Monitoring schedule (%s) is ready', schedule_name)
```

```python
sm = boto3.client('sagemaker')
```

```python
cfn_stack = boto3.resource('cloudformation')
cfn_stack_client = boto3.client('cloudformation')
```

```python
s3 = boto3.client('s3')
```

```python
logger = logging.getLogger()
```

```python
schedule_name = get_schedule_name(event)
create_monitoring_schedule(event)
```

```python
delete_monitoring_schedule(schedule_name)
```

```python
is_schedule_ready(schedule_name)
```

```python
sm.create_monitoring_schedule(MonitoringScheduleName=schedule_name,
    MonitoringScheduleConfig=monitoring_schedule_config)
```

```python
logger.info('Monitoring schedule (%s) is ready', schedule_name)
```
is_ready = True
elif status == 'Pending':
    logger.info('Monitoring schedule (%s) still creating, waiting and polling again...', schedule_name)
else:
    raise Exception('Monitoring schedule ({}) has unexpected status: {}')
return is_ready

def create_monitoring_schedule_config(event):
    props = event['ResourceProperties']
    return {
        "ScheduleConfig": {
            "ScheduleExpression": props['ScheduleExpression'],

        }
    }

def delete_monitoring_schedule(schedule_name):
Invoke real-time endpoints

After you deploy your model using SageMaker hosting services, you can test your model on that endpoint by sending it test data. You can test your endpoints using Amazon SageMaker Studio, the AWS CLI, or AWS SDKs.

Test Your Endpoint Using Amazon SageMaker Studio

After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p. 2414)) you can check that endpoint with Amazon SageMaker Studio.

Note
Note: SageMaker only supports endpoint testing with Amazon SageMaker Studio for real-time endpoints.

1. Launch Amazon SageMaker Studio.
2. Select the SageMaker Components and registries icon on the left sidebar.
3. From the dropdown, choose Endpoints.
4. Search for your endpoint by name and double-click on the name of your endpoint. The endpoint names listed within the SageMaker resources panel are defined when you deploy a model. You can deploy your model in several ways:
   - The SageMaker Python SDK Model Class sagemaker.model.Model.deploy.
   - The AWS SDK for Python (Boto3) SageMaker Service Client API CreateEndpoint.
   - The SageMaker console. Select Inference in the left panel and then select Endpoint configuration. Provide an endpoint name within the Endpoint name field.
5. (Optional) You can optionally provide a custom URL to send your request to. In the Configure endpoint URL and headers field provide the URL of where your model is hosted. Leave this field blank if you are using a SageMaker endpoint. You can also optionally add multiple key-value headers to pass additional information to the inference request.
6. A new tab will populate in the Studio workspace. Select the Test inference tab.
7. Send a request to your endpoint by providing sample data in JSON format. Use the JSON editor to submit a request to your endpoint.
8. Select Send Request.
9. When you send the request an Inference output card will appear on the right-hand side of the console.

The top of the card will display the type of request that was sent to the endpoint (currently only JSON is accepted). Within the card there are four main fields: Status, Execution Length, Request Time, and Result Time.

- **Status**: displays the request status. There are three types of statuses:
  - Complete - If the request is successful, the status will display Complete and the execution length will is calculated by tracking the request time.
  - Failed - If the request fails for any reason. A failure response will appear within the **Failure Reason** accordion.
Amazon SageMaker Developer Guide
Invoke real-time endpoints

• Pending - A spinning, circular icon will appear while the inference request is pending.
• Execution Length: How long the invocation takes (end time minus the start time) in milliseconds.
• Request Time: How many minutes have passed since the request was sent.
• Result Time: How many minutes have passed since the result was returned.

Test Your Endpoint Using AWS SDKs
After you deploy your model to an endpoint (see Create your endpoint and deploy your model (p.
you can check your endpoint with the InvokeEndpoint API using one of the AWS SDKs. If the
invocation is successful, SageMaker will return an HTTP 200 response. You can index the returned
response dictionary object to ﬁnd out more about the response headers. For more information, see
InvokeEndpoint.
The following demonstrates how to use InvokeEndpoint to check the status of your endpoint using
the AWS SDK for Python (Boto3). Provide the name of your endpoint. This is the name you speciﬁed for
EndpointName when you created your endpoint with CreateEndpoint.
Provide input data in the Body ﬁeld for SageMaker to pass to the model. The data must be in the same
format that was used for training.
import boto3
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)
# The name of the endpoint. The name must be unique within an AWS Region in your AWS
account.
endpoint_name='<endpoint-name>'
# After you deploy a model into production using SageMaker hosting
# services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint(
EndpointName=endpoint_name,
Body=bytes('{"features": ["This is great!"]}', 'utf-8') #
Replace with your own data.
)
# Optional - Print the response body and decode it so it is human read-able.
print(response['Body'].read().decode('utf-8'))

Once you have the response object (in the aforementioned example it is stored in a variable
called response) you can index it to check the HTTP status, the name of the deployed model
(InvokedProductionVariant), and other ﬁelds.
The proceeding code snippet prints the HTTPStatusCode stored in the response variable:
print(response["HTTPStatusCode"])

For more information, see InvokeEndpoint in the SageMaker API Reference Guide.

Test Your Endpoint Using the AWS CLI
The following demonstrates how to use InvokeEndpoint to check the status of your endpoint using
the AWS CLI. Provide the name of your endpoint. This is the name you speciﬁed for EndpointName
when you created your endpoint with CreateEndpoint.

2534

))


Provide input data in the Body field for SageMaker to pass to the model. The data must be in the same format that was used for training. The example code template shows how to send binary data to your endpoint.

```
aws sagemaker-runtime invoke-endpoint \
   --endpoint-name endpoint_name \
   --body fileb://$file_name \
   output_file.txt
```

For more information on when to use `file://` over `fileb://` when passing contents of a file to a parameter of the AWS CLI, see Best Practices for Local File Parameters.

See `invoke-endpoint` in the AWS CLI Command Reference guide for more information on additional parameters you can pass.

If the above invocation shows a snippet such as following, it means the command executed successfully. Otherwise, check whether input payload is in correct format.

```
{
   "ContentType": "<content_type>; charset=utf-8",
   "InvokedProductionVariant": "<Variant>"
}
```

View the output of the invocation by checking the file output file (`output_file.txt` in this example).

```
more output_file.txt
```

### Serverless Inference

Amazon SageMaker Serverless Inference is a purpose-built inference option that makes it easy for you to deploy and scale ML models. Serverless Inference is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies. This takes away the undifferentiated heavy lifting of selecting and managing servers. Serverless Inference integrates with AWS Lambda to offer you high availability, built-in fault tolerance and automatic scaling.

With a pay-per-use model, Serverless Inference is a cost-effective option if you have an infrequent or unpredictable traffic pattern. During times when there are no requests, Serverless Inference scales your endpoint down to 0, helping you to minimize your costs. For more information about pricing for Serverless Inference, see Amazon SageMaker Pricing.

You can integrate Serverless Inference with your MLOps Pipelines to streamline your ML workflow, and you can use a serverless endpoint to host a model registered with Model Registry (p. 2592).

Serverless Inference is generally available in all AWS commercial Regions where SageMaker is available (except the AWS China Regions). For more information about Amazon SageMaker regional availability, see the AWS Regional Services List.

### How it works

The following diagram shows the workflow of Serverless Inference and the benefits of using a serverless endpoint.
When you create a serverless endpoint, SageMaker provisions and manages the compute resources for you. Then, you can make inference requests to the endpoint and receive model predictions in response. SageMaker scales the compute resources up and down as needed to handle your request traffic, and you only pay for what you use.

The following sections provide additional details about Serverless Inference and how it works.

**Topics**

- Container support (p. 2536)
- Memory size (p. 2536)
- Concurrent invocations (p. 2537)
- Cold starts (p. 2537)
- Feature exclusions (p. 2537)

**Container support**

For your endpoint container, you can choose either a SageMaker-provided container or bring your own. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a list of available SageMaker images, see Available Deep Learning Containers Images. If you are bringing your own container, you must modify it to work with SageMaker. For more information about bringing your own container, see Adapting Your Own Inference Container (p. 2772).

For serverless endpoints, we recommend creating only one worker in the container and only loading one copy of the model. Note that this is unlike real-time endpoints, where some SageMaker containers may create a worker for each vCPU to process inference requests and load the model in each worker.

If you already have a container for a real-time endpoint, you can use the same container for your serverless endpoint, though some capabilities are excluded. To learn more about the container capabilities that are not supported in Serverless Inference, see Feature exclusions (p. 2537). If you choose to use the same container, SageMaker escrows (retains) a copy of your container image until you delete all endpoints that use the image. SageMaker encrypts the copied image at rest with a SageMaker-owned AWS KMS key.

**Memory size**

Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs. Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection.
for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Regardless of the memory size you choose, your serverless endpoint has 5 GB of ephemeral disk storage available. For help with container permissions issues when working with storage, see Troubleshooting (p. 2549).

**Concurrent invocations**

Serverless Inference manages predefined scaling policies and quotas for the capacity of your endpoint. Serverless endpoints have a quota for how many concurrent invocations can be processed at the same time. If the endpoint is invoked before it finishes processing the first request, then it handles the second request concurrently. You can set the maximum concurrency for a single endpoint up to 200, and the total number of serverless endpoint variants you can host in a Region is 50. The total concurrency you can share between all serverless endpoints per Region in your account is 200. The maximum concurrency for an individual endpoint prevents that endpoint from taking up all of the invocations allowed for your account, and any endpoint invocations beyond the maximum are throttled.

To learn how to set the maximum concurrency for your endpoint, see Create an endpoint configuration (p. 2542). For more information about quotas and limits, see Amazon SageMaker endpoints and quotas in the AWS General Reference. To request a service limit increase, contact AWS Support. For instructions on how to request a service limit increase, see Supported Regions and Quotas (p. 31).

**Cold starts**

If your endpoint does not receive traffic for a while and then your endpoint suddenly receives new requests, it can take some time for your endpoint to spin up the compute resources to process the requests. This is called a cold start. Since serverless endpoints provision compute resources on demand, your endpoint may experience cold starts. A cold start can also occur if your concurrent requests exceed the current concurrent request usage. The cold start time depends on your model size, how long it takes to download your model, and the start-up time of your container.

To monitor how long your cold start time is, you can use the Amazon CloudWatch metric ModelSetupTime to monitor your serverless endpoint. This metric tracks the time it takes to launch new compute resources for your endpoint. To learn more about using CloudWatch metrics with serverless endpoints, see Monitor a Serverless Endpoint (p. 2549).

**Feature exclusions**

Some of the features currently available for SageMaker Real-time Inference are not supported for Serverless Inference, including GPUs, AWS marketplace model packages, private Docker registries, Multi-Model Endpoints, KMS keys, VPC configuration, network isolation, data capture, multiple production variants, Model Monitor, and inference pipelines.

You cannot convert your instance-based, real-time endpoint to a serverless endpoint. If you try to update your real-time endpoint to serverless, you receive a ValidationError message. You can convert a serverless endpoint to real-time, but once you make the update, you cannot roll it back to serverless.

**Getting started**

You can create, update, describe, and delete a serverless endpoint using the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. You can invoke your endpoint using the AWS SDKs, the Amazon SageMaker Python SDK, and the AWS CLI. For more information about how to set up and use a serverless endpoint, read the guide Create, Invoke, Update, and Delete an Endpoint (p. 2538).
Example notebooks and blogs

For Jupyter notebook examples that show end-to-end serverless endpoint workflows, see the Serverless Inference example notebooks.

Create, Invoke, Update, and Delete an Endpoint

Unlike other SageMaker real-time endpoints, Serverless Inference manages compute resources and scaling policies for you, reducing complexity so you can focus on your ML model instead of on managing infrastructure. The following guide highlights the key capabilities of serverless endpoints: how to create, invoke, update, describe, or delete an endpoint. You can use the SageMaker console, the AWS SDKs, the Amazon SageMaker Python SDK, or the AWS CLI to manage your serverless endpoints.

Topics

• Prerequisites (p. 2538)
• Create a serverless endpoint (p. 2540)
• Invoke a serverless endpoint (p. 2547)
• Update a serverless endpoint (p. 2547)
• Describe a serverless endpoint (p. 2548)
• Delete a serverless endpoint (p. 2549)

Prerequisites

Before you can create a serverless endpoint, complete the following prerequisites.

1. **Set up an AWS account.** You first need an AWS account and an AWS Identity and Access Management administrator user. For instructions on how to set up an AWS account, see How do I create and activate a new AWS account?. For instructions on how to secure your account with an IAM administrator user, see Creating your first IAM admin user and user group in the IAM User Guide.
2. **Create an Amazon S3 bucket.** You use an Amazon S3 bucket to store your model artifacts. To learn how to create a bucket, see Create your first S3 bucket in the Amazon S3 User Guide.
3. **Upload your model artifacts to your S3 bucket.** For instructions on how to upload your model to your bucket, see Upload an object to your bucket in the Amazon S3 User Guide.
4. **Create an IAM role for Amazon SageMaker.** Amazon SageMaker needs access to the S3 bucket that stores your model. Create an IAM role with a policy that gives SageMaker read access to your bucket. The following procedure shows how to create a role in the console, but you can also use the CreateRole API from the IAM User Guide. For information on giving your role more granular permissions based on your use case, see SageMaker Roles (p. 3113).
   a. Sign in to the IAM console.
   b. In the navigation tab, choose Roles.
   c. Choose Create Role.
   d. For **Select type of trusted entity**, choose **AWS service** and then choose **SageMaker**.
   e. Choose **Next: Permissions** and then choose **Next: Tags**.
   f. (Optional) Add tags as key-value pairs if you want to have metadata for the role.
   g. Choose **Next: Review**.
   h. For **Role name**, enter a name for the new role that is unique within your AWS account. You cannot edit the role name after creating the role.
   i. (Optional) For **Role description**, enter a description for the new role.
   j. Choose **Create role**.
5. **Attach S3 bucket permissions to your SageMaker role.** After creating an IAM role, attach a policy that gives SageMaker permission to access the S3 bucket containing your model artifacts.

   a. In the IAM console navigation tab, choose **Roles**.
   b. From the list of roles, search for the role you created in the previous step by name.
   c. Choose your role, and then choose **Attach policies**.
   d. For **Attach permissions**, choose **Create policy**.
   e. In the **Create policy** view, select the **JSON** tab.
   f. Add the following policy statement into the JSON editor. Make sure to replace `<your-bucket-name>` with the name of the S3 bucket that stores your model artifacts. If you want to restrict the access to a specific folder or file in your bucket, you can also specify the Amazon S3 folder path, for example, `<your-bucket-name>/model-folder`.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "s3:GetObject",
         "Resource": "arn:aws:s3:::<your-bucket-name>/*"
       }
     ]
   }
   ```

   g. Choose **Next: Tags**.
   h. (Optional) Add tags in key-value pairs to the policy.
   i. Choose **Next: Review**.
   j. For **Name**, enter a name for the new policy.
   k. (Optional) Add a **Description** for the policy.
   l. Choose **Create policy**.
   m. After creating the policy, return to **Roles** in the IAM console and select your SageMaker role.
   n. Choose **Attach policies**.
   o. For **Attach permissions**, search for the policy you created by name. Select it and choose **Attach policy**.

6. **Select a prebuilt Docker container image or bring your own.** The container you choose serves inference on your endpoint. SageMaker provides containers for built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see [Available Deep Learning Containers Images](#).

   If none of the existing SageMaker containers meet your needs, you may need to create your own Docker container. For information about how to create your Docker image and make it compatible with SageMaker, see [Use Your Own Inference Code](#). To use your container with a serverless endpoint, the container image must reside in an Amazon ECR repository within the same AWS account that creates the endpoint.

7. (Optional) **Register your model with Model Registry.** SageMaker Model Registry ([p. 2592](#)) helps you catalog and manage versions of your models for use in ML pipelines. For more information about registering a version of your model, see [Create a Model Group](#) and [Register a Model Version](#). For an example of a Model Registry and Serverless Inference workflow, see the following example notebook.
Create a serverless endpoint

To create a serverless endpoint, you can use the Amazon SageMaker console, the APIs, or the AWS CLI. You can create a serverless endpoint using a similar process as a real-time endpoint (p. 2413).

Topics

- Create a model (p. 2540)
- Create an endpoint configuration (p. 2542)
- Create an endpoint (p. 2544)

Create a model

To create your model, you must provide the location of your model artifacts and container image. You can also use a model version from SageMaker Model Registry (p. 2592). The examples in the following sections show you how to create a model using the CreateModel API, Model Registry, and the Amazon SageMaker console.

To create a model (using Model Registry)

Model Registry (p. 2592) is a feature of SageMaker that helps you catalog and manage versions of your model for use in ML pipelines. To use Model Registry with Serverless Inference, you must first register a model version in a Model Registry model group. To learn how to register a model in Model Registry, follow the procedures in Create a Model Group (p. 2593) and Register a Model Version (p. 2597).

The following example requires you to have the ARN of a registered model version and uses the AWS SDK for Python (Boto3) to call the CreateModel API. For Serverless Inference, Model Registry is currently only supported by the AWS SDK for Python (Boto3). For the example, specify the following values:

- For model_name, enter a name for the model.
- For sagemaker_role, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2538) section.
- For ModelPackageName, specify the ARN for your model version, which must be registered to a model group in Model Registry.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Specify a name for the model
model_name = "<name-for-model>"

#Specify a Model Registry model version
container_list = [
    {'ModelPackageName': <model-version-arn>}
]

#Create the model
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
```

---

2540
To create a model (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateModel API. Specify the following values:

- For sagemaker_role, you can use the default SageMaker-created role or a customized SageMaker IAM role from Step 4 of the Prerequisites (p. 2538) section.
- For model_url, specify the Amazon S3 URI to your model.
- For container, retrieve the container you want to use by its Amazon ECR path. This example uses a SageMaker-provided XGBoost container. If you have not selected a SageMaker container or brought your own, see Step 6 of the Prerequisites (p. 2538) section for more information.
- For model_name, enter a name for the model.

```python
#Setup
import boto3
import sagemaker
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker permission to access AWS services.
sagemaker_role = sagemaker.get_execution_role()

#Get model from S3
model_url = "s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz"

#Get container image (prebuilt example)
from sagemaker import image_uris
container = image_uris.retrieve("xgboost", region, "0.90-1")

#Create model
model_name = "<name-for-model>"
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = [{
        "Image": container,
        "Mode": "SingleModel",
        "ModelDataUrl": model_url,
    }]
)
```

To create a model (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Models.
4. Choose Create model.
5. For Model name, enter a name for the model that is unique to your account and AWS Region.
6. For IAM role, either select an IAM role you have already created (see Prerequisites (p. 2538)) or allow SageMaker to create one for you.
7. In Container definition 1, for Container input options, select Provide model artifacts and input location.
8. For **Provide model artifacts and inference image options**, select **Use a single model**.
9. For **Location of inference code image**, enter an Amazon ECR path to a container. The image must either be a SageMaker-provided first party image (e.g. TensorFlow, XGBoost) or an image that resides in an Amazon ECR repository within the same account in which you are creating the endpoint. If you do not have a container, go back to Step 6 of the Prerequisites (p. 2538) section for more information.
10. For **Location of model artifacts**, enter the Amazon S3 URI to your ML model. For example, `s3://DOC-EXAMPLE-BUCKET/models/model.tar.gz`.
11. (Optional) For **Tags**, add key-value pairs to create metadata for your model.
12. Choose **Create model**.

### Create an endpoint configuration

After you create a model, create an endpoint configuration. You can then deploy your model using the specifications in your endpoint configuration. In the configuration, you specify whether you want a real-time or serverless endpoint. To create a serverless endpoint configuration, you can use the Amazon SageMaker console, the CreateEndpointConfig API, or the AWS CLI. The API and console approaches are outlined in the following sections.

#### To create an endpoint configuration (using API)

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpointConfig API. Specify the following values:

- For **EndpointConfigName**, choose a name for the endpoint configuration. The name should be unique within your account in a Region.
- For **ModelName**, use the name of the model you want to deploy. It should be the same model that you used in the Create a model (p. 2540) step.
- For **ServerlessConfig**:
  - Set **MemorySizeInMB** to 2048. For this example, we set the memory size to 2048 MB, but you can choose any of the following values for your memory size: 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB.
  - Set **MaxConcurrency** to 20. For this example, we set the maximum concurrency to 20. The maximum number of concurrent invocations you can set for a serverless endpoint is 200, and the minimum value you can choose is 1.

```python
response = client.create_endpoint_config(
    EndpointConfigName="<your-endpoint-configuration>",
    ProductionVariants=[
        {
            "ModelName": "<your-model-name>",
            "VariantName": "AllTraffic",
            "ServerlessConfig": {
                "MemorySizeInMB": 2048,
                "MaxConcurrency": 20
            }
        }
    ]
)
```

#### To create an endpoint configuration (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoint configurations**.
4. Choose **Create endpoint configuration**.
5. For **Endpoint configuration name**, enter a name that is unique within your account in a Region.
6. For **Type of endpoint**, select **Serverless**.

7. For **Production variants**, choose **Add model**.
8. Under **Add model**, select the model you want to use from the list of models and then choose **Save**.
9. After adding your model, under **Actions**, choose **Edit**.
10. For **Memory size**, choose the memory size you want in GB.
11. For **Max Concurrency**, enter your desired maximum concurrent invocations for the endpoint. The maximum value you can enter is 200 and the minimum is 1.

12. Choose **Save**.

13. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint configuration.

14. Choose **Create endpoint configuration**.

### Create an endpoint

To create a serverless endpoint, you can use the Amazon SageMaker console, the CreateEndpoint API, or the AWS CLI. The API and console approaches are outlined in the following sections. Once you create your endpoint, it can take a few minutes for the endpoint to become available.

**To create an endpoint (using API)**

The following example uses the AWS SDK for Python (Boto3) to call the CreateEndpoint API. Specify the following values:

- For **EndpointName**, enter a name for the endpoint that is unique within a Region in your account.
- For **EndpointConfigName**, use the name of the endpoint configuration that you created in the previous section.

```python
response = client.create_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-endpoint-config>"
)"
To create an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. Choose **Create endpoint**.
5. For **Endpoint name**, enter a name that is unique within a Region in your account.
6. For **Attach endpoint configuration**, select **Use an existing endpoint configuration**.
7. For **Endpoint configuration**, select the name of the endpoint configuration you created in the previous section and then choose **Select endpoint configuration**.
8. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint.
9. Choose **Create endpoint**.
Create and configure endpoint

To deploy models to Amazon SageMaker, first create an endpoint. Provide an endpoint configuration to specify which models to deploy and the hardware requirements for each. See Deploying a Model on Amazon SageMaker Hosting Services. Learn more about the API.

Endpoint

Endpoint name
Your application uses this name to access this endpoint.
example-endpoint
Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an AWS Region.

Attach endpoint configuration

○ Use an existing endpoint configuration
Use an existing endpoint configuration or clone an endpoint configuration.
○ Create a new endpoint configuration
Add models and configure the instance and initial weight for each model.

New endpoint configuration

Add tag

Cancel Create endpoint
Invoke a serverless endpoint

In order to perform inference using a serverless endpoint, you must send an HTTP request to the endpoint. You can use the `InvokeEndpoint` API or the AWS CLI, which make a POST request to invoke your endpoint. The maximum request and response payload size for serverless invocations is 4 MB. Note that a cold start (or a delay in spinning up compute resources) on the endpoint may delay the response time to up to 4 minutes:

- The model must download and the server must respond successfully to `/ping` within 3 minutes.
- The timeout for the container to respond to inference requests to `/invocations` is 1 minute.

For more information on cold starts for serverless endpoints, see Cold starts (p. 2537).

To invoke an endpoint

The following example uses the AWS SDK for Python (Boto3) to call the `InvokeEndpoint` API. Note that unlike the other API calls in this guide, for `InvokeEndpoint`, you must use SageMaker Runtime as the client. Specify the following values:

- For `endpoint_name`, use the name of the in-service serverless endpoint you want to invoke.
- For `content_type`, specify the MIME type of your input data in the request body (for example, `application/json`).
- For `payload`, use your request payload for inference. Your payload should be in bytes or a file-like object.

```python
runtime = boto3.client("sagemaker-runtime")
endpoint_name = "<your-endpoint-name>"
content_type = "<request-mime-type>"
payload = "<your-request-body>"
response = client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType=content_type,
    Body=payload
)
```

Update a serverless endpoint

Before updating your endpoint, create a new endpoint configuration or use an existing endpoint configuration. The endpoint configuration is where you specify the changes for your update. Then, you can update your endpoint with the SageMaker console, the `UpdateEndpoint` API, or the AWS CLI. The process for updating a serverless endpoint is the same as the process for updating a real-time endpoint (p. 2413). Note that when updating your endpoint, you can experience cold starts when making requests to the endpoint because SageMaker must re-initialize your container and model.

Create a new endpoint configuration

To create a new serverless endpoint configuration, see the previous procedure in Create an endpoint configuration (p. 2542). You can also create a real-time endpoint configuration to switch from serverless to instance-based capacity.

Update the endpoint

Examples of how to update your endpoint using the `UpdateEndpoint` API and the SageMaker console are outlined in the following sections.
To update the endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the UpdateEndpoint API. Specify the following values:

- For EndpointName, use the name of the endpoint you're updating.
- For EndpointConfigName, use the name of the endpoint configuration that you want to use for the update.

```python
def update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<new-endpoint-config>",
)
```

To update the endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to update.
5. Choose Update endpoint.
6. For Change the Endpoint configuration, choose Use an existing endpoint configuration.
7. From the list of endpoint configurations, select the one you want to use for your update.
8. Choose Select endpoint configuration.
9. Choose Update endpoint.

Describe a serverless endpoint

You might want to retrieve information about your endpoint, including details such as the endpoint's ARN, current status, deployment configuration, and failure reasons. You can find information about your endpoint using the SageMaker console, the DescribeEndpoint API, or the AWS CLI.

To describe an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the DescribeEndpoint API. For EndpointName, use the name of the endpoint you want to check.

```python
def describe_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To describe an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, choose the endpoint you want to check.

The endpoint page contains the information about your endpoint.
Delete a serverless endpoint

You can delete your serverless endpoint using the SageMaker console, the DeleteEndpoint API, or the AWS CLI. The following examples show you how to delete your endpoint through the API and the SageMaker console.

To delete an endpoint (using API)

The following example uses the AWS SDK for Python (Boto3) to call the DeleteEndpoint API. For EndpointName, use the name of the serverless endpoint you want to delete.

```python
response = client.delete_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To delete an endpoint (using the console)

1. Sign in to the Amazon SageMaker console.
2. In the navigation tab, choose Inference.
3. Next, choose Endpoints.
4. From the list of endpoints, select the endpoint you want to delete.
5. Choose the Actions drop-down list, and then choose Delete.
6. When prompted again, choose Delete.

Your endpoint should now begin the deletion process.

Monitor a Serverless Endpoint

To monitor your serverless endpoint, you can use Amazon CloudWatch alarms. CloudWatch is a service that collects metrics in real time from your AWS applications and resources. An alarm watches metrics as they are collected and gives you the ability to pre-specify a threshold and the actions to take if that threshold is breached. For example, your CloudWatch alarm can send you a notification if your endpoint breaches an error threshold. By setting up CloudWatch alarms, you gain visibility into the performance and functionality of your endpoint.

To learn more about CloudWatch metrics you can use to monitor your endpoints in SageMaker, see SageMaker Endpoint Invocation Metrics (p. 3191). The ModelSetupTime metric tracks the cold start time for your endpoint, or the time it takes to launch new compute resources for your serverless endpoint. This metric depends on your model size and the container's start-up time. Serverless endpoints can also use the Invocations4XXErrors, Invocations5XXErrors, and Invocations metrics in the AWS/SageMaker namespace. In the aws/sagemaker/Endpoints namespace, they can use the MemoryUtilization metric. For more information about CloudWatch alarms, see Using Amazon CloudWatch User Guide.

If you want to monitor the logs from your endpoint for debugging or progress analysis, you can use Amazon CloudWatch Logs. The SageMaker-provided log group that you can use for serverless endpoints is /aws/sagemaker/Endpoints/[EndpointName]. For more information about using CloudWatch Logs in SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201). To learn more about CloudWatch Logs, see What is Amazon CloudWatch Logs? in the Amazon CloudWatch Logs User Guide.

Troubleshooting

If you are having trouble with Serverless Inference, refer to the following troubleshooting tips.
Container issues

If the container you use for a serverless endpoint is the same one you used on an instance-based endpoint, your container may not have permissions to write files. This can happen for the following reasons:

- Your serverless endpoint fails to create or update due to a ping health check failure.
- The Amazon CloudWatch logs for the endpoint show that the container is failing to write to some file or directory due to a permissions error.

To fix this issue, you can try to add read, write, and execute permissions for `other` on the file or directory and then rebuild the container. You can perform the following steps to complete this process:

1. In the Dockerfile you used to build your container, add the following command:
   ```bash
   RUN chmod o+rwX <file or directory name>
   ```
2. Rebuild the container.
3. Upload the new container image to Amazon ECR.
4. Try to create or update the serverless endpoint again.

Asynchronous inference

Amazon SageMaker Asynchronous Inference is a new capability in SageMaker that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to 15 minutes), and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker models and only need to specify the `AsyncInferenceConfig` object while creating your endpoint configuration with the `EndpointConfig` field in the `CreateEndpointConfig` API. The following diagram shows the architecture and workflow of Asynchronous Inference.
To invoke the endpoint, you need to place the request payload in Amazon S3 and provide a pointer to this payload as a part of the `InvokeEndpointAsync` request. Upon invocation, SageMaker queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check prediction results (p. 2562).

**Note**
The presence of an asynchronous inference configuration (`AsyncInferenceConfig`) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

**How Do I Get Started?**

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Create, invoke, and update an Asynchronous Endpoint (p. 2551) for information on how to create, invoke, update, and delete an asynchronous endpoint.
- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Note that if your endpoint uses any of the features listed in this Exclusions (p. 2590) page, you cannot use Asynchronous Inference.

**Create, invoke, and update an Asynchronous Endpoint**

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with the AWS SDKs and the Amazon SageMaker Python SDK.

**Topics**

- Prerequisites (p. 2552)
Create, invoke, and update an Asynchronous Endpoint

- Create an Asynchronous Inference Endpoint (p. 2554)
- Invoke an Asynchronous Endpoint (p. 2557)
- Update an Asynchronous Endpoint (p. 2558)
- Delete an Asynchronous Endpoint (p. 2558)

**Prerequisites**

To use asynchronous endpoints, first make sure you have met these prerequisites.

1. **Create an IAM role for Amazon SageMaker.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3 and Amazon SNS. Using this role, SageMaker can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
   
   b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
   
   c. For **Select type of trusted entity**, choose **AWS service**.
   
   d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker**. Then choose **Next: Permissions**.

      - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.
   
   e. Choose **Next: Tags**.
   
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#).
   
   g. Choose **Next: Review**.
   
   h. Type in a **Role name**.
   
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both **PRODROLE** and **prodrole**. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
   
   j. (Optional) For **Role description**, type a description for the new role.
   
   k. Review the role and then choose **Create role**.

   Note the SageMaker role ARN. To find the role ARN using the console, do the following:

   i. Go to the IAM console: [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/)
   
   ii. Select **Roles**.
   
   iii. Search for the role you just created by typing in the name of the role in the search field.
   
   iv. Select the role.
   
   v. The role ARN is at the top of the **Summary** page.

2. **Add Amazon SageMaker, Amazon S3 and Amazon SNS Permissions to your IAM Role.**

   Once the role is created, grant SageMaker, Amazon S3, and optionally Amazon SNS permissions to your IAM role.
Choose Roles in the IAM console. Search for the role you created by typing in your role name in the Search field.

a. Choose your role.

b. Next, choose Attach Policies.

c. Amazon SageMaker Asynchronous Inference needs permission to perform the following actions: "sagemaker:CreateModel", "sagemaker:CreateEndpointConfig", "sagemaker:CreateEndpoint", and "sagemaker:InvokeEndpointAsync".

These actions are included in the AmazonSageMakerFullAccess policy. Add this policy to your IAM role. Search for AmazonSageMakerFullAccess in the Search field. Select AmazonSageMakerFullAccess.

d. Choose Attach policy.

e. Next, choose Attach Policies to add Amazon S3 permissions.

f. Select Create policy.

g. Select the JSON tab.

h. Add the following policy statement:

```
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Action": [
         "s3:GetObject",
         "s3:PutObject",
         "s3:AbortMultipartUpload",
         "s3:ListBucket"
       ],
       "Effect": "Allow",
       "Resource": "arn:aws:s3:::bucket_name/*"
     }
   ]
}
```

i. Choose Next: Tags.

j. Type in a Policy name.

k. Choose Create policy.

l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

```
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Action": [
         "sns:Publish"
       ],
       "Effect": "Allow",
     }
   ]
}
```

3. Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

4. Select a prebuilt Docker inference image or create your own Inference Docker Image.
SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images.

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See Use Your Own Inference Code (p. 2782) for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an EndpointConfig object when you specify AsyncInferenceConfig using the EndpointConfig API.

Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

b. Subscribe to the topic. For instructions, see Subscribing to an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your AWS account, and it has a unique ARN. The ARN is in the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

For more information about Amazon SNS, see the Amazon SNS Developer Guide.

**Create an Asynchronous Inference Endpoint**

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker hosting services:

- Create a model in SageMaker with CreateModel.
- Create an endpoint configuration with CreateEndpointConfig.
- Create an HTTPS endpoint with CreateEndpoint.

To create an endpoint, you first create a model with CreateModel, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using CreateEndpointConfig where you specify one or more models that were created using the CreateModel API to deploy and the resources that you want SageMaker to provision. Create your endpoint with CreateEndpoint using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the UpdateEndpoint API. Send and receive inference requests from the model hosted at the endpoint with InvokeEndpointAsync. You can delete your endpoints with the DeleteEndpoint API.

For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Use Your Own Inference Code (p. 2782) for information on how to create your Docker image.
Create a Model

The following example shows how to create a model using the AWS SDK for Python (Boto3). The first few lines define:

- `sagemaker_client`: A low-level SageMaker client object that makes it easy to send and receive requests to AWS services.
- `sagemaker_role`: A string variable with the SageMaker IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your AWS region.

```python
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<account>:role/*"
```

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named `demo-xgboost-model.tar.gz`. The full Amazon S3 URI is stored in a string variable `model_url`:

```python
#Create a variable w/ the model S3 URI
s3_bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
bucket_prefix='saved_models'
model_s3_key = f"{bucket_prefix}/demo-xgboost-model.tar.gz"

#Specify S3 bucket w/ model
model_url = f"s3://{s3_bucket}/{model_s3_key}"
```

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

```python
from sagemaker import image_uris

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework='xgboost', version='0.90-1')
```

Create a model in Amazon SageMaker with `CreateModel`. Specify the following:

- **ModelName**: A name for your model (in this example it is stored as a string variable called `model_name`).
- **ExecutionRoleArn**: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- **PrimaryContainer**: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

```python
model_name = '<The_name_of_the_model>'
```
Create_model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })

Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with CreateEndpointConfig. Amazon SageMaker hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with CreateModel, to deploy the resources that you want Amazon SageMaker to provision. Specify the AsyncInferenceConfig object and provide an output Amazon S3 location for OutputConfig. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

The following example shows how to create an endpoint configuration using AWS SDK for Python (Boto3):

```python
import datetime
from time import gmtime, strftime

# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S', gmtime())}""  

# The name of the model that you want to host. This is the name that you specified when creating the model.
model_name='<The_name_of_your_model>'

create_endpoint_config_response = sagemaker_client.create_endpoint_config(  
    EndpointConfigName=endpoint_config_name, # You will specify this name in a CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at this endpoint.
    ProductionVariants=[  
        {  
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }  
    ],
    AsyncInferenceConfig={  
        "OutputConfig": {  
            # Location to upload response outputs when no location is provided in the request.
            "S3OutputPath": f"s3://{s3_bucket}/{bucket_prefix}/output"  
        },  
        "ClientConfig": {  
            # (Optional) Specify the max number of inflight invocations per instance
```
Create, invoke, and update an Asynchronous Endpoint

In the aforementioned example, you specify the following keys for `OutputConfig` for the `AsyncInferenceConfig` field:

- **S3OutputPath**: Location to upload response outputs when no location is provided in the request.
- **NotificationConfig**: (Optional) SNS topics that post notifications to you when an inference request is successful (`SuccessTopic`) or if it fails (`ErrorTopic`).

You can also specify the following optional argument for `ClientConfig` in the `AsyncInferenceConfig` field:

- **MaxConcurrentInvocationsPerInstance**: (Optional) The maximum number of concurrent requests sent by the SageMaker client to the model container.

### Create Endpoint

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an AWS Region in your AWS account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker uses the endpoint to provision resources and deploy models.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
```

When you call the `CreateEndpoint` API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. This lets SageMaker check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```json
{
    "eventVersion":"1.0",
    "eventSource":"aws:sagemaker",
    "eventName":"TestNotification"
}
```

### Invoke an Asynchronous Endpoint

Get inferences from the model hosted at your asynchronous endpoint with `InvokeEndpointAsync`. 
Note
If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

Specify the location of your inference data in the `InputLocation` field and the name of your endpoint for `EndpointName`:

```python
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker hosting
# services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName=endpoint_name,
    InputLocation=input_location)
```

You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

**Update an Asynchronous Endpoint**

Update an asynchronous endpoint with the `UpdateEndpoint` API. When you update an endpoint, SageMaker first provisions and switches to the new endpoint configuration you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an `EndpointConfig` with an endpoint that is live or while the `UpdateEndpoint` or `CreateEndpoint` operations are being performed on the endpoint.

```python
# The name of the endpoint. The name must be unique within an AWS Region in your AWS account.
endpoint_name='<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

sagemaker_client.update_endpoint(
    EndpointConfigName=endpoint_config_name,
    EndpointName=endpoint_name
)
```

When Amazon SageMaker receives the request, it sets the endpoint status to **Updating**. After updating the asynchronous endpoint, it sets the status to **InService**. To check the status of an endpoint, use the `DescribeEndpoint` API. For a full list of parameters you can specify when updating an endpoint, see the `UpdateEndpoint` API.

**Delete an Asynchronous Endpoint**

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker hosted endpoint with the `DeleteEndpoint` API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker frees up all of the resources that were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.
Delete your SageMaker model with the `DeleteModel` API or with the SageMaker console.

**Boto3**

```python
import boto3

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name='<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>'))
```

**SageMaker console**

2. Expand the **Inference** dropdown list.
3. Select **Endpoints**.
4. Search for endpoint in the **Search endpoints** search bar.
5. Select your endpoint.
6. Choose **Delete**.

In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker model, and the asynchronous endpoint configuration itself.

## Monitor asynchronous endpoint

You can monitor SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see What is Amazon CloudWatch?

### Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- OverheadLatency
- Invocations
- InvocationsPerInstance

### Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see Monitor SageMaker with Amazon CloudWatch.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.</td>
<td>Units: None Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
Asynchronous Inference Endpoint Metrics

These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the `EndpointName` dimension:

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApproximateBacklogSize</td>
<td>The number of items in the queue for an endpoint that are currently being processed or yet to be processed.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateBacklogSizePerInstance</td>
<td>Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
<tr>
<td>ApproximateAgeOfOldestRequest</td>
<td>Age of the oldest request in the queue.</td>
<td>Units: Seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Max, Min</td>
</tr>
</tbody>
</table>

The following metrics are published with the `EndpointName` and `VariantName` dimensions:

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Unit/Stats</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestDownloadFailures</td>
<td>When an inference failure occurs due to an issue downloading the request from Amazon S3.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>ResponseUploadFailures</td>
<td>When an inference failure occurs due to an issue uploading the response to Amazon S3.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Description</td>
<td>Unit/Stats</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>NotificationFailures</td>
<td>When an issue occurs publishing notifications.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>RequestDownloadLatency</td>
<td>Total time to download the request payload.</td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Min, Max, Sample Count</td>
</tr>
<tr>
<td>ResponseUploadLatency</td>
<td>Total time to upload the response payload.</td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Average, Sum,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Min, Max, Sample Count</td>
</tr>
<tr>
<td>ExpiredRequests</td>
<td>Number of requests in the queue that fail due to reaching their specified</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>request TTL.</td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationFailures</td>
<td>If an invocation fails for any reason.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationsProcessed</td>
<td>Number of async invocations processed by the endpoint.</td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid statistics: Sum</td>
</tr>
<tr>
<td>TimeInBacklog</td>
<td>Total time the request was queued before being processed. This does not</td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>include the actual processing time (i.e. downloading time, uploading time,</td>
<td>Valid statistics: Average, Sum,</td>
</tr>
<tr>
<td></td>
<td>model latency).</td>
<td>Min, Max, Sample Count</td>
</tr>
<tr>
<td>TotalProcessingTime</td>
<td>Time the inference request was received by SageMaker to the time the</td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>request finished processing. This includes time in backlog and time to</td>
<td>Valid statistics: Average, Sum,</td>
</tr>
<tr>
<td></td>
<td>upload and send response notifications, if any.</td>
<td>Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see SageMaker Jobs and Endpoint Metrics.

**Logs**

In addition to the Model container logs that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

/aws/sagemaker/Endpoints/[EndpointName]

The log stream name consists of:

[production-variant-name]/[instance-id]/data-log.
Log lines contain the request's inference ID so that errors can be easily mapped to a particular request.

**Check prediction results**

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.

**Amazon SNS Topics**

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

**Note**

In order to receive Amazon SNS notifications, your IAM role must have `sns:Publish` permissions. See the Prerequisites (p. 2552) for information on requirements you must satisfy to use Asynchronous Inference.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the `AsyncInferenceConfig` field when you create an endpoint configuration with `CreateEndpointConfig`. You can specify both an Amazon SNS `ErrorTopic` and an `SuccessTopic`.

```python
import boto3
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.create_endpoint_config(
    EndpointConfigName=<endpoint_config_name>, # You specify this name in a CreateEndpoint request.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": "model_name",
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            "S3OutputPath": "s3://<bucket>/<output_directory>" # Location to upload response outputs when no location is provided in the request.
        },
        "NotificationConfig": {
        }
    }
)
```
After creating your endpoint and invoking it, you receive a notification from your Amazon SNS topic. For example, if you subscribed to receive email notifications from your topic, you receive an email notification every time you invoke your endpoint. The following example shows the JSON content of a successful invocation email notification.

```json
{
  "awsRegion":"us-east-1",
  "eventTime":"2022-01-25T22:46:00.608Z",
  "receivedTime":"2022-01-25T22:46:00.455Z",
  "invocationStatus":"Completed",
  "requestParameters":{
    "contentType":"text/csv",
    "endpointName":"<example-endpoint>",
    "inputLocation":"s3://<bucket>/<input-directory>/input-data.csv"
  },
  "responseParameters":{
    "contentType":"text/csv; charset=utf-8",
    "outputLocation":"s3://<bucket>/<output_directory>/prediction.out"
  },
  "inferenceId":"11111111-2222-3333-4444-555555555555",
  "eventVersion":"1.0",
  "eventSource":"aws:sagemaker",
  "eventName":"InferenceResult"
}
```

Check Your S3 Bucket

When you invoke an endpoint with `InvokeEndpointAsync`, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker session class to programmatically check for an output.

The following stores the output dictionary of `InvokeEndpointAsync` as a variable named `response`. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called `output_location`.

```python
import uuid
import boto3

sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
    ContentType="text/libsvm"  # Specify the content type of your data
)

output_location = response['OutputLocation']
print(f"OutputLocation: {output_location}")
```

For information about supported content types, see Common Data Formats for Inference (p. 1788).

With the Amazon S3 output location, you can then use a SageMaker Python SDK SageMaker Session Class to read in Amazon S3 files. The following code example shows how to create a function (get_output) that repeatedly attempts to read a file from the Amazon S3 output location:
import sagemaker
import urllib, time
from botocore.exceptions import ClientError
sagemaker_session = sagemaker.session.Session()

def get_output(output_location):
    output_url = urllib.parse.urlparse(output_location)
    bucket = output_url.netloc
    key = output_url.path[1:]
    while True:
        try:
            return sagemaker_session.read_s3_file(
                bucket=bucket,
                key=key,
            )
        except ClientError as e:
            if e.response['Error']['Code'] == 'NoSuchKey':
                print("waiting for output...")
                time.sleep(2)
                continue
            raise

output = get_output(output_location)
print(f"Output: {output}"

---

### Autoscale an asynchronous endpoint

Amazon SageMaker supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already created a SageMaker model deployment. Deployed models are referred to as a production variant. See [Deploy the Model to SageMaker Hosting Services](https://docs.aws.amazon.com/sagemaker/latest/dg/deploy-model-howto.html) for more information about deploying a model endpoint. To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. For information on how to define a scaling policy, see [Define a scaling policy](https://docs.aws.amazon.com/sagemaker/latest/dg/define-scaling-policy.html). After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see [Apply a scaling policy](https://docs.aws.amazon.com/sagemaker/latest/dg/apply-scaling-policy.html).

For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker autoscaling documentation.

### Define a Scaling Policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see [TargetTrackingScalingPolicyConfiguration](https://docs.aws.amazon.com/autoscaling/application/reference/policy-configuration-target-tracking-scaling-policy.html) in the Application Auto Scaling API Reference.
For asynchronous endpoints SageMaker strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, CustomizedMetricSpecification, called ApproximateBacklogSizePerInstance.

```python
TargetTrackingScalingPolicyConfiguration={
    'TargetValue': 5.0, # The target value for the metric. Here the metric is:
    'SageMakerVariantInvocationsPerInstance': {
        'CustomizedMetricSpecification': {
            'MetricName': 'ApproximateBacklogSizePerInstance',
            'Namespace': 'AWS/SageMaker',
            'Dimensions': [
                {'Name': 'EndpointName', 'Value': '<endpoint_name>'}
            ],
            'Statistic': 'Average',
        }
    }
}
```

**Define a Scaling Policy that Scales to 0**

The following shows you how to both define and register your endpoint variant with application autoscaling using the AWS SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the `RegisterScalableTarget` method to register the production variant. We set `MinCapacity` to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```python
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + '<endpoint_name>' + '/variant/' + '<variant1>'

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.

**Use Batch Transform**

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.
To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records (p. 2568). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

**Topics**

- Use Batch Transform to Get Inferences from Large Datasets (p. 2566)
- Speed up a Batch Transform Job (p. 2567)
- Use Batch Transform to Test Production Variants (p. 2567)
- Batch Transform Errors (p. 2567)
- Batch Transform Sample Notebooks (p. 2568)
- Associate Prediction Results with Input Records (p. 2568)
- Storage in Batch Transform (p. 2574)

**Use Batch Transform to Get Inferences from Large Datasets**

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following example.

```
Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
... 
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM
```

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiples files, one instance might process input1.csv, and another instance might process the file named input2.csv. If you have one input file but initialize multiple compute instances, only one instance processes the input file and the rest of the instances are idle.

You can also split input files into mini-batches. For example, you might create a mini-batch from input1.csv by including only two of the records.

```
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM
```

**Note**

SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the MaxPayloadInMB limit.

To split input files into mini-batches when you create a batch transform job, set the `SplitType` parameter value to `Line`. If `SplitType` is set to `None` or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request. Note that Batch Transform doesn't support CSV-formatted input that contains embedded newline characters. You can control the size of the mini-batches by using the `BatchStrategy` and `MaxPayloadInMB` parameters. `MaxPayloadInMB` must not be greater than 100 MB. If you specify the optional `MaxConcurrentTransforms` parameter, then the value of `(MaxConcurrentTransforms * MaxPayloadInMB)` must also not exceed 100 MB.
If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as input1.csv and input2.csv, the output files are named input1.csv.out and input2.csv.out. The batch transform job stores the output files in the specified location in Amazon S3, such as s3://awsexamplebucket/output/.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file input1.csv.out, based on the input file shown earlier, would look like the following.

Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM

To combine the results of multiple output files into a single output file, set the AssembleWith parameter to Line.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set MaxPayloadInMB to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the CreateTransformJob API. For more information about the correlation between batch transform input and output objects, see OutputDataConfig. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform (p. 91).

Speed up a Batch Transform Job

If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. The ideal value for MaxConcurrentTransforms is equal to the number of compute workers in the batch transform job. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Use Batch Transform to Test Production Variants

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 2453).

Batch Transform Errors

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid
incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as failed. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

Exceeding the MaxPayloadInMB limit causes an error. This might happen with a large dataset if it can't be split, the SplitType parameter is set to none, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as ERROR, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

Batch Transform Sample Notebooks

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see Batch Transform with PCA and DBSCAN Movie Clusters. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the Advanced functionality section. To open a notebook, choose its Use tab, then choose Create copy.

Associate Prediction Results with Input Records

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

Topics
- Workflow for Associating Inferences with Input Records (p. 2568)
- Use Data Processing in Batch Transform Jobs (p. 2569)
- Supported JSONPath Operators (p. 2570)
- Batch Transform Examples (p. 2571)

Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the InputFilter parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the JoinSource parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use OutputFilter to store the specified portion of the joined dataset in the output file.

Use Data Processing in Batch Transform Jobs

When creating a batch transform job with CreateTransformJob to process data:

1. Specify the portion of the input to pass to the model with the InputFilter parameter in the DataProcessing data structure.
2. Join the raw input data with the transformed data with the JoinSource parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the OutputFilter parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the SageMakerOutput attribute to the input file or creates a new JSON output file with the SageMakerInput and SageMakerOutput attributes. For more information, see DataProcessing.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the DataProcessing structure, it must support your chosen format for both input and output files. For example, with the TransformOutput field of the
CreateTransformJob API, you must set both the ContentType and Accept parameters to one of the following values: text/csv, application/json, or application/jsonlines. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 2571). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 982).

The record delimiters for the input and output must also be consistent with your chosen file input. The SplitType parameter indicates how to split the records in the input dataset. The AssembleWith parameter indicates how to reassemble the records for the output. If you set input and output formats to text/csv, you must also set the SplitType and AssembleWith parameters to line. If you set the input and output formats to application/jsonlines, you can set both SplitType and AssembleWith to line.

For CSV files, you cannot use embedded newline characters. For JSON files, the attribute name SageMakerOutput is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

### Supported JSONPath Operators

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. `[0],[1:]`. CSV data should also follow RFC format.

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td><a href=",'%3Cname%3E'">'&lt;name&gt;'</a></td>
<td>A bracket-notated element or multiple child elements.</td>
<td>['$[id]', 'SageMakerOutput']</td>
</tr>
<tr>
<td><a href=",,%3Cnumber%3E">&lt;number&gt;</a></td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1], $[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5], $[:5], $[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $\.field1.['child1','child2'] is supported while $\.field1.['child1','child2.grandchild'] is not.

For more information about JSONPath operators, see JsonPath on GitHub.
Amazon SageMaker Developer Guide
Associate Prediction Results with Input

Batch Transform Examples
The following examples show some common ways to join input data with prediction results.
Topics
• Example: Output Only Inferences (p. 2571)
• Example: Output Inferences Joined with Input Data (p. 2571)
• Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input
(CSV) (p. 2572)
• Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input
(CSV) (p. 2573)

Example: Output Only Inferences
By default, the DataProcessing parameter doesn't join inference results with input. It outputs only the
inference results.
If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK
and specify the following settings in a transformer call.
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")

To output inferences using the AWS SDK for Python, add the following code to your CreateTransformJob
request. The following code mimics the default behavior.
{

}

"DataProcessing": {
"InputFilter": "$",
"JoinSource": "None",
"OutputFilter": "$"
}

Example: Output Inferences Joined with Input Data
If you're using the Amazon SageMaker Python SDK to combine the input data with the inferences in
the output ﬁle, specify the assemble_with and accept parameters when initializing the transformer
object. When you use the transform call, specify Input for the join_source parameter, and specify the
split_type and content_type parameters as well. The split_type parameter must have the same
value as assemble_with, and the content_type parameter must have the same value as accept.
For more information about the parameters and their accepted values, see the Transformer page in the
Amazon SageMaker Python SDK.
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/
csv")
sm_transformer.transform(…, join_source="Input", split_type="Line", content_type="text/
csv")

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the
following code to your CreateTransformJob request. The values for Accept and ContentType must
match, and the values for AssembleWith and SplitType must also match.
{

"DataProcessing": {

2571


"JoinSource": "Input"
},
"TransformOutput": {
  "Accept": "text/csv",
  "AssembleWith": "Line"
},
"TransformInput": {
  "ContentType": "text/csv",
  "SplitType": "Line"
}
}

For JSON or JSON Lines input files, the results are in the SageMakerOutput key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair {"key":1}, the data transform result might be {"label":1}.

SageMaker stores both in the input file in the SageMakerInput key.

```
{
  "key":1,
  "SageMakerOutput":{"label":1}
}
```

**Note**
The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the SageMakerInput key and the results are stored as the SageMakerOutput value.

For a CSV file, for example, if the record is [1,2,3], and the label result is [1], then the output file would contain [1,2,3,1].

**Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK to join your input data with the inference output while excluding an ID column from the transformer input, specify the same parameters from the preceding example as well as a JSONPath subexpression for the input_filter in your transformer call. For example, if your input data includes five columns and the first one is the ID column, use the following transform request to select all columns except the ID column as features. The transformer still outputs all of the input columns joined with the inferences. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(..., assemble_with="Line", accept="text/csv")
sm_transformer.transform(..., split_type="Line", content_type="text/csv",
  input_filter="$[1:]", join_source="Input")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your `CreateTransformJob` request.

```
{
  "DataProcessing": {
    "InputFilter": "$[1:]",
    "JoinSource": "Input"
  },
  "TransformOutput": {
    "Accept": "text/csv",
    "AssembleWith": "Line"
  }
}
```
To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to `"$[1:]"`. The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, `$[1:4]` specifies the second through fifth columns.

If you omit the number after the colon, for example, `[5:]`, the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, `[5:]`, the subset includes all columns from the first column (index 0) through the sixth column.

**Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)**

If you are using the Amazon SageMaker Python SDK, you can specify the output to join only specific input columns (such as the ID column) with the inferences by specifying the `output_filter` in the transformer call. The `output_filter` uses a JSONPath subexpression to specify which columns to return as output after joining the input data with the inference results. The following request shows how you can make predictions while excluding an ID column and then join the ID column with the inferences. Note that in the following example, the last column (index -1) of the output contains the inferences. If you are using JSON files, SageMaker stores the inference results in the attribute `SageMakerOutput`. For more information about the parameters and their accepted values, see the Transformer page in the Amazon SageMaker Python SDK.

```python
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line", accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
input_filter="$[1:]", join_source="Input", output_filter="$[0,-1]"
)
```

If you are using the AWS SDK for Python (Boto 3), join only the ID column with the inferences by adding the following code to your `CreateTransformJob` request.

```json
{
   "DataProcessing": {
      "InputFilter": "$[1:]",
      "JoinSource": "Input",
      "OutputFilter": "$[0,-1]"
   },
   "TransformOutput": {
      "Accept": "text/csv",
      "AssembleWith": "Line"
   },
   "TransformInput": {
      "ContentType": "text/csv",
      "SplitType": "Line"
   }
}
```

**Warning**

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the inferences in the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.
Storage in Batch Transform

When you run a batch transform job, Amazon SageMaker attaches an Amazon Elastic Block Store storage volume to Amazon EC2 instances that process your job. The volume stores your model, and the size of the storage volume is fixed at 30 GB. You have the option to encrypt your model at rest in the storage volume.

**Note**
If you have a large model, you may encounter an `InternalServerError`.

For more information about Amazon EBS storage and features, see the following pages:

- Amazon EBS in the Amazon EC2 User Guide for Linux Instances
- Amazon EBS volumes in the Amazon EC2 User Guide for Linux Instances

**Note**
G4dn instances come with their own local SSD storage. To learn more about G4dn instances, see the Amazon EC2 G4 Instances page.

Deployment guardrails

Deployment guardrails are a set of model deployment options in Amazon SageMaker Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes, such as canary and linear, give you granular control over the traffic shifting process from your current model to the new one during the course of the update. There are also built-in safeguards such as auto-rollbacks that help you catch issues early and automatically take corrective action before they significantly impact production.

Deployment guardrails provide the following benefits:

- **Deployment safety while updating production environments.** A regressive update to a production environment can cause unplanned downtime and business impact, such as increased model latency and high error rates. Deployment guardrails help you mitigate those risks by providing best practices and built-in operational safety guardrails.

- **Fully managed deployment.** SageMaker takes care of setting up and orchestrating these deployments and integrates them with endpoint update mechanisms. You do not need to build and maintain orchestration, monitoring, or rollback mechanisms. You can leverage SageMaker to set up and orchestrate these deployments and focus on leveraging ML for your applications.

- **Visibility.** You can track the progress of your deployment through the `DescribeEndpoint` API or through Amazon CloudWatch Events (for supported endpoints (p. 2590)). To learn more about events in SageMaker, see the Endpoint deployment state change section in Automating Amazon SageMaker with Amazon EventBridge (p. 3205). Note that if your endpoint uses any of the features in the Exclusions (p. 2590) page, you cannot use CloudWatch Events.

**Note**
Deployment guardrails only apply to Asynchronous inference (p. 2550) and Real-time inference (p. 2413) endpoint types.

How to Get Started

We support blue/green deployments with multiple traffic shifting modes (p. 2577). A traffic shifting mode is a configuration that specifies how SageMaker routes endpoint traffic to a new fleet containing...
your updates. The following traffic shifting modes provide you with different levels of control over the endpoint update process:

- **Blue/Green: All At Once** (p. 2579) shifts all of your endpoint traffic from the blue fleet to the green fleet. Once the traffic shifts to the green fleet, your pre-specified Amazon CloudWatch alarms begin monitoring the green fleet for a set amount of time (the baking period). If no alarms trip during the baking period, then SageMaker terminates the blue fleet.

- **Blue/Green: Canary** (p. 2582) lets you shift one small portion of your traffic (a canary) to the green fleet and monitor it for a baking period. If the canary succeeds on the green fleet, then SageMaker shifts the rest of the traffic from the blue fleet to the green fleet before terminating the blue fleet.

- **Blue/Green: Linear** (p. 2586) provides even more customization over the number of traffic-shifting steps and the percentage of traffic to shift for each step. While canary shifting lets you shift traffic in two steps, linear shifting extends this to \( n \) linearly spaced steps.

You can create and manage your deployment through the `UpdateEndpoint` and `CreateEndpoint` SageMaker API and AWS Command Line Interface commands. See the individual deployment pages for more details on how to set up your deployment. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2590) page, you cannot use deployment guardrails.

To follow guided examples that shows how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

### Auto-Rollback Configuration and Monitoring

Amazon CloudWatch alarms are a prerequisite for using baking periods in deployment guardrails. You can only use the auto-rollback functionality in deployment guardrails if you set up CloudWatch alarms that can monitor an endpoint. If any of your alarms trip during the specified monitoring period, SageMaker initiates a complete rollback to the old endpoint to protect your application. If you do not have any CloudWatch alarms set up to monitor your endpoint, then the auto-rollback functionality does not work during your deployment.

To learn more about Amazon CloudWatch, see What is Amazon CloudWatch? in the Amazon CloudWatch User Guide.

### Alarm Examples

To help you get started, we provide the following examples to demonstrate the capabilities of CloudWatch alarms. In addition to using or modifying the following examples, you can create your own alarms and configure the alarms to monitor various metrics on the specified fleets for a certain period of time. To see more SageMaker metrics and dimensions you can add to your alarms, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190).

**Topics**

- Monitor invocation errors on both old and new fleets (p. 2575)
- Monitor model latency on the new fleet (p. 2576)

**Monitor invocation errors on both old and new fleets**

The following CloudWatch alarm monitors an endpoint's average error rate. You can use this alarm with any deployment guardrails traffic shifting type to provide overall monitoring on both the old and new fleets. If the alarm trips, then SageMaker initiates a rollback to the old fleet.

Invocation errors coming from both the old fleet and new fleet contribute to the average error rate. If the average error rate exceeds the specified threshold, then the alarm trips. This particular example monitors the 4xx errors (client errors) on both the old and new fleets for the duration of a deployment. You can also monitor the 5xx errors (server errors) by using the metric `Invocation5XXErrors`. 
Note
For this alarm type, if your old fleet trips the alarm during the deployment, SageMaker terminates your deployment. Therefore, if your current production fleet already causes errors, consider using or modifying one of the following examples that only monitors the new fleet for errors.

```json
#Applied deployment type: all types
{
  "AlarmName": "EndToEndDeploymentHighErrorRateAlarm",
  "AlarmDescription": "Monitors the error rate of 4xx errors",
  "MetricName": "Invocation4XXErrors",
  "Namespace": "AWS/SageMaker",
  "Statistic": "Average",
  "Dimensions": [
    {"Name": "EndpointName", "Value": "<your-endpoint-name>"},
    {"Name": "VariantName", "Value": "AllTraffic"}
  ],
  "Period": 600,
  "EvaluationPeriods": 2,
  "Threshold": 1,
  "ComparisonOperator": "GreaterThanThreshold",
  "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:

- For **AlarmName** and **AlarmDescription**, enter a name and description you choose for the alarm.
- For **MetricName**, use the value **Invocation4XXErrors** to monitor for 4xx errors on the endpoint.
- For **Namespace**, use the value **AWS/SageMaker**. You can also specify your own custom metric, if applicable.
- For **Statistic**, use **Average**. This means that the alarm takes the average error rate over the evaluation periods when calculating whether the error rate has exceeded the threshold.
- For the dimension **EndpointName**, use the name of the endpoint you are updating as the value.
- For the dimension **VariantName**, use the value **AllTraffic** to specify all endpoint traffic.
- For **Period**, use **600**. This sets the alarm's evaluation periods to 10 minutes long.
- For **EvaluationPeriods**, use **2**. This value tells the alarm to consider the two most recent evaluation periods when determining the alarm status.

**Monitor model latency on the new fleet**

The following CloudWatch alarm example monitors the new fleet's model latency during your deployment. You can use this alarm to monitor only the new fleet and exclude the old fleet. The alarm lasts for the entire deployment. This example gives you comprehensive, end-to-end monitoring of the new fleet and initiates a rollback to the old fleet if the new fleet has any response time issues.

CloudWatch publishes the metrics with the dimension **EndpointConfigName:{New-Ep-Config}** after the new fleet starts receiving traffic, and these metrics last even after the deployment is complete.

You can use the following alarm example with any deployment type.

```json
#Applied deployment type: all types

2576
Blue/Green Deployments

When you update your endpoint, Amazon SageMaker automatically uses a blue/green deployment to maximize the availability of your endpoints. In a blue/green deployment, SageMaker provisions a new fleet with the updates (the green fleet). Then, SageMaker shifts traffic from the old fleet (the blue fleet) to the green fleet. Once the green fleet operates smoothly for a set evaluation period (called the baking period), SageMaker terminates the blue fleet. With the additional capabilities in blue/green deployments, you can utilize traffic shifting modes and auto-rollback monitoring to protect your endpoint from significant production impact.

The following list describes the key features of blue/green deployments in SageMaker:

- **Traffic shifting modes.** The traffic shifting modes for deployment guardrails let you control the volume of traffic and number of traffic-shifting steps between the blue fleet and the green fleet. This capability gives you the ability to progressively evaluate the performance of the green fleet without fully committing to a 100% traffic shift.

- **Baking period.** The baking period is a set amount of time to monitor the green fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking
period, then all endpoint traffic rolls back to the blue fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.

- **Auto-rollbacks.** You can specify Amazon CloudWatch alarms that SageMaker uses to monitor the green fleet. If an issue with the updated code trips any of the alarms, SageMaker initiates an auto-rollback to the blue fleet in order to maintain availability thereby minimizing risk.

## Traffic Shifting Modes

The various traffic shifting modes in blue/green deployments give you more granular control over traffic shifting between the blue fleet and the green fleet. The available traffic shifting modes for blue/green deployments are all at once, canary, and linear. The following table shows a comparison of the options.

**Important**

For blue/green deployments that involve multiple stage traffic shifting or baking periods, you are billed for both the fleets for the duration of the update, irrespective of the traffic to the fleet. This is in contrast to blue/green deployments with all at once traffic shifting and no baking periods, where you are only billed for one fleet during the course of the update.

<table>
<thead>
<tr>
<th>Name</th>
<th>What is it?</th>
<th>Pros</th>
<th>Cons</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>All at once</td>
<td>Shifts all of the traffic to the new fleet in a single step.</td>
<td>Minimizes the overall update duration.</td>
<td>Regressive updates affect 100% of the traffic.</td>
<td>Use this option to minimize update time and cost.</td>
</tr>
<tr>
<td>Canary</td>
<td>Traffic shifts in two steps. The first (canary) step shifts a small portion of the traffic followed by the second step, which shifts the remainder of the traffic.</td>
<td>Confines the blast radius of regressive updates to only the canary fleet.</td>
<td>Both fleets are operational in parallel for entire deployment.</td>
<td>Use this option to balance between minimizing the blast radius of regressive updates and minimizing the time that two fleets are operational.</td>
</tr>
<tr>
<td>Linear</td>
<td>A fixed portion of the traffic shifts in a pre-specified number of equally spaced steps.</td>
<td>Minimizes the risk of regressive updates by shifting traffic over several steps.</td>
<td>The update duration and cost are proportional to the number of steps.</td>
<td>Use this option to minimize risk by spreading out deployment across multiple steps.</td>
</tr>
</tbody>
</table>

## Get Started

Once you specify your desired deployment configuration, SageMaker handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing UpdateEndpoint and CreateEndpoint SageMaker API and AWS Command Line Interface commands. Note that if your endpoint uses any of the features listed in the Exclusions (p. 2590) page, you cannot use deployment guardrails. See the individual deployment pages for more details on how to set up your deployment:

- Blue/Green Update with All At Once Traffic Shifting (p. 2579)
- Blue/Green Update with Canary Traffic Shifting (p. 2582)
- Blue/Green Update with Linear Traffic Shifting (p. 2582)
To follow guided examples that show how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

**All At Once Traffic Shifting**

With all at once traffic shifting, you can quickly roll out an endpoint update using the safety guardrails of a blue/green deployment. You can use this traffic shifting option to minimize the update duration while still taking advantage of the availability guarantees of blue/green deployments. The baking period feature helps you to monitor the performance and functionality of your new instances before terminating your old instances, ensuring that your new fleet is fully operational.

The following diagram shows how all at once traffic shifting manages the old and new fleets.
When you use all at once traffic shifting, SageMaker routes 100% of the traffic to the new fleet (green fleet). Once the green fleet starts receiving traffic, the baking period begins. The baking period is a set amount of time in which pre-specified Amazon CloudWatch alarms monitor the performance of the green fleet. If no alarms trip during the baking period, SageMaker terminates the old fleet (blue fleet). If any alarms trip during the baking period, then an auto-rollback initiates and 100% of the traffic shifts back to the blue fleet.

**Prerequisites**

Before setting up a deployment with all at once traffic shifting, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic rolls back to your blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2575). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure All At Once Traffic Shifting**

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the SageMaker UpdateEndpoint API or the update-endpoint command in the AWS Command Line Interface to initiate the deployment.

**Topics**

- How to update an endpoint (API) (p. 2580)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2581)
- How to update an endpoint (CLI) (p. 2581)

**How to update an endpoint (API)**

The following example shows how you can update your endpoint with all at once traffic shifting using UpdateEndpoint in the Amazon SageMaker API.

```python
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "ALL_AT_ONCE"
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {"AlarmName": "<your-cw-alarm>"}
            ]
        }
    }
)
```

To configure the all at once traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
• Under DeploymentConfig and BlueGreenUpdatePolicy, in TrafficRoutingConfiguration, set the Type parameter to ALL_AT_ONCE. This specifies that the deployment uses the all at once traffic shifting mode.

• For TerminationWaitInSeconds, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.

• For MaximumExecutionTimeoutInSeconds, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.

• In AutoRollbackConfiguration, within the Alarms field, you can add your CloudWatch alarms by name. Create one AlarmName: `<your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same DeploymentConfig options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the RetainDeploymentConfig option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set RetainDeploymentConfig to True to keep the DeploymentConfig options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName='<your-endpoint-name>',
    EndpointConfigName='<your-config-name>',
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green all at once deployment using the update-endpoint command.

```
update-endpoint
--endpoint-name <your-endpoint-name>
--endpoint-config-name <your-config-name>
--deployment-config '{"BlueGreenUpdatePolicy": {
    "TrafficRoutingConfiguration": {
        "Type": "ALL_AT_ONCE",
        "TerminationWaitInSeconds": 600,
        "MaximumExecutionTimeoutInSeconds": 1800
    },
    "AutoRollbackConfiguration": {
        "Alarms": [
            {
                "AlarmName": <your-alarm>
            }
        ]
    }
}}'
```

To configure the all at once traffic shifting option, do the following:

• For endpoint-name, use the name of the endpoint you want to update.

• For endpoint-config-name, use the name of the endpoint configuration you want to use.

• For deployment-config, use a BlueGreenUpdatePolicy JSON object.

**Note**

If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.
Canary Traffic Shifting

With canary traffic shifting, you can test a portion of your endpoint traffic on the new fleet while the old fleet serves the remainder of the traffic. This testing step is a safety guardrail that validates the new fleet's functionality before shifting all of your traffic to the new fleet. You still have the benefits of a blue/green deployment, and the added canary feature lets you ensure that your new (green) fleet can serve inference before letting it handle 100% of the traffic.

The portion of your green fleet that turns on to receive traffic is called the canary, and you can choose the size of this canary. Note that the canary size should be less than or equal to 50% of the new fleet's capacity. Once the baking period finishes and no pre-specified Amazon CloudWatch alarms trip, the rest of the traffic shifts from the old (blue) fleet to the green fleet. Canary traffic shifting provides you with more safety during your deployment since any issues with the updated model only impact the canary.

The following diagram shows how canary traffic shifting manages the distribution of traffic between the blue and green fleets.
Blue/Green Deployments

Deployment Stages
- Canary - Create
- Canary - CanaryFlipTraffic
- Canary - CanaryBake

Deployment Stages
- Canary - FirstFlipTraffic
- Canary - FirstBake
- Canary - Cleanup
Once SageMaker provisions the green fleet, SageMaker routes a portion of the incoming traffic (for example, 25%) to the canary. Then the baking period begins, during which your CloudWatch alarms monitor the performance of the green fleet. During this time, both the blue fleet and green fleet are partially active and receiving traffic. If any of the alarms trip during the baking period, then SageMaker initiates a rollback and all traffic returns to the blue fleet. If none of the alarms trip, then all of the traffic shifts to the green fleet and there is a final baking period. If the final baking period finishes without tripping any alarms, then the green fleet serves all traffic and SageMaker terminates the blue fleet.

**Prerequisites**

Before setting up a deployment with canary traffic shifting, you must create Amazon CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2575). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure Canary Traffic Shifting**

Once you are ready for your deployment and have set up Amazon CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the update-endpoint command in the AWS CLI to initiate the deployment.

**Topics**

- How to update an endpoint (API) (p. 2584)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2585)
- How to update an endpoint (CLI) (p. 2585)

**How to update an endpoint (API)**

The following example of the UpdateEndpoint API shows how you can update an endpoint with canary traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "CANARY",
                "CanarySize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 30
                },
                "WaitIntervalInSeconds": 600
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                
            ]
        }
    }
)
```

2584
To configure the canary traffic shifting option, do the following:

- For `EndpointName`, use the name of the existing endpoint you want to update.
- For `EndpointConfigName`, use the name of the endpoint configuration you want to use.
- Under `DeploymentConfig` and `BlueGreenUpdatePolicy`, in `TrafficRoutingConfiguration`, set the `Type` parameter to `CANARY`. This specifies that the deployment uses canary traffic shifting.
- In the `CanarySize` field, you can change the size of the canary by modifying the `Type` and `Value` parameters. For `Type`, use `CAPACITY_PERCENT`, meaning the percentage of your green fleet you want to use as the canary, and then set `Value` to 30. In this example, you use 30% of the green fleet's capacity as the canary. Note that the canary size should be equal to or less than 50% of the green fleet's capacity.
- For `WaitIntervalInSeconds`, use 600. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each interval shift. This interval is the duration of the canary baking period. In the preceding example, SageMaker waits for 10 minutes after the canary shift and then completes the second and final traffic shift.
- For `TerminationWaitInSeconds`, use 600. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 10 minutes after the final baking period before terminating the blue fleet.
- For `MaximumExecutionTimeoutInSeconds`, use 1800. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In `AutoRollbackConfiguration`, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.

### How to update an endpoint with an existing blue/green update policy (API)

When you use the `CreateEndpoint` API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous `UpdateEndpoint` API example. There are no changes to the `CreateEndpoint` API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the `UpdateEndpoint` API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the `UpdateEndpoint` API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

### How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green canary deployment using the `update-endpoint` command.
To configure the canary traffic shifting option, do the following:

- For `--endpoint-name`, use the name of the endpoint you want to update.
- For `--endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `--deployment-config`, use a BlueGreenUpdatePolicy JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

**Linear Traffic Shifting**

Linear traffic shifting enables you to gradually shift traffic from your old fleet (blue fleet) to your new fleet (green fleet). With linear traffic shifting, you can shift traffic in multiple steps, minimizing the chance of a disruption to your endpoint. This blue/green deployment option gives you the most granular control over traffic shifting.

You can choose either the number of instances or the percentage of the green fleet's capacity to activate during each step. Each linear step should only be between 10-50% of the green fleet's capacity. For each step, there is a baking period during which your pre-specified Amazon CloudWatch alarms monitor metrics on the green fleet. Once the baking period finishes and no alarms trip, the active portion of your green fleet continues receiving traffic and a new step begins. If alarms trip during any of the baking periods, 100% of the endpoint traffic rolls back to the blue fleet.

The following diagram shows how linear traffic shifting routes traffic to the blue and green fleets.
Amazon SageMaker Developer Guide

Blue/Green Deployments

Deployment Stages:
- Create
- Linear
- Linear Flip
- Linear Rollout
- Linear - Demo
Once SageMaker provisions the new fleet, the first portion of the green fleet turns on and receives traffic. SageMaker deactivates the same size portion of the blue fleet, and the baking period begins. If any alarms trip, all of the endpoint traffic rolls back to the blue fleet. If the baking period finishes, then the next step begins. Another portion of the green fleet activates and receives traffic, part of the blue fleet deactivates, and another baking period begins. The same process repeats until the blue fleet is fully deactivated and the green fleet is fully active and receiving all traffic. If an alarm goes off at any point, SageMaker terminates the shifting process and 100% of the traffic rolls back to the blue fleet.

**Prerequisites**

Before setting up a deployment with linear traffic shifting, you must create CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring (p. 2575). To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the Amazon CloudWatch User Guide.

**Configure Linear Traffic Shifting**

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker UpdateEndpoint API or the update-endpoint command in the AWS CLI to initiate the deployment.

Topics

- How to update an endpoint (API) (p. 2588)
- How to update an endpoint with an existing blue/green update policy (API) (p. 2589)
- How to update an endpoint (CLI) (p. 2585)

**How to update an endpoint (API)**

The following example of the UpdateEndpoint API shows how you can update an endpoint with linear traffic shifting.

```python
import boto3
client = boto3.client("sagemaker")
response = client.update_endpoint(  
    EndpointName="<your-endpoint-name>",  
    EndpointConfigName="<your-config-name>",  
    DeploymentConfig={  
        "BlueGreenUpdatePolicy": {  
            "TrafficRoutingConfiguration": {  
                "Type": "LINEAR",  
                "LinearStepSize": {  
                    "Type": "CAPACITY_PERCENT",  
                    "Value": 20  
                },  
                "WaitIntervalInSeconds": 300  
            },  
            "TerminationWaitInSeconds": 300,  
            "MaximumExecutionTimeoutInSeconds": 3600  
        },  
        "AutoRollbackConfiguration": {  
            "Alarms": [  
                {  
                    "AlarmName": "<your-cw-alarm>"  
                }  
            ]  
        }  
    }  
)
```

2588
To configure the linear traffic shifting option, do the following:

- For **EndpointName**, use the name of the existing endpoint you want to update.
- For **EndpointConfigName**, use the name of the endpoint configuration you want to use.
- Under **DeploymentConfig** and **BlueGreenUpdatePolicy**, in **TrafficRoutingConfiguration**, set the **Type** parameter to **LINEAR**. This specifies that the deployment uses linear traffic shifting.
- In the **LinearStepSize** field, you can change the size of the steps by modifying the **Type** and **Value** parameters. For **Type**, use **CAPACITY_PERCENT**, meaning the percentage of your green fleet you want to use as the step size, and then set **Value** to 20. In this example, you turn on 20% of the green fleet's capacity for each traffic shifting step. Note that when customizing your linear step size, you should only use steps that are 10-50% of the green fleet's capacity.
- For **WaitIntervalInSeconds**, use 300. The parameter tells SageMaker to wait for the specified amount of time (in seconds) between each traffic shift. This interval is the duration of the baking period between each linear step. In the preceding example, SageMaker waits for 5 minutes between each traffic shift.
- For **TerminationWaitInSeconds**, use 300. This parameter tells SageMaker to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker waits for 5 minutes after the final baking period before terminating the blue fleet.
- For **MaximumExecutionTimeoutInSeconds**, use 3600. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 1 hour to finish.
- In **AutoRollbackConfiguration**, within the **Alarms** field, you can add your CloudWatch alarms by name. Create one **AlarmName**: `<your-cw-alarm>` entry for each alarm you want to use.

### How to update an endpoint with an existing blue/green update policy (API)

When you use the `CreateEndpoint` API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same **DeploymentConfig** options as the previous `UpdateEndpoint` API example. There are no changes to the `CreateEndpoint` API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the `UpdateEndpoint` API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the `UpdateEndpoint` API, set `RetainDeploymentConfig` to **True** to keep the **DeploymentConfig** options from your original endpoint configuration.

```python
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

### How to update an endpoint (CLI)

If you are using the AWS CLI, the following example shows how to start a blue/green linear deployment using the `update-endpoint` command.

```
update-endpoint
```
To configure the linear traffic shifting option, do the following:

- For `--endpoint-name`, use the name of the endpoint you want to update.
- For `--endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `--deployment-config`, use a BlueGreenUpdatePolicy JSON object.

**Note**
If you would rather save your JSON object in a file, see Generating AWS CLI skeleton and input parameters in the AWS CLI User Guide.

### Exclusions

You can only use deployment guardrails with newly created endpoints. There are also feature-based exclusions that make your endpoint incompatible with deployment guardrails at this time. If your endpoint uses any of the following features, you cannot use deployment guardrails on your endpoint, and your endpoint will fall back to using a blue/green deployment with all at once traffic shifting and no final baking period.

- Marketplace containers
- Multi-container endpoints
- Multi-model endpoints
- Multi-variant endpoints
- Endpoints that use Inf1 (Inferentia-based) instances
- Endpoints that use Amazon SageMaker Model Monitor (with data capture enabled)
- Amazon Elastic Inference endpoints

### Inference cost optimization best practices

The following content provides techniques and considerations for optimizing the cost of endpoints. You can use these recommendations to optimize the cost for both new and existing endpoints.

### Best practices

To optimize your SageMaker Inference costs, follow these best practices.

**Pick the best inference option for the job.**

SageMaker offers 4 different inference options to provide the best inference option for the job. You may be able to save on costs by picking the inference option that best matches your workload.

- **Use real-time inference** for low latency workloads with predictable traffic patterns that need to have consistent latency characteristics and are always available. You pay for using the instance.
• Use **serverless inference** for synchronous workloads that have a spiky traffic pattern and can accept variations in the p99 latency. Serverless inference automatically scales to meet your workload traffic so you don't pay for any idle resources. You only pay for the duration of the inference request. The same model and containers can be used with both real-time and serverless inference so you can switch between these two modes if your needs change.

• Use **asynchronous inference** for asynchronous workloads that process up to 1 GB of data (such as text corpus, image, video, and audio) that are latency insensitive and cost sensitive. With asynchronous inference, you can control costs by specifying a fixed number of instances for the optimal processing rate instead of provisioning for the peak. You can also scale down to zero to save additional costs.

• Use **batch inference** for workloads for which you need inference for a large set of data for processes that happen offline (that is, you don't need a persistent endpoint). You pay for the instance for the duration of the batch inference job.

**Opt in to a SageMaker Savings Plan.**

• If you have a consistent usage level across all SageMaker services, you can opt in to a SageMaker Savings Plan to help reduce your costs by up to 64%.

• **Amazon SageMaker Savings Plans** provide a flexible pricing model for Amazon SageMaker, in exchange for a commitment to a consistent amount of usage (measured in $/hour) for a one-year or three-year term. These plans automatically apply to eligible SageMaker ML instance usages including SageMaker Studio Notebook, SageMaker On-Demand Notebook, SageMaker Processing, SageMaker Data Wrangler, SageMaker Training, SageMaker Real-Time Inference, and SageMaker Batch Transform regardless of instance family, size, or Region. For example, you can change usage from a CPU ml.c5.xlarge instance running in US East (Ohio) to a ml.Inf1 instance in US West (Oregon) for inference workloads at any time and automatically continue to pay the Savings Plans price.

**Optimize your model to run better.**

• Unoptimized models can lead to longer run times and use more resources. You may choose to use more or bigger instances to improve performance; however, this leads to higher costs.

• By optimizing your models to be more performant, you may be able to lower costs by using fewer or smaller instances while keeping the same or better performance characteristics. You can use **SageMaker Neo** with SageMaker Inference to automatically optimize models. For more details and samples, see Optimize model performance using Neo (p. 2666).

**Use the most optimal instance type and size for real-time inference.**

• SageMaker Inference has over 70 instance types and sizes that can be used to deploy ML models including AWS Inferentia and Graviton chipsets that are optimized for ML. Choosing the right instance for your model helps ensure you have the most performant instance at the lowest cost for your models.

• By using **Inference Recommender**, you can quickly compare different instances to understand the performance of the model and the costs. With these results, you can choose the instance to deploy with the best return on investment.

**Improve efficiency and costs by combining multiple endpoints into a single endpoint for real-time inference.**

• Costs can quickly add up when you deploy multiple endpoints, especially if the endpoints don't fully utilize the underlying instances. To understand if the instance is under-utilized, check the utilization metrics (CPU, GPU, etc) in Amazon CloudWatch for your instances. If you have more than one of
these endpoints, you can combine the models or containers on these multiple endpoints into a single endpoint.

- Using Multi-model endpoints (MME) or Multi-container endpoints (MCE), you can deploy multiple ML models or containers in a single endpoint to share the instance across multiple models or containers and improve your return on investment. To learn more, see this Save on inference costs by using Amazon SageMaker multi-model endpoints or Deploy multiple serving containers on a single instance using Amazon SageMaker multi-container endpoints on the AWS Machine Learning blog.

Set up autoscaling to match your workload requirements for real-time and asynchronous inference.

- Without autoscaling, you need to provision for peak traffic or risk model unavailability. Unless the traffic to your model is steady throughout the day, there will be excess unused capacity. This leads to low utilization and wasted resources.
- Autoscaling is an out-of-the-box feature that monitors your workloads and dynamically adjusts the capacity to maintain steady and predictable performance at the possible lowest cost. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances, helping you reduce your compute cost. To learn more, see Configuring autoscaling inference endpoints in Amazon SageMaker on the AWS Machine Learning blog.

Register and Deploy Models with Model Registry

With the SageMaker model registry you can do the following:

- Catalog models for production.
- Manage model versions.
- Associate metadata, such as training metrics, with a model.
- Manage the approval status of a model.
- Deploy models to production.
- Automate model deployment with CI/CD.

Catalog models by creating model package groups that contain different versions of a model. You can create a model group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the model registry adds it to the model group as a new model version. A typical workflow might look like the following:

- Create a model group.
- Create an ML pipeline that trains a model. For information about SageMaker pipelines, see Create and Manage SageMaker Pipelines (p. 2831).
- For each run of the ML pipeline, create a model version that you register in the model group you created in the first step.

Model Registry Structure

The SageMaker Model Registry is structured as several model groups with model packages in each group. Each model package in a model group corresponds to a trained model. The version of each model package is a numerical value that starts at 1 and is incremented with each new model package added to a model group. For example, if 5 model packages are added to a model group, the model package
versions will be 1, 2, 3, 4, and 5. The example Model Registry shown in the following image contains 3 model groups, where each group contains the model packages related to a particular ML problem.

There are two types of model packages in SageMaker. One type is used in the AWS Marketplace, and the other is used in the Model Registry. Model packages used in the AWS Marketplace are not versionable entities and are not associated with model groups in the Model Registry. For more information about model packages used in the AWS Marketplace, see Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace (p. 3039).

The model packages used in the Model Registry are versioned, and must be associated with a model group. The ARN of this model package type has the structure: 'arn:aws:sagemaker:region:account:model-group/version'

The following topics show you how to use the Model Registry.

Topics
- Create a Model Group (p. 2593)
- Register a Model Version (p. 2597)
- View Model Groups and Versions (p. 2604)
- View the Details of a Model Version (p. 2606)
- Update the Approval Status of a Model (p. 2609)
- Deploy a Model from the Registry (p. 2612)
- View the Deployment History of a Model (p. 2615)

Create a Model Group

A model group contains a group of versioned models. Create a model group by using either the AWS SDK for Python (Boto3) or Amazon SageMaker Studio.

Create a Model Package Group (Boto3)

To create a model group by using Boto3, call the create_model_package_group method and specify a name and description as parameters. The following example shows how to create a model group. The response from the create_model_package_group call is the Amazon Resource Name (ARN) of the new model package group.
First, import the required packages and set up the SageMaker Boto3 client.

```python
import time
import os
from sagemaker import get_execution_role, session
import boto3

region = boto3.Session().region_name
role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the model group.

```python
import time
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}

create_model_package_group_response = sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn : {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
```

---

**Create a Model Package Group (Amazon SageMaker Studio)**

To create a model group in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see *Onboard to Amazon SageMaker Domain (p. 36).*
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. Choose **Model registry**.
4. Choose **Create model group.**
5. In the Create new model group dialog box, enter the following information:
   
   • Enter the name of the new model group in the Name field.
   • (Optional) Enter a description for the model group in the Description field.
   • (Optional) Enter any key-value pairs you want to associate with the model group in the Tags field. For information about using tags, see Tagging AWS resources in the AWS General Reference.
   • (Optional) Choose a project with which to associate the model group in the Project field. For information about projects, see Automate MLOps with SageMaker Projects (p. 2861).

6. Choose Create model group.
Register a Model Version

You can register an Amazon SageMaker model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model) and the inference code for the model.

An inference pipeline is a SageMaker model composed of a linear sequence of two to fifteen containers that process inference requests. You register an inference pipeline by specifying the containers and the associated environment variables. For more information on inference pipelines, see Host models along with pre-processing logic as serial inference pipeline behind one endpoint (p. 2446).

You can register a model with an inference pipeline, by specifying the containers and the associated environment variables. To create a model version with an inference pipeline by using either the AWS SDK for Python (Boto3) or by creating a step in a SageMaker model building pipeline, use the following steps.

Topics
- Register a Model Version (SageMaker Pipelines) (p. 2598)
- Register a Model Version (Boto3) (p. 2598)
- Register a Model Version from a Different Account (p. 2598)
Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a RegisterModel step in your pipeline. For information about creating a RegisterModel step as part of a pipeline, see Step 8: Define a RegisterModel Step to Create a Model Package (p. 2841).

Register a Model Version (Boto3)

To register a model version by using Boto3, call the create_model_package method.

First, you set up the parameter dictionary to pass to the create_model_package method.

```python
# Specify the model source
model_url = "s3://your-bucket-name/model.tar.gz"

modelpackage_inference_specification = {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": '25775804811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-
                xgboost:1.2-1',
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]
# ["ModelDataUrl"]=model_url

create_model_package_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}

create_model_package_input_dict.update(modelpackage_inference_specification)

Then you call the create_model_package method, passing in the parameter dictionary that you just set up.

```python
create_model_package_response = sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

Register a Model Version from a Different Account

To register model versions with a model package group created by a different AWS account, you must add a cross-account AWS Identity and Access Management resource policy to enable that account. For example, one AWS account in your organization is responsible for training models, and a different account is responsible for managing, deploying, and updating models. You create IAM resource policies and apply the policies to the specific account resource to which you want to grant access for this case. For more information about cross-account resource policies in AWS, see Cross-account policy evaluation logic in the AWS Identity and Access Management User Guide.
Note
You must also use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model registry in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions. The following is an example that creates cross-account policies for the model package group and applies these policies to that specific resource.

The following configuration must be set in the source account which registers models cross-account in a model package group. In this example, the source account is the model training account which will train and then register the model cross-account into the Model Registry of the model registry account.

The example assumes that you previously defined the following variables:

- `model_package_group_name` - The model group to which you want to grant access.
- `model_package_group_arn` - The model group arn to which you want to grant cross-account access.
- `bucket` - The S3 bucket where the model training artifacts are stored.

To be able to deploy a model created in a different account, the user must have a role that has access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker managed policies, see AWS Managed Policies for Amazon SageMaker (p. 3131).

Required IAM resource policies

The following diagram captures the policies required to allow cross-account model registration. As shown, these policies need to be active during model training to properly register the model into the model registry account.
Amazon ECR, Amazon S3, and AWS KMS policies are demonstrated in the following code samples.

**Sample Amazon ECR policy**

```json
{
   'Version': '2012-10-17',
   'Statement': [ 
      {
         'Sid': 'AddPerm',
         'Effect': 'Allow',
      }
   ]
}```
'Principal': {
    'AWS': 'arn:aws:iam::{model_registry_account}:root'
},
'Action': [
    'ecr:BatchGetImage',
    'ecr:Describe*'
]
}
}

Sample Amazon S3 policy

{
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': [
                's3:GetObject',
                's3:GetBucketAcl',
                's3:GetObjectAcl'
            ],
            'Resource': 'arn:aws:s3:::{bucket}/*'
        }
    ]
}

Sample AWS KMS policy

{
    'Version': '2012-10-17',
    'Statement': [
        {
            'Sid': 'AddPerm',
            'Effect': 'Allow',
            'Principal': {
                'AWS': 'arn:aws:iam::{model_registry_account}:root'
            },
            'Action': [
                'kms:Decrypt',
                'kms:GenerateDataKey*'
            ],
            'Resource': '*/'
        }
    ]
}

Apply resource policies to accounts

The following policy configuration applies the policies discussed in the previous section and must be put in the model training account.

```
import json

# The model registry account id of the model package group
model_registry_account = '111111111111'
```
# The model training account id where training happens
model_training_account = '222222222222'

# 1. Create a policy for access to the ECR repository
# in the model training account for the model registry account model package group
ecr_repository_policy = {'Version': '2012-10-17',
    'Statement':[['Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
        'Action': ['ecr:BatchGetImage', 'ecr:Describe*']
    ]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = model_training_account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# 2. Create a policy in the model training account for access to the S3 bucket
# where the model is present in the model registry account model package group
bucket_policy = {'Version': '2012-10-17',
    'Statement':[['Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {'AWS': f'arn:aws:iam::{model_registry_account}:root'},
        'Action': ['s3:GetObject', 's3:GetBucketAcl', 's3:GetObjectAcl'],
        'Resource': 'arn:aws:s3:::{bucket}/*'
    ]
}

# Convert the S3 policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new bucket policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy
)

# 3. Create the KMS grant for the key used during training for encryption
# in the model training account to the model registry account model package group
client = boto3.client('kms')
response = client.create_grant(
    GranteePrincipal=model_registry_account,
    KeyId=kms_key_id
    Operations=[
        'Decrypt',
        'GenerateDataKey',
    ],
The following configuration needs to be put in the model registry account where the model package group exists.

```python
# The model registry account id of the model package group
model_registry_account = '111111111111'

# 1. Create policy to allow the model training account to access the ModelPackageGroup
model_package_group_policy = {'Version': '2012-10-17',
    'Statement': [
        {'Sid': 'AddPermModelPackageVersion',
         'Effect': 'Allow',
         'Principal': {'AWS': f'arn:aws:iam::{model_training_account}:root'},
         'Action': ['sagemaker:CreateModelPackage'],
         'Resource': f'arn:aws:sagemaker:{region}:{model_registry_account}:model-package/{model_package_group_name}/*'
        }
    ]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)
```

Finally, use the `create_model_package` action from the model training account to register the model package in the cross-account.

```python
# Specify the model source
model_url = "s3://(bucket)/model.tar.gz"

# Set up the parameter dictionary to pass to the create_model_package method
modelpackage_inference_specification = {
    "InferenceSpecification": {
    "Containers": [
        {
            "Image": f'{model_training_account}.dkr.ecr.us-east-2.amazonaws.com/decision-trees-sample:latest',
            "ModelDataUrl": model_url
        }
    ],
    "SupportedContentTypes": [ "text/csv" ],
    "SupportedResponseMIMETypes": [ "text/csv" ],
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]['Containers'][0]["ModelDataUrl"]=model_url
create_model_package_input_dict = {
    "ModelPackageGroupName": model_package_group_arn,
    "ModelPackageDescription": "Model to detect 3 different types of irises (Setosa, Versicolour, and Virginica)",
    "ModelApprovalStatus": "PendingManualApproval"
}
View Model Groups and Versions

Model groups and versions help you organize your models. You can view a list of the model versions in a model group.

View a List of Model Versions in a Group

You can view all of the model versions that are associated with a model group. If a model group represents all models that you train to address a specific ML problem, you can view all of those related models.

View a List of Model Versions in a Group (Boto3)

To view model versions associated with a model group by using Boto3, call the list_model_packages method, and pass the name of the model group as the value of the ModelPackageGroupName parameter. The following code lists the model versions associated with the model group you created in Create a Model Package Group (Boto3) (p. 2593).

```
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

View a List of Model Versions in a Group (Amazon SageMaker Studio)

To view a list of the model versions in a model group, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Components and registries icon (🔗).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view.

5. A new tab appears with a list of the model versions in the model group, as shown in the following image.
View the Details of a Model Version

You can view details of a specific model version by using either the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio.

View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a model group.

   ```python
   sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
   ```

   The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.

   ```json
   {'ModelPackageSummaryList':
    [{'ModelPackageGroupName': 'AbaloneMPG-1603932988329896',
      'ModelPackageVersion': 1,
      'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
      'ModelPackageDescription': 'TestMe',
      'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
      'ModelPackageStatus': 'Completed',
      'ModelApprovalStatus': 'Approved'},
    ...],
   'ResponseMetadata': {'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',
                        'HTTPStatusCode': 200,
                        'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbccddeeff',
                                        'content-type': 'application/x-amz-json-1.1',
                                        'content-length': '349',
                                        'date': 'Mon, 23 Nov 2020 04:56:50 GMT'},
                        'RetryAttempts': 0}}
   ```

2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

   ```python
   sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1")
   ```

   The output of this call is a JSON object with the model version details.

   ```json
   {'ModelPackageGroupName': 'ModelGroup1',
    'ModelPackageVersion': 1,
    'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1',
    'ModelPackageDescription': 'Test Model',
    'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000, tzinfo=tzlocal()),
    'InferenceSpecification': {'Containers': [{'Image': '257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.0-1-cpu-py3',
                                               'ImageDigest': 'sha256:99fa6a02c0ff19ae333297a5926f8497ca7bcd2a391b7d600300204ee803bca66',

   ```
View the Details of a Model Version (Amazon SageMaker Studio)

To view the details of a model version in Amazon SageMaker Studio, complete the following steps.

1. Sign in to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).

2. In the left navigation pane, choose the Components and registries icon (>Create).

3. Choose Model registry.

4. From the model groups list, double-click the model group you want to view.
5. A new tab appears with a list of the model versions in the model group, as shown in the following image.

6. In the list of model versions, double-click the model version for which you want to view details.

7. On the model version tab that opens, choose one of the following to see details about the model version:

   - **Activity**: Shows events for the model version, such as approval status updates.
   - **Metrics**: Shows quality metrics for the model. For metrics to appear, you must enable data capture for your model by using SageMaker Model Monitor. For information about capturing data, see [Capture data](p. 2507).
   - **Settings**: Shows information such as the project with which the model version is associated, the pipeline that generated the model, the model group, and the model's location in Amazon S3.
Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to Approved. Setting the status to Approved can initiate CI/CD deployment for the model. If the model version does not perform to your requirements, you can update the approval status to Rejected.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker pipeline. For information about creating a condition step in a SageMaker pipeline, see Pipeline Steps (p. 2799).

When you use one of the SageMaker provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.

- **PendingManualApproval to Approved** – initiates CI/CD deployment for the approved model version
- **PendingManualApproval to Rejected** – No action
- **Rejected to Approved** – initiates CI/CD deployment for the approved model version
- **Approved to Rejected** – initiates CI/CD to deploy the latest model version with an Approved status

You can update the approval status of a model version by using the AWS SDK for Python (Boto3) or by using Amazon SageMaker Studio. You can also update the approval status of a model version as part of a condition step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see SageMaker Pipelines Overview (p. 2795).

**Update the Approval Status of a Model (Boto3)**

When you created the model version in Register a Model Version (p. 2597), you set the ModelApprovalStatus to PendingManualApproval. You update the approval status for the model by calling update_model_package. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to Approved.

```python
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response =
    sm_client.update_model_package(**model_package_update_input_dict)
```

**Update the Approval Status of a Model (Amazon SageMaker Studio)**

The following procedure shows how to manually change the approval status from Approved to Rejected.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Components and registries icon (🔍).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view. A new tab opens with a list of the model versions in the group.

5. In the list of model versions, right-click the model version you want to update and choose **Update model version status**.
6. In the **Update model version status** dialog box, for **Status** choose **Rejected**, and then choose **Update status**.

![Update model version status dialog box](image)

- **Status** dropdown: Rejected

- **Comment - optional**: 

  ![Comment field](image)

- **If you reject a previously approved model version, and have automatic pipeline triggers in place, this change may impact the CI/CD pipeline associated with this project.**
Deploy Model

Deploy a Model from the Registry

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.

When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the model registry are automatically deployed to production. For information about using SageMaker MLOps projects, see Automate MLOps with SageMaker Projects (p. 2861).

You can also enable an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models.

Topics
- Deploy a Model from the Registry (SageMaker SDK) (p. 2612)
- Deploy a Model from the Registry (Boto3) (p. 2612)
- Deploy a Model Version from a Different Account (p. 2613)

Deploy a Model from the Registry (SageMaker SDK)

To deploy a model version using the Amazon SageMaker Python SDK use the following code snippet:

```python
from sagemaker import ModelPackage
from time import gmtime, strftime

model_package_arn = 'arn:aws:sagemaker:us-east-2:12345678901:model-package/modeltest/1'
model = ModelPackage(role=role,
                     model_package_arn=model_package_arn,
                     sagemaker_session=sagemaker_session)
model.deploy(initial_instance_count=1, instance_type='ml.m5.xlarge')
```

Deploy a Model from the Registry (Boto3)

To deploy a model version using the AWS SDK for Python (Boto3), complete the following steps:

1. Create a model object from the model version by calling the `create_model` method. Pass the Amazon Resource Name (ARN) of the model version as part of the `Containers` for the model object.

   The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`, and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

   ```python
   model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
   print("Model name : {}".format(model_name))
   container_list = [{"ModelPackageName": model_version_arn}]

   create_model_response = sm_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = role,
       Containers = container_list
   )
   print("Model arn : {}".format(create_model_response["ModelArn"]))
   ```

2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.
endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sm_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType':'ml.m4.xlarge',
        'InitialVariantWeight':1,
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName':'AllTraffic'}])

3. Create the endpoint by calling create_endpoint.

endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))
create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])

Deploy a Model Version from a Different Account

You can permit an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create these resource policies, you apply the policy to the specific resource to which you want to grant access. For more information about cross-account resource policies in AWS, see Cross-account policy evaluation logic in the AWS Identity and Access Management User Guide.

Note
You must use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the model group resides, and the Amazon S3 bucket where the model versions are stored.

To be able to deploy a model that was created in a different account, you must have a role that has access to SageMaker actions, such as a role with the AmazonSageMakerFullAccess managed policy. For information about SageMaker managed policies, see AWS Managed Policies for Amazon SageMaker (p. 3131).

The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

The example assumes that you previously defined the following variables:

- bucket - The Amazon S3 bucket where the model versions are stored.
- kms_key_id - The KMS key used to encrypt the training output.
- model_package_group_name - The model group to which you want to grant cross-account access.
- model_package_group_arn - The model group arn to which you want to grant cross-account access.
import json

# The cross-account id to grant access to
cross_account_id = "123456789012"

# Create the policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['ecr:*']
    }]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# Create a policy for accessing the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': 's3:*',
        'Resource': f'arn:aws:s3:::{bucket}/**'
    }]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy
)

# Create the KMS grant for encryption in the source account to the
# model registry account model package group
client = boto3.client('kms')
response = client.create_grant(
    GranteePrincipal=cross_account_id,
    KeyId=kms_key_id
    Operations=[
        'Decrypt',
        'GenerateDataKey',
    ],
)
# 3. Create a policy for access to the model package group.
```
model_package_group_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPermModelPackageGroup',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['sagemaker:DescribeModelPackageGroup'],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package-group/' +
        (model_package_group_name)
    },
    {  
        'Sid': 'AddPermModelPackageVersion',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['sagemaker:DescribeModelPackage',
        'sagemaker:ListModelPackages',
        'sagemaker:UpdateModelPackage',
        'sagemaker:CreateModel'],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package/' +
        (model_package_group_name) + '*'
    }]
}
```

# Convert the policy from JSON dict to string
```
model_package_group_policy = json.dumps(model_package_group_policy)
```

# Set the policy to the model package group
```
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)
```

print('ModelPackageGroupArn : ' +
      (create_model_package_group_response['ModelPackageGroupArn'])))
print("First Versioned ModelPackageArn: " + model_package_arn)
print("Second Versioned ModelPackageArn: " + model_package_arn2)
print("Success! You are all set to proceed for cross-account deployment.")

View the Deployment History of a Model

View the deployments for a model version Amazon SageMaker Studio by opening the tab for that model version.

View the deployment history for a model version

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the left navigation pane, choose the Components and registries icon (🔗).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.

6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose **Activity**. Deployments for the model version appear as events in the activity list with an **Event type** of **ModelDeployment**.
Deploy models at the edge with SageMaker Edge Manager

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

Why Use Edge Manager?

Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay over time. Monitoring models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

How Does it Work?

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker inference engine (Edge Manager agent), and maintaining models on the devices.

SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring.
and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker Ground Truth and retrain the models in SageMaker.

How Do I Use SageMaker Edge Manager?

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. Read the Getting Started section - This section walks you through setting up your first edge packaging job and creating your first fleet.
2. Explore Edge Manager Jupyter notebook examples - Example notebooks are stored in the amazon-sagemaker-examples GitHub repository in the sagemaker_edge_manager folder.

Getting Started

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker Edge Manager prerequisites.

Topics
- Setting Up (p. 2619)
- Train, Compile, and Package Your Model (p. 2622)
- Create and Register Fleets and Authenticate Devices (p. 2624)
- Download and Set Up Edge Manager (p. 2628)
- Run Agent (p. 2631)

Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker and AWS IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

1. Set up an AWS account.

   Create an AWS account and an IAM administrator user. For instructions on how to set up your AWS account, see How do I create and activate a new AWS account? For instructions on how to create an administrator user in your AWS account, see Creating your first IAM admin user and group.

2. Create an IAM role for Amazon SageMaker.

   SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3. Using this role, SageMaker can run under your account and access to your Amazon S3 bucket.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.

c. For Select type of trusted entity, choose AWS service.

d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.

- This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.

e. Choose Next: Tags.

f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.

g. Choose Next: Review.

h. Type in a Role name.

i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.

j. (Optional) For Role description, type a description for the new role.

k. Review the role and then choose Create role.

Note the SageMaker Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:

i. Go to the IAM console: https://console.aws.amazon.com/iam/

ii. Select Roles.

iii. Search for the role you just created by typing in the name of the role in the search field.

iv. Select the role.

v. The role ARN is at the top of the Summary page.

3. Create an IAM role for AWS IoT.

The AWS IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker client object.

Configure an IAM role in your AWS account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with AWS IoT services.

Create a role for AWS IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker.

a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.

c. For Select type of trusted entity, choose AWS service.

d. Choose the service that you want to allow to assume this role. In this case, choose IoT. Select IoT as the Use Case.

e. Choose Next: Permissions.

f. Choose Next: Tags.

 g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.

h. Choose Next: Review.

i. Type in a Role name. The role name must start with SageMaker.
j. (Optional) For **Role description**, type a description for the new role.

k. Review the role and then choose **Create role**.

l. Once the role is created, choose **Roles** in the IAM console. Search for the role you created by typing in role name in the **Search** field.

m. Choose your role.

n. Next, choose **Attach Policies**.

o. Search for `AmazonSageMakerEdgeDeviceFleetPolicy` in the **Search** field. Select `AmazonSageMakerEdgeDeviceFleetPolicy`.

p. Choose **Attach policy**.

q. Add the following policy statement to the trust relationship:

```
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Effect": "Allow",
       "Principal": {
         "Service": "credentials.iot.amazonaws.com",
         "Action": "sts:AssumeRole"
       },
     },
     {
       "Effect": "Allow",
       "Principal": {
         "Service": "sagemaker.amazonaws.com",
         "Action": "sts:AssumeRole"
       }
     }
   ]
}
```

A trust policy is a **JSON policy document** in which you define the principals that you trust to assume the role. For more information about trust policies, see **Roles terms and concepts**.

r. Note the AWS IoT role ARN. You use the AWS IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:

i. Go to the IAM console: https://console.aws.amazon.com/iam/

ii. Choose **Roles**.

iii. Search for the role you created by typing in the name of the role in the **Search** field.

iv. Select the role.

v. The role ARN is on the Summary page.

4. **Create an Amazon S3 bucket.**

SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

b. Choose **Create bucket**.

c. In **Bucket name**, enter a name for your bucket.

d. In **Region**, choose the AWS Region where you want the bucket to reside.

e. In **Bucket settings for Block Public Access**, choose the settings that you want to apply to the bucket.

f. Choose **Create bucket**.

For more information about creating Amazon S3 buckets, see **Getting started with Amazon S3**.
Train, Compile, and Package Your Model

In this section you will create SageMaker and AWS IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. **Import libraries and create client objects.**

   This tutorial uses the AWS SDK for Python (Boto3) to create clients to interact with SageMaker, Amazon S3, and AWS IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:

   ```python
   import boto3
   import json
   import time

   AWS_REGION = 'us-west-2'  # Specify your Region
   bucket = 'bucket-name'

   sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)
   iot_client = boto3.client('iot', region_name=AWS_REGION)
   ```

   Define variables and assign them the role ARN you created for SageMaker and AWS IoT as strings:

   ```python
   # Replace with the role ARN you created for SageMaker
   sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

   # Replace with the role ARN you created for AWS IoT.
   # Note: The name must start with 'SageMaker'
   iot_role_arn = "arn:aws:iam::<account>:role/SageMaker*"
   ```

2. **Train a machine learning model.**

   See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

   If you do not have a model yet, you can use a pre-trained model for the next steps in this tutorial. For example, you can save the MobileNet V2 models from the TensorFlow framework. MobileNet V2 is an image classification model optimized for mobile applications. For more information about MobileNet V2, see the [MobileNet GitHub README](#).

   Type the following into your Jupyter Notebook to save the pre-trained MobileNet V2 model:

   ```python
   # Save the MobileNet V2 model to local storage
   import tensorflow as tf
   model = tf.keras.applications.MobileNetV2()
   model.save("mobilenet_v2.h5")
   ```

   **Note**

   - If you do not have TensorFlow installed, you can do so by running `pip install tensorflow=2.4`
   - Use TensorFlow version 2.4 or lower for this tutorial.
The model will be saved into the `mobilenet_v2.h5` file. Before packaging the model, you will need to first compile your model using SageMaker Neo. See Supported Frameworks, Devices, Systems, and Architectures (p. 2708) to check if your version of TensorFlow (or other framework of choice) is currently supported by SageMaker Neo.

SageMaker Neo requires models to be stored as a compressed TAR file. Repackage it as a compressed TAR file (*.tar.gz):

```python
# Package MobileNet V2 model into a TAR file
import tarfile
tarfile_name='mobilenet-v2.tar.gz'
with tarfile.open(tarfile_name, mode='w:gz') as archive:
    archive.add('mobilenet-v2.h5')
```

3. **Upload your model to Amazon S3.**

Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an AWS CLI command to upload the model the to the Amazon S3 bucket you created earlier in a directory called `models`. Type in the following into your Jupyter Notebook:

```
!aws s3 cp mobilenet-v2.tar.gz s3://{bucket}/models/
```

4. **Compile your model with SageMaker Neo.**

Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URI where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

For the MobileNet V2 model, use the following:

```python
framework = 'tensorflow'
target_device = 'jetson_nano'
data_shape = '{"data": [1,3,224,224]}
```

SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect? (p. 2668). For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures (p. 2708).

Use the `CreateCompilationJob` API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker to store your compiled model, and your edge device target.

```python
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{bucket}/{model_directory}/{}'.format(bucket, model_directory, tarfile_name)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{bucket}/{compilation_output_dir}'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
```
5. **Package your compiled model.**

Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the create_edge_packaging API or the SageMaker console.

You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up (p. 2619) section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```python
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version=1.1

# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

Use CreateEdgePackagingJob to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was stored in the variable compilation_job_name). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker to store the packaged model.

```python
def sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output
    }
)
```

---

**Create and Register Fleets and Authenticate Devices**

In this section you will create your AWS IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to AWS IoT Core, associate the role alias with AWS IoT that was generated when you created your fleet, get your AWS account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.
1. **Create AWS IoT things.**

   SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and endpoints in the AWS cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to AWS IoT, you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure the IAM role for your devices.

   First, create AWS IoT thing objects with the AWS IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

   ```python
   iot_thing_name = 'sample-device'
   iot_thing_type = 'getting-started-demo'

   iot_client.create_thing_type(
       thingTypeName=iot_thing_type
   )

   # Create an AWS IoT thing objects
   iot_client.create_thing(
       thingName=iot_thing_name,
       thingTypeName=iot_thing_type
   )
   ```

2. **Create your device fleet.**

   Create a device fleet with the SageMaker client object defined in a previous step. You can also use the SageMaker console to create a device fleet.

   ```python
   import time
   device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
   device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]

   Specify your IoT role ARN. This lets AWS IoT grant temporary credentials to devices.

   device_model_directory='device_output'
   s3_device_fleet_output = 's3://{}/{}'.format(bucket, device_model_directory)

   sagemaker_client.create_device_fleet(
       DeviceFleetName=device_fleet_name,
       RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
       OutputConfig={
           'S3OutputLocation': s3_device_fleet_output
       } )

   An AWS IoT role alias is created when you create a device fleet. This role alias is associated with AWS IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

   To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the AWS IoT thing name as shown in the following example:

   ```python
   # Device name should be 36 characters
   device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]

   sagemaker_client.register_devices(
       device_name=device_name,
       thing_name=iot_thing_name,
       thing_type=iot_thing_type
   )
   ```
DeviceFleetName=device_fleet_name,
Devices=[
    {
        "DeviceName": device_name,
        "IotThingName": iot_thing_name
    }
]
)

4. **Create X.509 certificates.**

After creating the AWS IoT thing object, you must create a X.509 device certificate for your thing object. This certificate authenticates your device to AWS IoT Core.

Use the following to create a private key, public key, and a X.509 certificate file using the AWS IoT client defined (iot_client) earlier.

```python
# Creates a 2048-bit RSA key pair and issues an X.509 certificate
# using the issued public key.
create_cert = iot_client.create_keys_and_certificate(
    setAsActive=True
)

# Get certificate from dictionary object and save in its own
with open('./device.pem.crt', 'w') as f:
    for line in create_cert['certificatePem'].split('
'):
        f.write(line)
        f.write('
')

# Get private key from dictionary object and save in its own
with open('./private.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PrivateKey'].split('
'):
        f.write(line)
        f.write('
')

# Get a private key from dictionary object and save in its own
with open('./public.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PublicKey'].split('
'):
        f.write(line)
        f.write('
')
```

5. **Associate the role alias with AWS IoT.**

When you create a device fleet with SageMaker (sagemaker_client.create_device_fleet()), a role alias is generated for you. An AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates, and then obtain short-lived AWS credentials from an IAM role that is associated with an AWS IoT role alias. The role alias allows you to change the role of the device without having to update the device. Use DescribeDeviceFleet to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name =
    sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)[
        'IotRoleAlias'
    ]
start_index = full_role_alias_name.find('SageMaker')
# Find beginning of role name
role_alias_name = full_role_alias_name[start_index:]
```

Use the iot_client to facilitate associating the role alias generated from creating the device fleet with AWS IoT.
role_alias = iot_client.describe_role_alias(
    roleAlias=role_alias_name)

For more information about IAM role alias, see Role alias allows access to unused services.

You created and registered a certificate with AWS IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

alias_policy = {
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iot:AssumeRoleWithCertificate",
        "Resource": role_alias['roleAliasDescription']['roleAliasArn']
    }
}

policy_name = 'aliaspolicy-'+ str(time.time()).split('.')[0]
aliaspolicy = iot_client.create_policy(policyName=policy_name,
    policyDocument=json.dumps(alias_policy))

# Attach policy
iot_client.attach_policy(policyName=policy_name,
    target=create_cert['certificateArn'])

6. Get your AWS account-specific endpoint for the credentials provider.

Edge devices need an endpoint in order to assume credentials. Obtain your AWS account-specific endpoint for the credentials provider.

# Get the unique endpoint specific to your AWS account that is making the call.
iot_endpoint = iot_client.describe_endpoint(
    endpointType='iot:CredentialProvider'
)

endpoint="https://{}/role-aliases/{}/credentials".format(iot_endpoint['endpointAddress'],role_alias_name)

7. Get the official Amazon root CA file and upload it to the Amazon S3 bucket.

Use the following in your Jupyter Notebook or AWS CLI (if you use your terminal, remove the '!'
magic function):

!wget https://www.amazontrust.com/repository/AmazonRootCA1.pem

Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses curl, but you can use any HTTP client.

!curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem $endpoint

If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

!aws s3 cp private.pem.key s3://(bucket)/authorization-files/
!aws s3 cp device.pem.crt s3://(bucket)/authorization-files/
!aws s3 cp AmazonRootCA1.pem s3://(bucket)/authorization-files/
Clean your working directory by moving your keys and certificate to a different directory:

```bash
# Optional - Clean up working directory
mkdir authorization-files
mv private.pem.key device.pem.crt AmazonRootCA1.pem authorization-files/
```

## Download and Set Up Edge Manager

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Jetson Nano which uses a Linux operating system and has an ARM64 architecture. For more information about what operating system and architecture supported devices use, see Supported Devices, Chip Architectures, and Systems (p. 2710).

   Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the u-west-2 Region.

   ```bash
   !aws s3 ls s3://sagemaker-edge-release-store-us-west-2-linux-armv8/Releases/ | sort -r
   ```

   This returns release artifacts sorted by their version.

<table>
<thead>
<tr>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRE 1.20210512.96da6cc/</td>
</tr>
<tr>
<td>PRE 1.20210305.a4bc999/</td>
</tr>
<tr>
<td>PRE 1.20201218.81f481f/</td>
</tr>
<tr>
<td>PRE 1.20201207.02d0e97/</td>
</tr>
</tbody>
</table>

   The version has the following format: `<MAJOR_VERSION>,<YYYY-MM-DD>,<SHA-7>`. It consists of three components:

   - `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.
   - `<YYYY-MM-DD>`: The time stamp of the artifact release.
   - `<SHA-7>`: The repository commit ID from which the release is built.

   Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

   ```bash
   !aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
   ```

   Once you have the artifact, unzip the zipped TAR file. The following unzips the TAR file and stores it in a directory called `agent_demo`:  

   ```bash
   ```
Upload the agent release artifacts to your Amazon S3 bucket. The following code example copies the content within `agent_demo` and uploads it to a directory within your Amazon S3 bucket called `agent_demo`:

```bash
!aws s3 cp --recursive ./agent_demo s3://{bucket}/agent_demo
```

You also need the signing root certificates from the release bucket:

```bash
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-west-2/us-west-2.pem ./
```

Upload the signing root certificate to your Amazon S3 bucket:

```bash
!aws s3 cp us-west-2.pem s3://{bucket}/authorization-files/
```

2. **Define a SageMaker Edge Manager agent configuration file.**

First, define the agent configuration file as follows:

```python
sagemaker_edge_config = {
    "sagemaker_edge_core_device_name": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_root_certs_path": "/agent_demo/certificates",
    "sagemaker_edge_provider_aws_ca_cert_file": "/agent_demo/iot-credentials/AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "/agent_demo/iot-credentials/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "/agent_demo/iot-credentials/private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "endpoint",
    "sagemaker_edge_provider_aws_iot_credential_provider": "Aws",
    "sagemaker_edge_provider_s3_bucket_name": bucket,
    "sagemaker_edge_core_capture_data_destination": "Cloud"
}
```

Replace the following:

- "device_name" with the name of your device (this string was stored in an earlier step in a variable named `device_name`).
- "device_fleet_name" with the name of your device fleet (this string was stored an earlier step in a variable named `device_fleet_name`)
- "endpoint" with your AWS account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named `endpoint`).

Next, save it as a JSON file:

```python
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
```
Upload the configuration file to your Amazon S3 bucket:

```bash
!aws s3 cp sagemaker_edge_config.json s3://{bucket}/
```

3. **Copy the release artifacts, configuration file, and credentials to your device.**

The following instructions are performed on the edge device itself.

**Note**

You must first install Python, the AWS SDK for Python (Boto3), and the AWS CLI on your edge device.

Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

```bash
mkdir agent_demo
cd agent_demo
```

Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

```bash
# Copy release artifacts
aws s3 cp s3://<bucket-name>/agent_demo/ ./ --recursive
```

(The contents of the release artifact was stored in a directory called `agent_demo` in a previous step). Replace `<bucket-name>` and `agent_demo` with the name of your Amazon S3 bucket and the file path to your release artifacts, respectively.

Go the `/bin` directory and make the binary files executable:

```bash
cd bin
chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example
cd agent_demo
```

Make a directory to store your AWS IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable `bucket`):

```bash
mkdir iot-credentials
cd iot-credentials
aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./
```

 Cd . . /

Make a directory to store your model signing root certificates:

```bash
mkdir certificates
cd certificates
aws s3 cp s3://<bucket-name>/authorization-files/us-west-2.pem ./
```

2630
cd agent_demo

Copy your configuration file to your device:

```bash
#Download config file from S3
aws s3 cp s3:<bucket-name>/sagemaker_edge_config.json ./
cd agent_demo
```

Your `agent_demo` directory on your edge device should look similar to the following:

```text
###agent_demo
|    ### bin
|        ### sagemaker_edge_agent_binary
|        ### sagemaker_edge_agent_client_example
|    ### sagemaker_edge_config.json
|    ### certificates
|        ###us-west-2.pem
|    ### iot-credentials
|        ### AmazonRootCA1.pem
|        ### device.pem.crt
|        ### private.pem.key
|    ### docs
|        ### api
|        ### examples
|        ### ATTRIBUTIONS.txt
|    ### LICENSE.txt
|    ### RELEASE_NOTES.md
```

## Run Agent

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.

1. **Launch the agent.**

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the [gRPC documentation](https://grpc.io/).

   To use gRPC, perform the following steps:

   b. Generate server and client code using the protocol buffer compiler.
   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.
   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.
The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the /bin directory of your release artifact. The sagemaker_edge_agent_binary binary executable is in this directory.

To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

```
./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c
  sagemaker_edge_config.json
```

2. **Check your device.**

Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

```
sagemaker_client.describe_device(
  DeviceName=device_name,
  DeviceFleetName=device_fleet_name
)
```

For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

```
{
  "DeviceName": "sample-device",
  "DeviceFleetName": "demo-device-fleet",
  "IoTThingName": "sample-thing-name-1",
  "RegistrationTime": 1600977370,
  "LatestHeartbeat": 1600977370,
  "Models": [
    {
      "ModelName": "mobilenet_v2.tar.gz",
      "ModelVersion": "1.1",
      "LatestSampleTime": 1600977370,
      "LatestInference": 1600977370
    }
  ]
}
```

The timestamp provided by `LatestHeartbeat` indicates the last signal that was received from the device. `LatestSampleTime` and `LatestInference` describe the timestamp of the last data sample and inference, respectively.

3. **Check your fleet.**

Check that your fleet is working with `GetDeviceFleetReport`. Provide the name of the fleet the device belongs to.

```
sagemaker_client.get_device_fleet_report(
  DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.
Set Up Devices and Fleets

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console.

Topics
- Create a Fleet (p. 2633)
- Register a Device (p. 2637)
- Check Status (p. 2639)

Create a Fleet

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console https://console.aws.amazon.com/sagemaker.

Create a Fleet (Boto3)

Use the CreateDeviceFleet API to create a fleet. Specify a name for the fleet, your AWS IoT Role ARN for the RoleArn field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an AWS KMS Key ID.

```python
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-device-fleet",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        "S3OutputLocation": "s3://fleet-bucket/package_output",
    },
    AgentVersions:[{"Version": "1.1", "AgentCount": 2}]
)"
```
An AWS IoT Role Alias is created for you when you create a device fleet. The AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates and then obtain short-lived AWS credentials from an IAM role that is associated with the AWS IoT role alias.

Use `DescribeDeviceFleet` to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
```

Use `DescribeDeviceFleet` API to get a description of fleets you created.

```python
sagemaker_client.describe_device_fleet()
```

By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in AWS IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.

```json
```

## Create a Fleet (Console)

You can create a Edge Manager packaging job using the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose **Edge Manager** and then choose **Edge device fleets**.
2. Choose **Create device fleet**.
3. Enter a name for the device fleet in the **Device fleet name** field. Choose **Next**.
4. On the **Output configuration** page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by selecting an existing AWS KMS key from the dropdown list or by entering a key's ARN. Choose *Submit*. 
5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the Device fleet tags section.

### Register a Device

**Important**

Device registration is required to use any part of SageMaker Edge Manager.

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console at https://console.aws.amazon.com/sagemaker.

**Register a Device (Boto3)**

To register your device, first create and register an AWS IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

To connect your device to AWS IoT you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure IAM role for your devices.

See the Getting Started Guide for an in-depth example or the Explore AWS IoT Core services in hands-on tutorial.

Use the RegisterDevices API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and AWS IoT thing name associated with the device.

```python
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
)
Register a Device (Console)

You can register your device using the SageMaker console at https://console.aws.amazon.com/sagemaker.

1. In the SageMaker console, choose **Edge Inference** and then choose **Edge devices**.
2. Choose **Register devices**.

3. In the **Device properties** section, enter the name of the fleet the device belongs to under the **Device fleet name** field. Choose **Next**.

4. In the **Device source** section, add your devices one by one. You must include a **Device Name** for each device in your fleet. You can optionally provide a description (in the **Description** field) and an

```json
Devices=[
    {
        "DeviceName": "sample-device-1",
        "IotThingName": "sample-thing-name-1",
        "Description": "Device #1"
    }
],
Tags=[
    {
        "Key": "string",
        "Value": "string"
    }
]"
```
Internet of Things (IoT) object name (in the **IoT name** field). Choose **Submit** once you have added all your devices.

### Device source

#### Add devices one by one

<table>
<thead>
<tr>
<th>Device Name</th>
<th>Description - <em>optional</em></th>
<th>IoT name - <em>optional</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter device name</td>
<td>Enter description</td>
<td>Enter IoT name</td>
</tr>
</tbody>
</table>

Add another device

You can add up to 50 devices

The **Devices** page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and AWS IoT name, if you provided one.

Choose a device to view the device's details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

### Check Status

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/) to interactively choose a fleet for a status check. You can also use the AWS SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

To check the status of an individual device, use **DescribeDevice** API. A list containing one or more models is provided if a models have been deployed to the device.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

Running **DescribeDevice** returns:

```json
{
    "DeviceName": "sample-device",
    "Description": "this is a sample device",
    "DeviceFleetName": "sample-device-fleet",
    "IoTThingName": "SampleThing",
    "ARN": "arn:aws:iot:us-east-1:1234567890:thing/sample-device-1"
}
```
"RegistrationTime": 1600977370,
"LatestHeartbeat": 1600977370,
"Models": [
    {
      "ModelName": "sample-model",
      "ModelVersion": "1.1",
      "LatestSampleTime": 1600977370,
      "LatestInference": 1600977370
    }
]

• Check a fleet of devices.

To check the status of the fleet, use the GetDeviceFleetReport API. Provide the name of the device fleet to get a summary of the fleet.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

• Check for a heartbeat.

Each device within a fleet periodically generates a signal, or “heartbeat”. The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

Check the last heartbeat with made by a device with the DescribeDevice API. Specify the name of the device and the fleet to which the edge device belongs.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

Package Model

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

Topics

- Prerequisites (p. 2640)
- Package a Model (Amazon SageMaker Console) (p. 2642)
- Package a Model (Boto3) (p. 2645)

Prerequisites

To package a model, you must do the following:

1. Compile your machine learning model with SageMaker Neo.

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see Compile and Deploy Models with Neo. If you are first-time user of SageMaker Neo, go through Getting Started with Neo Edge Devices.

2. Get the name of your compilation job.
Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and choose **Compilation jobs** to find a list of compilations that have been submitted to your AWS account. The names of submitted compilation jobs are in the **Name** column.

3. **Get your IAM ARN.**

You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

Use one of the following methods to get your IAM ARN:

- **Programmatically with the SageMaker Python SDK**

```python
import sagemaker

# Initialize SageMaker Session object so you can interact with AWS resources
sess = sagemaker.Session()

# Get the role ARN
role = sagemaker.get_execution_role()

print(role)

>> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
```

For more information about using the SageMaker Python SDK, see the [SageMaker Python SDK API](https://boto3.amazonaws.com/v1/documentation/api/).  

- **Using the AWS Identity and Access Management (IAM) console**

Navigate to the IAM console at https://console.aws.amazon.com/iam/. In the **IAM Resources** section, choose **Roles** to view a list of roles in your AWS account. Select or create a role that has **AmazonSageMakerFullAccess**, **AWSIoTFullAccess**, and **AmazonS3FullAccess**.

For more information on IAM, see [What is IAM?](https://aws.amazon.com/identity-access-management/)

4. **Have an S3 bucket URI.**

You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

Use one of the following methods to create an Amazon S3 bucket:

- **Programmatically with the SageMaker Python SDK**

You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: `sagemaker-{region}-{aws-account-id}`. To create a default bucket with the SageMaker Python SDK, use the following:

```python
import sagemaker

session=sagemaker.create_session()

bucket=session.default_bucket()
```

- **Using the Amazon S3 console**

Package a Model (Amazon SageMaker Console)

You can create a SageMaker Edge Manager packaging job using the SageMaker console at https://console.aws.amazon.com/sagemaker/. Before continuing, make sure you have satisfied the Prerequisites (p. 2640).

1. In the SageMaker console, choose **Edge Inference** and then choose **Edge packaging jobs**, as shown in the following image.

   ![Edge packaging jobs](image)

2. On the **Job properties** page, enter a name for your packaging job under **Edge packaging job name**. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under **Model name** and **Model version**, respectively.

3. Next, select an **IAM role**. You can chose a role or let AWS create a role for you. You can optionally specify a **resource key ARN** and **job tags**.

4. Choose **Next**.
5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose Next.
6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

**Output configuration**

Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optionally) specify a KMS key.

**S3 bucket URI**

Enter your S3 bucket URI where you want devices to store sample data.

```
s3://bucket-example/sagemaker-edge/device-output
```

To find a path, go to Amazon S3

**Encryption key - optional**

Encrypt your data. Choose an existing KMS key or enter a key's ARN.

```
No Custom Encryption
```

The **Status** column on the Edge packaging jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.
The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

### Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the AWS SDK for Python (Boto3). Before continuing, make sure you have satisfied the [Prerequisites](#).

To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```python
# Import AWS SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    }
)
```

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```python
response = sagemaker_client.describe_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

This returns a dictionary that can be used to poll the status of the packaging job:

```python
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name"
    )

    if response['EdgePackagingJobStatus'] == 'Completed':
        break
    elif response['EdgePackagingJobStatus'] == 'Failed':
        raise RuntimeError('Packaging job failed')
    print('Packaging model...')
    time.sleep(30)
print('Done!')
```
For a list of packaging jobs, use `ListEdgePackagingJobs`. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for `NameContains`, a partial name for `ModelNameContains` to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with `SortBy`, and by which direction to sort for `SortOrder` (either `Ascending` or `Descending`).

```python
sagemaker_client.list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use `StopEdgePackagingJob` and provide the name of your edge packaging job.

```python
sagemaker_client.stop_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the Boto3 documentation.

## Edge Manager Agent

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

There are two methods of installing and deploying the Edge Manager agent onto your edge devices:

1. Download the agent as a binary from the Amazon S3 release bucket. For more information, see Download and Set Up Edge Manager Agent Manually (p. 2646).
2. Use the AWS IoT Greengrass V2 console or the AWS CLI to deploy `aws.greengrass.SageMakerEdgeManager`. See Create AWS IoT Greengrass V2 Components (p. 2652).

### Download and Set Up Edge Manager Agent Manually

Download the Edge Manager agent based on your operating system, architecture, and your AWS Region. The agent is periodically updated, so you have the option to choose your agent based on release dates and versions. Once you have the agent, create a JSON configuration file. Specify the device IoT thing name, fleet name, device credentials, and other key-value pairs. See Running SageMaker Edge Manager Agent (p. 2648) for full a list of keys you must specify in the configuration file. You can run the agent as an executable binary or link against it as a Dynamic Shared Object.

### How the Agent Works

The agent runs on the CPU of your devices. The agent runs inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent supports the GPU in the provided Deep Learning Runtime (DLR).

The agent is released in binary format for supported operating systems. Check that your operating system is supported and meets the minimum OS requirement in the following table:

**Linux**

- **Version**: Ubuntu 18.04
Supported Binary Formats: x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

Windows

Version: Windows 10 version 1909

Supported Binary Formats: x86-32 bit (DLL) and x86-64 bit (DLL)

Installing Edge Manager Agent

To use Edge Manager agent, you first must obtain the release artifacts and a Root Certificate. The release artifacts are stored in an Amazon S3 bucket in the us-west-2 Region. To download the artifacts, specify your operating system (<OS>) and the VERSION.

Based on your operating system, replace <OS> with one of the following:

<table>
<thead>
<tr>
<th>Windows 32-bit</th>
<th>Windows 64-bit</th>
<th>Linux x86-64</th>
<th>Linux ARMv8</th>
</tr>
</thead>
<tbody>
<tr>
<td>windows-x86</td>
<td>windows-x64</td>
<td>linux-x64</td>
<td>linux-armv8</td>
</tr>
</tbody>
</table>

The VERSION is broken into three components: <MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>, where:

- <MAJOR_VERSION>: The release version. The release version is currently set to 1.
- <YYYY-MM-DD>: The time stamp of the artifacts release.
- <SHA-7>: The repository commit ID from which the release is built.

You must provide the MAJOR_VERSION and the time stamp in <YYYY-MM-DD> format. We suggest you use the latest artifact release time stamp. Use the following to get the latest time stamp.

Run the following in your command line to get the latest time stamp. Replace <OS> with your operating system:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0
PRE 1.20201218.81f481f/
PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version has a major release version of 1, a time stamp of 20201218 (in <YYYY-MM-DD> format), and a 81f481f SHA-7 commit ID.

**Note**

The preceding command assumes you have configured the AWS Command Line Interface. For more information, about how to configure the settings that the AWS CLI uses to interact with AWS, see Configuring the AWS CLI.

Based on your operating system, use the following commands to install the artifacts:
You also must download a Root Certificate. This certificate validates model artifacts signed by AWS before loading them onto your edge devices.

Replace `<OS>` corresponding to your platform from the list of supported operation systems and replace `<REGION>` with your AWS Region.

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-<OS>/Certificates/<REGION>/<REGION>.pem
```

### Running SageMaker Edge Manager Agent

You can run SageMaker Edge Manager agent can as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or you can link against it as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux. Running as a shared object (.dll) is supported on Windows.

On Linux, we recommend that you run the binary via a service that’s a part of your initialization (`init`) system. If you want to run the binary directly, you can do so in a terminal as shown in the following example. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent, first create a JSON configuration file. Specify the following key-value pairs:

- `sagemaker_edge_core_device_name`: The name of the device. This device name needs to be registered along with the device fleet in the SageMaker Edge Manager console.
- `sagemaker_edge_core_device_fleet_name`: The name of the fleet the device belongs to.
- `sagemaker_edge_core_region`: AWS region associated with the device, the fleet and Amazon S3 buckets. This corresponds to the region where the device is registered and where the Amazon S3
bucket is created (they are expected to be the same). The models themselves can be compiled with SageMaker Neo in a different region, this configuration is not related to model compilation region.

- `sagemaker_edge_core_root_certs_path`: The absolute folder path to root certificates. This is used to validate the device with the relevant AWS account.
- `sagemaker_edge_provider_aws_ca_cert_file`: The absolute path to Amazon Root CA certificate (AmazonRootCA1.pem). This is used to validate the device with the relevant AWS account. AmazonCA is a certificate owned by AWS.
- `sagemaker_edge_provider_aws_cert_file`: The absolute path to AWS IoT signing root certificate (*.pem.crt).
- `sagemaker_edge_provider_aws_cert_pk_file`: The absolute path to AWS IoT private key. (*.pem.key).
- `sagemaker_edge_provider_aws_iot_cred_endpoint`: The AWS IoT credentials endpoint (identifier.iot.region.amazonaws.com). This endpoint is used for credential validation. See Connecting devices to AWS IoT for more information.
- `sagemaker_edge_provider_provider`: This indicates the implementation of provider interface being used. The provider interface communicates with the end network services for uploads, heartbeats and registration validation. By default this is set to "Aws". We allow custom implementations of the provider interface. Can be set to None for no provider or Custom for custom implementation with relevant shared object path provided.
- `sagemaker_edge_provider_provider_path`: Provides the absolute path to the provider implementation shared object (.so or .dll file). The "Aws" provider dll/so file is provided with the agent release. This field is mandatory.
- `sagemaker_edge_provider_s3_bucket_name`: The name of your Amazon S3 bucket (not the Amazon S3 bucket URI). The bucket must have a sagemaker string within its name.
- `sagemaker_edge_log_verbose`: Optional. Set debug log. Select either True or False.
- `sagemaker_edge_core_log_systemd_path`: For Linux only, systemd implements the agent crash counter metric. Set the absolute path of libsystemd to enable the crash counter metric. The default libsystemd path can be found by running "whereis libsystemd" in the device terminal.
- `sagemaker_edge_core_capture_data_destination`: The destination for uploading capture data. Choose either Cloud or Disk. Default is set to "Disk". Setting to "Disk" will write the input/output tensor(s) and auxiliary data to the local file system at a location of preference. When writing to "Cloud" use the Amazon S3 bucket name provided in the `sagemaker_edge_provider_s3_bucket_name` configuration.
- `sagemaker_edge_core_capture_data_disk_path`: Set the absolute path in the local file system, where capture data files will be written into when "Disk" is the destination. This field is not used when "Cloud" is specified as the destination.
- `sagemaker_edge_core_folder_prefix`: The parent prefix in Amazon S3 where captured data is stored when you specify "Cloud" as the capture data destination (sagemaker_edge_core_capture_data_disk_path). Captured data is stored in a sub-folder under sagemaker_edge_core_capture_data_disk_path if "Disk" is set as the data destination.
- `sagemaker_edge_core_capture_data_buffer_size`: The capture data circular buffer size. It indicates maximum number of requests stored in the buffer.
- `sagemaker_edge_core_capture_data_batch_size`: The capture data batch size. It indicates size of a batch of requests that are handled from the buffer. This value must to be less than sagemaker_edge_core_capture_data_buffer_size. A maximum of half the size of the buffer is recommended for batch size.
- `sagemaker_edge_core_capture_data_push_period_seconds`: The capture data push period in seconds. A batch of requests in the buffer is handled when there are batch size requests in the buffer, or when this time period hits (whichever comes first). This configuration sets that time period.
- `sagemaker_edge_core_capture_data_base64_embed_limit`: The limit for uploading capture data in bytes. Integer value.
Your configuration file should look similar to the following (with your specific values specified). In this example the default AWS provider("Aws") is used and no periodic upload is specified.

```json
{
  "sagemaker_edge_core_device_name": "device-name",
  "sagemaker_edge_core_device_fleet_name": "fleet-name",
  "sagemaker_edge_core_region": "region",
  "sagemaker_edge_core_root_certs_path": "<Absolute path to root certificates>",
  "sagemaker_edge_provider_provider": "Aws",
  "sagemaker_edge_provider_provider_path": "/path/to/libprovider-aws.so",
  "sagemaker_edge_provider_aws_ca_cert_file": "<Absolute path to Amazon Root CA certificate>/AmazonRootCA1.pem",
  "sagemaker_edge_provider_aws_cert_file": "<Absolute path to AWS IoT signing root certificate>/device.pem.crt",
  "sagemaker_edge_provider_aws_cert_pk_file": "<Absolute path to AWS IoT private key>/private.pem.key",
  "sagemaker_edge_provider_aws_iot_cred_endpoint": "https://<AWS IoT Endpoint Address>",
  "sagemaker_edge_core_capture_data_destination": "Cloud",
  "sagemaker_edge_core_capture_data_batch_size": 10,
  "sagemaker_edge_core_capture_data_base64_embed_limit": 2,
  "sagemaker_edge_log_verbose": false
}
```

Included in the release artifact is a binary executable called `sagemaker_edge_agent_binary` in the `bin` directory. To run the binary, use the `-a` flag to create a socket file descriptor (.sock) in a directory of your choosing and specify the path of the agent JSON config file you created with the `-c` flag.

```
./sagemaker_edge_agent_binary -a <ADDRESS_TO_SOCKET> -c <PATH_TO_CONFIG_FILE>
```

For example:

```
./sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
```

In this example, a socket file descriptor named `sagemaker_edge_agent_example.sock` is created in the `/tmp` directory and points to a configuration file that is in the same working directory as the agent called `sagemaker_edge_config.json`.

## Deploy Model Package and Edge Manager Agent with AWS IoT Greengrass

SageMaker Edge Manager integrates AWS IoT Greengrass version 2 to simplify accessing, maintaining, and deploying the Edge Manager agent and model to your devices. Without AWS IoT Greengrass V2, setting up your devices and fleets to use SageMaker Edge Manager requires you to manually copy the Edge Manager agent from an Amazon S3 release bucket. You use the agent to make predictions with models loaded onto your edge devices. With AWS IoT Greengrass V2 and SageMaker Edge Manager integration, you can now use AWS IoT Greengrass V2 components. Components are pre-built software modules that can connect your edge devices to AWS services or third-party service via AWS IoT Greengrass.

You must install the AWS IoT Greengrass Core software onto your device(s) if you want to use AWS IoT Greengrass V2 to deploy the SageMaker Edge Manager agent and your model. For more information about device requirements and how to set up your devices, see Setting up AWS IoT Greengrass core devices in the AWS IoT Greengrass documentation.
You use a pre-built component, an autogenerated component, and a custom component for your Edge Manager application. The public SageMaker Edge Manager component is maintained by SageMaker. The private component is autogenerated when you package your machine learning model with the `CreateEdgePackagingJob` API and specify "GreengrassV2Component" for the Edge Manager API field `PresetDeploymentType`. The third component is the inference application that is responsible for preprocessing and making inferences on your device. You must create this component. See either ??? (p. 2654) in the SageMaker Edge Manager documentation or Create custom AWS IoT Greengrass components in the AWS IoT Greengrass documentation for more information on how to create custom components.

**Prerequisites**

SageMaker Edge Manager uses AWS IoT Greengrass V2 to simplify the deployment of the Edge Manager agent, your machine learning models, and your inference application to your device(s) with the use of components. To make it easier to maintain your AWS IAM roles, Edge Manager allows you to reuse your existing AWS IoT role alias. If you do not have one yet, Edge Manager generates a role alias as part of the Edge Manager packaging job. You no longer need to associate a role alias generated from the SageMaker Edge Manager packaging job with your AWS IoT Role.

Before you start, you must:

1. Install the AWS IoT Greengrass Core software. For detailed information, see Install the AWS IoT Greengrass Core software.
2. Set up AWS IoT Greengrass V2. For more information, see Install AWS IoT Greengrass Core software with manual resource provisioning.

**Note**

- Make sure the AWS IoT thing name is all lowercase and does not contain characters except (optionally) dashes (#).
- The IAM Role must start with SageMaker*

3. Attach the following permission and inline policy to the IAM role created during AWS IoT Greengrass V2 setup.
   - Navigate to the IAM console https://console.aws.amazon.com/iam/.
   - Search for the role you created by typing in the role name in the Search field.
   - Choose your role.
   - Next, choose Attach policies.
   - Search for `AmazonSageMakerEdgeDeviceFleetPolicy`.
   - Select `AmazonSageMakerFullAccess` (This is an optional step that makes it easier for you to reuse this IAM role in model compilation and packaging).
   - Select Add inline policy.

```json
{
    "Version":"2012-10-17",
    "Statement":[
        {
            "Sid":"GreengrassComponentAccess",
            "Effect":"Allow",
            "Action":[
                "greengrass:CreateComponentVersion",
                "greengrass:DescribeComponent"
            ],
            "Resource":"
        }
    ]
}
```

- Click Attach policy.
- Select **Trust relationship**.
- Click **Edit trust relationship**.
- Replace the content with the following.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "credentials.iot.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

4. Create an Edge Manager device fleet. For information on how to create a fleet, see Set Up Devices and Fleets (p. 2633).
5. Register your device with the same name as your AWS IoT thing name created during the AWS IoT Greengrass V2 setup.
6. Create at least one custom private AWS IoT Greengrass component. This component is the application that runs inference on the device. See Create a Hello World custom component (p. 2654)

**Note**

- The SageMaker Edge Manager and AWS IoT Greengrass integration only works for AWS IoT Greengrass v2.
- Both your AWS IoT thing name and Edge Manager device name must be the same.
- SageMaker Edge Manager does not load local AWS IoT certificates and call the AWS IoT credential provider endpoint directly. Instead, SageMaker Edge Manager uses the AWS IoT Greengrass v2 TokenExchangeService and it fetches a temporary credential from a TES endpoint.

**Create AWS IoT Greengrass V2 Components**

AWS IoT Greengrass uses *components*, a software module that is deployed to and runs on a AWS IoT Greengrass core device. You will need (at a minimum) three components:

1. A public Edge Manager Agent AWS IoT Greengrass component.  
2. A model component that is autogenerated when you package your machine learning model with either the AWS SDK for Python (Boto3) API or with the SageMaker console.  
3. A private, custom component for the inference application.

The Edge Manager Agent AWS IoT Greengrass component (1) deploys the Edge Manager Agent binary.

The model component (2) is autogenerated when you create an edge packaging job with either the AWS SDK for Python (Boto3) API or the SageMaker console. For information on how to generate the model component, see Autogenerated Component (p. 2653).
The private custom component (3) is the application that you use to implement the Edge Manager Agent client application, as well as do any preprocessing and post-processing of the inference results. For more information about how to create a custom component, see Autogenerated Component (p. 2653) or Create custom AWS IoT Greengrass components.

Autogenerated Component

Generate the model component with the CreateEdgePackagingJob API and specify GreengrassV2Component for the SageMaker Edge Manager packaging job API field PresetDeploymentType. When you call the CreateEdgePackagingJob API, Edge Manager takes your SageMaker Neo–compiled model in Amazon S3 and creates a model component. The model component is automatically stored in your account. You can view any of your components by navigating to the AWS IoT console https://console.aws.amazon.com/iot/. Select Greengrass and then select Core devices. The page has a list of AWS IoT Greengrass core devices associated with your account. If a model component name is not specified in PresetDeploymentConfig, the default name generated consists of "SagemakerEdgeManager" and the name of your SageMaker Edge Manager packaging job. The following example demonstrates how to specify Edge Manager to create a AWS IoT Greengrass V2 component with the CreateEdgePackagingJob API.

```python
import sagemaker
import boto3

# Create a SageMaker client object to make it easier to interact with other AWS services.
sagemaker_client = boto3.client('sagemaker', region=<YOUR_REGION>)

# Replace with your IAM Role ARN
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace string with the name of your already created S3 bucket.
bucket = 'edge-manager-demo-bucket'

# Specify a name for your edge packaging job.
edge_packaging_name = "edge_packag_job_demo"

# Replace the following string with the name you used for the SageMaker Neo compilation job.
compilation_job_name = "getting-started-demo"

# The name of the model and the model version.
model_name = "sample-model"
model_version = "1.1"

# Output directory in S3 where you want to store the packaged model.
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}{}'.format(bucket, packaging_output_dir)

# The name you want your Greengrass component to have.
component_name = "SagemakerEdgeManager" + edge_packaging_name

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output,
        "PresetDeploymentType": "GreengrassV2Component",
        "PresetDeploymentConfig": "{\"ComponentName\":\"sample-component-name\", \"ComponentVersion\":\"1.0.2\"}"}
)
```
You can also create the autogenerated component with the SageMaker console. Follow steps 1-6 in Package a Model (Amazon SageMaker Console) (p. 2642)

Enter the Amazon S3 bucket URI where you want to store the output of the packaging job and optional encryption key.

Complete the following to create the model component:

1. Choose **Preset deployment**.
2. Specify the name of the component for the **Component name** field.
3. Optionally, provide a description of the component, a component version, the platform OS, or the platform architecture for the **Component description**, **Component version**, **Platform OS**, and **Platform architecture**, respectively.
4. Choose **Submit**.

**Create a Hello World custom component**

The custom application component is used to perform inference on the edge device. The component is responsible for loading models to SageMaker Edge Manager, invoking the Edge Manager agent for inference, and unloading the model when the component is shut down. Before you create your component, ensure the agent and application can communicate with SageMaker Edge Manager. To do this, configure **gRPC**. The SageMaker Edge Manager agent uses methods defined in Protobuf Buffers and the gRPC server to establish communication with the client application on the edge device and the cloud.

To use gRPC, you must:

1. Create a gRPC stub using the .proto file provided when you download the Edge Manager agent from Amazon S3 release bucket.
2. Write client code with the language you prefer.

You do not need to define the service in a .proto file (1). The service .proto files are included in the compressed TAR file when you download the SageMaker Edge Manager agent release binary from the Amazon S3 release bucket.

Install gRPC and other necessary tools on your host machine and create gRPC stubs `agent_pb2_grpc.py` and `agent_pb2.py` in Python. Make sure you have `agent.proto` in your local directory.

```
%%bash
pip install grpcio
pip install grpcio-tools
python3 -m grpc_tools.protoc --proto_path=. --python_out=. --grpc_python_out=. agent.proto
```

The preceding code generates the gRPC client and server interfaces from your .proto service definition (2). In other words, it creates the gRPC model in Python. The API folder contains the Protobuf specification for communicating with the agent.

Next, use the gRPC API to write a client and server for your service (2). The following example script, `edge_manager_python_example.py`, uses Python to load, list, and unload a yolov3 model to the edge device.

```python
import grpc
from PIL import Image
import agent_pb2
import agent_pb2_grpc
import os
```
model_path = '{PATH-TO-SagemakerEdgeManager-COMPONENT}'
agent_socket = 'unix:///tmp/aws.greengrass.SageMakerEdgeManager.sock'
agent_channel = grpc.insecure_channel(agent_socket, options=(('grpc.enable_http_proxy', 0),))
agent_client = agent_pb2_grpc.AgentStub(agent_channel)

def list_models():
    return agent_client.ListModels(agent_pb2.ListModelsRequest())

def list_model_tensors(models):
    return {
        model.name: {
            'inputs': model.input_tensor_metadatas,
            'outputs': model.output_tensor_metadatas
        }
        for model in list_models().models
    }

def load_model(model_name, model_path):
    load_request = agent_pb2.LoadModelRequest()
    load_request.url = model_path
    load_request.name = model_name
    return agent_client.LoadModel(load_request)

def unload_model(name):
    unload_request = agent_pb2.UnLoadModelRequest()
    unload_request.name = name
    return agent_client.UnLoadModel(unload_request)

def predict_image(model_name, image_path):
    image_tensor = agent_pb2.Tensor()
    image_tensor.byte_data = Image.open(image_path).tobytes()
    image_tensor_metadata = list_model_tensors(list_models())[model_name]['inputs'][0]
    image_tensor.tensor_metadata.name = image_tensor_metadata.name
    image_tensor.tensor_metadata.data_type = image_tensor_metadata.data_type
    for shape in image_tensor_metadata.shape:
        image_tensor.tensor_metadata.shape.append(shape)
    predict_request = agent_pb2.PredictRequest()
    predict_request.name = model_name
    predict_request.tensors.append(image_tensor)
    predict_response = agent_client.Predict(predict_request)
    return predict_response

def main():
    try:
        unload_model('your-model')
    except:
        pass

    print('LoadModel...', end='')
    try:
        load_model('your-model', model_path)
        print('done.')
    except Exception as e:
        print()
        print(e)
print('Model already loaded!')

print('ListModels...', end='')
try:
    print(list_models())
    print('done.')
except Exception as e:
    print()
    print(e)
    print('List model failed!')

print('Unload model...', end='')
try:
    unload_model('your-model')
    print('done.')
except Exception as e:
    print()
    print(e)
    print('unload model failed!')

if __name__ == '__main__':
    main()

Ensure model_path points to the name of the AWS IoT Greengrass component containing the model if you use the same client code example.

You can create your AWS IoT Greengrass V2 Hello World component once you have generated your gRPC stubs and you have your Hello World code ready. To do so:

- Upload your edge_manager_python_example.py, agent_pb2_grpc.py, and agent_pb2.py to your Amazon S3 bucket and note down their Amazon S3 path.
- Create a private component in the AWS IoT Greengrass V2 console and define the recipe for your component. Specify the Amazon S3 URI to your Hello World application and gRPC stub in the following recipe.

```---
RecipeFormatVersion: 2020-01-25
ComponentName: com.sagemaker.edgePythonExample
ComponentVersion: 1.0.0
ComponentDescription: Sagemaker Edge Manager Python example
ComponentPublisher: Amazon Web Services, Inc.
ComponentDependencies:
  aws.greengrass.SageMakerEdgeManager:
    VersionRequirement: '>=1.0.0'
    DependencyType: HARD
Manifests:
  - Platform:
    os: linux
    architecture: "/amd64|x86/"
  Lifecycle:
    install: |
      - apt-get install python3-pip
      pip3 install grpcio
      pip3 install grpcio-tools
      pip3 install protobuf
      pip3 install Pillow
    run: |
      script: |
        python3 {(artifacts:path)}/edge_manager_python_example.py
  Artifacts:
    - URI: <code-s3-path>
    - URI: <pb2-s3-path>
```
Deployment to Your Device

Deploy your components with the AWS IoT console or with the AWS CLI.

To deploy your components (console)

Deploy your AWS IoT Greengrass components with the AWS IoT console.

1. In the AWS IoT Greengrass console at https://console.aws.amazon.com/iot/navigation menu, choose Deployments.
2. On the Components page, on the Public components tab, choose aws.greengrass.SageMakerEdgeManager.
4. From Add to deployment, choose one of the following:
   a. To merge this component to an existing deployment on your target device, choose Add to existing deployment, and then select the deployment that you want to revise.
   b. To create a new deployment on your target device, choose Create new deployment. If you have an existing deployment on your device, choosing this step replaces the existing deployment.
5. On the Specify target page, do the following:
   a. Under Deployment information, enter or modify the friendly name for your deployment.
   b. Under Deployment targets, select a target for your deployment, and choose Next. You cannot change the deployment target if you are revising an existing deployment.
6. On the Select components page, under My components, choose:
   • com.<CUSTOM-COMPONENT-NAME>
   • aws.greengrass.SageMakerEdgeManager
   • SagemakerEdgeManager.<YOUR-PACKAGING-JOB>
7. On the Configure components page, choose com.greengrass.SageMakerEdgeManager, and do the following.
   a. Choose Configure component.
   b. Under Configuration update, in Configuration to merge, enter the following configuration.

   ```json
   {
   "DeviceFleetName": "device-fleet-name",
   "BucketName": "DOC-EXAMPLE-BUCKET"
   }
   ```

   Replace device-fleet-name with the name of the edge device fleet that you created, and replace DOC-EXAMPLE-BUCKET with the name of the Amazon S3 bucket that is associated with your device fleet.
   c. Choose Confirm, and then choose Next.
8. On the Configure advanced settings page, keep the default configuration settings, and choose Next.

To deploy your components (AWS CLI)

1. Create a deployment.json file to define the deployment configuration for your SageMaker Edge Manager components. This file should look like the following example.
Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.

SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.
The proto file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this proto file.

**Note**
There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where VERSION is broken into three components: 

<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>. See Installing Edge Manager Agent (p. 2647) for information on how to obtain the release version (<MAJOR_VERSION>), time stamp of the release artifact (<YYYY-MM-DD>), and the repository commit ID (SHA-7)

Linux

The zip archive can be extracted with the command:

```
tar -xvzf <VERSION>.tgz
```

Windows

The zip archive can be extracted with the UI or command:

```
unzip <VERSION>.tgz
```

The release artifact hierarchy (after extracting the tar/zip archive) is shown below. The agent proto file is available under api/.

```

**Topics**

- Load Model (p. 2660)
- Unload Model (p. 2661)
- List Models (p. 2661)
- Describe Model (p. 2662)
Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the EdgePackagingJob operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model’s signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```cpp
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
// rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);
```

Input

```cpp
// request for LoadModel rpc call
message LoadModelRequest {
  string url = 1;
  string name = 2;  // Model name needs to match regex "^[a-zA-Z0-9](\-*[a-zA-Z0-9])*")
}
```

Output

```cpp
// response for LoadModel rpc call
message LoadModelResponse {
  Model model = 1;
}

// Model represents the metadata of a model
// url - url representing the path of the model
// name - name of model
// input_tensor_metadatas - TensorMetadata array for the input tensors
// output_tensor_metadatas - TensorMetadata array for the output tensors
// Note:
// 1. input and output tensor metadata could empty for dynamic models.
// message Model {
```
Unload Model

Unloads a previously loaded model. It is identified via the model alias which was provided during `loadModel`. If the alias is not found or model is not loaded then returns error.

```java
// perform unload for a model
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist
// rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);
```

Input

```java
// request for UnLoadModel rpc call
// message UnLoadModelRequest {
  string name = 1; // Model name needs to match regex "^[a-zA-Z0-9-]*[a-zA-Z0-9-]+";
}
```

Output

```java
// response for UnLoadModel rpc call
// message UnLoadModelResponse {}
```

List Models

Lists all the loaded models and their aliases.

```java
// lists the loaded models
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// rpc ListModels(ListModelsRequest) returns (ListModelsResponse);
```

Input

```java
// request for ListModels rpc call
// message ListModelsRequest {}
Describe Model

Describes a model that is loaded on the agent.

```protobuf
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
//
// rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
```

Input

```protobuf
// request for DescribeModel rpc call
//
// message DescribeModelRequest {
//   string name = 1;
// }
```

Output

```protobuf
// response for DescribeModel rpc call
//
// message DescribeModelResponse {
//   Model model = 1;
// }
```

Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

```protobuf
// allows users to capture input and output tensors along with auxiliary data.
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 5. ALREADY_EXISTS - capture initiated for the given capture_id
// 6. RESOURCE_EXHAUSTED - buffer is full cannot accept any more requests.
// 7. OUT_OF_RANGE - timestamp is in the future.
// 8. INVALID_ARGUMENT - capture_id is not of expected format.
```
//
// rpc CaptureData(CaptureDataRequest) returns (CaptureDataResponse);

Input

enum Encoding {
  CSV = 0;
  JSON = 1;
  NONE = 2;
  BASE64 = 3;
}

// AuxiliaryData represents a payload of extra data to be capture along with inputs and outputs of inference
// encoding - supports the encoding of the data
// data - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.
//
message AuxiliaryData {
  string name = 1;
  Encoding encoding = 2;
  oneof data {
    bytes byte_data = 3;
    SharedMemoryHandle shared_memory_handle = 4;
  }
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// request for CaptureData rpc call
//
message CaptureDataRequest {
  string model_name = 1;
  string capture_id = 2; //uuid string
  Timestamp inference_timestamp = 3;
  repeated Tensor input_tensors = 4;
  repeated Tensor output_tensors = 5;
  repeated AuxiliaryData inputs = 6;
  repeated AuxiliaryData outputs = 7;
}

Output

//
Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the `CaptureData()` is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

Input

```protobuf
// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
//
// rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns
// (GetCaptureDataStatusResponse);

// request for GetCaptureDataStatus rpc call
//
message GetCaptureDataStatusRequest {
  string capture_id = 1;
}
```

Output

```protobuf
enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}

// response for GetCaptureDataStatus rpc call
//
message GetCaptureDataStatusResponse {
  CaptureDataStatus status = 1;
}
```

Predict

The `Predict` API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

```protobuf
// perform inference on a model.
//
// Note:
```
// 1. users can chose to send the tensor data in the protobuf message or
// through a shared memory segment on a per tensor basis, the Predict
// method with handle the decode transparently.
// 2. serializing large tensors into the protobuf message can be quite expensive,
// based on our measurements it is recommended to use shared memory of
// tenors larger than 256KB.
// 3. SMEdge IPC server will not use shared memory for returning output tensors,
// i.e., the output tensor data will always send in byte form encoded
// in the tensors of PredictResponse.
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all
// these call will be serialized under the hood. this shall be addressed
// in a later release.
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch
//
// rpc Predict(PredictRequest) returns (PredictResponse);

Input

// request for Predict rpc call
//
message PredictRequest {
  string name = 1;
  repeated Tensor tensors = 2;
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in
// two ways:
// a. send across the raw bytes of the multi-dimensional tensor
// array
// b. send a SharedMemoryHandle which contains the posix shared
// memory segment
// tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in
// two ways:
// a. send across the raw bytes of the multi-dimensional tensor
// array
// b. send a SharedMemoryHandle which contains the posix shared
// memory segment
// tensor array.
//
message Tensor {
Optimize model performance using Neo

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional
software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks (p. 2682) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures (p. 2708) for edge devices.

**How it Works**

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a model, see Use Neo to Compile a Model (p. 2668). With a few CLI commands, an API invocation, or a
few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker endpoint or on an AWS IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

**Neo Sample Notebooks**

For sample notebooks that use SageMaker Neo to train, compile, optimize, and deploy machine learning models to make inferences, see:

- MNIST Training, Compilation and Deployment with MXNet Module
- MNIST Training, Compilation and Deployment with Tensorflow Module
- Deploying pre-trained PyTorch vision models with SageMaker Neo
- Model Optimization with an Image Classification Example
- Model Optimization with XGBoost Example

For instructions on how to run these example notebooks in SageMaker, see [Example Notebooks (p. 250)](https://docs.aws.amazon.com/sagemaker/latest/dg/). If you need instructions on how to create a notebook instance to run these examples, see [Use Amazon SageMaker Notebook Instances (p. 237)](https://docs.aws.amazon.com/sagemaker/latest/dg/). To navigate to the relevant example in your notebook instance, choose the **Amazon SageMaker Examples** tab to see a list of all of the SageMaker samples. To open a notebook, choose its **Use** tab, then choose **Create copy**.

**Use Neo to Compile a Model**

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the Neo CLI, the Amazon SageMaker console, or the Amazon SageMaker SDK.

**Topics**
- Prepare Model for Compilation (p. 2668)
- Compile a Model (AWS Command Line Interface) (p. 2674)
- Compile a Model (Amazon SageMaker Console) (p. 2676)
- Compile a Model (Amazon SageMaker SDK) (p. 2681)

**Prepare Model for Compilation**

SageMaker Neo requires machine learning models satisfy specific input data shape. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

**Topics**
- What input data shapes does SageMaker Neo expect? (p. 2668)
- Saving Models for SageMaker Neo (p. 2670)

**What input data shapes does SageMaker Neo expect?**

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:
Keras

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: 
  ```
  {'input_1':[1,3,224,224]}
  ```

- For two inputs: 
  ```
  {'input_1': [1,3,224,224], 'input_2':[1,3,224,224]}
  ```

MXNet/ONNX

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: 
  ```
  {'data': [1,3,1024,1024]}
  ```

- For two inputs: 
  ```
  {'var1': [1,1,28,28], 'var2':[1,1,28,28]}
  ```

PyTorch

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: 
  ```
  {'input0':[1,3,224,224]}
  ```

- For one input in list format: 
  ```
  [[1,3,224,224]]
  ```

- For two inputs in dictionary format: 
  ```
  {'input0':[1,3,224,224], 'input1': [1,3,224,224]}
  ```

- For two inputs in list format: 
  ```
  [[1,3,224,224], [1,3,224,224]]
  ```

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: 
  ```
  {'input': [1,1024,1024,3]}
  ```

- For two inputs: 
  ```
  {'data1': [1,28,28,1], 'data2':[1,28,28,1]}
  ```

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: 
  ```
  {'input': [1,224,224,3]}
  ```

Note

SageMaker Neo only supports TensorFlow Lite for edge device targets. For a list of supported SageMaker Neo edge device targets, see the SageMaker Neo Devices (p. 2710) page. For a list of supported SageMaker Neo cloud instance targets, see the SageMaker Neo Supported Instance Types and Frameworks (p. 2682) page.

XGBoost

An input data name and shape are not needed.
Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (*.tar.gz).

Keras

Keras models require one model definition file (.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the SavedModel after exporting.

Below is an example of how to export a tf.keras model as a frozen graph (option two):

```python
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
  input_shape=(224, 224, 3), pooling='avg')
model.summary()

# Save as a SavedModel
export_dir = 'saved_model/'
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(':')[0] for inp in model.inputs]
output_node_names = [output.name.split(':')[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=['serve'])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess,
      sess.graph.as_graph_def(),
      output_node_names)

    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb",
      as_text=False)

import tarfile
tar = tarfile.open("frozen_graph.tar.gz", "w:gz")
tar.add("frozen_graph.pb")
tar.close()
```

Warning

Do not export your model with the SavedModel class using `model.save(<path>,
  save_format='tf')`. This format is suitable for training, but it is not suitable for inference.

MXNet

MXNet models must be saved as a single symbol file *-symbol.json and a single parameter *-params files.

Gluon Models

Define the neural network using the HybridSequential Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```python
from mxnet import nd, sym
```
Amazon SageMaker Developer Guide
Compile Models
from mxnet.gluon import nn
def get_net():
net = nn.HybridSequential() # Here we use the class HybridSequential.
net.add(nn.Dense(256, activation='relu'),
nn.Dense(128, activation='relu'),
nn.Dense(2))
net.initialize()
return net
# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()
# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)
# hybridize model
net.hybridize()
net(x)
# export model
net.export('<model_name>') # this will create model-symbol.json and model-0000.params
files
import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
tar.add(name)
tar.close()

For more information about hybridizing models, see the MXNet hybridize documentation.
Gluon Model Zoo (GluonCV)
GluonCV model zoo models come pre-hybridized. So you can just export them.
import numpy as np
import mxnet as mx
import gluoncv as gcv
from gluoncv.utils import export_block
import tarfile
net = gcv.model_zoo.get_model('<model_name>', pretrained=True) # For example, choose
<model_name> as resnet18_v1
export_block('<model_name>', net, preprocess=True, layout='HWC')
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
tar.add(name)
tar.close()

Non Gluon Models
All non-Gluon models when saved to disk use *-symbol and *.params ﬁles. They are therefore
already in the correct format for Neo.
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>',0,sym,args,aux) # this will create
<model_name>-symbol.json and <model_name>-0000.params files

2671


import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()

PyTorch

PyTorch models must be saved as a definition file (.pt or .pth) with input datatype of float32.

To save your model, use torch.jit.trace followed by torch.save. This will save an object to a disk file and by default uses python pickle (pickle_module=pickle) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

import torch
import torchvision

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
import tarfile
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()

TensorFlow

TensorFlow requires one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file is required.

Pre-Trained Model

The following code example shows how to use the tar Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the ! magic command at the beginning of the statement):

# Download SSD_Mobilenet trained model
!wget http://download.tensorflow.org/models/object_detection/
ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
!tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Compress the tar file and save it in a directory called 'model.tar.gz'
!tar czvf model.tar.gz ssd_mobilenet_v2_coco_2018_03_29/frozen_inference_graph.pb

The command flags used in this example accomplish the following:

- c: Create an archive
- z: Compress the archive with gzip
- v: Display archive progress
- f: Specify the filename of the archive
Built-In Estimators

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in `.fit` method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```python
from sagemaker.tensorflow import TensorFlow
estimator = TensorFlow(entry_point='mnist.py',
                       role=role,  # param role can be arn of a sagemaker execution role
                       framework_version='1.15.3',
                       py_version='py3',
                       training_steps=1000,
                       evaluation_steps=100,
                       instance_count=2,
                       instance_type='ml.c4.xlarge')
```

Then train the model with `.fit` built-in method:

```python
estimator.fit(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```python
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/')[-1])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                              input_shape={'data':[1, 784]},  # Batch size 1, 3 channels, 224x224 Images.
                                              output_path=output_path,
                                              framework='tensorflow', framework_version='1.15.3')
```

You can also use the `sagemaker.estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```python
import sagemaker
from sagemaker.image_uris import retrieve
sagemaker_session = sagemaker.Session()
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
training_image = retrieve(framework='image-classification',
                          region=aws_region, image_scope='training')

# Create estimator object for training
estimator = sagemaker.estimator.Estimator(image_uri=training_image,
                                          role=role,  # param role can be arn of a sagemaker execution role
                                          instance_count=1,
                                          instance_type='ml.p3.8xlarge',
                                          volume_size = 50,
                                          max_run = 360000,
                                          input_mode = 'File',
                                          output_path=s3_training_output_location,
                                          base_job_name='image-classification-training')
```

2673
# Setup the input data_channels to be used later for training.

```python
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,
                                           content_type='application/x-recordio',
                                           s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,
                                                content_type='application/x-recordio',
                                                s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}
```

# Train model

```python
estimator.fit(inputs=data_channels, logs=True)
```

# Compile model with Neo

```python
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                              input_shape={'data':[1, 3, 224, 224],
                                                           'softmax_label':[1]},
                                              output_path=s3_compilation_output_location,
                                              framework='mxnet',
                                              framework_version='1.7')
```

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker SDK) (p. 2681).

## Compile a Model (AWS Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using AWS Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

1. Create a Compilation Job

   With the CreateCompilationJob API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

   The following table demonstrates how to configure CreateCompilationJob API based on whether your target is a device or a platform.

   **Device Example**

   ```json
   {
   "CompilationJobName": "neo-compilation-job-demo",
   "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyymmdd2hhmmss",
   "InputConfig": {
   "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
   "DataInputConfig": "{data': [1,3,1024,1024]}",
   "Framework": "MXNET"
   },
   "OutputConfig": {
   "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
   # A target device specification example for a ml_c5 instance family
   "TargetDevice": "ml_c5"
   },
   "StoppingCondition": {
   "MaxRuntimeInSeconds": 300
   }
   ```
You can optionally specify the framework version you used with the `FrameworkVersion` field if you used the PyTorch framework to train your model and your target device is a `ml_*` target.

```json
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "PYTORCH",
        # The FrameworkVersion field is only supported when compiling for PyTorch framework and ml_* targets,
        # excluding ml_inf. Supported values are 1.4 or 1.5 or 1.6 . Default is 1.6
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5",
        # When compiling for ml_* instances using PyTorch framework, use the "CompilerOptions" field in
        # OutputConfig to provide the correct data type ("dtype") of the model’s input. Default assumed is "float32"
        "CompilerOptions": "{'dtype': 'long'}"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

**Note**

This API field is only supported for PyTorch.

**Platform Example**

```json
{
    "CompilationJobName": "neo-test-compilation-job",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target platform configuration example for a p3.2xlarge instance
        "TargetPlatform": {
            "Os": "LINUX",
            "Arch": "X86_64",
            "Accelerator": "NVIDIA"
        },
        "CompilerOptions": "{'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code': 'sm_70'}"
    }
}
```

2675
Note

For the OutputConfig API operation, the TargetDevice and TargetPlatform API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of DataInputConfig depending on frameworks, see What input data shapes Neo expects.

For more information about setting up the configurations, see the InputConfig, OutputConfig, and TargetPlatform API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \
--region us-west-2
# You should get CompilationJobArn
```

3. Describe the compilation job by running the following command:

```
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```

4. Stop the compilation job by running the following command:

```
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
# There is no output for compilation-job operation
```

5. List the compilation job by running the following command:

```
aws sagemaker list-compilation-jobs \
--region us-west-2
```

**Compile a Model (Amazon SageMaker Console)**

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

1. In the Amazon SageMaker console, choose **Compilation jobs**, and then choose **Create compilation job**.
2. On the Create compilation job page, under Job name, enter a name. Then select an IAM role.

3. If you don’t have an IAM role, choose Create a new role.

4. On the Create an IAM role page, choose Any S3 bucket, and choose Create role.
5. Non PyTorch Frameworks

Within the Input configuration section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the Location of model artifacts input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

For the Data input configuration field, enter the JSON string that specifies the shape of the input data. For Machine learning framework, choose the framework of your choice.

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

PyTorch Framework

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for ml_* (except ml_INF) target, you can optionally specify the version of PyTorch you used.
To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

**Note**
When compiling for ml_* instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model's input. The default is set to "float32".

**Warning**
If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file.
6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.

7. Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

8. Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.
Compile a Model (Amazon SageMaker SDK)

You can use the `compile_model` API in the Amazon SageMaker SDK for Python to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

**Note**

You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```python
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
input_shape=expected_trained_model_input,
output_path='insert s3 output path',
env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```

The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the Neo Model Compilation Sample Notebooks section.

Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and AWS Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the AWS CLI, the SageMaker Console, or the SageMaker SDK for Python. See, Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and AWS Inferentia instances using the SageMaker SDK for Python, AWS SDK for Python (Boto3), AWS CLI, or the AWS console.

If you deploy your model using AWS CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

Topics

- Supported Instance Types and Frameworks (p. 2682)
Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, AWS Inferentia instance types, or Amazon Elastic Inference accelerators.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see Deploy a Model with Cloud Instances. For information on how to deploy your compiled model with Elastic Inference accelerators, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2740).

Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.7.0</td>
<td>Supports 1.7.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.h5)</td>
<td></td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.4, 1.5, 1.6, 1.7 or 1.8</td>
<td>Supports 1.4, 1.5, 1.6, 1.7 and 1.8</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.3 or 2.4</td>
<td>Supports 1.15.3 and 2.4</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory</td>
<td></td>
</tr>
<tr>
<td>-----------</td>
<td>-------------------</td>
<td>--------------</td>
<td>--------</td>
<td>--------------------------------------</td>
<td>----------</td>
</tr>
<tr>
<td>XGBoost</td>
<td>1.3.3</td>
<td>Supports 1.3.3 or earlier</td>
<td>Decision Trees</td>
<td>One XGBoost model file (.model) where the number of nodes in a tree is less than (2^{31})</td>
<td>that contains variables For frozen models, only one .pb or .pbtxt file</td>
</tr>
</tbody>
</table>

**Note**

“Model Version” is the version of the framework used to train and export the model.

**Instance Types**

You can deploy your SageMaker compiled model to one of the cloud instances listed below:

<table>
<thead>
<tr>
<th>Instance</th>
<th>Compute Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1_c4</td>
<td>Standard</td>
</tr>
<tr>
<td>m1_c5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m4</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_p2</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_p3</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_g4dn</td>
<td>Accelerated computing</td>
</tr>
</tbody>
</table>

For information on the available vCPU, memory, and price per hour for each instance type, see Amazon SageMaker Pricing.

**Note**

When compiling for `m1_*` instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (`dtype`) of the model’s input. The default is set to "float32".

**AWS Inferentia**

SageMaker Neo supports the following deep learning frameworks for Inferentia:
<table>
<thead>
<tr>
<th>Framework</th>
<th>Framework Version</th>
<th>Model Version</th>
<th>Models</th>
<th>Toolkits</th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.5.1</td>
<td>Supports 1.5.1 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.7.1</td>
<td>Supports 1.7.1 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.0</td>
<td>Supports 1.15.0 or earlier</td>
<td>Image Classification</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file</td>
</tr>
</tbody>
</table>

**Note**

"Model Version" is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to AWS Inferentia-based Amazon EC2 Inf1 instances. AWS Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the ml_INF1 instance to deploy your compiled models.

**Amazon Elastic Inference**

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>2.3.2</td>
<td>Supports 2.3</td>
<td>Image Classification, Object Detection, Semantic</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory</td>
</tr>
</tbody>
</table>
You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2740).

Deploy a Model

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.

For Inf1 instances, models need to be compiled specifically for ml.inf1 instances. Models compiled for other instance types are not guaranteed to work with ml.inf1 instances.

For Elastic Inference accelerators, models need to be compiled specifically for ml_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2740).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: Amazon SageMaker SDK for Python, SDK for Python (Boto3), AWS Command Line Interface, and the SageMaker console https://console.aws.amazon.com/SageMaker.

Note
For deploying a model using AWS CLI, the console, or Boto3, see Neo Inference Container Images to select the inference image URI for your primary container.

Topics
- Prerequisites (p. 2685)
- Deploy a Compiled Model Using SageMaker SDK (p. 2691)
- Deploy a Compiled Model Using Boto3 (p. 2694)
- Deploy a Compiled Model Using the AWS CLI (p. 2696)
- Deploy a Compiled Model Using the Console (p. 2697)

Prerequisites

Note
Follow the instructions in this section if you compiled your model using AWS SDK for Python (Boto3), AWS CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from this list.
2. An entry point script file:
   a. For PyTorch and MXNet models:
If you trained your model using SageMaker, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo, the training script (mnist.py) implements the required functions.

If you did not train your model using SageMaker, you need to provide an entry point script (inference.py) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MxNet or Model Directory Structure for PyTorch.

When using Neo Inference Optimized Container images with PyTorch and MXNet on CPU and GPU instance types, the inference script must implement the following functions:

- **model_fn**: Loads the model. (Optional)
- **input_fn**: Converts the incoming request payload into a numpy array.
- **predict_fn**: Performs the prediction.
- **output_fn**: Converts the prediction output into the response payload.
- Alternatively, you can define **transform_fn** to combine **input_fn**, **predict_fn**, and **output_fn**.

The following are examples of inference.py script within a directory named code (code/inference.py) for PyTorch and MXNet (Gluon and Module). The examples first load the model and then serve it on image data on a GPU:

**MXNet Module**

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple
Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
    mod = mx.mod.Module(symbol=sym, context=ctx, label_names=None)
    exe = mod.bind(for_training=False,
                   data_shapes=[('data', (1,3,224,224))],
                   label_shapes=mod._label_shapes)
    mod.set_params(arg_params, aux_params, allow_missing=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    mod.forward(Batch([data]))
    return mod

def transform_fn(mod, image, input_content_type, output_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                           mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]))
```
std = mx.nd.array([0.229, 0.224, 0.225])
transposed = normalized.transpose((2, 0, 1))
batched = transposed.expand_dims(axis=0)
casted = batched.astype(dtype='float32')
processed_input = casted.as_in_context(ctx)

# prediction/inference
mod.forward(Batch([processed_input]))

# post-processing
prob = mod.get_outputs()[0].asnumpy().tolist()
prob_json = json.dumps(prob)
return prob_json, output_content_type

MXNet Gluon

import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json', ['data'], 'compiled-0000.params', ctx=ctx)

    # Hybridize the model & pass required options for Neo: static_alloc=True &
    # static_shape=True
    block.hybridize(static_alloc=True, static_shape=True)

    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    warm_up = block(data)
    return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255, mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batched = transposed.expand_dims(axis=0)
    casted = batched.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type
import os
import torch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.
    ""

    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')
    with torch.neon.config(model_dir=model_dir, neo_runtime=True):
        model = torch.jit.load(model_path)
        device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
        model = model.to(device)

        # We recommend that you run warm-up inference during model load
        sample_input_path = os.path.join(model_dir, 'sample_input.pkl')
        with open(sample_input_path, 'rb') as input_file:
            model_input = pickle.load(input_file)

        if torch.is_tensor(model_input):
            model_input = model_input.to(device)
        elif isinstance(model_input, tuple):
            model_input = (inp.to(device) for inp in model_input if torch.is_tensor(inp))
            model(*model_input)
        else:
            print("Only supports a torch tensor or a tuple of torch tensors")

    return model

def transform_fn(model, request_body, request_content_type, response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    ""

    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(mean=[2688,2688,2688],std=[1,1,1])
    ])
    return preprocess(decoded)
PyTorch 1.5 and Newer

Use `neopytorch` to specify the file path of the model if you trained with PyTorch version 1.5 and newer.
def transform_fn(model, request_body, request_content_type,
                 response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """
    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[0.485, 0.456, 0.406],
            std=[0.229, 0.224, 0.225]),
    ])
    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)

    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    batchified = batchified.to(device)
    output = model.forward(batchified)
    return json.dumps(output.cpu().numpy().tolist()), response_content_type

b. For inf1 instances or onnx, xgboost, keras container images

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- neo_preprocess: Converts the incoming request payload into a numpy array.
- neo_postprocess: Converts the prediction output from Neo Deep Learning Runtime into the response body.

Note
The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see Neo Model Compilation Sample Notebooks.

c. For TensorFlow models

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script inference.py file that can be used at the time of inference. The script should implement either a either a pair of input_handler and output_handler functions or a single handler function.

Note
Note that if handler function is implemented, input_handler and output_handler are ignored.

The following is a code example of inference.py script that you can put together with the compile model to perform custom pre- and post-processing on an image classification model. The SageMaker client sends the image file as an application/x-image content type to the input_handler function, where it is converted to JSON. The converted image file is then sent to the Tensorflow Model Server (TFX) using the REST API.
import json
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST API
    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details
    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    ""
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512)))
    image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
    body = json.dumps({"signature_name": "serving_default", "instances":
                       image.tolist()})
    return body

def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the client.
    Args:
    data (obj): the TensorFlow serving response
    context (Context): an object containing request and configuration details
    Returns:
    (bytes, string): data to return to client, response content type
    ""
    if data.status_code != 200:
        raise ValueError(data.content.decode('utf-8'))
    response_content_type = context.accept_header
    prediction = data.content
    return prediction, response_content_type

If there is no custom pre- or post-processing, the SageMaker client converts the file image to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

**Deploy a Compiled Model Using SageMaker SDK**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

**Topics**

- If you compiled your model using the SageMaker SDK (p. 2692)
- If you compiled your model using MXNet or PyTorch (p. 2692)
• If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow (p. 2693)

If you compiled your model using the SageMaker SDK

The `sagemaker.Model` object handle for the compiled model supplies the `deploy()` function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is `ml_c5`.

```python
predictor = compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.c5.4xlarge')
# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the `deploy()` API under the framework-specific Model APIs. For MXNet, it is `MXNetModel` and for PyTorch, it is `PyTorchModel`. When you are creating and deploying an SageMaker model, you must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 and specify the `entry_point` parameter as the inference script (`inference.py`) and the `source_dir` parameter as the directory location (`code`) of the inference script. To prepare the inference script (`inference.py`) follow the Prerequisites step.

The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

**MXNet**

```python
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')
# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.4 and Older**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
)
entry_point='inference.py',
source_dir='code',
framework_version='1.4.0',
py_version='py3',
image_uri='insert appropriate ECR Image URI for PyTorch',
env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

PyTorch 1.5 and Newer

from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.5',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

Note

The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

Construct a TensorFlowModel object, then call deploy:

role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
    framework_version='1.15.3',
    role=role,
    image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
    initial_instance_count=1)

See Deploying directly from model artifacts for more information.

You can select a Docker image Amazon ECR URI that meets your needs from this list.
For more information on how to construct a TensorFlowModel object, see the SageMaker SDK.

**Note**  
Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as “warming up” the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```python
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data,
        shape=test_data.shape, dtype=tf.float32))
    log = prediction_log_pb2.PredictionLog(
        predict_log=prediction_log_pb2.PredictLog(request=request))
    writer.write(log.SerializeToString())
```

For more information on how to “warm up” your model, see the TensorFlow TFX page.

**Deploy a Compiled Model Using Boto3**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).

**Topics**
- Deploy the Model (p. 2694)

**Deploy the Model**

After you have satisfied the prerequisites, use the create_model, create_endpoint_config, and create_endpoint APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```python
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': '<insert the ECR Image URI>',
    },
```

2694
'ModelDataUrl': 's3://path/to/model/artifact/model.tar.gz',
'Environment': {},
ExecutionRoleArn='ARN for AmazonSageMaker-

print ("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-
    endpoint-configuration',
    ProductionVariants=[
        {
            'VariantName': <provide your variant
            name>,
            'ModelName': 'my-sagemaker-model',
            'InitialInstanceCount': 1,
            'InstanceType': <provide your instance
type here>
        }
    ]
)

print ("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
create_endpoint_api_response = client.create_endpoint(
    EndpointName='provide your endpoint name',
    EndpointConfigName='insert your endpoint config name',
)

print ("create_endpoint API response", create_endpoint_api_response)

Note
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be
attached to the AmazonSageMaker-ExecutionRole IAM role.

For full syntax of create_model, create_endpoint_config, and create_endpoint APIs, see
create_model, create_endpoint_config, and create_endpoint, respectively.

If you did not train your model using SageMaker, specify the following environment variables:

MXNet and PyTorch

"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}

TensorFlow

"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
If you trained your model using SageMaker, specify the environment variable 
SAGEMAKER_SUBMIT_DIRECTORY as the full Amazon S3 bucket URI that contains the training script.

**Deploy a Compiled Model Using the AWS CLI**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the AWS CLI.

**Topics**
- Deploy the Model (p. 2696)

**Deploy the Model**

After you have satisfied the prerequisites, use the create-model, create-endpoint-config, and create-endpoint AWS CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

**Create a Model**

From Neo Inference Container Images, select the inference image URI and then use create-model API to create a SageMaker model. You can do this with two steps:

1. Create a `create_model.json` file. Within the file, specify the name of the model, the image URI, the path to the `model.tar.gz` file in your Amazon S3 bucket, and your SageMaker execution role:

   ```json
   {
     "ModelName": "insert model name",
     "PrimaryContainer": {
       "Image": "insert the ECR Image URI",
       "ModelDataUrl": "insert S3 archive URL",
       "Environment": {"See details below"}
     },
     "ExecutionRoleArn": "ARN for AmazonSageMaker-ExecutionRole"
   }
   
   If you trained your model using SageMaker, specify the following environment variable:

   ```json
   "Environment": {
     "SAGEMAKER_SUBMIT_DIRECTORY" : "[Full S3 path for *.tar.gz file containing the training script]"
   }
   
   If you did not train your model using SageMaker, specify the following environment variables:
   MXNet and PyTorch

   ```json
   "Environment": {
     "SAGEMAKER_PROGRAM": "inference.py",
     "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
     "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
     "SAGEMAKER_REGION": "insert your region",
     "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
   }
   ```
TensorFlow

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region"
}
```

**Note**
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

```
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the create-model API, see create-model.

**Create an Endpoint Configuration**

After creating a SageMaker model, create the endpoint configuration using the create-endpoint-config API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as create_config.json:

```
{
  "EndpointConfigName": "<provide your endpoint config name>",
  "ProductionVariants": [
    {
      "VariantName": "<provide your variant name>",
      "ModelName": "my-sagemaker-model",
      "InitialInstanceCount": 1,
      "InstanceType": "<provide your instance type here>",
      "InitialVariantWeight": 1.0
    }
  ]
}
```

Now run the following AWS CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the create-endpoint-config API, see create-endpoint-config.

**Create an Endpoint**

After you have created your endpoint configuration, create an endpoint using the create-endpoint API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>'
--endpoint-config-name '<insert your endpoint config name>'
```

For the full syntax of the create-endpoint API, see create-endpoint.

**Deploy a Compiled Model Using the Console**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), the AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy...

Topics

- Deploy the Model (p. 2698)

Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

1. Choose Models, and then choose Create models from the Inference group. On the Create model page, complete the Model name, IAM role, and VPC fields (optional), if needed.

2. To add information about the container used to deploy your model, choose Add container container, then choose Next. Complete the Container input options, Location of inference code image, and Location of model artifacts, and optionally, Container host name, and Environmental variables fields.
3. To deploy Neo-compiled models, choose the following:

- **Container input options**: Choose **Provide model artifacts and inference image**.
- **Location of inference code image**: Choose the inference image URI from Neo Inference Container Images, depending on the AWS Region and kind of application.
- **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
- **Environment variables**:
  - Leave this field blank for **SageMaker XGBoost**.
  - If you trained your model using SageMaker, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
  - If you did not train your model using SageMaker, specify the following environment variables:

<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOG_LEVEL</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>Key</td>
<td>Values for MXNet and PyTorch</td>
<td>Values TensorFlow</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
<td>&lt;your region&gt;</td>
</tr>
<tr>
<td>MMS_DEFAULT_RESPONSE_TIME</td>
<td>500</td>
<td>Leave this field blank for TF</td>
</tr>
</tbody>
</table>

4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the **Create model landing page**, choose **Create endpoint**.

5. In **Create and configure endpoint** diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.

6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.
7. Choose Edit next to the name of the model and specify the correct Instance type on the Edit Production Variant page. It is imperative that the Instance type value match the one specified in your compilation job.
8. Choose Save.

9. On the New endpoint configuration page, choose Create endpoint configuration, and then choose Create endpoint.

Request Inferences from a Deployed Service

If you have followed instructions in Deploy a Model (p. 2685), you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

Topics

- Request Inferences from a Deployed Service (Amazon SageMaker SDK) (p. 2702)
- Request Inferences from a Deployed Service (Boto3) (p. 2704)
- Request Inferences from a Deployed Service (AWS CLI) (p. 2705)

Request Inferences from a Deployed Service (Amazon SageMaker SDK)

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires application/json as the content type.
**PyTorch and MXNet**

If you are using **PyTorch v1.4 or later** or **MXNet 1.7.0 or later** and you have an Amazon SageMaker endpoint InService, you can make inference requests using the `predictor` package of the SageMaker SDK for Python.

**Note**
The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

**SageMaker Python SDK v1.x**

```python
from sagemaker.predictor import RealTimePredictor
endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**SageMaker Python SDK v2.x**

```python
from sagemaker.predictor import Predictor
endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**TensorFlow**
The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```python
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})
predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)

### Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and `invoke_endpoint()` API once you have an SageMaker endpoint. The following code example shows how to send an image for inference:

**PyTorch and MXNet**

```python
import boto3
import json

endpoint = 'insert name of your endpoint here'
runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory with open(image, 'rb') as f:
# payload = f.read()
# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode())
```

**TensorFlow**

For TensorFlow submit an input with `application/json` for the content type:

```python
from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({'instances': image.tolist()})
io_c_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
io_c_response = client.invoke_endpoint(?EndpointName=ioc_predictor_endpoint_name,
Body=body,
ContentType=content_type)
```

**XGBoost**

For an XGBoost application, you should submit a CSV text instead:

```python
```
```python
import boto3
import json

endpoint = 'insert your endpoint name here'
runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv', Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())
```

Note that BYOM allows for a custom content type. For more information, see `runtime_InvokeEndpoint`.

**Request Inferences from a Deployed Service (AWS CLI)**

Inference requests can be made with the `sagemaker-runtime invoke-endpoint` once you have an Amazon SageMaker endpoint InService. You can make inference requests with the AWS Command Line Interface (AWS CLI). The following example shows how to send an image for inference:

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful.

For TensorFlow submit an input with `application/json` as the content type.

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
--body fileb://input.json --content-type=application/json output_file.txt
```

**Inference Container Images**

Based on your use case, replace the highlighted portion in the inference image URI template provided below with appropriate values.

**Amazon SageMaker XGBoost**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

**Keras**

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-keras:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 2.2.4.

Replace `instance_type` with either `cpu` or `gpu`. 

2705
MXNet

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-mxnet:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.8.0.

Replace `instance_type` with either cpu or gpu.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-mxnet:fx_version-instance_type-py3
```

Replace `aws_region` with either us-east-1 or us-west-2.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.1.

Replace `instance_type` with inf.

ONNX

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-onnx:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.0.

Replace `instance_type` with either cpu or gpu.

PyTorch

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-pytorch:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.4, 1.5, 1.6, 1.7 or 1.8.

Replace `instance_type` with either cpu or gpu.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-pytorch:fx_version-instance_type-py3
```
Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.5.1`.

Replace `instance_type` with `inf`.

**TensorFlow**

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.15.3` or `2.4`.

Replace `instance_type` with either `cpu` or `gpu`.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Note that for instance type `inf` only `us-east-1` and `us-west-2` are supported.

Replace `fx_version` with `1.15.0`.

Replace `instance_type` with `inf`.

The following table maps `aws_account_id` with `aws_region`. Use this table to find the correct inference image URI you need for your application.

<table>
<thead>
<tr>
<th><code>aws_account_id</code></th>
<th><code>aws_region</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>785573368785</td>
<td>us-east-1</td>
</tr>

</tbody>
</table>
Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments' Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use AWS services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 AWS Configuration for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics

- Supported Frameworks, Devices, Systems, and Architectures (p. 2708)
- Deploy Models (p. 2718)
- Getting Started with Neo on Edge Devices (p. 2719)

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models (p. 2712) section.
Note

- Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see Troubleshoot Ambarella Errors (p. 2729).
- TIM-VX (libtim-vx.so) is required for i.MX 8M Plus. For information on how to build TIM-VX, see the TIM-VX GitHub repository.

Topics

- Supported Frameworks (p. 2709)
- Supported Devices, Chip Architectures, and Systems (p. 2710)
- Tested Models (p. 2712)

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

<table>

For more information about JSON key-value compiler options for each target device, see the `CompilerOptions` field in the `OutputConfig API` data type.

**Systems and Chip Architectures**

The following look-up tables provide information regarding available operating systems and architectures for Neo model compilation jobs.

**Linux**

<table>
<thead>
<tr>
<th></th>
<th>X86_64</th>
<th>X86</th>
<th>ARM64</th>
<th>ARM_EABIHF</th>
<th>ARM_EABI</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

**Tested Models**

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.
**Note**

This is not a comprehensive list of models that can be compiled with Neo.

See [Supported Frameworks](p. 2709) and SageMaker Neo Supported Operators to find out if you can compile your model with SageMaker Neo.

**Deploy Models**

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using DLR, or you can use AWS IoT Greengrass.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, Supported Frameworks, Devices, Systems, and Architectures to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see Use Neo to Compile a Model.

**Deploy a Compiled Model (DLR)**

DLR is a compact, common runtime for deep learning models and decision tree models. DLR uses the TVM runtime, Treelite runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:
Deploy a Model (AWS IoT Greengrass)

AWS IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With AWS IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all AWS IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with AWS IoT Greengrass, see How to configure optimized machine learning inference using the AWS Management Console.

Getting Started with Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using AWS CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

Note

You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.

Prerequisites

1. **Install Boto3**

   If you are running these commands on your edge device, you must install the AWS SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device's terminal or within a Jupyter notebook instance:

   **Terminal**
   ```bash
   pip install boto3
   ```

   **Jupyter Notebook**
   ```bash
   !pip install boto3
   ```

2. **Set Up AWS Credentials**

   You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the AWS credentials should be stored in the file ~/.aws/credentials on your edge device. Within the credentials file, you should see two environment variables: aws_access_key_id and aws_secret_access_key.

   In your terminal, run:
The AWS General Reference Guide has instructions on how to get the necessary `aws_access_key_id` and `aws_secret_access_key`. For more information on how to set up credentials on your device, see the Boto3 documentation.

3. **Set up an IAM Role and attach policies.**

Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the AWS CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```python
import boto3

AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)

role_name = 'role-name'

policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        },
    ],
    'Version': '2012-10-17'
}

new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)

role_arn = new_role['Role']['Arn']
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```python
role_arn = new_role['Role']['Arn']
```
Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```python
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

4. **Create an Amazon S3 bucket to store your model artifacts**

SageMaker Neo will access your model artifacts from Amazon S3

**Boto3**

```python
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if boto3.resource('s3').Bucket(bucket) not in boto3.resource('s3').buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
    )
else:
    print(f'Bucket {bucket} already exists. No action needed. ')
```

**CLI**

```bash
aws s3 mb s3://name-of-your-bucket --region specify-your-region

# Check your bucket exists
aws s3 ls s3://name-of-your-bucket/
```

5. **Train a machine learning model**

See [Train a Model with Amazon SageMaker](#) for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#)

If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd_mobilenet` model from TensorFlow's website. The model you just copied is an object detection model trained from the COCO dataset. Type the following into your Jupyter notebook:

```bash
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip 
```
Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tar file (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```bash
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

   Once you have trained your machine learning model, store it in an S3 bucket.

   **Boto3**

   ```python
   # Upload model
   s3_client.upload_file(Filename=model_filename, Bucket=bucket, Key=model_filename)
   ```

   **CLI**

   ```bash
   Replace your-model-filename and your-S3-bucket with the name of your S3 bucket.
   ```

   ```bash
   aws s3 cp your-model-filename s3://your-S3-bucket
   ```

---

### Step 1: Compile the Model

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker Neo. You can compile your model using the AWS CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. **The Amazon S3 bucket URI where you stored the trained model.**

   If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the AWS CLI:

   ```bash
   aws s3 ls
   ```

   For example:

   ```bash
   # aws s3 ls
   2020-11-02 17:08:50 bucket
   ```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:
3. **The machine learning framework you used to train your model.**

Define the framework you used to train your model.

```python
framework = 'framework-name'
```

For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

```python
framework = 'tflite'
```

For a complete list of Neo-supported frameworks, see Supported Frameworks, Devices, Systems, and Architectures.

4. **The shape of your model's input.**

Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. The key is the exact name of an input tensor in the model.

```python
data_shape = {'name': [tensor-shape]}
```

For example:

```python
data_shape = {'normalized_input_image_tensor': [1, 300, 300, 3]}
```

**Note**

Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect? The key in this dictionary must be changed to the new input tensor’s name.

5. **Either the name of the target device to compile for or the general details of the hardware platform**

```python
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```python
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in Supported Frameworks, Devices, Systems, and Architectures.

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```python
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')
```
response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time
while True:
    response = sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
print('Done!')

If you want additional information for debugging, include the following print statement:

print(response)

If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (s3_output_location). Download your compiled model locally:

object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)

**Step 2: Set Up Your Device**

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install AWS IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the coco_ssd_mobilenet object detection algorithm and you will use DLR.

1. **Install additional packages**

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

   For example, for the coco_ssd_mobilenet object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.
### Install inference engine on your device

To run your Neo-compiled model, install the **Deep Learning Runtime (DLR)** on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86_64 CPU targets running Linux, you can install the latest release of the DLR package using the following `pip` command:

```bash
!pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, refer to [Releases](#) for prebuilt binaries, or [Installing DLR](#) for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```bash
```

### Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

   ```bash
   # Download compiled model locally to edge device
   object_path = f'output/{model_name}-{target_device}.tar.gz'
   neo_compiled_model = f'compiled-{model_name}.tar.gz'
   s3_client.download_file(bucket_name, object_path, neo_compiled_model)

   # Extract model from .tar.gz so DLR can use it
   !mkdir ./dlr_model # make a directory to store your model (optional)
   !tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model
   ```

2. **Import DLR and an initialized `DLRModel` object.**

   ```python
   import dlr
   device = 'cpu'
   model = dlr.DLRModel('./dlr_model', device)
   ```

3. **Download an image for inferencing and format it based on how your model was trained.**

   For the `coco_ssd_mobilenet` example, you can download an image from the [COCO dataset](#) and then reform the image to 300x300:

   ```python
   from PIL import Image

   # Download an image for model to make a prediction
   input_image_filename = './input_image.jpg'
   !curl https://farm9.staticflickr.com/8325/8077197378_79ef4805e2.jpg --output {input_image_filename}

   # Format image so model can make predictions
   resized_image = image.resize((300, 300))
   ```
4. **Use DLR to make inferences.**

Finally, you can use DLR to make a prediction on the image you just downloaded:

```python
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the [neo-ai-dlr Github repository](https://github.com/awslabs/neo-ai-dlr).

## Troubleshoot Errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

**Did you encounter an error before you deployed your model?** If yes, see [Troubleshoot Neo Compilation Errors](#). 

**Did you encounter an error after you compiled your model?** If yes, see [Troubleshoot Neo Inference Errors](#). 

**Did you encounter an error trying to compile your model for Ambarella devices?** If yes, see [Troubleshoot Ambarella Errors](#).

### Error Classification Types

This list classifies the user errors you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are system errors.

**Client permission error**

Neo passes the errors for these straight through from the dependent service.

- *Access Denied* when calling `sts:AssumeRole`
- *Any 400* error when calling Amazon S3 to download or upload a client model
- *PassRole* error

**Load error**

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (*.pb or *.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (*.pth).
- **MXNET**: Expect only one symbol file (*.json) and one parameter file (*.params).
- **XGBoost**: Expect only one XGBoost model file (*.model). The input model has size limitation.

**Compilation error**

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:
• **OperatorNotImplemented**: An operator has not been implemented.

• **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.

• **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.

• **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

**Topics**

- Troubleshoot Neo Compilation Errors (p. 2727)
- Troubleshoot Neo Inference Errors (p. 2729)
- Troubleshoot Ambarella Errors (p. 2729)

**Troubleshoot Neo Compilation Errors**

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

**Topics**

- How to Use This Page (p. 2727)
- Framework-Related Errors (p. 2727)
- Infrastructure-Related Errors (p. 2728)
- Check your compilation log (p. 2728)

**How to Use This Page**

Attempt to resolve your error by going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See What input data shapes does SageMaker Neo expect? (p. 2668)
2. Check common framework-specific errors.
3. Check if your error is an infrastructure error.
4. Check your compilation log.

**Framework-Related Errors**

**TensorFlow**

Check your compilation log

2. Select the region you created the compilation job from the Region dropdown list in the top right.
3. In the navigation pane of the Amazon CloudWatch, choose Logs. Select Log groups.
4. Search for the log group called /aws/sagemaker/CompilationJobs. Select the log group.
5. Search for the logstream named after the compilation job name. Select the log stream.

**Troubleshoot Neo Inference Errors**

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to PyTorch 1.4.0 or later and MXNet v1.7.0 or later.

- Make sure the first inference (warm-up inference) on a valid input data is done in `model_fn()`, if you defined a `model_fn` in your inference script, otherwise the following error message may be seen on the terminal when `predict API` is called:

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from '<users-sagemaker-endpoint>' with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

  **On the terminal:**

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from '<users-sagemaker-endpoint>' with message "{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" } ".

  **In CloudWatch:**

  W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>

</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
</tr>
</tbody>
</table>

- Make sure that the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

  An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from '<users-sagemaker-endpoint>' with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."

**Troubleshoot Ambarella Errors**

SageMaker Neo requires models to be packaged in a compressed TAR file (*.tar.gz). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation.
Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
- A JSON configuration file
- Calibration images

For example, the contents of your compressed TAR file should look similar to the following example:

```plaintext
###amba_config.json
###calib_data
|    ### data1
|    ### data2
|    ### .
|    ### .
|    ### .
|    ### data500
###mobilenet_v1_1.0_0224_frozen.pb
```

The directory is configured as follows:

- `amba_config.json`: Configuration file
- `calib_data`: Folder containing calibration images
- `mobilenet_v1_1.0_0224_frozen.pb`: TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see Supported Frameworks (p. 2709).

### Setting up the Configuration File

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with `config.json`. The following chart shows the contents of the configuration file.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputs</td>
<td>Dictionary mapping input layers to attribute.</td>
<td><code>{inputs:{&quot;data&quot;:{...},&quot;data1&quot;:{...}}}</code></td>
</tr>
<tr>
<td>&quot;data&quot;</td>
<td>Input layer name. Note: &quot;data&quot; is an example of the name you can use to label the input layer.</td>
<td>&quot;data&quot;</td>
</tr>
<tr>
<td>shape</td>
<td>Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses.</td>
<td>&quot;shape&quot;: &quot;1,3,224,224&quot;</td>
</tr>
<tr>
<td>filepath</td>
<td>Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG.</td>
<td>&quot;filepath&quot;: &quot;calib_data/&quot;</td>
</tr>
<tr>
<td>colorformat</td>
<td>Color format that model expects. This will be used while</td>
<td>&quot;colorformat&quot;:&quot;RGB&quot;</td>
</tr>
</tbody>
</table>
### Key

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>converting images to binary. Supported values: [RGB, BGR]. Default is RGB.</td>
<td></td>
</tr>
<tr>
<td>mean</td>
<td>Mean value to be subtracted from the input. Can be a single value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.</td>
<td><code>&quot;mean&quot;:128.0</code></td>
</tr>
<tr>
<td>scale</td>
<td>Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.</td>
<td><code>&quot;scale&quot;: 255.0</code></td>
</tr>
</tbody>
</table>

The following is a sample configuration file:

```json
{
    "inputs": {
        "data": {
            "shape": "1, 3, 224, 224",
            "filepath": "calib_data/",
            "colorformat": "RGB",
            "mean": [128, 128, 128],
            "scale": [128.0, 128.0, 128.0]
        }
    }
}
```

### Calibration Images

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

**How many images should you use?**

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

**What are the recommended image formats?**

Calibration images can be in a raw binary format or image formats such as JPG and PNG.

Your calibration folder can contain a mixture of images and binary files. If the calibration folder contains both images and binary files, the toolchain first converts the images to binary files. Once the conversion is complete, it uses the newly generated binary files along with the binary files that were originally in the folder.
Can I convert the images into binary format first?

Yes. You can convert the images to the binary format with open-source packages such as OpenCV or PIL. Crop and resize the images so they satisfy the input layer of your trained model.

Mean and Scale

You can specify mean and scaling pre-processing options to the Amberalla toolchain. These operations are embedded into the network and are applied during inference on each input. Do not provide processed data if you specify the mean or scale. More specifically, do not provide data you have subtracted the mean from or have applied scaling to.

Use Amazon SageMaker Elastic Inference (EI)

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as Amazon SageMaker hosted models, but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker notebook instance so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see Importing an ONNX model into MXNet.

- Attach EI to a Notebook Instance (p. 2738)
- Use EI on Amazon SageMaker Hosted Endpoints (p. 2740)

How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.
The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>
<tr>
<th>Accelerator Type</th>

</tbody>
</table>

Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
- Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- Amazon Elastic Inference Overview
- Choosing an Instance and Accelerator Type for Your Model
- Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance (p. 2738). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances
Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2740).

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the EI-enabled PyTorch binary files from the public amazonei-pytorch Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.

- SageMaker Python SDK - Deploy TensorFlow models
- SageMaker Python SDK - Deploy MXNet models
- SageMaker Python SDK - Deploy PyTorch models

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use the low-level AWS SDK for Python (Boto 3).

Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification Algorithm (p. 1829) and Object Detection Algorithm (p. 1911) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

- Using Amazon Elastic Inference with MXNet on Amazon SageMaker
- Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
- Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
- Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker
Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

- You want to use a customized role or permission policy.
- You want to use a VPC for your hosted model or notebook instance.

**Note**
If you already have an execution role that has the AmazonSageMakerFullAccess managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

**Topics**
- Set Up Required Permissions (p. 2735)
- Use a Custom VPC to Connect to EI (p. 2737)

**Set Up Required Permissions**

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the AmazonSageMakerFullAccess managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see Creating a Role for an AWS Service (Console) in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see Adding and Removing IAM Policies.

Add these permissions specifically for connecting EI in an IAM policy.

```json
{
  "Effect": "Allow",
  "Action": [
    "elastic-inference:Connect",
    "ec2:DescribeVpcEndpoints"
  ],
  "Resource": "*"
}
```

The following IAM policy is the complete list of required permissions to use EI in SageMaker.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "elastic-inference:Connect",
        "ec2:DescribeVpcEndpoints"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": ["elastic-inference:Connect"]
    }
  ]
}
```
"sagemaker:*",
],
"Resource": "**
}
{
"Effect": "Allow",

}
Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.
For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose `com.amazonaws.<region>.elastic-inference.runtime`. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.

Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Notebook instances.
3. Choose Create notebook instance.
4. For Notebook instance name, provide a unique name for your notebook instance.
5. For notebook instance type, choose a CPU instance such as ml.t2.medium.
6. For Elastic Inference (EI), choose an instance from the list, such as ml.eia2.medium.
7. For IAM role, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For VPC - Optional, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as No VPC. If you use a VPC follow the instructions at Use a Custom VPC to Connect to EI (p. 2737).
9. (Optional) For Lifecycle configuration - optional, either leave it as No configuration or choose a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 243).
10. (Optional) For Encryption key - optional, Optional) If you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For Volume Size In GB - optional, leave the default value of 5.
12. (Optional) For Tags, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose Create Notebook Instance.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.
Use EI in Local Mode in SageMaker

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview.

Use EI in Local Mode with SageMaker TensorFlow Estimators and Models

To use EI with TensorFlow in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about Amazon SageMaker Python SDK TensorFlow estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/tensorflow/index.html.

The following code shows how to use local mode with an estimator object. To call the `deploy` method, you must have previously either:

- Trained the model by calling the `fit` method of an estimator.
- Pass a model artifact when you initialize the model object.

```python
# Deploys the model to a local endpoint
tf_predictor = tf_model.deploy(initial_instance_count=1,
                               instance_type='local',
                               accelerator_type='local_sagemaker_notebook')
```

Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models

To use EI with MXNet in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about Amazon SageMaker Python SDK MXNet estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
                                     instance_type='local',
                                     accelerator_type='local_sagemaker_notebook')
```

For a complete example of using EI in local mode with MXNet, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html.
Use EI in Local Mode with SageMaker PyTorch Estimators and Models

To use EI with PyTorch in local mode, when you call the deploy method of an estimator or a model object, specify local for instance_type and local_sagemaker_notebook for accelerator_type. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see SageMaker PyTorch Estimators and Models.

The following code shows how to use local mode with an estimator object. You must have previously called the fit method of the estimator to train the model.

```python
# Deploys the model to a local endpoint
pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
                                          instance_type='local',
                                          accelerator_type='local_sagemaker_notebook')
```

Use EI on Amazon SageMaker Hosted Endpoints

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the Image Classification Algorithm (p. 1829) or Object Detection Algorithm (p. 1911) build-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.

Topics

- Use EI with a SageMaker TensorFlow Container (p. 2740)
- Use EI with a SageMaker MXNet Container (p. 2741)
- Use EI with a SageMaker PyTorch Container (p. 2741)
- Use EI with Your Own Container (p. 2742)

Use EI with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the accelerator_type input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                                          accelerator_type='local_sagemaker_notebook')
```
Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

Use EI with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.
For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

**Use an Estimator Object**

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                              instance_type='ml.m4.xlarge',
                              accelerator_type='ml.eia2.medium')
```

**Use a Model Object**

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                         instance_type='ml.m4.xlarge',
                         accelerator_type='ml.eia2.medium')
```

**Use EI with Your Own Container**

To use EI with a model in a custom container that you build, use the low-level AWS SDK for Python (Boto 3), download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.

**Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container**

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at console.aws.amazon.com/s3/buckets/amazonei-tensorflow. For information about building a container that uses the EI-enabled version of TensorFlow, see https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket available at console.aws.amazon.com/s3/buckets/amazonei-apachemxnet. For information about building a container that uses the EI-enabled version of MXNet, see https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container. You can download the Elastic Inference enabled binary for PyTorch from the public Amazon S3 bucket at console.aws.amazon.com/s3/buckets/amazonei-pytorch. For information about building a container that uses the Elastic Inference enabled version of PyTorch, see Building your image.

**Create an EI Endpoint with AWS SDK for Python (Boto 3)**

To create an endpoint by using AWS SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you specify one of the EI instance types as the `AcceleratorType` field for that `ProductionVariant`. You then pass that endpoint configuration when you create the endpoint.
Create an Endpoint Configuration

To use EI, you need to specify an accelerator type in the endpoint configuration.

```python
# Create Endpoint Configuration
from time import gmtime, strftime

endpoint_config_name = 'ImageClassificationEndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sagemaker.create_endpoint_config(  
    EndpointConfigName = endpoint_config_name,  
    ProductionVariants=[{  
        'InstanceType':'ml.m4.xlarge',  
        'InitialInstanceCount':1,  
        'ModelName':model_name,  
        'VariantName':'AllTraffic',  
        'AcceleratorType':'ml.eia2.medium'}])
print("Endpoint Config Arn: " + create_endpoint_config_response['EndpointConfigArn'])
```

Create an Endpoint

After you create an endpoint configuration with an accelerator type, you can create an endpoint.

```python
endpoint_name = 'ImageClassificationEndpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
endpoint_response = sagemaker.create_endpoint(  
    EndpointName=endpoint_name,  
    EndpointConfigName=endpoint_config_name)
```

After creating the endpoint, you can invoke it using the `invoke_endpoint` method in a Boto3 runtime object, as you would any other endpoint.
Using Docker containers with SageMaker

Amazon SageMaker makes extensive use of Docker containers for build and runtime tasks. SageMaker provides prebuilt Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases. For information on how to bring your own containers for use with Amazon SageMaker Studio, see Bring your own SageMaker image (p. 146).

Topics
- Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker (p. 2744)
- Docker Container Basics (p. 2745)
- Use Prebuilt SageMaker Docker images (p. 2745)
- Adapting Your Own Docker Container to Work with SageMaker (p. 2759)
- Create a container with your own algorithms and models (p. 2775)
- Example Notebooks: Use Your Own Algorithm or Model (p. 2791)
- Troubleshooting your Docker containers (p. 2793)

Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. However, your level of engagement with containers depends on your use case.

- **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK by specifying the algorithm or framework version when creating your Estimator. The built-in algorithms available are itemized and described in the Use Amazon SageMaker Built-in Algorithms (p. 982) topic. For more information on the available frameworks, see ML Frameworks and Toolkits (p. 13). For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get Started with Amazon SageMaker (p. 34) topic.

- **Use prebuilt SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks currently supported by SageMaker, see Prebuilt SageMaker Docker Images for Deep Learning (p. 2746). For information on the scikit-learn and SparkML prebuilt container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2746).
For more information about using frameworks with the Amazon SageMaker Python SDK, see their respective topics in Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13).

- **Extend a prebuilt SageMaker container image.** If you would like to extend a prebuilt SageMaker algorithm or model Docker image, you can modify the SageMaker image to satisfy your needs. For an example, see Extending our PyTorch containers.

- **Adapt an existing container image:** If you would like to adapt a pre-existing container image to work with SageMaker, you need to modify the Docker container to enable either the SageMaker Training or Inference toolkit. For an example that shows how to build your own containers to train and host an algorithm, see Bring Your Own R Algorithm.

## Docker Container Basics

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see Docker overview.

The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

### SageMaker Functions

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used. While you don’t need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

### Containers with SageMaker Studio

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you cannot create and upload a Docker container from a SageMaker Studio instance. However, you can use a prebuilt SageMaker container as long as that container was created outside of Studio.

## Use Prebuilt SageMaker Docker images

Amazon SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the prebuilt SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

**Note**

For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see SageMaker RL Containers.

### Topics

- Prebuilt SageMaker Docker Images for Deep Learning (p. 2746)
- Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2746)
- Train a Deep Graph Network (p. 2748)
- Extend a Prebuilt Container (p. 2751)
Prebuilt SageMaker Docker Images for Deep Learning

SageMaker provides prebuilt Docker images that include deep learning framework libraries and other dependencies needed for training and inference. For a complete list of the available pre-built Docker images, see Deep Learning Containers Images.

If you are not using the Amazon SageMaker Python SDK and one of its estimators to retrieve the pre-built images, you have to retrieve them yourself.

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>
<td>PyTorch</td>
<td>Using PyTorch with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>

Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Extending Our PyTorch Containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.

Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.
Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark M:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>`

  For example, `746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:0.23-1-cpu-py3`

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>`

  For example, `341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4`

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>746614075791</td>
<td>us-west-1</td>
</tr>
<tr>
<td>246618743249</td>
<td>us-west-2</td>
</tr>
<tr>
<td>683313688378</td>
<td>us-east-1</td>
</tr>
<tr>
<td>257758044811</td>
<td>us-east-2</td>
</tr>
<tr>
<td>354813040037</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td>366743142698</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>121021644041</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>783357654285</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>720646828776</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>141502667606</td>
<td>eu-west-1</td>
</tr>
<tr>
<td>764974769150</td>
<td>eu-west-2</td>
</tr>
<tr>
<td>492215442770</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>341280168497</td>
<td>ca-central-1</td>
</tr>
</tbody>
</table>
ACCOUNT_ID | REGION_NAME
---|---
414596584902 | us-gov-west-1

Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available sagemaker-sparkml-serving image in the ca-central-1 Region:

```
aws ecr describe-images \
  --region ca-central-1 \
  --registry-id 341280168497 \
  --repository-name sagemaker-sparkml-serving
```

Train a Deep Graph Network

In this overview, you learn how to get started with a deep graph network by using one of the DGL containers in Amazon Elastic Container Registry (Amazon ECR). You can also see links to practical examples for deep graph networks.

What Is a Deep Graph Network?

Deep graph networks refer to a type of neural network that is trained to solve graph problems. A deep graph network uses an underlying deep learning framework like PyTorch or MXNet. The potential for graph networks in practical AI applications is highlighted in the Amazon SageMaker tutorials for Deep Graph Library (DGL). Examples for training models on graph datasets include social networks, knowledge bases, biology, and chemistry.
Several examples are provided using Amazon SageMaker's deep learning containers that are preconfigured with DGL. If you have special modules you want to use with DGL, you can also build your own container. The examples involve heterographs, which are graphs that have multiple types of nodes and edges, and draw on a variety of applications across disparate scientific fields, such as bioinformatics and social network analysis. DGL provides a wide array of graph neural network implementations for different types models. Some of the highlights include:

- Graph convolutional network (GCN)
- Relational graph convolutional network (R-GCN)
- Graph attention network (GAT)
- Deep generative models of graphs (DGMG)
- Junction tree neural network (JTNN)

Get Started

DGL is available as a deep learning container in Amazon ECR. You can select deep learning containers when you write your estimator function in an Amazon SageMaker notebook. You can also craft your own custom container with DGL by following the Bring Your Own Container guide. The easiest way to get started with a deep graph network uses one of the DGL containers in Amazon ECR.

**Note**
Backend framework support is limited to PyTorch and MXNet.

Setup
If you are using Amazon SageMaker Studio, you need to clone the examples repository first. If you are using a notebook instance, you can find the examples by choosing the SageMaker icon at bottom of the left toolbar.

**To clone the Amazon SageMaker SDK and notebook examples repository**

1. From the JupyterLab view in Amazon SageMaker, go to the File Browser at the top of the left toolbar. From the File Browser panel, you can see a new navigation at the top of the panel.
2. Choose the icon on the far right to clone a Git repository.
3. Add the repository URL: https://github.com/awslabs/amazon-sagemaker-examples.git
4. Browse the newly added folder and its contents. The DGL examples are stored in the sagemaker-python-sdk folder.

**Run a Graph Network Training Example**

**To train a deep graph network**

1. From the JupyterLab view in Amazon SageMaker, browse the example notebooks and look for DGL folders. Several files may be included to support an example. Examine the README for any prerequisites.
2. Run the .ipynb notebook example.
3. Find the estimator function, and note the line where it is using an Amazon ECR container for DGL and a specific instance type. You may want to update this to use a container in your preferred Region.
4. Run the function to launch the instance and use the DGL container for training a graph network. Charges are incurred for launching this instance. The instance self-terminates when the training is complete.

**Examples**

An example of knowledge graph embedding (KGE) is provided. It uses the Freebase dataset, a knowledge base of general facts. An example use case would be to graph the relationships of persons and predict their nationality.

An example implementation of a graph convolutional network (GCN) shows how you can train a graph network to predict toxicity. A physiology dataset, Tox21, provides toxicity measurements for how substances affect biological responses.

Another GCN example shows you how to train a graph network on a scientific publications bibliography dataset, known as Cora. You can use it to find relationships between authors, topics, and conferences.

The last example is a recommender system for movie reviews. It uses a graph convolutional matrix completion (GCMC) network trained on the MovieLens datasets. These datasets consist of movie titles, genres, and ratings by users.

**Use a Deep Learning Container with DGL**

The following example uses preconfigured deep learning containers. This is the easiest to try since it works out of the box on Amazon SageMaker.

- Semi-supervised classification of a knowledge base using a GCN
Bring Your Own Container with DGL

The following examples enable you to bring your own container (BYOC). Read the BYOC guide and familiarize yourself with that process before trying these. Configuration is required.

- Molecular property prediction of toxicity using a GCN
- Recommender system for movies using a GCMC implementation

Extend a Prebuilt Container

If a prebuilt SageMaker container doesn't fulfill all of your requirements, you can extend the existing image to accommodate your needs. Even if there is direct support for your environment or framework, you may want to add additional functionality or configure your container environment differently. By extending a prebuilt image, you can leverage the included deep learning libraries and settings without having to create an image from scratch. You can extend the container to add libraries, modify settings, and install additional dependencies.

The following tutorial shows how to extend a prebuilt SageMaker image and publish it to Amazon ECR.

Topics

- Requirements to Extend a Prebuilt Container (p. 2751)
- Extend SageMaker Containers to Run a Python Script (p. 2751)

Requirements to Extend a Prebuilt Container

To extend a pre-built SageMaker image, you need to set the following environment variables within your Dockerfile. For more information on environment variables with SageMaker containers, see the SageMaker Training Toolkit GitHub repo.

- SAGEMAKER_SUBMIT_DIRECTORY: The directory within the container in which the Python script for training is located.
- SAGEMAKER_PROGRAM: The Python script that should be invoked and used as the entry point for training.

You can also install additional libraries by including the following in your Dockerfile:

```
RUN pip install <library>
```

The following tutorial shows how to use these environment variables.

Extend SageMaker Containers to Run a Python Script

In this tutorial, you learn how to extend the SageMaker PyTorch container with a Python file that uses the CIFAR-10 dataset. By extending the SageMaker PyTorch container, you utilize the existing training solution made to work with SageMaker. This tutorial extends a training image, but the same steps can be taken to extend an inference image. For a full list of the available images, see Available Deep Learning Containers Images.

To run your own training model using the SageMaker containers, build a Docker container through a SageMaker Notebook instance.

**Step 1: Create an SageMaker Notebook Instance**

1. Open the SageMaker console.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.

SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS, such as AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time when the role was created, separated by a T.

d. For Root Access, choose Enable.

e. Choose Create notebook instance.

4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon SageMaker to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and Upload the Dockerfile and Python Training Scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.

2. Create a Dockerfile text file in the docker_test_folder directory.

   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
```
Extend a Prebuilt Container

ENV SAGEMAKER_PROGRAM cifar10.py

The Dockerfile script performs the following tasks:

- FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04 – Downloads the SageMaker PyTorch base image. You can replace this with any SageMaker base image you want to bring to build containers.

- ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code – Sets /opt/ml/code as the training script directory.

- COPY cifar10.py /opt/ml/code/cifar10.py – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- ENV SAGEMAKER_PROGRAM cifar10.py – Sets your cifar10.py training script as the entrypoint script.

d. On the left directory navigation pane, the text file name might automatically be named untitled.txt. To rename the file, right-click the file, choose Rename, rename the file as Dockerfile without the .txt extension, and then press Ctrl+s or Command+s to save the file.

3. Create or upload a training script cifar10.py in the docker_test_folder. You can use the following example script for this exercise.

```python
import ast
import argparse
import logging
import os
import torch
import torch.distributed as dist
import torch.nn as nn
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision
import torchvision.models
import torchvision.transforms as transforms
import torch.nn.functional as F

logger=logging.getLogger(__name__)
logger.setLevel(logging.DEBUG)

classes=('plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'ship', 'truck')

# https://github.com/pytorch/tutorials/blob/master/beginner_source/blitz/cifar10_tutorial.py#L118

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1=nn.Conv2d(3, 6, 5)
        self.pool=nn.MaxPool2d(2, 2)
        self.conv2=nn.Conv2d(6, 16, 5)
        self.fc1=nn.Linear(16 * 5 * 5, 120)
        self.fc2=nn.Linear(120, 84)
        self.fc3=nn.Linear(84, 10)

    def forward(self, x):
        x=self.pool(F.relu(self.conv1(x)))
```

2753
x=self.pool(F.relu(self.conv2(x)))
x=x.view(-1, 16 * 5 * 5)
x=F.relu(self.fc1(x))
x=F.relu(self.fc2(x))
x=self.fc3(x)
return x

def _train(args):
    is_distributed=len(args.hosts) > 1 and args.dist_backend is not None
    logger.debug("Distributed training - {}".format(is_distributed))

    if is_distributed:
        # Initialize the distributed environment.
        world_size=len(args.hosts)
        os.environ['WORLD_SIZE']=str(world_size)
        host_rank=args.hosts.index(args.current_host)
        dist.init_process_group(backend=args.dist_backend, rank=host_rank,
                                world_size=world_size)
        logger.info('Initialized the distributed environment: \'{\}\' backend on {} nodes.
'.format(args.dist_backend, world_size) + 'Current host rank is {}. Using cuda: {}
Number of gpus: {}\'.format(dist.get_world_size(), torch.cuda.is_available(), args.num_gpus))

        device='cuda' if torch.cuda.is_available() else 'cpu'
        logger.info("Device Type: {}".format(device))

        logger.info("Loading Cifar10 dataset")
        transform=transforms.Compose(
            [transforms.ToTensor(),
             transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

        trainset=torchvision.datasets.CIFAR10(root=args.data_dir, train=True,
                                              download=False, transform=transform)
        train_loader=torch.utils.data.DataLoader(trainset, batch_size=args.batch_size,
                                                  shuffle=True, num_workers=args.workers)

        testset=torchvision.datasets.CIFAR10(root=args.data_dir, train=False,
                                               download=False, transform=transform)
        test_loader=torch.utils.data.DataLoader(testset, batch_size=args.batch_size,
                                                  shuffle=False, num_workers=args.workers)

        logger.info("Model loaded")
        model=Net()

        if torch.cuda.device_count() > 1:

Step 3: Build the Container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose conda_pytorch_p36 in the Notebook section.

2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```
   % cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```
   ! pwd
   ```

   output: /home/ec2-user/SageMaker/docker_test_folder

3. Log in to Docker to access the base container:

   ```
   ! aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
   ```

4. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```
   ! docker build -t pytorch-extended-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

   **Note**

   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```

   Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the `-f` flag. For example, if you named your Dockerfile Dockerfile-text.txt, run the following command:

   ```
   ! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
   ```

Step 4: Test the Container

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose Notebook in conda_pytorch_p36 framework. The rest of the code snippets must run from the Jupyter notebook instance.

2. Download the CIFAR-10 dataset.

   ```
   import torch
   ```
import torchvision
import torchvision.transforms as transforms

def _get_transform():
    return transforms.Compose([transforms.ToTensor(),
                               transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

def get_train_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    trainset=torchvision.datasets.CIFAR10(root=data_dir, train=True,
                                           download=True, transform=transform)
    return torch.utils.data.DataLoader(trainset, batch_size=4,
                                        shuffle=True, num_workers=2)

def get_test_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    testset=torchvision.datasets.CIFAR10(root=data_dir, train=False,
                                          download=True, transform=transform)
    return torch.utils.data.DataLoader(testset, batch_size=4,
                                         shuffle=False, num_workers=2)

trainloader=get_train_data_loader('/tmp/pytorch-example/cifar-10-data')
testloader=get_test_data_loader('/tmp/pytorch-example/cifar-10-data')

3. Set role to the role used to create your Jupyter notebook. This is used to configure your SageMaker Estimator.

    from sagemaker import get_execution_role
    role=get_execution_role()

4. Paste the following example script into the notebook code cell to configure a SageMaker Estimator using your extended container.

    from sagemaker.estimator import Estimator
    hyperparameters={'epochs': 1}
    estimator=Estimator(
                      image_uri='pytorch-extended-container-test',
                      role=role,
                      instance_count=1,
                      instance_type='local',
                      hyperparameters=hyperparameters)
    estimator.fit('file:///tmp/pytorch-example/cifar-10-data')

5. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

Step 5: Push the Container to Amazon Elastic Container Registry (Amazon ECR)

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.

    Run the following command lines in a notebook cell.
%%sh

# Specify an algorithm name
algorithm_name=pytorch-extended-container-test

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]; then
    aws ecr create-repository --repository-name ${algorithm_name} > /dev/null
fi

# Log into Docker
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}

2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3
client=boto3.client('sts')
account=client.get_caller_identity()['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="pytorch-extended-container-test"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)

ecr_image
# This should return something like
# 12-digits-of-your-account.dkr.ecr.us-east-2.amazonaws.com/tf-2.2-test:latest
```

3. Use the ecr_image retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker PyTorch estimator.

```python
import sagemaker
from sagemaker import get_execution_role
```
Adapting Your Own Docker Container to Work with SageMaker

You can adapt an existing Docker image to work with SageMaker. You may need to use an existing, external Docker image with SageMaker when you have a container that satisfies feature or safety requirements that are not currently supported by a prebuilt SageMaker image. There are two toolkits that allow you to bring your own container and adapt it to work with SageMaker:

- SageMaker Training Toolkit
- SageMaker Inference Toolkit

The following topics show how to adapt your existing image using the SageMaker Training and Inference toolkits:

**Topics**
- Individual Framework Libraries (p. 2760)
- Using the SageMaker Training and Inference Toolkits (p. 2760)
- Adapting Your Own Training Container (p. 2761)
- Adapting Your Own Inference Container (p. 2772)

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    image_uri=ecr_image,
    role=get_execution_role(),
    base_job_name='pytorch-extended-container-test',
    instance_count=1,
    instance_type='ml.p2.xlarge'
)

# start training
estimator.fit()

# deploy the trained model
predictor = estimator.deploy(1, instance_type)
```
Individual Framework Libraries

In addition to the SageMaker Training Toolkit and SageMaker Inference Toolkit, SageMaker also provides toolkits specialized for TensorFlow, MXNet, PyTorch, and Chainer. The following table provides links to the GitHub repositories that contain the source code for each framework and their respective serving toolkits. The instructions linked are for using the Python SDK to run training algorithms and host models on SageMaker. The functionality for these individual libraries is included in the SageMaker Training Toolkit and SageMaker Inference Toolkit.

<table>
<thead>

</tbody>
</table>

Using the SageMaker Training and Inference Toolkits

The SageMaker Training and SageMaker Inference toolkits implement the functionality that you need to adapt your containers to run scripts, train algorithms, and deploy models on SageMaker. When installed, the library defines the following for users:

- The locations for storing code and other resources.
- The entry point that contains the code to run when the container is started. Your Dockerfile must copy the code that needs to be run into the location expected by a container that is compatible with SageMaker.
- Other information that a container needs to manage deployments for training and inference.

SageMaker Toolkits Containers Structure

When SageMaker trains a model, it creates the following file folder structure in the container's /opt/ml directory.

```bash
/opt/ml
### input
#  ### config
#    ### hyperparameters.json
#    ### resourceConfig.json
#    ### data
#      ### <channel_name>
#        ### <input data>
### model
#  ### code
#  ### output
```
When you run a model training job, the SageMaker container uses the `/opt/ml/input/` directory, which contains the JSON files that configure the hyperparameters for the algorithm and the network layout used for distributed training. The `/opt/ml/input/` directory also contains files that specify the channels through which SageMaker accesses the data, which is stored in Amazon Simple Storage Service (Amazon S3). The SageMaker containers library places the scripts that the container will run in the `/opt/ml/code/` directory. Your script should write the model generated by your algorithm to the `/opt/ml/model/` directory. For more information, see Use Your Own Training Algorithms (p. 2775).

When you host a trained model on SageMaker to make inferences, you deploy the model to an HTTP endpoint. The model makes real-time predictions in response to inference requests. The container must contain a serving stack to process these requests.

In a hosting or batch transform container, the model files are located in the same folder to which they were written during training.

```
/opt/ml/model
#
### <model files>
```

For more information, see Use Your Own Inference Code (p. 2782).

### Single Versus Multiple Containers

You can either provide separate Docker images for the training algorithm and inference code or you can use a single Docker image for both. When creating Docker images for use with SageMaker, consider the following:

- Providing two Docker images can increase storage requirements and cost because common libraries might be duplicated.
- In general, smaller containers start faster for both training and hosting. Models train faster and the hosting service can react to increases in traffic by automatically scaling more quickly.
- You might be able to write an inference container that is significantly smaller than the training container. This is especially common when you use GPUs for training, but your inference code is optimized for CPUs.
- SageMaker requires that Docker containers run without privileged access.
- Both Docker containers that you build and those provided by SageMaker can send messages to the `Stdout` and `Stderr` files. SageMaker sends these messages to Amazon CloudWatch logs in your AWS account.

For more information about how to create SageMaker containers and how scripts are executed inside them, see the SageMaker Training Toolkit and SageMaker Inference Toolkit repositories on GitHub. They also provide lists of important environmental variables and the environmental variables provided by SageMaker containers.

### Adapting Your Own Training Container

To run your own training model, build a Docker container using the Amazon SageMaker Training Toolkit through an Amazon SageMaker notebook instance.

**Step 1: Create a SageMaker notebook instance**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.
      SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS. For example, AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time at which the role was created, separated by a T.
   d. For Root Access, choose Enable.
   e. Choose Create notebook instance.

4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon SageMaker to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and upload the Dockerfile and Python training scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.
2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3-jupyter

# Install sagemaker-training toolkit that contains the common functionality necessary to create a container compatible with SageMaker and the Python SDK.
RUN pip3 install sagemaker-training

# Copies the training code inside the container
COPY train.py /opt/ml/code/train.py

# Defines train.py as script entrypoint
ENV SAGEMAKER_PROGRAM train.py
```
The Dockerfile script performs the following tasks:

- **FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3-jupyter** – Downloads the TensorFlow Docker base image. You can replace this with any Docker base image you want to bring to build containers, as well as with AWS pre-built container base images.
- **RUN pip install sagemaker-training** – Installs SageMaker Training Toolkit that contains the common functionality necessary to create a container compatible with SageMaker.
- **COPY train.py /opt/ml/code/train.py** – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.
- **ENV SAGEMAKER_PROGRAM train.py** – Takes your training script `train.py` as the entrypoint script copied in the `/opt/ml/code` folder of the container. This is the only environmental variable that you must specify when you build your own container.

**d.** On the left directory navigation pane, the text file name might automatically be named `untitled.txt`. To rename the file, right-click the file, choose **Rename**, rename the file as `Dockerfile` without the `.txt` extension, and then press **Ctrl+s** or **Command+s** to save the file.

3. Create or upload a training script `train.py` in the `docker_test_folder`. You can use the following example script for this exercise.

```python
import tensorflow as tf

mnist = tf.keras.datasets.mnist

(x_train, y_train), (x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

model = tf.keras.models.Sequential([tf.keras.layers.Flatten(input_shape=(28, 28)),
                                     tf.keras.layers.Dense(128, activation='relu'),
                                     tf.keras.layers.Dropout(0.2),
                                     tf.keras.layers.Dense(10, activation='softmax')])

model.compile(optimizer='adam',
              loss='sparse_categorical_crossentropy',
              metrics=['accuracy'])

model.fit(x_train, y_train, epochs=1)

model.evaluate(x_test, y_test)
```

**Step 3: Build the container**

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the **New Launch** icon and then choose **conda_tensorflow2_p36** in the **Notebook** section.

2. Run the following command in the first notebook cell to change to the `docker_test_folder` directory:

   `% cd ~/SageMaker/docker_test_folder`

   This returns your current directory as follows:

   `! pwd`
output: /home/ec2-user/SageMaker/docker_test_folder

3. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

```bash
! docker build -t tf-custom-container-test .
```

The Docker build command must be run from the Docker directory you created, in this case `docker_test_folder`.

**Note**

If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

```bash
unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
```

Remember that `docker` looks for a file specifically called `Dockerfile` without any extension within the current directory. If you named it something else, you can pass in the file name manually with the `-f` flag. For example, if you named your Dockerfile as `Dockerfile-text.txt`, run the following command:

```bash
! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
```

---

**Step 4: Test the container**

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose **New Launcher** and choose **Notebook** in **conda_tensorflow_p36** framework.

2. Paste the following example script into the notebook code cell to configure a SageMaker Estimator.

**SageMaker Python SDK v1**

```python
from sagemaker.estimator import Estimator

estimator = Estimator(image_name='tf-custom-container-test',
                      role='arn:aws:iam::111122223333:role/role-name',
                      instance_count=1,
                      instance_type='local')

estimator.fit()
```

**SageMaker Python SDK v2**

```python
from sagemaker.estimator import Estimator

estimator = Estimator(image_uri='tf-custom-container-test',
                      role='arn:aws:iam::111122223333:role/role-name',
                      instance_count=1,
                      instance_type='local')

estimator.fit()
```

3. Replace the 'Put_Your_ARN_Here' value with the IAM role ARN number you copied to a notepad file when you configured the notebook instance. The ARN should look like the following: `arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788`.
4. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

**Step 5: Push the container to Amazon Elastic Container Registry (Amazon ECR)**

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.

Run the following command lines in a notebook cell.

```bash
# Specify an algorithm name
algorithm_name=tf-custom-container-test
account=$(aws sts get-caller-identity --query Account --output text)
# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}
fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"
# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi
# Get the login command from ECR and execute it directly
aws ecr get-login-password --region ${region}|docker login --username AWS --password-stdin ${fullname}
# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

**Note**

This bash shell script may raise a permission issue similar to the following error message:

"denied: User: [ARN] is not authorized to perform: ecr:InitiateLayerUpload on resource: arn:aws:ecr:us-east-1:[id]:repository/tf-custom-container-test"

If this error occurs, you need to attach the `AmazonEC2ContainerRegistryFullAccess` policy to your IAM role. Go to the IAM console, choose Roles from the left navigation pane, look up the IAM role you used for the Notebook instance. Under the Permission tab, choose the Attach policies button, and search the `AmazonEC2ContainerRegistryFullAccess` policy. Mark the check box of the policy, and choose Attach policy to finish.
2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3
account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'tf-custom-container-test'
tag = ':latest'
region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix, ecr_repository + tag)
byoc_image_uri
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/sagemaker-byoc-test:latest
```

3. Use the `ecr_image` retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker estimator with the `byoc_image_uri` and initiates a training job on an Amazon EC2 instance.

SageMaker Python SDK v1

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator = Estimator(image_uri=byoc_image_uri, 
                      role=get_execution_role(), 
                      base_job_name='tf-custom-container-test-job', 
                      instance_count=1, 
                      instance_type='ml.p2.xlarge')

# start training
estimator.fit()

# deploy the trained model
predictor = estimator.deploy(1, instance_type)
```

SageMaker Python SDK v2

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator = Estimator(image_uri=byoc_image_uri, 
                      role=get_execution_role(), 
                      base_job_name='tf-custom-container-test-job', 
                      instance_count=1, 
                      instance_type='ml.p2.xlarge')

# start training
estimator.fit()
```
# deploy the trained model
predictor = estimator.deploy(1, instance_type)

For a full example that shows how to test a custom container locally and push it to an Amazon ECR image, see the Building Your Own TensorFlow Container example notebook.

**Tip**
To profile and debug training jobs to monitor system utilization issues (such as CPU bottlenecks and GPU underutilization) and identify training issues (such as overfitting, overtraining, exploding tensors, and vanishing gradients), use Amazon SageMaker Debugger. For more information, see

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger:

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 2111).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

**Tip**
This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 2761) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

### Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

<table>
<thead>
<tr>
<th># # # debugger_custom_container_test_notebook.ipynb # a</th>
</tr>
</thead>
<tbody>
<tr>
<td>notebook to run python snippet codes</td>
</tr>
<tr>
<td># # # debugger_custom_container_test_folder</td>
</tr>
<tr>
<td># this is a docker folder</td>
</tr>
<tr>
<td># # # your-training-script.py</td>
</tr>
<tr>
<td># your training script with Debugger hook</td>
</tr>
<tr>
<td># # # Dockerfile</td>
</tr>
<tr>
<td># a</td>
</tr>
</tbody>
</table>

2767
Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

**Note**

This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```python
# An example of training script (your-training-script.py)
import tensorflow.compat.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...

    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
              validation_data=(X_valid, Y_valid),
              shuffle=True,

              # smdebug modification: Pass the Debugger hook in the main() as a Keras callback
              callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")
    parser.add_argument(...)
    args = parser.parse_args()
    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook = smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == '__main__':
    main()
```

For more information about registering the Debugger hook for the supported frameworks and algorithms, see the following links in the SMDebug client library:

- SMDebug TensorFlow hook
• SMDebug PyTorch hook

• SMDebug MXNet hook
• SMDebug XGBoost hook

In the following example notebooks' training scripts, you can find more examples about how to add the Debugger hooks to training scripts and collect output tensors in detail:

• Debugger in script mode with the TensorFlow 2.1 framework

To see the difference between using Debugger in a Deep Learning Container and in script mode, open this notebook and put it and the previous Debugger in a Deep Learning Container TensorFlow v2.1 notebook example side by side.
In script mode, the hook configuration part is removed from the script in which you set the estimator. Instead, the Debugger hook feature is merged into the training script, TensorFlow Keras ResNet training script in script mode. The training script imports the `smdebug` library in the required TensorFlow Keras environment to communicate with the TensorFlow ResNet50 algorithm. It also manually implements the `smdebug` hook functionality by adding the `callbacks=[hook]` argument inside the `train` function (in line 49), and by adding the manual hook configuration (in line 89) provided through SageMaker Python SDK.
This script mode example runs the training job in the TF 2.1 framework for direct comparison with the zero script change in the TF 2.1 example.
The benefit of setting up Debugger in script mode is the flexibility to choose framework versions not covered by AWS Deep Learning Containers.

• Using Amazon SageMaker Debugger in a PyTorch Container in Script Mode

This notebook enables Debugger in script mode in PyTorch v1.3.1 framework. PyTorch v1.3.1 is supported by SageMaker containers, and this example shows details of how to modify a training script.
The SageMaker PyTorch estimator is already in script mode by default.
In the notebook, the line to activate `script_mode` is not included in the estimator configuration.
This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.
Adapting Your Own Training Container

# Specify a docker base image

FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3

RUN /usr/bin/python3 -m pip install --upgrade pip

RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and
the smdebug library

RUN pip install sagemaker-training

RUN pip install smdebug

CMD ["bin/bash"]

If you want to use a pre-built AWS Deep Learning Container image, see
Available AWS Deep Learning Containers Images.

Build and Push the Custom Training Container to
Amazon ECR

Create a test notebook,
docker_custom_container_test_notebook.ipynb, and
run the following code in the notebook cell. This will access the
docker_byoc_test_docker directory, build the docker with the
specified algorithm_name, and push the docker container to your Amazon
ECR.

```python
import boto3

account_id =

boto3.client('sts').get_caller_identity().get('Account')

ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name

uri_suffix = 'amazonaws.com'

if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'

byoc_image_uri = '{}.dkr.ecr.{}.{}'.format(account_id, region,
                                      uri_suffix, ecr_repository + tag)

!docker build -t $ecr_repository docker

!$(aws ecr get-login --region $region --registry-ids $account_id
--no-include-email)

!aws ecr create-repository --repository-name $ecr_repository

!docker tag {ecr_repository + tag} $byoc_image_uri

!docker push $byoc_image_uri
```

Tip

If you use one of the AWS Deep Learning Container base images,
run the following code to log in to Amazon ECR and access to the
Deep Learning Container image repository.

```bash
! aws ecr get-login-password --region {region}
| docker login --username AWS --password-stdin
763104351884.dkr.ecr.us-east-1.amazonaws.com
```

2770
Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the smdebug core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```python
import sagemaker

from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig,
CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)  
debugger_hook_config=DebuggerHookConfig(...)  

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point='./debugger_custom_container_test_folder/your-training-script.py',
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
estimator.fit()
```

Step 6: Clean up resources

To clean up resources when done with the get started example

1. Open the SageMaker console, choose the notebook instance `RunScriptNotebookInstance`, choose `Actions`, and choose `Stop`. It can take a few minutes for the instance to stop.

2. After the instance `Status` changes to `Stopped`, choose `Actions`, choose `Delete`, and then choose `Delete` in the dialog box. It can take a few minutes for the instance to be deleted. The notebook instance disappears from the table when it has been deleted.

3. Open the Amazon S3 console and delete the bucket that you created for storing model artifacts and the training dataset.

4. Open the IAM console and delete the IAM role. If you created permission policies, you can delete them, too.
Adapting Your Own Inference Container

If none of the Amazon SageMaker prebuilt inference containers suffice for your situation, and you want to use your own Docker container, use the SageMaker Inference Toolkit to adapt your container to work with SageMaker hosting. To adapt your container to work with SageMaker hosting, create the inference code in one or more Python script files and a Dockerfile that imports the inference toolkit.

The inference code includes an inference handler, a handler service, and an entrypoint. In this example, they are stored as three separate Python files. All three of these Python files must be in the same directory as your Dockerfile.

For an example Jupyter notebook that shows a complete example of extending a container by using the SageMaker inference toolkit, see Amazon SageMaker Multi-Model Endpoints using your own algorithm container.

Step 1: Create an Inference Handler

The SageMaker inference toolkit is built on the multi-model server (MMS). MMS expects a Python script that implements functions to load the model, pre-process input data, get predictions from the model, and process the output data in a model handler.

The model_fn Function

There are default implementations for the model_fn function, named default_model_fn, on the SageMaker PyTorch and MXNet Inference toolkits. The default implementation loads models saved using torchscript, of the form .pt or .pth. If your model requires custom methods to load, or you want to perform extra steps when loading your model, you must implement the model_fn function. The following simple example shows an implementation of a model_fn function that loads a PyTorch model:

```python
def model_fn(self, model_dir):
    import torch
    logger.info('model_fn')
    device = "cuda" if torch.cuda.is_available() else "cpu"
    with open(os.path.join(model_dir, 'model.pth'), 'rb') as f:
        model = torch.jit.load(f)
    return model.to(device)
```

The input_fn Function

The input_fn function is responsible for deserializing your input data so that it can be passed to your model. It takes input data and content type as parameters, and returns deserialized data. The SageMaker inference toolkit provides a default implementation that deserializes the following content types:

- JSON
- CSV
- Numpy array
- NPZ

If your model requires a different content type, or you want to preprocess your input data before sending it to the model, you must implement the input_fn function. The following example shows a simple implementation of the input_fn function.
from sagemaker_inference import content_types, decoder
def input_fn(self, input_data, content_type):
    """A default input_fn that can handle JSON, CSV and NPZ formats.
    Args:
    input_data: the request payload serialized in the content_type format
    content_type: the request content_type
    Returns: input_data deserialized into torch.FloatTensor or torch.cuda.FloatTensor depending if cuda is available.
    """
    return decoder.decode(input_data, content_type)

The predict_fn Function

The predict_fn function is responsible for getting predictions from the model. It takes the model and the data returned from input_fn as parameters, and returns the prediction. There is no default implementation for the predict_fn. You must implement it yourself. The following is a simple implementation of the predict_fn function for a PyTorch model.

def predict_fn(self, data, model):
    """A default predict_fn for PyTorch. Calls a model on data deserialized in input_fn.
    Runs prediction on GPU if cuda is available.
    Args:
    data: input data (torch.Tensor) for prediction deserialized by input_fn
    model: PyTorch model loaded in memory by model_fn
    Returns: a prediction
    """
    return model(data)

The output_fn Function

The output_fn function is responsible for serializing the data that the predict_fn function returns as a prediction. The SageMaker inference toolkit implements a default output_fn function that serializes Numpy arrays, JSON, and CSV. If your model outputs any other content type, or you want to perform other post-processing of your data before sending it to the user, you must implement your own output_fn function. The following shows a simple output_fn function for a PyTorch model.

from sagemaker_inference import encoder
def output_fn(self, prediction, accept):
    """A default output_fn for PyTorch. Serializes predictions from predict_fn to JSON, CSV or NPY format.
    Args:
    prediction: a prediction result from predict_fn
    accept: type which the output data needs to be serialized
    Returns: output data serialized
    """
    return encoder.encode(prediction, accept)

Step 2: Implement a Handler Service

The handler service is executed by the model server. The handler service implements initialize and handle methods. The initialize method is invoked when the model server starts, and the handle method is invoked for all incoming inference requests to the model server. For more information, see
Amazon SageMaker Developer Guide
Adapting Your Own Inference Container

Custom Service in the Multi-model server documentation. The following is an example of a handler
service for a PyTorch model server.
from sagemaker_inference.default_handler_service import DefaultHandlerService
from sagemaker_inference.transformer import Transformer
from sagemaker_pytorch_serving_container.default_inference_handler import
DefaultPytorchInferenceHandler
class HandlerService(DefaultHandlerService):
"""Handler service that is executed by the model server.
Determines specific default inference handlers to use based on model being used.
This class extends ``DefaultHandlerService``, which define the following:
- The ``handle`` method is invoked for all incoming inference requests to the model
server.
- The ``initialize`` method is invoked at model server start up.
Based on: https://github.com/awslabs/mxnet-model-server/blob/master/docs/
custom_service.md
"""
def __init__(self):
transformer =
Transformer(default_inference_handler=DefaultPytorchInferenceHandler())
super(HandlerService, self).__init__(transformer=transformer)

Step 3: Implement an Entrypoint
The entrypoint starts the model server by invoking the handler service. You specify the location of the
entrypoint in your Dockerﬁle. The following is an example of an entrypoint.
from sagemaker_inference import model_server
model_server.start_model_server(handler_service=HANDLER_SERVICE)

Step 4: Write a Dockerﬁle
In your Dockerfile, copy the model handler from step 2 and specify the Python ﬁle from the previous
step as the entrypoint in your Dockerfile. The following is an example of the lines you can add to your
Dockerﬁle to copy the model handler and specify the entrypoint. For a full example of a Dockerﬁle for an
inference container, see Dockerﬁle.
# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py
# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/entrypoint.py"]

Step 5: Build and Register Your Container
Now you can build your container and register it in Amazon Elastic Container Registry (Amazon ECR). The
following shell script from the sample notebook builds the container and uploads it to an Amazon ECR
repository in your AWS account.

Note

SageMaker hosting supports using inference containers that are stored in repositories other
than Amazon ECR. For information, see Use a Private Docker Registry for Real-Time Inference
Containers (p. 2785).
The following shell script shows how to build and register a container.

2774


Create a container with your own algorithms and models

If none of the existing SageMaker containers meet your needs and you don’t have an existing container of your own, you may need to create a new Docker container. The following sections show how to create Docker containers with your training and inference algorithms for use with SageMaker.

**Topics**
- Use Your Own Training Algorithms (p. 2775)
- Use Your Own Inference Code (p. 2782)

**Use Your Own Training Algorithms**

This section explains how Amazon SageMaker interacts with a Docker container that runs your custom training algorithm. Use this information to write training code and create a Docker image for your training algorithms.

**Topics**
How Amazon SageMaker Runs Your Training Image

To configure a Docker container to run as an executable, use an `ENTRYPOINT` instruction in a Dockerfile. Note the following:

- For model training, Amazon SageMaker runs the container as follows:

  ```
  docker run image train
  
  SageMaker overrides any default `CMD` statement in a container by specifying the `train` argument after the image name. The `train` argument also overrides arguments that you provide using `CMD` in the Dockerfile.
  ```

- In your Dockerfile, use the `exec` form of the `ENTRYPOINT` instruction:

  ```
  ENTRYPOINT ["executable", "param1", "param2", ...]
  
  For example:

  ```
  ENTRYPOINT ["python", "k-means-algorithm.py"]
  ```

  The `exec` form of the `ENTRYPOINT` instruction starts the executable directly, not as a child of `/bin/sh`. This enables it to receive signals like `SIGTERM` and `SIGKILL` from SageMaker APIs. Note the following:

  - The `CreateTrainingJob` API has a stopping condition that directs SageMaker to stop model training after a specific time.

  - The `StopTrainingJob` API issues the equivalent of the `docker stop`, with a 2-minute timeout command to gracefully stop the specified container:

    ```
    docker stop -t120
    
    The command attempts to stop the running container by sending a `SIGTERM` signal. After the 2-minute timeout, the API sends `SIGKILL` and forcibly stops the containers. If the container handles the `SIGTERM` gracefully and exits within 120 seconds from receiving it, no `SIGKILL` is sent.

    Note
    If you want access to the intermediate model artifacts after SageMaker stops the training, add code to handle saving artifacts in your `SIGTERM` handler.

    - If you plan to use GPU devices for model training, make sure that your containers are `nvidia-docker` compatible. Include only the CUDA toolkit on containers; don't bundle NVIDIA drivers with the image. For more information about `nvidia-docker`, see `NVIDIA/nvidia-docker`.

  ```

  2776
• You can't use the tini initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.
• /opt/ml and all sub-directories are reserved by SageMaker training. When building your algorithm's Docker image, please ensure you don't place any data required by your algorithm under them as the data may no longer be visible during training.

How Amazon SageMaker Provides Training Information

This section explains how SageMaker makes training information, such as training data, hyperparameters, and other configuration information, available to your Docker container.

When you send a CreateTrainingJob request to SageMaker to start model training, you specify the Amazon Elastic Container Registry (Amazon ECR) path of the Docker image that contains the training algorithm. You also specify the Amazon Simple Storage Service (Amazon S3) location where training data is stored and algorithm-specific parameters. SageMaker makes this information available to the Docker container so that your training algorithm can use it. This section explains how we make this information available to your Docker container. For information about creating a training job, see CreateTrainingJob. For more information on the way that SageMaker containers organize information, see Using the SageMaker Training and Inference Toolkits (p. 2760).

Topics
• Hyperparameters (p. 2777)
• Environment Variables (p. 2777)
• Input Data Configuration (p. 2777)
• Training Data (p. 2778)
• Distributed Training Configuration (p. 2779)

Hyperparameters

SageMaker makes the hyperparameters in a CreateTrainingJob request available in the Docker container in the /opt/ml/input/config/hyperparameters.json file.

Environment Variables

The following environment variables are set in the container:

• TRAINING_JOB_NAME – Specified in the TrainingJobName parameter of the CreateTrainingJob request.
• TRAINING_JOB_ARN – The Amazon Resource Name (ARN) of the training job returned as the TrainingJobArn in the CreateTrainingJob response.
• All environment variables specified in the Environment parameter in the CreateTrainingJob request.

Input Data Configuration

You specify data channel information in the InputDataConfig parameter in a CreateTrainingJob request. SageMaker makes this information available in the /opt/ml/input/config/inputdataconfig.json file in the Docker container.

For example, suppose that you specify three data channels (train, evaluation, and validation) in your request. SageMaker provides the following JSON:
Use Your Own Training Algorithms

```json
{
    "train": {"ContentType": "trainingContentType",
              "TrainingInputMode": "File",
              "S3DistributionType": "FullyReplicated",
              "RecordWrapperType": "None"},
    "evaluation": {"ContentType": "evalContentType",
                   "TrainingInputMode": "File",
                   "S3DistributionType": "FullyReplicated",
                   "RecordWrapperType": "None"},
    "validation": {"TrainingInputMode": "File",
                   "S3DistributionType": "FullyReplicated",
                   "RecordWrapperType": "None"}
}
```

**Note**
SageMaker provides only relevant information about each data channel (for example, the channel name and the content type) to the container, as shown. `S3DistributionType` will be set as `FullyReplicated` if specify EFS or FSxLustre as input data sources.

### Training Data

The `TrainingInputMode` parameter in the `AlgorithmSpecification` of the `CreateTrainingJob` request specifies how the training dataset is made available. The following input modes are available:

- **File mode**
  - `TrainingInputMode` parameter written to `inputdataconfig.json`: "File"
  - Data channel directory in the Docker container: `/opt/ml/input/data/channel_name`
  - Supported data sources: Amazon Simple Storage Service (Amazon S3), Amazon Elastic File System (Amazon EFS), and Amazon FSx for Lustre
  
  A directory is created for each channel. For example, if you have three channels named `training`, `validation`, and `testing`, SageMaker makes three directories in the Docker container:
  - `/opt/ml/input/data/training`
  - `/opt/ml/input/data/validation`
  - `/opt/ml/input/data/testing`

  **Note**
  Channels that use file system data sources such as Amazon EFS and Amazon FSx must use File mode. If a file system is specified, the directory path provided in the channel is mounted at `/opt/ml/input/data/channel_name`.

- **FastFile mode**
  - `TrainingInputMode` parameter written to `inputdataconfig.json`: "FastFile"
  - Data channel directory in the Docker container: `/opt/ml/input/data/channel_name`
  - Supported data sources: Amazon S3

  The channel directory is mounted as read-only.

Algorithms that support File mode can seamlessly work with FastFile mode with no code changes.

**Note**
Channels that use FastFile mode must use a `S3DataType` of "S3Prefix". FastFile mode presents a folder view that uses the forward slash (/) as the delimiter for grouping Amazon S3 objects into folders. `S3Uri` prefixes must not correspond to a partial folder name. For example, if an Amazon S3 dataset contains `s3://my-bucket/train-01/data.csv`, then neither `s3://my-bucket/train` nor `s3://my-bucket/train-01` are allowed as `S3Uri` prefixes.
A trailing forward slash is recommended to define a channel corresponding to a folder. For example, the s3://my-bucket/train-01/ channel for the train-01 folder. Without the trailing forward slash, the channel would be ambiguous if there existed another folder s3://my-bucket/train-011/ or file s3://my-bucket/train-01.txt/.

- **Pipe mode**
  - TrainingInputMode parameter written to inputdataconfig.json: "Pipe"
  - Data channel directory in the Docker container: /opt/ml/input/data/channel_name_epoch_number
  - Supported data sources: Amazon S3

You need to read from a separate pipe for each channel. For example, if you have three channels named training, validation, and testing, you need to read from the following pipes:

- /opt/ml/input/data/training_0, /opt/ml/input/data/training_1, ...
- /opt/ml/input/data/validation_0, /opt/ml/input/data/validation_1, ...
- /opt/ml/input/data/testing_0, /opt/ml/input/data/testing_1, ...

Read the pipes sequentially. For example, if you have a channel called training, read the pipes in this sequence:

1. Open /opt/ml/input/data/training_0 in read mode and read it to end-of-file (EOF) or, if you are done with the first epoch, close the pipe file early.
2. After closing the first pipe file, look for /opt/ml/input/data/training_1 and read it until you have completed the second epoch, and so on.

If the file for a given epoch doesn't exist yet, your code may need to retry until the pipe is created. There is no sequencing restriction across channel types. For example, you can read multiple epochs for the training channel and only start reading the validation channel when you are ready. Or, you can read them simultaneously if your algorithm requires that.

For an example of a Jupyter notebook that shows how to use Pipe mode when bringing your own container, see Bring your own pipe-mode algorithm to Amazon SageMaker.

**Distributed Training Configuration**

If you're performing distributed training with multiple containers, SageMaker makes information about all containers available in the /opt/ml/input/config/resourceconfig.json file.

To enable inter-container communication, this JSON file contains information for all containers. SageMaker makes this file available for both File and Pipe mode algorithms. The file provides the following information:

- **current_host**—The name of the current container on the container network. For example, algo-1. Host values can change at any time. Don't write code with specific values for this variable.
- **hosts**—The list of names of all containers on the container network, sorted lexicographically. For example, ["algo-1", "algo-2", "algo-3"] for a three-node cluster. Containers can use these names to address other containers on the container network. Host values can change at any time. Don't write code with specific values for these variables.
- **network_interface_name**—The name of the network interface that is exposed to your container. For example, containers running the Message Passing Interface (MPI) can use this information to set the network interface name.
- **Do not use the information in /etc/hostname or /etc/hosts because it might be inaccurate.**
- **Hostname information may not be immediately available to the algorithm container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.**

The following is an example file on node 1 in a three-node cluster:
Run Training with EFA

SageMaker provides integration with EFA devices to accelerate High Performance Computing (HPC) and machine learning applications. This integration allows you to leverage an EFA device when running your distributed training jobs. You can add EFA integration to an existing Docker container that you bring to SageMaker. The following information outlines how to configure your own container to use an EFA device for your distributed training jobs.

Prerequisites

Your container must satisfy the SageMaker Training container specification.

Install EFA and required packages

Your container must download and install the EFA software. This allows your container to recognize the EFA device, and provides compatible versions of Libfabric and Open MPI.

Any tools like MPI and NCCL must be installed and managed inside the container to be used as part of your EFA-enabled training job. The following example shows how to modify the Dockerfile of your EFA-enabled container to install EFA, MPI, OFI, NCCL, and NCCL-TEST.

Note

When using PyTorch with EFA on your container, the NCCL version of your container should match the NCCL version of your PyTorch installation. To verify the PyTorch NCCL version, use the following command:

torch.cuda.nccl.version()

ARG OPEN_MPI_PATH=/opt/amazon/openmpi/
ENV NCCL_VERSION=2.7.8
ENV EFA_VERSION=1.11.2
ENV BRANCH_OFI=1.1.1

# EFA and MPI SETUP
RUN cd $HOME \
    && curl -O https://s3-us-west-2.amazonaws.com/aws-efa-installer/aws-efa-installer-
    $(EFA_VERSION).tar.gz \
    && tar -xf aws-efa-installer-$(EFA_VERSION).tar.gz \ 
    && cd aws-efa-installer \ 
    && ./efa_installer.sh -y --skip-kmod -g \
    ENV PATH="$OPEN_MPI_PATH/bin:$PATH"
    ENV LD_LIBRARY_PATH="$OPEN_MPI_PATH/lib:$LD_LIBRARY_PATH"

# NCCL, OFI, NCCL-TEST SETUP
RUN cd $HOME \
    && git clone https://github.com/NVIDIA/nccl.git -b v${NCCL_VERSION}-1 \ 
    && cd nccl \ 
    && make -j64 src.build BUILDDIR=/usr/local

RUN apt-get update && apt-get install -y autoconf
$RUN cd $HOME \
  && git clone https://github.com/aws/aws-ofi-nccl.git -b v${BRANCH_OFI} \
  && cd aws-ofi-nccl \
  && ./autogen.sh \
  && ./configure --with-libfabric=/opt/amazon/efa \
  --with-mpi=/opt/amazon/openmpi \
  --with-cuda=/usr/local/cuda \
  --with-nccl=/usr/local --prefix=/usr/local \
  && make && make install$

$RUN cd $HOME \
  && git clone https://github.com/NVIDIA/nccl-tests \
  && cd nccl-tests \
  && make MPI=1 MPI_HOME=/opt/amazon/openmpi CUDA_HOME=/usr/local/cuda NCCL_HOME=/usr/local

**Considerations when creating your container**

The EFA device is mounted to the container as `/dev/infiniband/uverbs0` under the list of devices accessible to the container. On P4d instances, the container has access to 4 EFA devices. The EFA devices can be found in the list of devices accessible to the container as:

- `/dev/infiniband/uverbs0`
- `/dev/infiniband/uverbs1`
- `/dev/infiniband/uverbs2`
- `/dev/infiniband/uverbs3`

To get information about hostname, peer hostnames, and network interface (for MPI) from the `resourceconfig.json` file provided to each container instances, see [Distributed Training Configuration](#). Your container handles regular TCP traffic among peers through the default Elastic Network Interfaces (ENI), while handling OFI (kernel bypass) traffic through the EFA device.

**Verify that your EFA device is recognized**

To verify that the EFA device is recognized, run the following command from within your container.

```
/opt/amazon/efa/bin/fi_info -p efa
```

Your output should look similar to the following.

```text
provider: efa
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-rdm
  version: 2.0
  type: FI_EP_RDM
  protocol: FI_PROTO_EFA
provider: efa
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-dgrm
  version: 2.0
  type: FI_EP_DGRAM
  protocol: FI_PROTO_EFA
provider: efa;ofi_rxd
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-dgrm
  version: 1.0
  type: FI_EP_RDM
  protocol: FI_PROTO_RXD
```
Running a training job with EFA

Once you've created an EFA-enabled container, you can run a training job with EFA using a SageMaker Estimator the same way as you would with any other Docker image. For more information on registering your container and using it for training, see Adapting Your Own Training Container.

How Amazon SageMaker Signals Algorithm Success and Failure

A training algorithm indicates whether it succeeded or failed using the exit code of its process.

A successful training execution should exit with an exit code of 0 and an unsuccessful training execution should exit with a non-zero exit code. These will be converted to Completed and Failed in the TrainingJobStatus returned by DescribeTrainingJob. This exit code convention is standard and is easily implemented in all languages. For example, in Python, you can use `sys.exit(1)` to signal a failure exit, and simply running to the end of the main routine will cause Python to exit with code 0.

In the case of failure, the algorithm can write a description of the failure to the failure file. See next section for details.

How Amazon SageMaker Processes Training Output

As your algorithm runs in a container, it generates output including the status of the training job and model and output artifacts. Your algorithm should write this information to the following files, which are located in the container's /output directory. Amazon SageMaker processes the information contained in this directory as follows:

- /opt/ml/output/failure—If training fails, after all algorithm output (for example, logging) completes, your algorithm should write the failure description to this file. In a DescribeTrainingJob response, SageMaker returns the first 1024 characters from this file as FailureReason.

- /opt/ml/model—Your algorithm should write all final model artifacts to this directory. SageMaker copies this data as a single object in compressed tar format to the S3 location that you specified in the CreateTrainingJob request. If multiple containers in a single training job write to this directory they should ensure no file/directory names clash. SageMaker aggregates the result in a tar file and uploads to S3.

Use Your Own Inference Code

You can use Amazon SageMaker to interact with Docker containers and run your own inference code in one of two ways:

- To use your own inference code with a persistent endpoint to get one prediction at a time, use SageMaker hosting services.
- To use your own inference code to get predictions for an entire dataset, use SageMaker batch transform.

Topics

- Use Your Own Inference Code with Hosting Services (p. 2783)
- Use Your Own Inference Code with Batch Transform (p. 2788)
Use Your Own Inference Code with Hosting Services

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for hosting services. Use this information to write inference code and create a Docker image.

**Topics**
- How SageMaker Runs Your Inference Image (p. 2783)
- How SageMakerLoads Your Model Artifacts (p. 2784)
- How Containers Serve Requests (p. 2784)
- How Your Container Should Respond to Inference Requests (p. 2784)
- How Your Container Should Respond to Health Check (Ping) Requests (p. 2785)
- Use a Private Docker Registry for Real-Time Inference Containers (p. 2785)

**How SageMaker Runs Your Inference Image**

To configure a container to run as an executable, use an **ENTRYPOINT** instruction in a Dockerfile. Note the following:

- For model inference, SageMaker runs the container as:

  ```
  docker run image serve
  ```

  SageMaker overrides default **CMD** statements in a container by specifying the **serve** argument after the image name. The **serve** argument overrides arguments that you provide with the **CMD** command in the Dockerfile.

- We recommend that you use the **exec** form of the **ENTRYPOINT** instruction:

  ```
  ENTRYPOINT ["executable", "param1", "param2"]
  ```

  For example:

  ```
  ENTRYPOINT ["python", "k_means_inference.py"]
  ```

  The **exec** form of the **ENTRYPOINT** instruction starts the executable directly, not as a child of `/bin/sh`. This enables it to receive signals like **SIGTERM** and **SIGKILL** from the SageMaker API operations, which is a requirement.

  For example, when you use the **CreateEndpoint** API to create an endpoint, SageMaker provisions the number of ML compute instances required by the endpoint configuration, which you specify in the request. SageMaker runs the Docker container on those instances.

  If you reduce the number of instances backing the endpoint (by calling the **UpdateEndpointWeightsAndCapacities** API), SageMaker runs a command to stop the Docker container on the instances that are being terminated. The command sends the **SIGTERM** signal, then it sends the **SIGKILL** signal thirty seconds later.
If you update the endpoint (by calling the `UpdateEndpoint` API), SageMaker launches another set of ML compute instances and runs the Docker containers that contain your inference code on them. Then it runs a command to stop the previous Docker containers. To stop a Docker container, command sends the `SIGTERM` signal, then it sends the `SIGKILL` signal 30 seconds later.

- SageMaker uses the container definition that you provided in your `CreateModel` request to set environment variables and the DNS hostname for the container as follows:
  - It sets environment variables using the `ContainerDefinition.Environment` string-to-string map.
  - It sets the DNS hostname using the `ContainerDefinition.ContainerHostname`.

- If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your `CreateEndpointConfig` request), make sure that your containers are `nvidia-docker` compatible. Don't bundle NVIDIA drivers with the image. For more information about `nvidia-docker`, see NVIDIA/nvidia-docker.

- You can't use the `tini` initializer as your entry point in SageMaker containers because it gets confused by the `train` and `serve` arguments.

**How SageMaker Loads Your Model Artifacts**

In your `CreateModel` request, the container definition includes the `ModelDataUrl` parameter, which identifies the S3 location where model artifacts are stored. SageMaker uses this information to determine from where to copy the model artifacts. It copies the artifacts to the `/opt/ml/model` directory for use by your inference code.

The `ModelDataUrl` must point to a tar.gz file. Otherwise, SageMaker won't download the file.

If you trained your model in SageMaker, the model artifacts are saved as a single compressed tar file in Amazon S3. If you trained your model outside SageMaker, you need to create this single compressed tar file and save it in a S3 location. SageMaker decompresses this tar file into `/opt/ml/model` directory before your container starts.

**How Containers Serve Requests**

Containers need to implement a web server that responds to `/invocations` and `/ping` on port 8080.

**How Your Container Should Respond to Inference Requests**

To obtain inferences, the client application sends a POST request to the SageMaker endpoint. For more information, see the `InvokeEndpoint` API. SageMaker passes the request to the container, and returns the inference result from the container to the client. Note the following:

- SageMaker strips all `POST` headers except those supported by `InvokeEndpoint`. SageMaker might add additional headers. Inference containers must be able to safely ignore these additional headers.
- To receive inference requests, the container must have a web server listening on port 8080 and must accept `POST` requests to the `/invocations` endpoint.
- A customer's model containers must accept socket connection requests within 250 ms.
- A customer's model containers must respond to requests within 60 seconds. The model itself can have a maximum processing time of 60 seconds before responding to the `/invocations`. If your model
is going to take 50-60 seconds of processing time, the SDK socket timeout should be set to be 70 seconds.

How Your Container Should Respond to Health Check (Ping) Requests

The CreateEndpoint and UpdateEndpoint API calls result in SageMaker starting new inference containers. Soon after container startup, SageMaker starts sending periodic GET requests to the /ping endpoint.

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the /invocations endpoint.

If the container does not begin to pass health checks, by consistently responding with 200s, during the 4 minutes after startup, CreateEndPoint will fail, leaving the endpoint in a failed state, and the update requested by UpdateEndpoint will not be completed.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on /ping attempts is 2 seconds.

Use a Private Docker Registry for Real-Time Inference Containers

Amazon SageMaker hosting enables you to use images stored in Amazon ECR to build your containers for real-time inference by default. Optionally, you can build containers for real-time inference from images in a private Docker registry. The private registry must be accessible from an Amazon VPC in your account. Models that you create based on the images stored in your private Docker registry must be configured to connect to the same VPC where the private Docker registry is accessible. For information about connecting your model to a VPC, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3178).

Your Docker registry must be secured with a TLS certificate from a known public certificate authority (CA).

Note
Your private Docker registry must allow inbound traffic from the security groups you specify in the VPC configuration for your model, so that SageMaker hosting is able to pull model images from your registry. SageMaker can pull model images from DockerHub if there's a path to the open internet inside your VPC.

Topics
- Store Images in a Private Docker Registry other than Amazon Elastic Container Registry (p. 2785)
- Use an Image from a Private Docker Registry for Real-time Inference (p. 2786)
- Allow SageMaker to authenticate to a private Docker registry (p. 2787)
- Create the Lambda function (p. 2787)
- Give your execution role permission to Lambda (p. 2788)
- Create an interface VPC endpoint for Lambda (p. 2788)

Store Images in a Private Docker Registry other than Amazon Elastic Container Registry

To use a private Docker registry to store your images for SageMaker real-time inference, create a private registry that is accessible from your Amazon VPC. For information about creating a Docker registry, see Deploy a registry server in the Docker documentation. The Docker registry must comply with the following:

- The registry must be a Docker Registry HTTP API V2 registry.
• The Docker registry must be accessible from the same VPC that you specify in the VpcConfig parameter that you specify when you create your model.

Use an Image from a Private Docker Registry for Real-time Inference

When you create a model and deploy it to SageMaker hosting, you can specify that it use an image from your private Docker registry to build the inference container. Specify this in the ImageConfig object in the PrimaryContainer parameter that you pass to a call to the create_model function.

To use an image stored in your private Docker registry for your inference container

1. Create the image configuration object and specify a value of Vpc for the RepositoryAccessMode field.

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc'
   }
   ```

2. If your private Docker registry requires authentication, add a RepositoryAuthConfig object to the image configuration object. For the RepositoryCredentialsProviderArn field of the RepositoryAuthConfig object, specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides credentials that allows SageMaker to authenticate to your private Docker Registry. For information about how to create the Lambda function to provide authentication, see Allow SageMaker to authenticate to a private Docker registry (p. 2787).

   ```python
   image_config = {
       'RepositoryAccessMode': 'Vpc',
       'RepositoryAuthConfig': {
           'RepositoryCredentialsProviderArn':
               'arn:aws:lambda:Region:Acct:function:FunctionName'
       }
   }
   ```

3. Create the primary container object that you want to pass to create_model, using the image configuration object that you created in the previous step.

   Provide your image in digest form. If you provide your image using the :latest tag, there is a risk that SageMaker pulls a newer version of the image than intended. Using the digest form ensures that SageMaker pulls the intended image version.

   ```python
   primary_container = {
       'ContainerHostname': 'ModelContainer',
       'Image': 'myteam.myorg.com/docker-local/my-inference-image:<IMAGE-TAG>',
       'ImageConfig': image_config
   }
   ```

4. Specify the model name and the execution role that you want to pass to create_model.

   ```python
   model_name = 'vpc-model'
   execution_role_arn = 'arn:aws:iam::123456789012:role/SageMakerExecutionRole'
   ```

5. Specify one or more security groups and subnets for the VPC configuration for your model. Your private Docker registry must allow inbound traffic from the security groups that you specify. The subnets that you specify must be in the same VPC as your private Docker registry.

   ```python
   vpc_config = {
       'SecurityGroupIds': ['sg-0123456789abcdef0'],
       'Subnets': ['subnet-0123456789abcdef0','subnet-0123456789abcdef1']
   }
   ```

```python
import boto3
sm = boto3.client('sagemaker')
```

7. Create the model by calling `create_model`, using the values you specified in the previous steps for the `PrimaryContainer` and `VpcConfig` parameters.

```python
try:
    resp = sm.create_model(
        ModelName=model_name,
        PrimaryContainer=primary_container,
        ExecutionRoleArn=execution_role_arn,
        VpcConfig=vpc_config,
    )
except Exception as e:
    print(f'error calling CreateModel operation: {e}')
else:
    print(resp)
```

8. Finally, call `create_endpoint_config` and `create_endpoint` to create the hosting endpoint, using the model that you created in the previous step.

```python
endpoint_config_name = 'my-endpoint-config'
sm.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {'VariantName': 'MyVariant',
         'ModelName': model_name,
         'InitialInstanceCount': 1,
         'InstanceType': 'ml.t2.medium'},
    ],
)
endpoint_name = 'my-endpoint'
sm.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
sm.describe_endpoint(EndpointName=endpoint_name)
```

### Allow SageMaker to authenticate to a private Docker registry

To pull an inference image from a private Docker registry that requires authentication, create an AWS Lambda function that provides credentials, and provide the Amazon Resource Name (ARN) of the Lambda function when you call `create_model`. When SageMaker runs `create_model`, it calls the Lambda function that you specified to get credentials to authenticate to your Docker registry.

#### Create the Lambda function

Create an AWS Lambda function that returns a response with the following form:

```python
def handler(event, context):
    response = {
        "Credentials": {"Username": "username", "Password": "password"}
    }
```
Depending on how you set up authentication for your private Docker registry, the credentials that your Lambda function returns can mean either of the following:

- If you set up your private Docker registry to use basic authentication, this is the `username` and `password` to authenticate to the registry.
- If you set up your private Docker registry to use bearer token authentication, the `username` and `password` are sent to your authorization server, which returns a Bearer token that can then be used to authenticate to the private Docker registry.

**Give your execution role permission to Lambda**

The execution role that you use to call `create_model` must have permissions to call AWS Lambda functions. Add the following to the permissions policy of your execution role.

```json
{
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:*:*:function:myLambdaFunction"
    ]
}
```

Where `myLambdaFunction` is the name of your Lambda function. For information about editing a role permissions policy, see Modifying a role permissions policy (console) in the *AWS Identity and Access Management User Guide*.

**Note**

An execution role with the `AmazonSageMakerFullAccess` managed policy attached to it has permission to call any Lambda function with `SageMaker` in its name.

**Create an interface VPC endpoint for Lambda**

Create an interface endpoint so that your Amazon VPC can communicate with your AWS Lambda function without sending traffic over the internet. For information about how to do this, see Configuring interface VPC endpoints for Lambda in the *AWS Lambda Developer Guide*.

SageMaker hosting sends a request through your VPC to `lambda.region.amazonaws.com`, to call your Lambda function. If you choose Private DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, make sure to map `lambda.region.amazonaws.com` to your Lambda interface endpoint.

**Use Your Own Inference Code with Batch Transform**

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for batch transform. Use this information to write inference code and create a Docker image.

**Topics**

- How SageMaker Runs Your Inference Image (p. 2789)
- How SageMaker Loads Your Model Artifacts (p. 2789)
- How Containers Serve Requests (p. 2790)
- How Your Container Should Respond to Inference Requests (p. 2790)
- How Your Container Should Respond to Health Check (Ping) Requests (p. 2791)
How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For batch transforms, SageMaker runs the container as:

  ```bash
docker run image serve
  ```

  SageMaker overrides default CMD statements in a container by specifying the serve argument after the image name. The serve argument overrides arguments that you provide with the CMD command in the Dockerfile.

- We recommend that you use the exec form of the ENTRYPOINT instruction:

  ```bash
  ENTRYPOINT ["executable", "param1", "param2"]
  ```

  For example:

  ```bash
  ENTRYPOINT ["python", "k_means_inference.py"]
  ```

- SageMaker sets environment variables specified in CreateModel and CreateTransformJob on your container. Additionally, the following environment variables are populated:
  - `SAGEMAKER_BATCH` is always set to true when the container runs in Batch Transform.
  - `SAGEMAKER_MAX_PAYLOAD_IN_MB` is set to the largest size payload that is sent to the container via HTTP.
  - `SAGEMAKER_BATCH_STRATEGY` is set to SINGLE_RECORD when the container is sent a single record per call to invocations and MULTI_RECORD when the container gets as many records as will fit in the payload.
  - `SAGEMAKER_MAX_CONCURRENT_TRANSFORMS` is set to the maximum number of /invocations requests that can be opened simultaneously.

  **Note**
  The last three environment variables come from the API call made by the user. If the user doesn’t set values for them, they aren’t passed. In that case, either the default values or the values requested by the algorithm (in response to the /execution-parameters) are used.

- If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your CreateTransformJob request), make sure that your containers are nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

- You can’t use the init initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

How SageMaker Loads Your Model Artifacts

In a CreateModel request, container definitions include the ModelDataURL parameter, which identifies the location in Amazon S3 where model artifacts are stored. When you use SageMaker to run inferences, it uses this information to determine from where to copy the model artifacts. It copies the artifacts to the /opt/ml/model directory in the Docker container for use by your inference code.
The `ModelDataUrl` parameter must point to a tar.gz file. Otherwise, SageMaker can’t download the file. If you train a model in SageMaker, it saves the artifacts as a single compressed tar file in Amazon S3. If you train a model in another framework, you need to store the model artifacts in Amazon S3 as a compressed tar file. SageMaker decompresses this tar file and saves it in the `/opt/ml/model` directory in the container before the batch transform job starts.

### How Containers Serve Requests

Containers must implement a web server that responds to invocations and ping requests on port 8080. For batch transforms, you have the option to set algorithms to implement execution-parameters requests to provide a dynamic runtime configuration to SageMaker. SageMaker uses the following endpoints:

- **ping**—Used to periodically check the health of the container. SageMaker waits for an HTTP 200 status code and an empty body for a successful ping request before sending an invocations request. You might use a ping request to load a model into memory to generate inference when invocations requests are sent.
- **(Optional) execution-parameters**—Allows the algorithm to provide the optimal tuning parameters for a job during runtime. Based on the memory and CPUs available for a container, the algorithm chooses the appropriate `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` values for the job.

Before calling the invocations request, SageMaker attempts to invoke the execution-parameters request. When you create a batch transform job, you can provide values for the `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` parameters. SageMaker determines the values for these parameters using this order of precedence:

1. The parameter values that you provide when you create the `CreateTransformJob` request.
2. The values that the model container returns when SageMaker invokes the execution-parameters endpoint.
3. The default parameter values, listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MaxConcurrentTransforms</code></td>
<td>1</td>
</tr>
<tr>
<td><code>BatchStrategy</code></td>
<td><code>MULTI_RECORD</code></td>
</tr>
<tr>
<td><code>MaxPayloadInMB</code></td>
<td>6</td>
</tr>
</tbody>
</table>

The response for a GET execution-parameters request is a JSON object with keys for `MaxConcurrentTransforms`, `BatchStrategy`, and `MaxPayloadInMB` parameters. This is an example of a valid response:

```json
{
  "MaxConcurrentTransforms": 8,
  "BatchStrategy": "MULTI_RECORD",
  "MaxPayloadInMB": 6
}
```

### How Your Container Should Respond to Inference Requests

To obtain inferences, Amazon SageMaker sends a POST request to the inference container. The POST request body contains data from Amazon S3. Amazon SageMaker passes the request to the container, and returns the inference result from the container, saving the data from the response to Amazon S3.
To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the `/invocations` endpoint. The inference request timeout and max retries can be configured through `ModelClientConfig`.

**How Your Container Should Respond to Health Check (Ping) Requests**

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the `/invocations` endpoint.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on `/ping` attempts is 2 seconds.

**Example Notebooks: Use Your Own Algorithm or Model**

The following Jupyter notebooks show how to use your own algorithms or pretrained models from an Amazon SageMaker notebook instance. For links to the GitHub repositories with the prebuilt Dockerfiles for the TensorFlow, MXNet, Chainer, and PyTorch frameworks and instructions on using the AWS SDK for Python (Boto3) estimators to run your own training algorithms on SageMaker Learner and your own models on SageMaker hosting, see Prebuilt SageMaker Docker Images for Deep Learning (p. 2746)

**Setup**

1. Create a SageMaker notebook instance. For instructions on how to create and access Jupyter notebook instances, see Use Amazon SageMaker Notebook Instances (p. 237).
2. Open the notebook instance you created.
3. Choose the **SageMaker Examples** tab for a list of all SageMaker example notebooks.
4. Open the sample notebooks from the **Advanced Functionality** section in your notebook instance or from GitHub using the provided links. To open a notebook, choose its **Use** tab, then choose **Create copy**.

**Host Models Trained in Scikit-learn**

To learn how to host models trained in Scikit-learn for making predictions in SageMaker by injecting them into first-party k-means and XGBoost containers, see the following sample notebooks.

- `kmeans_bring_your_own_model`
- `xgboost_bring_your_own_model`

**Package TensorFlow and Scikit-learn Models for Use in SageMaker**

To learn how to package algorithms that you have developed in TensorFlow and scikit-learn frameworks for training and deployment in the SageMaker environment, see the following notebooks. They show you how to build, register, and deploy your own Docker containers using Dockerfiles.

- `tensorflow_bring_your_own`
Train and Deploy a Neural Network on SageMaker

To learn how to train a neural network locally using MXNet or TensorFlow, and then create an endpoint from the trained model and deploy it on SageMaker, see the following notebooks. The MXNet model is trained to recognize handwritten numbers from the MNIST dataset. The TensorFlow model is trained to classify irises.

• mxnet_mnist_byom
• tensorflow_iris_byom

Training Using Pipe Mode

To learn how to use a Dockerfile to build a container that calls the train.py script and uses pipe mode to custom train an algorithm, see the following notebook. In pipe mode, the input data is transferred to the algorithm while it is training. This can decrease training time compared to using file mode.

• pipe_bring_your_own

Bring Your Own R Model

To learn how to use an R container to train and host a model with the R kernel installed in a notebook, see the following notebook. To take advantage of the AWS SDK for Python (Boto3), we use Python within the notebook. You can achieve the same results in R by invoking command line arguments.

• r_bring_your_own

Extend a Prebuilt PyTorch Container Image

To learn how to extend a prebuilt SageMaker PyTorch container image when you have additional functional requirements for your algorithm or model that the prebuilt Docker image doesn't support, see the following notebook.

• pytorch_extending_our_containers

Train and Debug Training Jobs on a Custom Container

To learn how to train and debug training jobs using SageMaker Debugger, see the following notebook. A training script provided through this example uses the TensorFlow Keras ResNet 50 model and the CIFAR10 dataset. A Docker custom container is built with the training script and pushed to Amazon ECR. While the training job is running, Debugger collects tensor outputs and identifies debugging problems. With smdebug client library tools, you can set a smdebug trial object that calls the training job and debugging information, check the training and Debugger rule status, and retrieve tensors saved in an Amazon S3 bucket to analyze training issues.

• build_your_own_container_with_debugger
Troubleshooting your Docker containers

The following are common errors that you might run into when using Docker containers with SageMaker. Each error is followed by a solution to the error.

- **Error: SageMaker has lost the Docker daemon.**

  To fix this error, restart Docker using the following command.

  ```bash
  sudo service docker restart
  ```

- **Error: The /tmp directory of your Docker container has run out of space.**

  Docker containers use the / and /tmp partitions to store code. These partitions can fill up easily when using large code modules in local mode. The SageMaker Python SDK supports specifying a custom temp directory for your local mode root directory to avoid this issue.

  To specify the custom temp directory in the EBS volume storage, create a file at the following path ~/.sagemaker/config.yaml and add the following configuration. The directory that you specify as container_root must already exist. The SageMaker Python SDK will not try to create it.

  ```yaml
  local:
  container_root: /home/ec2-user/SageMaker/temp
  ```

  With this configuration, local mode uses the /temp directory and not the default /tmp directory.
SageMaker Workflows

You can manage your Amazon SageMaker training and inference workflows using Amazon SageMaker Studio and the Amazon SageMaker Python SDK. With the available tools, you can simplify your SageMaker process and integrate it into your existing project.

The following workflow technologies are supported.

- **Amazon SageMaker Model Building Pipelines (p. 2794):** SageMaker's tool for building and managing end-to-end ML pipelines.
- **Airflow Workflows:** SageMaker APIs to export configurations for creating and managing Airflow workflows.
- **Kubernetes Orchestration (p. 2900):** SageMaker custom operators for your Kubernetes cluster, as well as custom components for Kubeflow Pipelines.
- **AWS Step Functions:** Create multi-step machine learning workflows in Python that orchestrate SageMaker infrastructure without having to provision your resources separately.

For more information on managing SageMaker training and inference, see Amazon SageMaker Python SDK Workflows.

Topics

- **Amazon SageMaker Model Building Pipelines (p. 2794)**
- **Automate MLOps with SageMaker Projects (p. 2861)**
- **Amazon SageMaker ML Lineage Tracking (p. 2882)**
- **Kubernetes Orchestration (p. 2900)**

Amazon SageMaker Model Building Pipelines

Amazon SageMaker Model Building Pipelines is a tool for building machine learning pipelines that take advantage of direct SageMaker integration. Because of this integration, you can create a pipeline and set up SageMaker Projects for orchestration using a tool that handles much of the step creation and management for you. SageMaker Pipelines provides the following advantages over other AWS workflow offerings:

**SageMaker Integration**

SageMaker Pipelines is integrated directly with SageMaker, so you don't need to interact with any other AWS services. You also don't need to manage any resources because SageMaker Pipelines is a fully managed service, which means that it creates and manages resources for you.

**SageMaker Python SDK Integration**

Because SageMaker Pipelines is integrated with the SageMaker Python SDK, you can create your pipelines programmatically using a high-level Python interface that you might already be familiar with. To view the SageMaker Python SDK documentation, see Pipelines.

**SageMaker Studio Integration**

SageMaker Studio offers an environment to manage the end-to-end SageMaker Pipelines experience. Using Studio, you can bypass the AWS console for your entire workflow management. For more information on managing SageMaker Pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2846).
Data Lineage Tracking

With SageMaker Pipelines you can track the history of your data within the pipeline execution. Amazon SageMaker ML Lineage Tracking lets you analyze where the data came from, where it was used as an input, and the outputs that were generated from it. For example, you can view the models created from an individual dataset, and you can view the datasets that went into creating an individual model. For more information, see Amazon SageMaker ML Lineage Tracking (p. 2882).

Step Reuse

With SageMaker Pipelines, you can designate steps for caching. When a step is cached, it is indexed for reuse later if the same step is executed again. As a result, you can reuse the output from previous step executions of the same step in the same pipeline without having to run the step again. For more information on step caching, see Caching Pipeline Steps (p. 2816).

Topics

- SageMaker Pipelines Overview (p. 2795)
- Create and Manage SageMaker Pipelines (p. 2831)

SageMaker Pipelines Overview

An Amazon SageMaker Model Building Pipelines pipeline is a series of interconnected steps that is defined by a JSON pipeline definition. This pipeline definition encodes a pipeline using a directed acyclic graph (DAG). This DAG gives information on the requirements for and relationships between each step of your pipeline. The structure of a pipeline's DAG is determined by the data dependencies between steps. These data dependencies are created when the properties of a step's output are passed as the input to another step. The following image is an example of a pipeline DAG:
The following topics describe fundamental SageMaker Pipelines concepts. For a tutorial describing the implementation of these concepts, see Create and Manage SageMaker Pipelines (p. 2831).

Topics
- Pipeline Structure and Execution (p. 2796)
- IAM Access Management (p. 2797)
- Pipeline Parameters (p. 2798)
- Pipeline Steps (p. 2799)
- Property Files and JsonGet (p. 2815)
- Caching Pipeline Steps (p. 2816)
- Retry Policy for Pipeline Steps (p. 2817)
- Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines (p. 2820)
- Amazon EventBridge Integration (p. 2825)
- Amazon SageMaker Experiments Integration (p. 2827)
- Troubleshooting Amazon SageMaker Model Building Pipelines (p. 2830)

Pipeline Structure and Execution

Topics
- Pipeline Structure (p. 2796)
- Pipeline Execution using Parallelism Configuration (p. 2796)

Pipeline Structure

An Amazon SageMaker Model Building Pipelines instance is composed of a name, parameters, and steps. Pipeline names must be unique within an (account, region) pair. All parameters used in step definitions must be defined in the pipeline. Pipeline steps listed automatically determine their order of execution by their data dependencies on one another. The SageMaker Pipelines service resolves the relationships between steps in the data dependency DAG to create a series of steps that the execution completes. The following is an example of a pipeline structure.

```python
from sagemaker.workflow.pipeline import Pipeline

pipeline_name = f"AbalonePipeline"

pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_type,
        processing_instance_count,
        training_instance_type,
        model_approval_status,
        input_data,
        batch_data,
    ],
    steps=[step_process, step_train, step_eval, step_cond],
)
```

Pipeline Execution using Parallelism Configuration

By default, a pipeline performs all steps that are available to run in parallel. You can control this behavior by using the ParallelismConfiguration property when creating or updating a pipeline, as well as when starting or retrying a pipeline execution.
Parallelism configurations are applied per execution. For example, if two executions are started they can each run a maximum of 50 steps concurrently, for a total of 100 concurrently running steps. Also, ParallelismConfiguration(s) specified when starting, retrying or updating an execution take precedence over parallelism configurations defined in the pipeline.

Example Creating a pipeline execution with ParallelismConfiguration

```python
pipeline = Pipeline(
    name="myPipeline",
    steps=[step_process, step_train]
)
pipeline.create(role, parallelism_config={"MaxParallelExecutionSteps": 50})
```

IAM Access Management

The following sections describe the AWS Identity and Access Management (IAM) requirements for Amazon SageMaker Model Building Pipelines. For an example of how you can implement these permissions, see Prerequisites (p. 2832).

Topics

- Pipeline Role Permissions (p. 2797)
- Pipeline Step Permissions (p. 2798)
- Service Control Policies with Pipelines (p. 2798)

Pipeline Role Permissions

Your pipeline requires an IAM pipeline execution role that is passed to SageMaker Pipelines when you create a pipeline. The role for the SageMaker instance that is creating the pipeline must have the `iam:PassRole` permission for the pipeline execution role in order to pass it. For more information on IAM roles, see IAM Roles.

Your pipeline execution role requires the following permissions:

- To pass any role to a SageMaker job within a pipeline, the `iam:PassRole` permission for the role that is being passed.
- `Create` and `Describe` permissions for each of the job types in the pipeline.
- Amazon S3 permissions to use the `JsonGet` function. You control access to your Amazon S3 resources using resource-based policies and identity-based policies. A resource-based policy is applied to your Amazon S3 bucket and grants SageMaker Pipelines access to the bucket. An identity-based policy gives your pipeline the ability to make Amazon S3 calls from your account. For more information on resource-based policies and identity-based policies, see Identity-based policies and resource-based policies.

```json
{
   "Action": [
      "s3:GetObject",
      "s3:HeadObject"
   ],
   "Resource": "arn:aws:s3:::<your-bucket-arn>/*",
   "Effect": "Allow"
}
```
Pipeline Step Permissions

SageMaker Pipelines include steps that run SageMaker jobs. In order for the pipeline steps to run these jobs, they require an IAM role in your account that provides access for the needed resource. This role is passed to the SageMaker service principal by your pipeline. For more information on IAM roles, see IAM Roles.

By default, each step takes on the pipeline execution role. You can optionally pass a different role to any of the steps in your pipeline. This ensures that the code in each step does not have the ability to impact resources used in other steps unless there is a direct relationship between the two steps specified in the pipeline definition. You pass these roles when defining the processor or estimator for your step. For examples of how to include these roles in these definitions, see the SageMaker Python SDK documentation.

Service Control Policies with Pipelines

Service control policies (SCPs) are a type of organization policy that you can use to manage permissions in your organization. SCPs offer central control over the maximum available permissions for all accounts in your organization. By using SageMaker Pipelines within your organization, you can ensure that data scientists manage your pipeline executions without having to interact with the AWS console.

If you're using a VPC with your SCP that restricts access to Amazon S3, you need to take steps to allow your pipeline to access other Amazon S3 resources.

To allow SageMaker Pipelines to access Amazon S3 outside of your VPC with the JsonGet function, update your organization's SCP to ensure that the role using SageMaker Pipelines can access Amazon S3. To do this, create an exception for roles that are being used by the SageMaker Pipelines executor via the pipeline execution role using a principal tag and condition key.

To allow SageMaker Pipelines to access Amazon S3 outside of your VPC

1. Create a unique tag for your pipeline execution role following the steps in Tagging IAM users and roles.
2. Grant an exception in your SCP using the Aws:PrincipalTag IAM condition key for the tag you created. For more information, see Creating, updating, and deleting service control policies.

Pipeline Parameters

You can introduce variables into your pipeline definition using parameters. You can reference parameters that you define throughout your pipeline definition. Parameters have a default value, which you can override by specifying parameter values when starting a pipeline execution. The default value must be an instance matching the parameter type. All parameters used in step definitions must be defined in your pipeline definition. Amazon SageMaker Model Building Pipelines supports the following parameter types:

- ParameterString – Representing a str Python type.
- ParameterInteger – Representing an int Python type.
- ParameterFloat – Representing a float Python type.

Parameters take the following format:

```python
<parameter> = <parameter_type>(
    name="<parameter_name>",
    default_value=<default_value>)
```
The following example shows a sample parameter implementation.

```python
from sagemaker.workflow.parameters import (
    ParameterInteger,
    ParameterString,
    ParameterFloat
)

processing_instance_count = ParameterInteger(
    name="ProcessingInstanceCount",
    default_value=1
)
```

You pass the parameter when creating your pipeline as shown in the following example.

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_count
    ],
    steps=[step_process]
)
```

You can also pass a parameter value that differs from the default value to a pipeline execution, as shown in the following example.

```python
execution = pipeline.start(
    parameters=dict(
        ProcessingInstanceType="ml.c5.xlarge",
        ModelApprovalStatus="Approved"
    )
)
```

You can manipulate parameters with SageMaker Python SDK functions like `sagemaker.workflow.functions.Join`. For more information on parameters, see SageMaker Pipelines Parameters.

### Pipeline Steps

SageMaker Pipelines are composed of steps. These steps define the actions that the pipeline takes and the relationships between steps using properties.

**Topics**
- Step Types (p. 2799)
- Step Properties (p. 2813)
- Data Dependency Between Steps (p. 2813)
- Custom Dependency Between Steps (p. 2814)
- Use a Custom Image in a Step (p. 2815)

### Step Types

The following describes the requirements of each step type and provides an example implementation of the step. These are not functional implementations because they don't provide the resource
and inputs needed. For a tutorial that implements these steps, see Create and Manage SageMaker Pipelines (p. 2831).

Amazon SageMaker Model Building Pipelines support the following step types:

- Processing (p. 2800)
- Training (p. 2801)
- Tuning (p. 2802)
- CreateModel (p. 2803)
- RegisterModel (p. 2803)
- Transform (p. 2804)
- Condition (p. 2804)
- Callback (p. 2805)
- Lambda (p. 2806)
- ClarifyCheck (p. 2808)
- QualityCheck (p. 2810)
- EMR (p. 2812)
- Fail (p. 2813)

Processing Step

You use a processing step to create a processing job for data processing. For more information on processing jobs, see Process Data and Evaluate Models.

A processing step requires a processor, a Python script that defines the processing code, outputs for processing, and job arguments. The following example shows how to create a ProcessingStep definition. For more information on processing step requirements, see the sagemaker.workflow.steps.ProcessingStep documentation.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                       role=<role>,
                                       instance_type='ml.m5.xlarge',
                                       instance_count=1)

from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep

step_process = ProcessingStep(
    name="AbaloneProcess",
    processor=sklearn_processor,
    inputs=[
      ProcessingInput(source=<input_data>, destination="/opt/ml/processing/input"),
    ],
    outputs=[
      ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
      ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
      ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="abalone/preprocessing.py"
)
```

Pass runtime parameters
You can pass runtime parameters to a processing step using the `get_run_args` method of the Amazon SageMaker Python SDK. This allows you to use processors besides `SKLearnProcessor`, such as `PySparkProcessor` and `SparkJarProcessor`.

The following example shows how to pass runtime parameters from a PySpark processor to a `ProcessingStep`.

```python
from sagemaker.spark.processing import PySparkProcessor
pyspark_processor = PySparkProcessor(framework_version='2.4',
                                     role='<role>',
                                     instance_type='ml.m5.xlarge',
                                     instance_count=1)

from sagemaker.processing import ProcessingInput, ProcessingOutput
run_args = pyspark_processor.get_run_args(
    "preprocess.py",
    inputs=[
        ProcessingInput(source='<input_data>', destination="/opt/ml/processing/input"),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    arguments=None
)

from sagemaker.workflow.steps import ProcessingStep
step_process = ProcessingStep(
    name="AbaloneProcess",
    processor=pyspark_processor,
    inputs=run_args.inputs,
    outputs=run_args.outputs,
    job_arguments=run_args.arguments,
    code=run_args.code
)
```

Training Step

You use a training step to create a training job to train a model. For more information on training jobs, see Train a Model with Amazon SageMaker.

A training step requires an estimator, as well as training and validation data inputs. The following example shows how to create a `TrainingStep` definition. For more information on training step requirements, see the `sagemaker.workflow.steps.TrainingStep` documentation.

```python
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TrainingStep

step_train = TrainingStep(
    name="TrainAbaloneModel",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs['train'].S3Output.S3Uri,
        ).S3Output.S3Uri,
```
Tuning Step

You use a tuning step to create a hyperparameter tuning job, also known as hyperparameter optimization (HPO). A hyperparameter tuning job runs multiple training jobs, each one producing a model version. For more information on hyperparameter tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

The tuning job is associated with the SageMaker experiment for the pipeline, with the training jobs created as trials. For more information, see Experiments Integration (p. 2827).

A tuning step requires a HyperparameterTuner and training inputs. You can retrain previous tuning jobs by specifying the warm_start_config parameter of the HyperparameterTuner. For more information on hyperparameter tuning and warm start, see Run a Warm Start Hyperparameter Tuning Job (p. 2207).

You use the get_top_model_s3_uri method of the sagemaker.workflow.steps.TuningStep class to get the model artifact from one of the top-performing model versions. For a notebook that shows how to use a tuning step in a SageMaker pipeline, see sagemaker-pipelines-tuning-step.ipynb.

Important
Tuning steps were introduced in Amazon SageMaker Python SDK v2.48.0 and Amazon SageMaker Studio v3.8.0. You must update Studio before you use a tuning step or the pipeline DAG doesn't display. To update Studio, see Shut down and Update SageMaker Studio (p. 173).

The following example shows how to create a TuningStep definition.

```python
from sagemaker.tuner import HyperparameterTuner
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TuningStep

step_tuning = TuningStep(
    name = "HPTuning",
    tuner = HyperparameterTuner(...),
    inputs = TrainingInput(s3_data=input_path)
)
```

Get the best model version

The following example shows how to get the best model version from the tuning job using the get_top_model_s3_uri method. At most, the top 50 performing versions are available ranked according to HyperParameterTuningJobObjective. The top_k argument is an index into the versions, where top_k=0 is the best-performing version and top_k=49 is the worst-performing version.

```python
best_model = Model(
    image_uri=image_uri,
    model_data=step_tuning.get_top_model_s3_uri(
        top_k=0,
        s3_bucket=sagemaker_session.default_bucket()
    ),
```
CreateModel Step

You use a CreateModel step to create a SageMaker model. For more information on SageMaker models, see Train a Model with Amazon SageMaker.

A create model step requires model artifacts and information about the SageMaker instance type that you need to use to create the model. The following example shows how to create a CreateModel step definition. For more information on CreateModel step requirements, see the sagemaker.workflow.steps.CreateModelStep documentation.

```python
from sagemaker.workflow.steps import CreateModelStep

step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=best_model,
    inputs=inputs
)
```

RegisterModel Step

You use a RegisterModel step to register a sagemaker.model.Model or a sagemaker.pipeline.PipelineModel with the Amazon SageMaker model registry. A PipelineModel represents an inference pipeline, which is a model composed of a linear sequence of containers that process inference requests.

For more information about how to register a model, see Register and Deploy Models with Model Registry (p. 2592). For more information on RegisterModel step requirements, see the sagemaker.workflow.step_collections.RegisterModel documentation.

The following example shows how to create a RegisterModel step that registers a PipelineModel.

```python
import time
from sagemaker.sklearn import SKLearnModel
from sagemaker.xgboost import XGBoostModel

code_location = 's3://{0}/{1}/code'.format(bucket_name, prefix)

sklearn_model = SKLearnModel(model_data=processing_step.properties.ProcessingOutputConfig.Outputs['model'].S3Output.S3Uri,
                              entry_point='inference.py',
                              source_dir='sklearn_source_dir/',
                              code_location=code_location,
                              framework_version='0.20.0',
                              role=role,
                              sagemaker_session=sagemaker_session,
                              py_version='py3')

xgboost_model = XGBoostModel(model_data=training_step.properties.ModelArtifacts.S3ModelArtifacts,
                             entry_point='inference.py',
                             source_dir='xgboost_source_dir/',
                             code_location=code_location,
                             framework_version='0.90-2',
                             py_version='py3',
                             sagemaker_session=sagemaker_session,
                             )
```
role=role)

from sagemaker.workflow.step_collections import RegisterModel
from sagemaker import PipelineModel
pipeline_model = PipelineModel(models=[sklearn_model, xgboost_model], role=role, sagemaker_session=sagemaker_session)

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    model=pipeline_model,
    content_types=['application/json'],
    response_types=['application/json'],
    inference_instances=['ml.t2.medium', 'ml.m5.xlarge'],
    transform_instances=['ml.m5.xlarge'],
    model_package_group_name='sipgroup',
)

If model isn't provided, the register model step requires an estimator as shown in the following example.

from sagemaker.workflow.step_collections import RegisterModel

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    estimator=xgb_train,
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    content_types=['text/csv'],
    response_types=['text/csv'],
    inference_instances=['ml.t2.medium', 'ml.m5.xlarge'],
    transform_instances=['ml.m5.xlarge'],
    model_package_group_name=model_package_group_name,
    approval_status=model_approval_status,
    model_metrics=model_metrics
)

Transform Step

You use a transform step for batch transformation to run inference on an entire dataset. For more information about batch transformation, see Run Batch Transforms with Inference Pipelines (p. 2452).

A transform step requires a transformer and the data on which to run batch transformation. The following example shows how to create a Transform step definition. For more information on Transform step requirements, see the sagemaker.workflow.steps.TransformStep documentation.

from sagemaker.inputs import TransformInput
from sagemaker.workflow.steps import TransformStep

step_transform = TransformStep(
    name="AbaloneTransform",
    transformer=transformer,
    inputs=TransformInput(data=batch_data)
)

Condition Step

You use a condition step to evaluate the condition of step properties to assess which action should be taken next in the pipeline.

A condition step requires a list of conditions, a list of steps to run if the condition evaluates to true, and a list of steps to run if the condition evaluates to false. The following example shows how to create a Condition step definition. For more information on Condition step requirements, see the sagemaker.workflow.condition_step.ConditionStep documentation.
Limitations

- SageMaker Pipelines doesn't support the use of nested condition steps. You can't pass a condition step as the input for another condition step.
- A condition step can't use identical steps in both branches. If you need the same step functionality in both branches, duplicate the step and give it a different name.

```python
from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.workflow.condition_step import (ConditionStep,
                                               JsonGet)

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value" ),
    right=6.0
)

step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[]
)
```

Callback Step

You use a Callback step to incorporate additional processes and AWS services into your workflow that aren't directly provided by Amazon SageMaker Model Building Pipelines. When a Callback step runs, the following procedure occurs:

- SageMaker Pipelines sends a message to a customer-specified Amazon Simple Queue Service (Amazon SQS) queue. The message contains a SageMaker Pipelines–generated token and a customer-supplied list of input parameters. After sending the message, SageMaker Pipelines waits for a response from the customer.
- The customer retrieves the message from the Amazon SQS queue and starts their custom process.
- When the process finishes, the customer calls one of the following APIs and submits the SageMaker Pipelines–generated token:
  - `SendPipelineExecutionStepSuccess`, along with a list of output parameters
  - `SendPipelineExecutionStepFailure`, along with a failure reason
- The API call causes SageMaker Pipelines to either continue the pipeline process or fail the process.

For more information on Callback step requirements, see the `sagemaker.workflow.callback_step.CallbackStep` documentation. For a complete solution, see Extend SageMaker Pipelines to include custom steps using callback steps.

**Important**

Callback steps were introduced in Amazon SageMaker Python SDK v2.45.0 and Amazon SageMaker Studio v3.6.2. You must update Studio before you use a Callback step or the pipeline DAG doesn't display. To update Studio, see Shut down and Update SageMaker Studio (p. 173).

The following sample demonstrates an implementation of the preceding procedure.
from sagemaker.workflow.callback_step import CallbackStep

step_callback = CallbackStep(
    name="MyCallbackStep",
    sqs_queue_url="https://sqs.us-east-2.amazonaws.com/012345678901/MyCallbackQueue",
    inputs={...},
    outputs=[...]
)

callback_handler_code = '  
    import boto3
    import json

    def handler(event, context):
        sagemaker_client=boto3.client("sagemaker")

        for record in event["Records"]:
            payload=json.loads(record["body"])
            token=payload["token"]

            # Custom processing
            # Call SageMaker to complete the step
            sagemaker_client.send_pipeline_execution_step_success(
                CallbackToken=token,
                OutputParameters={...}
            )
    ,

Stopping behavior

A pipeline process doesn't stop while a Callback step is running.

When you call StopPipelineExecution on a pipeline process with a running Callback step, SageMaker Pipelines sends an additional Amazon SQS message to the specified SQS queue. The body of the SQS message contains a Status field, which is set to Stopping. The following shows an example SQS message body.

```
{
    "token": "26vcYbeWsZ",
    "pipelineExecutionArn": "arn:aws:sagemaker:us-east-2:012345678901:pipeline/callback-pipeline/execution/7pinimwdh3a",
    "arguments": {
        "number": 5,
        "stringArg": "some-arg",
        "inputData": "s3://sagemaker-us-west-2-012345678901/abalone/abalone-dataset.csv"
    },
    "status": "Stopping"
}
```

You should add logic to your Amazon SQS message consumer to take any needed action (for example, resource cleanup) upon receipt of the message, followed by a call to SendPipelineExecutionStepSuccess or SendPipelineExecutionStepFailure.

Only when SageMaker Pipelines receives one of these calls does it stop the pipeline process.

Lambda Step

You use a Lambda step to run an AWS Lambda function. You can run an existing Lambda function, or SageMaker can create and run a new Lambda function. For a notebook that shows how to use a Lambda step in a SageMaker pipeline, see sagemaker-pipelines-lambda-step.ipynb.
Important
Lambda steps were introduced in Amazon SageMaker Python SDK v2.51.0 and Amazon SageMaker Studio v3.9.1. You must update Studio before you use a Lambda step or the pipeline DAG doesn't display. To update Studio, see Shut down and Update SageMaker Studio (p. 173).

SageMaker provides the sagemaker.lambda_helper.Lambda class to create, update, invoke, and delete Lambda functions. Lambda has the following signature.

```
Lambda(
    function_arn,  # Only required argument to invoke an existing Lambda function
    # The following arguments are required to create a Lambda function:
    function_name,
    execution_role_arn,
    zipped_code_dir,  # Specify either zipped_code_dir and s3_bucket, OR script
    s3_bucket,  # S3 bucket where zipped_code_dir is uploaded
    script,  # Path of Lambda function script
    handler,  # Lambda handler specified as "lambda_script.lambda_handler"
    timeout,  # Maximum time the Lambda function can run before the lambda step fails
    ...
)
```

The sagemaker.workflow.lambda_step.LambdaStep class has a lambda_func argument of type Lambda. To invoke an existing Lambda function, the only requirement is to supply the Amazon Resource Name (ARN) of the function to function_arn. If you don't supply a value for function_arn, you must specify handler and one of the following:

- **zipped_code_dir** – The path of the zipped Lambda function
- **s3_bucket** – Amazon S3 bucket where zipped_code_dir is to be uploaded
- **script** – The path of the Lambda function script file

The following example shows how to create a Lambda step definition that invokes an existing Lambda function.

```
from sagemaker.workflow.lambda_step import LambdaStep
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
        "train_file", "test_file"
    ]
)
```

The following example shows how to create a Lambda step definition that creates and invokes a Lambda function using a Lambda function script.

```
from sagemaker.workflow.lambda_step import LambdaStep
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
        "train_file", "test_file"
    ]
)
```
Amazon SageMaker Developer Guide
Pipeline Overview

```python
step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
        function_name="split-dataset-lambda",
        execution_role_arn=execution_role_arn,
        script="lambda_script.py",
        handler="lambda_script.lambda_handler",
        ...
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
        "train_file", "test_file"
    ]
)
```

**Inputs and outputs**

If your Lambda function has inputs or outputs, these must also be defined in your Lambda step.

When defining the Lambda step, inputs must be a dictionary of key-value pairs. Each value of the inputs dictionary must be a primitive type (string, integer, or float). Nested objects are not supported. If left undefined, the inputs value defaults to None.

The outputs value must be a list of keys. These keys refer to a dictionary defined in the output of the Lambda function. Like inputs, these keys must be primitive types, and nested objects are not supported.

**Timeout and stopping behavior**

The Lambda class has a timeout argument that specifies the maximum time that the Lambda function can run. The default value is 120 seconds with a maximum value of 10 minutes. If the Lambda function is running when the timeout is met, the Lambda step fails; however, the Lambda function continues to run.

A pipeline process can't be stopped while a Lambda step is running because the Lambda function invoked by the Lambda step can't be stopped. If you attempt to stop the process while the Lambda function is running, the pipeline waits for the Lambda function to finish or until the timeout is hit, whichever occurs first, and then stops. If the Lambda function finishes, the pipeline process status is Stopped. If the timeout is hit the pipeline process status is Failed.

**ClarifyCheck Step**

You can use the ClarifyCheck step to conduct baseline drift checks against previous baselines for bias analysis and model explainability. By doing this, you can generate and register your baselines for drift check in the RegisterModel (p. 2803) together with the model trained though the pipelines in the model building phase. These baselines for drift check can be used by Amazon SageMaker Model Monitor for your model endpoints so that you don't need to do a baseline suggestion separately. The ClarifyCheck step can also pull baselines for drift check from the model registry. The ClarifyCheck step leverages the Amazon SageMaker Clarify prebuilt container that provides a range of model monitoring capabilities, including constraint suggestion and constraint validation against a given baseline. For more information, see Getting Started with a SageMaker Clarify Container.

**Configuring the ClarifyCheck step**

You can configure the ClarifyCheck step to conduct only one of the following check types each time it's used in a pipeline.

- Data bias check
- Model bias check
• Model explainability check

You do this by setting the `clarify_check_config` parameter with one of the following check type values:

• DataBiasCheckConfig
• ModelBiasCheckConfig
• ModelExplainabilityCheckConfig

The `ClarifyCheck` step launches a processing job that runs the SageMaker Clarify prebuilt container and requires dedicated configurations for the check and the processing job. `ClarifyCheckConfig` and `CheckJobConfig` are helper functions for these configurations that are aligned with how the SageMaker Clarify processing job computes for checking model bias, data bias, or model explainability. For more information, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 2336).

Controlling step behaviors for drift check

The `ClarifyCheck` step requires the following two boolean flags to control its behavior:

• `skip_check`: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to `False`, the previous baseline of the configured check type must be available.
• `register_new_baseline`: This parameter indicates if a newly calculated baseline can be accessed though step property `BaselineUsedForDriftCheckConstraints`. If it is set to `False`, the previous baseline of the configured check type also must be available. This can be accessed through the `BaselineUsedForDriftCheckConstraints` property.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines (p. 2820).

Working with baselines

You can optionally specify the `model_package_group_name` to locate the existing baseline and the `ClarifyCheck` step pulls the `DriftCheckBaselines` on the latest approved model package in the model package group. Or, you can provide a previous baseline through the `supplied_baseline_constraints` parameter. If you specify both the `model_package_group_name` and the `supplied_baseline_constraints`, the `ClarifyCheck` step uses the baseline specified by the `supplied_baseline_constraints` parameter.

For more information on using the `ClarifyCheck` step requirements, see the `sagemaker.workflow.steps.ClarifyCheckStep` in the Amazon SageMaker SageMaker SDK for Python. For an Amazon SageMaker Studio notebook that shows how to use `ClarifyCheck` step in SageMaker Pipelines, see `sagemaker-pipeline-model-monitor-clarify-steps.ipynb`.

Example Create a `ClarifyCheck` step for data bias check

```python
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.workflow.clarify_check_step import DataBiasCheckConfig, ClarifyCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables

check_job_config = CheckJobConfig(
    role=role,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    volume_size_in_gb=120,
    sagemaker_session=sagemaker_session,
)
```
data_bias_data_config = DataConfig(
    s3_data_input_path=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
    s3_output_path=Join(on='/', values=['s3:', your_bucket, base_job_prefix,
        ExecutionVariables.PIPELINE_EXECUTION_ID, 'databiascheckstep']),
    label=0,
    dataset_type="text/csv",
    s3_analysis_config_output_path=data_bias_analysis_cfg_output_path,
)

data_bias_config = BiasConfig(
    label_values_or_threshold=[15.0], facet_name=[], facet_values_or_threshold=[[0.5]]
)

data_bias_check_config = DataBiasCheckConfig(
    data_config=data_bias_data_config,
    data_bias_config=data_bias_config,
)

data_bias_check_step = ClarifyCheckStep(
    name="DataBiasCheckStep",
    clarify_check_config=data_bias_check_config,
    check_job_config=check_job_config,
    skip_check=False,
    register_new_baseline=False
    supplied_baseline_constraints="s3://sagemaker-us-west-2-111122223333/baseline/analysis.json",
    model_package_group_name="MyModelPackageGroup"
)

QualityCheck Step

You can use the QualityCheck step to conduct baseline suggestions and drift checks against a previous baseline for data quality or model quality in a pipeline. By doing this, you can generate and register your baselines for drift check in the RegisterModel Step (p. 2803) step together with the model trained though the pipelines in the model building phase. Model Monitor can use these baselines for drift check for your model endpoints so that you don't need to do a baseline suggestion separately. The QualityCheck step can also pull baselines for drift check from the model registry. The QualityCheck step leverages the Amazon SageMaker Model Monitor prebuilt container, which has a range of model monitoring capabilities including constraint suggestion, statistics generation, and constraint validation against a baseline. For more information, see Amazon SageMaker Model Monitor prebuilt container (p. 2510).

Configuring the QualityCheck step

You can configure the QualityCheck step to conduct only one of the following check types each time it's used in a pipeline.

- Data quality check
- Model quality check

You do this by setting the quality_check_config parameter with one of the following check type values:

- DataQualityCheckConfig
- ModelQualityCheckConfig

The QualityCheck step launches a processing job that runs the Model Monitor prebuilt container and requires dedicated configurations for the check and the processing job. The QualityCheckConfig
and CheckJobConfig are helper functions for these configurations that are aligned with how Model Monitor creates a baseline for the model quality or data quality monitoring. For more information on the Model Monitor baseline suggestions, see Create a Baseline (p. 2488) and Create a Model Quality Baseline (p. 2494).

Controlling step behaviors for drift check

The QualityCheck step requires the following two Boolean flags to control its behavior:

- **skip_check**: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to False, the previous baseline of the configured check type must be available.
- **register_new_baseline**: This parameter indicates if a newly calculated baseline can be accessed through step properties BaselineUsedForDriftCheckConstraints and BaselineUsedForDriftCheckStatistics. If it is set to False, the previous baseline of the configured check type must also be available. These can be accessed through the BaselineUsedForDriftCheckConstraints and BaselineUsedForDriftCheckStatistics properties.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines (p. 2820).

Working with baselines

You can specify a previous baseline directly through the supplied_baseline_statistics and supplied_baseline_constraints parameters, or you can simply specify the model_package_group_name and the QualityCheck step pulls the DriftCheckBaselines on the latest approved model package in the model package group. When you specify the model_package_group_name, the supplied_baseline_constraints, and supplied_baseline_statistics, the QualityCheck step uses the baseline specified by supplied_baseline_constraints and supplied_baseline_statistics on the check type of the QualityCheck step you are running.

For more information on using the QualityCheck step requirements, see the sagemaker.workflow.steps.QualityCheckStep in the Amazon SageMaker SageMaker SDK for Python. For an Amazon SageMaker Studio notebook that shows how to use QualityCheck step in SageMaker Pipelines, see sagemaker-pipeline-model-monitor-clarify-steps.ipynb.

Example Create a qualityCheck step for data quality check

```python
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.workflow.quality_check_step import DataQualityCheckConfig, QualityCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables

cHECK_JOB_CONFIG = CheckJobConfig(  
    role=role,  
    instance_count=1,  
    instance_type="ml.c5.xlarge",  
    volume_size_in_gb=120,  
    sagemaker_session=sagemaker_session,  
)

data_quality_check_config = DataQualityCheckConfig(  
    baseline_dataset=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,  
    dataset_format=DatasetFormat.csv(header=False, output_columns_position="START"),  
    output_s3_uri=Join(on='/', values=["s3://", your_bucket, base_job_prefix,  
    ExecutionVariables.PIPELINE_EXECUTION_ID, 'dataqualitycheckstep'])  
)
```

2811
data_quality_check_step = QualityCheckStep(
    name="DataQualityCheckStep",
    skip_check=False,
    register_new_baseline=False,
    quality_check_config=data_quality_check_config,
    check_job_config=check_job_config,
    supplied_base_stats='s3://sagemaker-us-west-2-555555555555/baseline/statistics.json',
    supplied_base_constraints='s3://sagemaker-us-west-2-555555555555/baseline/constraints.json',
    model_package_group_name="MyModelPackageGroup"
)

Amazon EMR Step

You can use the Amazon SageMaker Model Building Pipelines Amazon EMR step to process EMR steps to a running Amazon EMR cluster. For more information, see Getting started with Amazon EMR.

The Amazon EMR step requires an EMRStepConfig having the Amazon S3 location of the JAR to be used by the Amazon EMR cluster and any arguments to be passed, as well as the Amazon EMR cluster ID.

Note

- Amazon EMR steps are supported in Amazon SageMaker SDK for Python v2.73.0 and Amazon SageMaker Studio v3.21.1. You must update Studio before you use an EMR step or the pipeline DAG will not display. To update Studio, see Shut down and Update SageMaker Studio (p. 173).
- Amazon EMR on EKS is not supported.
- You can only run a EMR step on a cluster that is in one of the following states: STARTING, BOOTSTRAPPING, RUNNING, or WAITING.
- You can have at most 256 EMR steps in PENDING on an EMR cluster; EMR steps submitted beyond that limit result in the pipeline execution failing. You may consider using Retry Policy for Pipeline Steps (p. 2817).

Example Create an Amazon EMR step definition that launches a new job on a EMR cluster.

```python
from sagemaker.workflow.emr_step import EMRStep

step_emr = EMRStep(
    name="EMRSampleStep", #required, step Name
    cluster_id="j-1YONHTCP3Y3K", #required, cluster id
    jar="s3://path/to/my/jarfolder", #required, location of the jar to run as a step
    args=["--verbose", "--force"], #optional list of arguments to pass to the jar
    main_class="com.my.Main1", #optional main class, this can be omitted if jar above has a manifest
    properties=[ #optional list of Java properties that are set when the step runs
        {"key": "mapred.tasktracker.map.tasks.maximum", "value": "2"},
        {"key": "mapreduce.map.sort.spill.percent", "value": "0.90"},
        {"key": "mapreduce.tasktracker.reduce.tasks.maximum", "value": "5"}
    ]
)
```
Fail Step

You use a `FailStep` to stop an Amazon SageMaker Model Building Pipelines execution when a desired condition or state is not achieved and to mark that pipeline's execution as failed. The `FailStep` also allows you to enter a custom error message, indicating the cause of the pipeline's execution failure.

**Note**

When a `FailStep` and other pipeline steps execute concurrently, the pipeline does not terminate until all concurrent steps are completed.

Limitations for using `FailStep`

- You cannot add a `FailStep` to the `DependsOn` list of other steps. For more information, see Custom Dependency Between Steps (p. 2814).
- Other steps cannot reference the `FailStep`. It is always the last step in a pipeline's execution.
- You cannot retry a pipeline execution ending with a `FailStep`.

You can create the `FailStep` `ErrorMessage` in the form of a static text string. Alternatively, you can also use Pipeline Parameters a `Join` operation, or other step properties to create a more informative error message.

**Example**

The following example code snippet uses a `FailStep` with an `ErrorMessage` configured with Pipeline Parameters and a `Join` operation.

```python
from sagemaker.workflow.fail_step import FailStep
from sagemaker.workflow.functions import Join
from sagemaker.workflow.parameters import ParameterInteger

mse_threshold_param = ParameterInteger(name="MseThreshold", default_value=5)
step_fail = FailStep(
    name="AbaloneMSEFail",
    error_message=Join(
        on=" ", values=["Execution failed due to MSE >", mse_threshold_param]
    ),
)
```

**Step Properties**

The `properties` attribute is used to add data dependencies between steps in the pipeline. These data dependencies are then used by SageMaker Pipelines to construct the DAG from the pipeline definition. These properties can be referenced as placeholder values and are resolved at runtime.

The `properties` attribute of a SageMaker Pipelines step matches the object returned by a `Describe` call for the corresponding SageMaker job type. For each job type, the `Describe` call returns the following response object:

- `ProcessingStep` – `DescribeProcessingJob`
- `TrainingStep` – `DescribeTrainingJob`
- `TransformStep` – `DescribeTransformJob`

**Data Dependency Between Steps**

You define the structure of your DAG by specifying the data relationships between steps. To create data dependencies between steps, pass the properties of one step as the input to another step in the pipeline. The step receiving the input isn't started until after the step providing the input finishes running.
A data dependency uses JsonPath notation in the following format. This format traverses the JSON property file, which means you can append as many `<property>` instances as needed to reach the desired nested property in the file. For more information on JsonPath notation, see the JsonPath repo.

```
<step_name>.properties.<property>.<property>
```

The following shows how to specify an Amazon S3 bucket using the `ProcessingOutputConfig` property of a processing step.

```
step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
```

To create the data dependency, pass the bucket to a training step as follows.

```
step_train = TrainingStep(
    name="CensusTrain",
    estimator=sklearn_train,
    inputs=TrainingInput(
        s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
    )
)
```

### Custom Dependency Between Steps

When you specify a data dependency, SageMaker Pipelines provides the data connection between the steps. Alternatively, one step can access the data from a previous step without directly using SageMaker Pipelines. In this case, you can create a custom dependency that tells SageMaker Pipelines not to start a step until after another step has finished running. You create a custom dependency by specifying a step's `DependsOn` attribute.

As an example, the following defines a step C that starts only after both step A and step B finish running.

```
{
    'Steps': [
        {'Name':'A', ...},
        {'Name':'B', ...},
        {'Name':'C', 'DependsOn': ['A', 'B']}
    ]
}
```

SageMaker Pipelines throws a validation exception if the dependency would create a cyclic dependency.

The following example creates a training step that starts after a processing step finishes running.

```
processing_step = ProcessingStep(...)  
training_step = TrainingStep(...)  
training_step.add_depends_on([processing_step])
```

The following example creates a training step that doesn't start until two different processing steps finish running.

```
processing_step_1 = ProcessingStep(...)  
processing_step_2 = ProcessingStep(...)  
training_step = TrainingStep(...)  
```
training_step.add_depends_on([processing_step_1, processing_step_2])

The following provides an alternate way to create the custom dependency.

training_step.add_depends_on([processing_step_1])
training_step.add_depends_on([processing_step_2])

The following example creates a training step that receives input from one processing step and waits for a different processing step to finish running.

processing_step_1 = ProcessingStep(...)  
processing_step_2 = ProcessingStep(...)  
training_step = TrainingStep(  
 inputs=TrainingInput(  
 s3_data=processing_step_1.properties.ProcessingOutputConfig.Outputs[  
 "train_data"  
 ].S3Output.S3Uri  
 )  
)  
training_step.add_depends_on([processing_step_2])

The following example shows how to retrieve a string list of the custom dependencies of a step.

custom_dependencies = training_step.depends_on

Use a Custom Image in a Step

You can use any of the available SageMaker Deep Learning Container images when you create a step in your pipeline.

You can also create a step using SageMaker Amazon S3 applications. A SageMaker Amazon S3 application is a tar.gz bundle with one or more Python scripts that can run within that bundle. For more information on application package bundling, see Deploying directly from model artifacts.

You can also use your own container with pipeline steps. Because you can't create an image from within Amazon SageMaker Studio, you must create your image using another method before using it with Amazon SageMaker Model Building Pipelines.

To use your own container when creating the steps for your pipeline, include the image URI in the estimator definition. For more information on using your own container with SageMaker, see Using Docker Containers with SageMaker.

Property Files and JsonGet

You use property files to store information from the output of a processing step. This is particularly useful when analyzing the results of a processing step to decide how a conditional step should be executed. The JsonGet function processes a property file and enables you to use JsonPath notation to query the property JSON file. For more information on JsonPath notation, see the JsonPath repo.

To store a property file for later use, you must first create a PropertyFile instance with the following format. The path parameter is the name of the JSON file to which the property file is saved. output_name must match the output_name of the ProcessingOutput that you define in your processing step. This enables the property file to capture the ProcessingOutput in the step.

```
from sagemaker.workflow.properties import PropertyFile
```
When you create your `ProcessingStep` instance, add the `property_files` parameter to list all of the parameter files that the Amazon SageMaker Model Building Pipelines service must index. This saves the property file for later use.

```python
property_files=[<property_file_instance>]
```

To use your property file in a condition step, add the `property_file` to the condition that you pass to your condition step as shown in the following example to query the JSON file for your desired property using the `json_path` parameter.

```python
cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=<property_file_instance>,
        json_path="mse"
    ),
    right=6.0
)
```

### Caching Pipeline Steps

When you use step signature caching, before SageMaker Pipelines executes a step, it attempts to find a previous execution of a step that was called with the same arguments. SageMaker Pipelines checks that the call signatures are identical. Pipelines doesn’t check whether the data or code to which the arguments point has changed. If Pipelines finds a previous execution, it creates a cache hit. Pipelines then propagates the values from the cache hit during execution, rather than recomputing the step.

Step caching only considers successful executions, so it never reuses failed executions. When multiple successful executions exist within the timeout period, Pipelines uses the result for the most recent successful execution. If no successful executions match in the timeout period, Pipelines doesn’t reuse any steps. If the executor finds a cache hit for a previous step execution that is still in progress, both steps continue executing and update the cache, if they’re successful.

You must opt in to step caching, otherwise it is off by default. When you enable step caching, you must also define a timeout. This timeout defines how old a previous execution can be to be considered for reuse.

Step caching is only scoped for individual pipelines, so you can’t reuse a step from another pipeline. Even if there is a step signature match in the other pipeline, the step is not reused.

Step caching is available for the following step types:

- Training
- Processing
- Transform

### Enabling Step Caching

To enable step caching, you must add a `CacheConfig` property to the step definition.
CacheConfig properties use the following format in the pipeline definition file.

```
{
   "CacheConfig": {
      "Enabled": false,
      "ExpireAfter": "<time>"
   }
}
```

The `Enabled` field may be true or false. `ExpireAfter` is a string that defines the timeout period. Any ISO 8601 duration string is a valid `ExpireAfter` value. The `ExpireAfter` duration can contain a year, month, week, day, hour, and minute value. Each value is consists of a number followed by a letter indicating the duration unit it is for. For example:

- "30d" = Thirty days
- "5y" = Five years
- "16m" = 16 minutes
- "30dT5h" = 30 days and five hours.

The following example shows how to enable caching for a training step using the Amazon SageMaker Python SDK.

```python
from sagemaker.workflow.steps import CacheConfig
cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
step_train = TrainingStep(
   name="TrainAbaloneModel",
   estimator=xgb_train,
   inputs=inputs,
   cache_config=cache_config)
```

**Retry Policy for Pipeline Steps**

Retry policies help you automatically retry your SageMaker Pipelines steps after an error occurs. Any pipeline step can encounter exceptions, and exceptions happen for various reasons. In some cases, a retry can resolve these issues. With a retry policy for pipeline steps, you can choose whether to retry a particular pipeline step or not.

The retry policy only supports the following pipeline steps:

- **Processing Step (p. 2800)**
- **Training Step (p. 2801)**
- **Tuning Step (p. 2802)**

**Note**

The SageMaker hyperparameter tuning job already conducts retries internally so it does not retry the `SageMaker.JOB_INTERNAL_ERROR` exception type, even if a retry policy is configured. If you really want to retry, you can program your own Retry Strategy using the SageMaker API.

- **CreateModel Step (p. 2803)**
- **RegisterModel Step (p. 2803)**
- **Transform Step (p. 2804)**
Supported exception types for the retry policy

The retry policy for pipeline steps supports the following exception types:

- **Step.SERVICE_FAULT**: These exceptions occur when an internal server error or transient error happens when calling downstream services. SageMaker Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.

- **Step.THROTTLING**: Throttling exceptions can occur while calling the downstream services. SageMaker Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.

- **SageMaker.JOB_INTERNAL_ERROR**: These exceptions occur when the SageMaker job returns InternalServerError. In this case, starting a new job may fix a transient issue.

- **SageMaker.CAPACITY_ERROR**: The SageMaker job may encounter Amazon EC2 InsufficientCapacityErrors, which leads to the SageMaker job’s failure. You can retry by starting a new SageMaker job to avoid the issue.

- **SageMaker.RESOURCE_LIMIT**: You can exceed the resource limit quota when running a SageMaker job. You can wait and retry running the SageMaker job after a short period and see if resources are released.

The JSON schema for the retry policy

The retry policy for Pipelines has the following JSON schema:

```json
"RetryPolicy": {
   "ExceptionType": [String]
   "IntervalSeconds": Integer
   "BackoffRate": Double
   "MaxAttempts": Integer
   "ExpireAfterMin": Integer
}
```

- **ExceptionType**: This field requires the following exception types in a string array format.
  - Step.SERVICE_FAULT
  - Step.THROTTLING
  - SageMaker.JOB_INTERNAL_ERROR
  - SageMaker.CAPACITY_ERROR
  - SageMaker.RESOURCE_LIMIT

- **IntervalSeconds** (optional): The number of seconds before the first retry attempt (1 by default). IntervalSeconds has a maximum value of 43200 seconds (12 hours).

- **BackoffRate** (optional): The multiplier by which the retry interval increases during each attempt (2.0 by default).

- **MaxAttempts** (optional): A positive integer that represents the maximum number of retry attempts (5 by default). If the error recurs more times than MaxAttempts specifies, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. MaxAttempts has a maximum value of 20.

- **ExpireAfterMin** (optional): A positive integer that represents the maximum timespan of retry. If the error recurs after ExpireAfterMin minutes counting from the step gets executed, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. ExpireAfterMin has a maximum value of 14,400 minutes (10 days).

**Note**

Only one of MaxAttempts or ExpireAfterMin can be given, but not both; if both are not specified, MaxAttempts becomes the default. If both properties are identified within one policy, then the retry policy generates a validation error.
Configuring a retry policy

The following is an example of a training step with a retry policy.

```json
{
    "Steps": [
        {
            "Name": "MyTrainingStep",
            "Type": "Training",
            "RetryPolicies": [
                {
                    "ExceptionType": [
                        "SageMaker.JOB_INTERNAL_ERROR",
                        "SageMaker.CAPACITY_ERROR"
                    ],
                    "IntervalSeconds": 1,
                    "BackoffRate": 2,
                    "MaxAttempts": 5
                }
            ]
        }
    ]
}
```

The following is an example of how to build a `TrainingStep` in SDK for Python (Boto3) with a retry policy.

```python
from sagemaker.workflow.retry import (StepRetryPolicy,
                                      StepExceptionTypeEnum,
                                      SageMakerJobExceptionTypeEnum,
                                      SageMakerJobStepRetryPolicy)

step_train = TrainingStep(
    name="MyTrainingStep",
    xxx,
    retry_policies=[
        // override the default
        StepRetryPolicy(
            exception_types=[
                StepExceptionTypeEnum.SERVICE_FAULT,
                StepExceptionTypeEnum.THROTTLING
            ],
            expire_after_min=5,
            interval_seconds=10,
            backoff_rate=2.0
        ),
        // retry when resource limit quota gets exceeded
        SageMakerJobStepRetryPolicy(
            exception_types=[SageMakerJobExceptionTypeEnum.RESOURCE_LIMIT]
            expire_after_min=120,
            interval_seconds=60,
            backoff_rate=2.0
        ),
        // retry when job failed due to transient error or EC2 ICE.
        SageMakerJobStepRetryPolicy(
            failure_reason_types=[
                SageMakerJobExceptionTypeEnum.JOB_INTERNAL_ERROR,
                SageMakerJobExceptionTypeEnum.JOB_CAPACITY_ERROR,
            ]
            max_attempts=10,
            interval_seconds=30,
        )
    ]
)
```
Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Model Building Pipelines

The following topic discusses how baselines and model versions evolve in the Amazon SageMaker Model Building Pipelines when using the ClarifyCheck (p. 2808) and QualityCheck (p. 2810) steps.

For the ClarifyCheck step, a baseline is a single file that resides in the step properties with the suffix constraints. For the QualityCheck step, a baseline is a combination of two files that resides in the step properties: one with the suffix statistics and the other with the suffix constraints. In the following topics we discuss these properties with a prefix that describes how they are used, impacting baseline behavior and lifecycle in these two pipeline steps. For example, the ClarifyCheck step always calculates and assigns the new baselines in the CalculatedBaselineConstraints property and the QualityCheck step does the same in the CalculatedBaselineConstraints and CalculatedBaselineStatistics properties.

Baseline calculation and registration for ClarifyCheck and QualityCheck steps

Both the ClarifyCheck and QualityCheck steps always calculate new baselines based on step inputs through the underlying processing job run. These newly calculated baselines are accessed through the properties with the prefix CalculatedBaseline. You can record these properties as the ModelMetrics of your model package in the RegisterModel (p. 2803) step. This model package can be registered with 5 different baselines. You can register it with one for each check type: data bias, model bias, and model explainability from running the ClarifyCheck step and model quality, and data quality from running the QualityCheck step. The register_new_baseline parameter dictates the value set in the properties with the prefix BaselineUsedForDriftCheck after a step runs.

The following table of potential use cases shows different behaviors resulting from the step parameters you can set for the ClarifyCheck and QualityCheck steps:

<table>
<thead>
<tr>
<th>Possible use case that you may consider for selecting this configuration</th>
<th>skip_check / register_new_ba</th>
<th>Does step do a drift check?</th>
<th>Value of step property CalculatedBaseline</th>
<th>Value of step property BaselineUsedForDriftCheck</th>
</tr>
</thead>
<tbody>
<tr>
<td>You are doing regular retraining with checks enabled to get a new model version, but you want to carry over the previous baselines as the DriftCheckBaselines in the model registry for your new model version.</td>
<td>False / False</td>
<td>Drift check runs against existing baselines</td>
<td>New baselines calculated by running the step</td>
<td>Baseline from the latest approved model in Model Registry or the baseline supplied as step parameter</td>
</tr>
</tbody>
</table>
### Pipeline Overview

<table>
<thead>
<tr>
<th>Possible use case that you may consider for selecting this configuration</th>
<th><code>skip_check / register_new_baseline</code></th>
<th>Does step do a drift check?</th>
<th>Value of step property <code>CalculatedBaseline</code></th>
<th>Value of step property <code>BaselineUsedForDriftCheck</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>You are doing regular retraining with checks enabled to get a new model version, but you want to refresh the DriftCheckBaselines in the model registry with the newly calculated baselines for your new model version.</td>
<td><code>False/True</code></td>
<td>Drift check runs against existing baselines</td>
<td>New baselines calculated by running the step</td>
<td>Newly calculated baseline by running the step (value of property <code>CalculatedBaseline</code>)</td>
</tr>
<tr>
<td>You are initiating the pipeline to retrain a new model version because there is a violation detected by Amazon SageMaker Model Monitor on an endpoint for a particular type of check, and you want to skip this type of check against the previous baseline, but carry over the previous baseline as DriftCheckBaselines in the model registry for your new model version.</td>
<td><code>True/False</code></td>
<td>No drift check</td>
<td>New baselines calculated by running</td>
<td>Baseline from the latest approved model in the model registry or the baseline supplied as step parameter</td>
</tr>
</tbody>
</table>
### Pipeline Overview

**Possible use case that you may consider for selecting this configuration**

<table>
<thead>
<tr>
<th>skip_check / register_new_baseline</th>
<th>Does step do a drift check?</th>
<th>Value of step property CalculatedBaseline</th>
<th>Value of step property BaselineUsedForDriftCheck</th>
</tr>
</thead>
<tbody>
<tr>
<td>True / True</td>
<td>No drift check</td>
<td>New baselines calculated by running the step</td>
<td>Newly calculated baseline by running the step (value of property CalculatedBaseline)</td>
</tr>
</tbody>
</table>

This happens in the following cases:

- You are starting the initial run of the pipeline, building your first model version, and generating the initial baselines.
- You are initiating the pipeline to retrain a new model version because there is a violation detected by Model Monitor on the endpoint for a particular type of check. If you want to **skip the check against the previous baseline and refresh the DriftCheckBaselines with the newly calculated baseline** in the model registry directly.

In the **RegisterModel** step, you can register the **BaselineUsedForDriftCheck** property as **DriftCheckBaselines**. These baseline files can then be used by Model Monitor for model and data quality checks. In addition, these baselines can also be used in the **ClarifyCheckStep** and **QualityCheck** step to compare newly trained models against the existing models that are registered in the model registry for future pipeline runs.

**Drift Detection against Previous Baselines in SageMaker Pipelines**

In the case of the **QualityCheck** step, when you initiate the pipeline for regular retraining to get a new model version, you may not want to run the training step if the data quality and the data bias has ??? (p. 2492) on the baselines of your previous approved model version. You also may not want to register the newly trained model version if the model quality, model bias, or model explainability violates the registered baseline of your previous approved model version when running the **ClarifyCheck** step. In these cases, you can enable the checks you want by setting the...
skip_check property of the corresponding check step set to False, resulting in the ClarifyCheck and QualityCheck step failing if violation is detected against previous baselines. The pipeline process then does not proceed so that the model drifted from the baseline isn't registered. ClarifyCheck and QualityCheck steps are able to get DriftCheckBaselines of the latest approved model version of a given model package group against which to compare. Previous baselines can also be supplied directly through supplied_baseline_constraints (in addition to supplied_baseline_statistics if it is a QualityCheck step) and are always prioritized over any baselines pulled from the model package group.

**Baseline and model version lifecycle and evolution with SageMaker Pipelines**

By setting register_new_baseline of your ClarifyCheck and QualityCheck step to False, your previous baseline is accessible through the step property prefix BaselineUsedForDriftCheck. You can then register these baselines as the DriftCheckBaselines in the new model version in the RegisterModel step. Once you approve this new model version in the model registry, the DriftCheckBaseline in this model version becomes available for the ClarifyCheck and QualityCheck steps in the next pipeline process. If you want to refresh the baseline of a certain check type for future model versions, you can set register_new_baseline to True so that the properties with prefix BaselineUsedForDriftCheck become the newly calculated baseline. In these ways, you can preserve your preferred baselines for a model trained in the future, or refresh the baselines for drift checks when needed, managing your baseline evolution and lifecycle throughout your model training iterations.

The following diagram illustrates a model-version-centric view of the baseline evolution and lifecycle.
Pipeline Run 1: initial run

Model Version 1
ModelMetrics: Base
DriftCheckBaselines: Base

Pipeline Run 2: Scheduled retraining new model version (Check Succeeded)

Model Version 2
ModelMetrics: Base

DriftCheckBaselines: Base
Amazon EventBridge Integration

You can schedule your Amazon SageMaker Model Building Pipelines executions using Amazon EventBridge. Amazon SageMaker Model Building Pipelines is supported as a target in Amazon EventBridge. This allows you to initiate the execution of your model building pipeline based on any event in your event bus. With EventBridge, you can automate your pipeline executions and respond automatically to events such as training job or endpoint status changes. Events include a new file being uploaded to your Amazon S3 bucket, a change in status of your Amazon SageMaker endpoint due to drift, and Amazon Simple Notification Service (SNS) topics.

The following SageMaker Pipelines actions can be automatically initiated:

- StartPipelineExecution

For more information on scheduling SageMaker jobs, see Automating SageMaker with Amazon EventBridge.

Schedule a Pipeline with Amazon EventBridge

To start a pipeline execution with Amazon CloudWatch Events, you must create an EventBridge rule. When you create a rule for events, you specify a target action to take when EventBridge receives an event that matches the rule. When an event matches the rule, EventBridge sends the event to the specified target and initiates the action defined in the rule.

The following tutorials show how to schedule a pipeline execution with EventBridge using the EventBridge console or the AWS CLI.

Prerequisites

- A role that EventBridge can assume with the SageMaker::StartPipelineExecution permission. This role can be created automatically if you create a rule from the EventBridge console; otherwise, you need to create this role yourself. For information on creating a SageMaker role, see SageMaker Roles.
- An Amazon SageMaker Pipeline to schedule. To create an Amazon SageMaker Pipeline, see Define a Pipeline.

Create an EventBridge rule using the EventBridge console

The following procedure shows how to create an EventBridge rule using the EventBridge console.

1. Navigate to the EventBridge console.
2. Select Rules on the left hand side.
3. Select Create Rule.
4. Enter a name and description for your rule.
5. Select how you want to initiate this rule. You have the following choices for your rule:
   - Event pattern: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. For more information on Event patterns, see Event Patterns in CloudWatch Events.
   - Schedule: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as “the first Monday of each month at 8am.” Schedule is not supported on a custom or partner event bus.
6. Select your desired Event bus.
7. Select the target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. Select SageMaker Pipeline in the target dropdown list.

8. Select the pipeline you want to initiate from the pipeline dropdown list.

9. Add parameters to pass to your pipeline execution using a name and value pair. Parameter values can be static or dynamic. For more information on Amazon SageMaker Pipeline parameters, see AWS::Events::Rule SagemakerPipelineParameters.

   • Static values are passed to the pipeline execution every time the pipeline is initiated. For example, if 
     
     ```json
     {"Name": "Instance_type", "Value": "ml.4xlarge"}
     ```

     is specified in the parameter list, then it is passed as a parameter in StartPipelineExecutionRequest every time EventBridge initiates the pipeline.

   • Dynamic values are specified using a JSON path. EventBridge parses the value from an event payload, then passes it to the pipeline execution. For example:

     ```json
     $.detail.param.value
     ```

10. Select the role to use for this rule. You can either use an existing role or create a new one.

11. (Optional) Add tags.

12. Select Create to finalize your rule.

Your rule is now in effect and ready to initiate your pipeline executions.

Create an EventBridge rule using the AWS CLI

The following procedure shows how to create an EventBridge rule using the AWS CLI.

1. Create a rule to be initiated. When creating an EventBridge rule using the AWS CLI, you have two options for how your rule is initiated, event pattern and schedule.

   • **Event pattern**: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. You can create a rule with event pattern using the following command:

     ```bash
     aws events put-rule --name <RULE_NAME> --event-pattern <YOUR_EVENT_PATTERN> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

   • **Schedule**: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as "the first Monday of each month at 8am." Schedule is not supported on a custom or partner event bus. You can create a rule with schedule using the following command:

     ```bash
     aws events put-rule --name <RULE_NAME> --schedule-expression <YOUR_CRON_EXPRESSION> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

2. Add target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. For each target, you must specify:

   • ARN: The resource ARN of your pipeline.
   • Role ARN: The ARN of the role EventBridge should assume to execute the pipeline.
   • Parameters: Amazon SageMaker pipeline parameters to pass.

3. Run the following command to pass a Amazon SageMaker pipeline as a target to your rule using put-targets:

     ```bash
     aws events put-targets --rule <RULE_NAME> --event-bus-name <EVENT_BUS_NAME> --targets "[{"Id":"<ID>", "Arn":"<RESOURCE_ARN>", "RoleArn":"<ROLE_ARN>"}]
     ```
Amazon SageMaker Experiments Integration

Amazon SageMaker Model Building Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when SageMaker Pipelines creates and executes a pipeline, the following SageMaker Experiments entities are created if they don't exist:

- An experiment for the pipeline
- A trial for every execution of the pipeline
- A trial component that's added to the trial for each SageMaker job created in a pipeline execution step

You can compare metrics such as model training accuracy across multiple pipeline executions just as you can compare such metrics across multiple trials of a SageMaker model training experiment.

The following sample shows the relevant parameters of the Pipeline class in the Amazon SageMaker Python SDK.

```python
Pipeline(
    name="MyPipeline",
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
        ExecutionVariables.PIPELINE_NAME,
        ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[...]
)
```

If you don't want an experiment and trial created for the pipeline, set `pipeline_experiment_config` to None.

**Note**
Experiments integration was introduced in the Amazon SageMaker Python SDK v2.41.0.

The following naming rules apply based on what you specify for the `ExperimentName` and `TrialName` parameters of `pipeline_experiment_config`:

- If you don't specify `ExperimentName`, the pipeline name is used for the experiment name.
  
  If you do specify `ExperimentName`, it's used for the experiment name. If an experiment with that name exists, the pipeline-created trials are added to the existing experiment. If an experiment with that name doesn't exist, a new experiment is created.

- If you don't specify `TrialName`, the pipeline execution ID is used for the trial name.
  
  If you do specify `TrialName`, it's used for the trial name. If a trial with that name exists, the pipeline-created trial components are added to the existing trial. If a trial with that name doesn't exist, a new trial is created.

**Note**
The experiment entities aren't deleted when the pipeline that created the entities is deleted. You can use the SageMaker Experiments API to delete the entities. For more information, see Clean Up Amazon SageMaker Experiment Resources (p. 2011).

For information about how to view the SageMaker Experiment entities associated with a pipeline, see View Experiment Entities Created by SageMaker Pipelines (p. 2853). For more information on SageMaker Experiments, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1991).
The following sections show examples of the previous rules and how they are represented in the pipeline definition file. For more information on pipeline definition files, see SageMaker Pipelines Overview (p. 2795).

**Topics**
- Default Behavior (p. 2828)
- Disable Experiments Integration (p. 2828)
- Specify a Custom Experiment Name (p. 2829)
- Specify a Custom Trial Name (p. 2829)

**Default Behavior**

**Create a pipeline**

The `pipeline_experiment_config` is omitted. `ExperimentName` defaults to the pipeline name. `TrialName` defaults to the execution ID.

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    steps=[step_train]
)
```

**Pipeline definition file**

```json
{
    "Version": "2020-12-01",
    "Parameters": [
    {
        "Name": "InputDataSource"
    },
    {
        "Name": "InstanceCount",
        "Type": "Integer",
        "DefaultValue": 1
    }
    ],
    "PipelineExperimentConfig": {
        "ExperimentName": {"Get": "Execution.PipelineName"},
        "TrialName": {"Get": "Execution.PipelineExecutionId"}
    },
    "Steps": [...]
}
```

**Disable Experiments Integration**

**Create a pipeline**

The `pipeline_experiment_config` is set to None.

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=None,
    steps=[step_train]
)
```
Pipeline definition file

This is the same as the preceding default example, without the PipelineExperimentConfig.

**Specify a Custom Experiment Name**

A custom experiment name is used. The trial name is set to the execution ID, as with the default behavior.

Create a pipeline

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
        "CustomExperimentName",
        ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[step_train]
)
```

Pipeline definition file

```json
{
  ...
  "PipelineExperimentConfig": {
    "ExperimentName": "CustomExperimentName",
    "TrialName": {
      "Get": "Execution.PipelineExecutionId"
    },
    "Steps": [...]  
  }
}
```

**Specify a Custom Trial Name**

A custom trial name is used and appended with the execution ID. The experiment name is set to the pipeline name, as with the default behavior.

Create a pipeline

```python
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
        ExecutionVariables.PIPELINE_NAME,
        Join(on="-", values=["CustomTrialName", ExecutionVariables.PIPELINE_EXECUTION_ID])
    ),
    steps=[step_train]
)
```

Pipeline definition file

```json
{
  ...
  "PipelineExperimentConfig": {
    "ExperimentName": {"Get": "Execution.PipelineName"},
    "TrialName": {
      "On": "-",
      "Values": ["CustomTrialName",
                  "Execution.PipelineExecutionId"]
    },
    "Steps": [...]  
  }
}
```
Troubleshooting Amazon SageMaker Model Building Pipelines

When using Amazon SageMaker Model Building Pipelines, you might run into issues for various reasons. This topic provides information about common errors and how to resolve them.

**Pipeline Definition Issues**

Your pipeline definition might not be formatted correctly. This can result in your execution failing or your job being inaccurate. These errors can be caught when the pipeline is created or when an execution occurs. If your definition doesn’t validate, SageMaker Pipelines returns an error message identifying the character where the JSON file is malformed. To fix this problem, review the steps created using the SageMaker Python SDK for accuracy.

You can only include steps in a pipeline definition once. Because of this, steps cannot exist as part of a condition step and a pipeline in the same pipeline.

**Examining Pipeline Logs**

You can view the status of your steps using the following command:

```
execution.list_steps()
```

Each step includes the following information:

- The ARN of the entity launched by the pipeline, such as SageMaker job ARN, model ARN, or model package ARN.
- The failure reason includes a brief explanation of the step failure.
- If the step is a condition step, it includes whether the condition is evaluated to true or false.
- If the execution reuses a previous job execution, the `CacheHit` lists the source execution.

You can also view the error messages and logs in the Amazon SageMaker Studio interface. For information about how to see the logs in Studio, see View a Pipeline Execution (p. 2850).

**Missing Permissions**

Correct permissions are required for the role that creates the pipeline execution, and the steps that create each of the jobs in your pipeline execution. Without these permissions, you may not be able to submit your pipeline execution or run your SageMaker jobs as expected. To ensure that your permissions are properly set up, see IAM Access Management (p. 2797).

**Job Execution Errors**

You may run into issues when executing your steps because of issues in the scripts that define the functionality of your SageMaker jobs. Each job has a set of CloudWatch logs. To view these logs from Studio, see View a Pipeline Execution (p. 2850). For information about using CloudWatch logs with SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201).

**Property File Errors**

You may have issues when incorrectly implementing property files with your pipeline. To ensure that your implementation of property files works as expected, see Property Files and `JsonGet` (p. 2815).
Create and Manage SageMaker Pipelines

You can use Amazon SageMaker Model Building Pipelines to create end-to-end workflows that manage and deploy SageMaker jobs. SageMaker Pipelines comes with SageMaker Python SDK integration, so you can build each step of your pipeline using a Python-based interface.

After your pipeline is deployed, you can view the directed acyclic graph (DAG) for your pipeline and manage your executions using Amazon SageMaker Studio. Using SageMaker Studio, you can get information about your current and historical pipelines, compare executions, see the DAG for your executions, get metadata information, and more. To learn how to view pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2846).

Topics
- Define a Pipeline (p. 2831)
- Run a pipeline (p. 2843)
- View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2846)

Define a Pipeline

To orchestrate your workflows with Amazon SageMaker Model Building Pipelines, you need to generate a directed acyclic graph (DAG) in the form of a JSON pipeline definition. The following image is a representation of the pipeline DAG that you create in this tutorial:

![Pipeline DAG](image_url)

You can generate your JSON pipeline definition using the SageMaker Python SDK. The following tutorial shows how to generate a pipeline definition for a pipeline that solves a regression problem to determine

2831
the age of an abalone based on its physical measurements. For a Jupyter notebook that includes the content in this tutorial that you can run, see Orchestrating Jobs with Amazon SageMaker Model Building Pipelines.

Topics
- Prerequisites (p. 2832)
- Create a Pipeline (p. 2833)

Prerequisites
To run the following tutorial you must do the following:

- Set up your notebook instance as outlined in Create a notebook instance. This gives your role permissions to read and write to Amazon S3, and create training, batch transform, and processing jobs in SageMaker.
- Grant your notebook permissions to get and pass its own role as shown in Modifying a role permissions policy. Add the following JSON snippet to attach this policy to your role. Replace `<your-role-arn>` with the ARN used to create your notebook instance.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetRole",
                "iam:PassRole"
            ],
            "Resource": "<your-role-arn>"
        }
    ]
}
```

- Trust the SageMaker service principal by following the steps in Modifying a role trust policy. Add the following statement fragment to the trust relationship of your role:

```json
{
    "Sid": "",
    "Effect": "Allow",
    "Principal": {
        "Service": "sagemaker.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
}
```

Set Up Your Environment
Create a new SageMaker session using the following code block. This returns the role ARN for the session. This role ARN should be the execution role ARN that you set up as a prerequisite.

```python
import boto3
import sagemaker
import sagemaker.session

region = boto3.Session().region_name
sagemaker_session = sagemaker.session.Session()
role = sagemaker.get_execution_role()
```
default_bucket = sagemaker_session.default_bucket()
model_package_group_name = f"AbaloneModelPackageGroupName"

Create a Pipeline

Run the following steps from your SageMaker notebook instance to create a pipeline including steps for preprocessing, training, evaluation, conditional evaluation, and model registration.

Step 1: Download the Dataset

This notebook uses the UCI Machine Learning Abalone Dataset. The dataset contains the following features:

- **length** – The longest shell measurement of the abalone.
- **diameter** – The diameter of the abalone perpendicular to its length.
- **height** – The height of the abalone with meat in the shell.
- **whole_weight** – The weight of the whole abalone.
- **shucked_weight** – The weight of the meat removed from the abalone.
- **viscera_weight** – The weight of the abalone viscera after bleeding.
- **shell_weight** – The weight of the abalone shell after meat removal and drying.
- **sex** – The sex of the abalone. One of 'M', 'F', or 'I', where 'I' is an infant abalone.
- **rings** – The number of rings in the abalone shell.

The number of rings in the abalone shell is a good approximation for its age using the formula \( \text{age} = \text{rings} + 1.5 \). However, obtaining this number is a time-consuming task. You must cut the shell through the cone, stain the section, and count the number of rings through a microscope. However, the other physical measurements are easier to determine. This notebook uses the dataset to build a predictive model of the variable rings using the other physical measurements.

To download the dataset

1. Download the dataset into your account's default Amazon S3 bucket.

   ```bash
   !mkdir -p data
   local_path = "data/abalone-dataset.csv"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file("dataset/abalone-dataset.csv",
   local_path
   )
   base_uri = f"s3://{default_bucket}/abalone"
   input_data_uri = sagemaker.s3.S3Uploader.upload(
       local_path=local_path,
       desired_s3_uri=base_uri,
   )
   print(input_data_uri)
   ```

2. Download a second dataset for batch transformation after your model is created.

   ```bash
   local_path = "data/abalone-dataset-batch"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file("dataset/abalone-dataset-batch",
   local_path
   ```
Step 2: Define Pipeline Parameters

This code block defines the following parameters for your pipeline:

- **processing_instance_type** – The ml.* instance type of the processing jobs.
- **processing_instance_count** – The instance count of the processing job.
- **training_instance_type** – The ml.* instance type of the training jobs.
- **input_data** – The Amazon S3 location of the input data.
- **batch_data** – The Amazon S3 location of the input data for batch transformation.
- **model_approval_status** – The approval status to register the trained model with for CI/CD. For more information, see Automate MLOps with SageMaker Projects (p. 2861).

```python
from sagemaker.workflow.parameters import (  
    ParameterInteger,  
    ParameterString,  
)

processing_instance_count = ParameterInteger(  
    name="ProcessingInstanceCount",  
    default_value=1  
)

processing_instance_type = ParameterString(  
    name="ProcessingInstanceType",  
    default_value="ml.m5.xlarge"  
)

training_instance_type = ParameterString(  
    name="TrainingInstanceType",  
    default_value="ml.m5.xlarge"  
)

model_approval_status = ParameterString(  
    name="ModelApprovalStatus",  
    default_value="PendingManualApproval"  
)

input_data = ParameterString(  
    name="InputData",  
    default_value=input_data_uri,  
)

batch_data = ParameterString(  
    name="BatchData",  
    default_value=batch_data_uri,  
)
```

Step 3: Define a Processing Step for Feature Engineering

This section shows how to create a processing step to prepare the data from the dataset for training.

**To create a processing step**

1. Create a directory for the processing script.
2. Create a file in the /abalone directory named preprocessing.py with the following content. This preprocessing script is passed in to the processing step for execution on the input data. The training step then uses the preprocessed training features and labels to train a model, and the evaluation step uses the trained model and preprocessed test features and labels to evaluate the model. The script uses scikit-learn to do the following:

- Fill in missing sex categorical data and encode it so it's suitable for training.
- Scale and normalize all numerical fields except for rings and sex.
- Split the data into training, test, and validation datasets.

```python
from sklearn.compose import ColumnTransformer
from sklearn.impute import SimpleImputer
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import StandardScaler, OneHotEncoder

# Because this is a headerless CSV file, specify the column names here.
feature_columns_names = [
    "sex",
    "length",
    "diameter",
    "height",
    "whole_weight",
    "shucked_weight",
    "viscera_weight",
    "shell_weight",
]
label_column = "rings"

feature_columns_dtype = {
    "sex": str,
    "length": np.float64,
    "diameter": np.float64,
    "height": np.float64,
    "whole_weight": np.float64,
    "shucked_weight": np.float64,
    "viscera_weight": np.float64,
    "shell_weight": np.float64
}
label_column_dtype = {"rings": np.float64}

# Let's define the data types of each column.
def merge_two_dicts(x, y):
    z = x.copy()
    z.update(y)
    return z

if __name__ == "__main__":
    base_dir = "/opt/ml/processing"
```

```bash
mkdir -p abalone
```
df = pd.read_csv(  
    f"{base_dir}/input/abalone-dataset.csv",  
    header=None,  
    names=feature_columns_names + [label_column],  
    dtype=merge_two_dicts(feature_columns_dtype, label_column_dtype)  
)  
numeric_features = list(feature_columns_names)  
numeric_features.remove("sex")  
numeric_transformer = Pipeline(  
    steps=[  
        ("imputer", SimpleImputer(strategy="median")),  
        ("scaler", StandardScaler())  
    ]  
)  
categorical_features = ["sex"]  
categorical_transformer = Pipeline(  
    steps=[  
        ("imputer", SimpleImputer(strategy="constant", fill_value="missing")),  
        ("onehot", OneHotEncoder(handle_unknown="ignore"))  
    ]  
)  

preprocess = ColumnTransformer(  
    transformers=[  
        ("num", numeric_transformer, numeric_features),  
        ("cat", categorical_transformer, categorical_features)  
    ]  
)  

y = df.pop("rings")  
X_pre = preprocess.fit_transform(df)  
y_pre = y.to_numpy().reshape(len(y), 1)  
X = np.concatenate((y_pre, X_pre), axis=1)  
np.random.shuffle(X)  
train, validation, test = np.split(X, [int(.7*len(X)), int(.85*len(X))])  

pd.DataFrame(train).to_csv(f"{base_dir}/train/train.csv", header=False, index=False)  
pd.DataFrame(validation).to_csv(f"{base_dir}/validation/validation.csv", header=False, index=False)  
pd.DataFrame(test).to_csv(f"{base_dir}/test/test.csv", header=False, index=False)

3. Create an instance of an SKLearnProcessor to pass in to the processing step.

from sagemaker.sklearn.processing import SKLearnProcessor

framework_version = "0.23-1"  
sklearn_processor = SKLearnProcessor(  
    framework_version=framework_version,  
    instance_type=processing_instance_type,  
    instance_count=processing_instance_count,  
    base_job_name="sklearn-abalone-process",  
    role=role,  
)

4. Create a processing step. This step takes in the SKLearnProcessor, the input and output  
channels, and the preprocessing.py script that you created. This is very similar to a processor
instance’s run method in the SageMaker Python SDK. The input_data parameter passed into ProcessingStep is the input data of the step itself. This input data is used by the processor instance when it runs.

Note the "train," "validation," and "test" named channels specified in the output configuration for the processing job. Step Properties such as these can be used in subsequent steps and resolve to their runtime values at execution.

```python
from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep

step_process = ProcessingStep(
    name="AbaloneProcess",
    processor=sklearn_processor,
    inputs=[
        ProcessingInput(source=input_data, destination="/opt/ml/processing/input"),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="abalone/preprocessing.py",
)
```

**Step 4: Define a Training step**

This section shows how to use the SageMaker XGBoost Algorithm to train a logistic regression model on the training data output from the processing steps.

**To define a training step**

1. Specify the model path where you want to save the models from training.

   ```python
   model_path = f"s3://{default_bucket}/AbaloneTrain"
   ```

2. Configure an estimator for the XGBoost algorithm and the input dataset. The training_instance_type is passed into the estimator. A typical training script loads data from the input channels, configures training with hyperparameters, trains a model, and saves a model to model_dir so that it can be hosted later. SageMaker uploads the model to Amazon S3 in the form of a model.tar.gz at the end of the training job.

   ```python
   from sagemaker.estimator import Estimator

   image_uri = sagemaker.image_uris.retrieve(
       framework="xgboost",
       region=region,
       version="1.0-1",
       py_version="py3",
       instance_type=training_instance_type,
   )

   xgb_train = Estimator(
       image_uri=image_uri,
       instance_type=training_instance_type,
       instance_count=1,
       output_path=model_path,
       role=role,
   )
   ```
3. Create a TrainingStep using the estimator instance and properties of the ProcessingStep. In particular, pass in the S3Uri of the "train" and "validation" output channel to the TrainingStep.

```python
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TrainingStep

step_train = TrainingStep(
    name="AbaloneTrain",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs[
                "train"
            ].S3Output.S3Uri,
            content_type="text/csv"
        ),
        "validation": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs[
                "validation"
            ].S3Output.S3Uri,
            content_type="text/csv"
        )
    },
)
```

**Step 5: Define a Processing Step for Model Evaluation**

This section shows how to create a processing step to evaluate the accuracy of the model. The result of this model evaluation is used in the condition step to determine which execute path to take.

**To define a processing step for model evaluation**

1. Create a file in the /abalone directory named evaluation.py. This script is used in a processing step to perform model evaluation. It takes a trained model and the test dataset as input, then produces a JSON file containing classification evaluation metrics.

```python
%%writefile abalone/evaluation.py
import json
import pathlib
import pickle
import tarfile
import joblib
import numpy as np
import pandas as pd
import xgboost

from sklearn.metrics import mean_squared_error
```
```python
if __name__ == "__main__":
    model_path = f"/opt/ml/processing/model/model.tar.gz"
    with tarfile.open(model_path) as tar:
        tar.extractall(path="."

    model = pickle.load(open("xgboost-model", "rb"))

test_path = "/opt/ml/processing/test/test.csv"
    df = pd.read_csv(test_path, header=None)
    y_test = df.iloc[:, 0].to_numpy()
    df.drop(df.columns[0], axis=1, inplace=True)

    X_test = xgboost.DMatrix(df.values)

    predictions = model.predict(X_test)

    mse = mean_squared_error(y_test, predictions)
    std = np.std(y_test - predictions)

    report_dict = {
        "regression_metrics": {
            "mse": {
                "value": mse,
                "standard_deviation": std
            }
        }
    }

    output_dir = "/opt/ml/processing/evaluation"
    pathlib.Path(output_dir).mkdir(parents=True, exist_ok=True)

    evaluation_path = f"{output_dir}/evaluation.json"
    with open(evaluation_path, "w") as f:
        f.write(json.dumps(report_dict))
```

2. Create an instance of a `ScriptProcessor` that is used to create a `ProcessingStep`.

```python
from sagemaker.processing import ScriptProcessor

script_eval = ScriptProcessor(
    image_uri=image_uri,
    command=["python3"],
    instance_type=processing_instance_type,
    instance_count=1,
    base_job_name="script-abalone-eval",
    role=role,
)
```

3. Create a `ProcessingStep` using the processor instance, the input and output channels, and the `evaluation.py` script. In particular, pass in the `S3ModelArtifacts` property from the `step_train` training step, as well as the `S3Uri` of the "test" output channel of the `step_process` processing step. This is very similar to a processor instance's run method in the SageMaker Python SDK.

```python
from sagemaker.workflow.properties import PropertyFile

evaluation_report = PropertyFile(
    name=\"EvaluationReport\",
    output_name=\"evaluation\",
    path=\"evaluation.json\"
)```
Step 6: Define a CreateModelStep for Batch Transformation

This section shows how to create a SageMaker model from the output of the training step. This model is used for batch transformation on a new dataset. This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a CreateModelStep for batch transformation

   ```python
   from sagemaker.model import Model

   model = Model(
       image_uri=image_uri,
       model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
       sagemaker_session=sagemaker_session,
       role=role,
   )
   ```

2. Define the model input for your SageMaker model.

   ```python
   from sagemaker.inputs import CreateModelInput

   inputs = CreateModelInput(
       instance_type="ml.m5.large",
       accelerator_type="ml.eia1.medium",
   )
   ```

3. Create your CreateModelStep using the CreateModelInput and SageMaker model instance you defined.

   ```python
   from sagemaker.workflow.steps import CreateModelStep
   ```
step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=model,
    inputs=inputs,
)

Step 7: Define a TransformStep to Perform Batch Transformation

This section shows how to create a TransformStep to perform batch transformation on a dataset after the model is trained. This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a TransformStep to perform batch transformation

1. Create a transformer instance with the appropriate compute instance type, instance count, and desired output Amazon S3 bucket URI. Pass in the ModelName property from the step_create_model CreateModel step.

   ```python
   from sagemaker.transformer import Transformer

   transformer = Transformer(
       model_name=step_create_model.properties.ModelName,
       instance_type="ml.m5.xlarge",
       instance_count=1,
       output_path=f"s3://{default_bucket}/AbaloneTransform"
   )
   ```

2. Create a TransformStep using the transformer instance you defined and the batch_data pipeline parameter.

   ```python
   from sagemaker.inputs import TransformInput
   from sagemaker.workflow.steps import TransformStep

   step_transform = TransformStep(
       name="AbaloneTransform",
       transformer=transformer,
       inputs=TransformInput(data=batch_data)
   )
   ```

Step 8: Define a RegisterModel Step to Create a Model Package

This section shows how to construct an instance of RegisterModel. The result of executing RegisterModel in a pipeline is a model package. A model package is a reusable model artifacts abstraction that packages all ingredients necessary for inference. It consists of an inference specification that defines the inference image to use along with an optional model weights location. A model package group is a collection of model packages. You can use a ModelPackageGroup for SageMaker Pipelines to add a new version and model package to the group for every pipeline execution. For more information about model registry, see Register and Deploy Models with Model Registry (p. 2592).

This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a RegisterModel step to create a model package

- Construct a RegisterModel step using the estimator instance you used for the training step. Pass in the S3ModelArtifacts property from the step_train training step and specify a ModelPackageGroup. SageMaker Pipelines creates this ModelPackageGroup for you.
Step 9: Define a Condition Step to Verify Model Accuracy

A ConditionStep allows SageMaker Pipelines to support conditional execution in your pipeline DAG based on the condition of step properties. In this case, you only want to register a model package if the accuracy of that model, as determined by the model evaluation step, exceeds the required value. If the accuracy exceeds the required value, the pipeline also creates a SageMaker Model and runs batch transformation on a dataset. This section shows how to define the Condition step.

To define a condition step to verify model accuracy

1. Define a ConditionLessThanOrEqualTo condition using the accuracy value found in the output of the model evaluation processing step, step_eval. Get this output using the property file you indexed in the processing step and the respective JSONPath of the mean squared error value, "mse".

```python
from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.workflow.condition_step import ConditionStep
from sagemaker.workflow.functions import JsonGet

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"
    ),
    right=6.0
)
```

2. Construct a ConditionStep. Pass the ConditionEquals condition in, then set the model package registration and batch transformation steps as the next steps if the condition passes.

```python
step_cond = ConditionStep(
    name="AbaloneMSECond",
    condition=cond_lte,
    next_steps=[step_register, step_transform]
)
```
Step 10: Create a Pipeline

Now that you've created all of the steps, combine them into a pipeline.

To create a pipeline

1. Define the following for your pipeline: name, parameters, and steps. Names must be unique within an (account, region) pair.

   Note
   A step can only appear once in either the pipeline's step list or the if/else step lists of the condition step. It cannot appear in both.

   from sagemaker.workflow.pipeline import Pipeline

   pipeline_name = f"AbalonePipeline"
   pipeline = Pipeline(
       name=pipeline_name,
       parameters=[
         processing_instance_type,
         processing_instance_count,
         training_instance_type,
         model_approval_status,
         input_data,
         batch_data,
       ],
       steps=[step_process, step_train, step_eval, step_cond],
   )

2. (Optional) Examine the JSON pipeline definition to ensure that it's well-formed.

   import json
   json.loads(pipeline.definition())

This pipeline definition is ready to submit to SageMaker. In the next tutorial, you submit this pipeline to SageMaker and start an execution.

Next step: Run a pipeline (p. 2843)

Run a pipeline

After you've created a pipeline definition using the SageMaker Python SDK, you can submit it to SageMaker to start your execution. The following tutorial shows how to submit a pipeline, start an execution, examine the results of that execution, and delete your pipeline.

Topics
- Prerequisites (p. 2844)
- Step 1: Start the Pipeline (p. 2844)
- Step 2: Examine a Pipeline Execution (p. 2844)
- Step 3: Override Default Parameters for a Pipeline Execution (p. 2845)
Prerequisites

This tutorial requires the following:

- A SageMaker notebook instance.
- A SageMaker Pipelines pipeline definition. This tutorial assumes you’re using the pipeline definition created by completing the Define a Pipeline (p. 2831) tutorial.

Step 1: Start the Pipeline

First, you need to start the pipeline.

To start the pipeline

1. Examine the JSON pipeline definition to ensure that it’s well-formed.

   ```python
   import json
   json.loads(pipeline.definition())
   ```

2. Submit the pipeline definition to the SageMaker Pipelines service to create a pipeline if it doesn’t exist, or update the pipeline if it does. The role passed in is used by SageMaker Pipelines to create all of the jobs defined in the steps.

   ```python
   pipeline.upsert(role_arn=role)
   ```

3. Start a pipeline execution.

   ```python
   execution = pipeline.start()
   ```

Step 2: Examine a Pipeline Execution

Next, you need to examine the pipeline execution.

To examine a pipeline execution

1. Describe the pipeline execution status to ensure that it has been created and started successfully.

   ```python
   execution.describe()
   ```

2. Wait for the execution to finish.

   ```python
   execution.wait()
   ```

3. List the execution steps and their status.

   ```python
   execution.list_steps()
   ```

Your output should look like the following:

```json
[{'StepName': 'AbaloneTransform',
```
4. After your pipeline execution is complete, download the resulting evaluation.json file from Amazon S3 to examine the report.

```python
evaluation_json = sagemaker.s3.S3Downloader.read_file("/evaluation.json").format(**step_eval.arguments["ProcessingOutputConfig"])["Outputs"][0]["S3Output"]["S3Uri"]
json.loads(evaluation_json)
```

### Step 3: Override Default Parameters for a Pipeline Execution

You can run additional executions of the pipeline by specifying different pipeline parameters to override the defaults.
To override default parameters

1. Create the pipeline execution. This starts another pipeline execution on a compute-optimized instance type and sets the model approval status to "Approved". This means that the model package version generated by the `RegisterModel` step is automatically ready for deployment through CI/CD pipelines, such as with SageMaker Projects. For more information, see Automate MLOps with SageMaker Projects (p. 2861).

   ```python
   execution = pipeline.start(
       parameters=dict(
           ProcessingInstanceType="ml.c5.xlarge",
           ModelApprovalStatus="Approved",
       )
   )
   ```

2. Wait for the execution to finish.

   ```python
   execution.wait()
   ```

3. List the execution steps and their status.

   ```python
   execution.list_steps()
   ```

4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

   ```python
   evaluation_json = sagemaker.s3.S3Downloader.read_file("{}\evaluation.json".format(
       step_eval.arguments["ProcessingOutputConfig"]['Outputs'][0]['S3Output']['S3Uri'])
   )
   json.loads(evaluation_json)
   ```

Step 4: Stop and Delete a Pipeline Execution

When you're finished with your pipeline, you can stop any ongoing executions and delete the pipeline.

To stop and delete a pipeline execution

1. Stop the pipeline execution.

   ```python
   execution.stop()
   ```

2. Delete the pipeline.

   ```python
   pipeline.delete()
   ```

View, Track, and Execute SageMaker Pipelines in SageMaker Studio

To view, track, and execute Amazon SageMaker Pipelines in Amazon SageMaker Studio, you must sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).

Topics
- View a Pipeline (p. 2847)
- View a Pipeline Execution (p. 2850)
• View Experiment Entities Created by SageMaker Pipelines (p. 2853)
• Execute a Pipeline (p. 2855)
• Track the Lineage of a SageMaker ML Pipeline (p. 2857)

View a Pipeline

This procedure shows you how to directly find a pipeline and view its details page. You can also find pipelines that are part of a project listed in the project's details page. For information on finding a pipeline that is part of a project, see Automate MLOps with SageMaker Projects (p. 2861).

To view a list of pipelines

1. In the left sidebar of Studio, choose the SageMaker resources icon.

2. Select Pipelines from the dropdown list.
3. Drag the right border of the **Components and registries** pane to the right to view all the columns. Use search to narrow the list of pipelines.

Search is a two-step process. First, you enter characters that match the column name you want to search. Second, you enter characters to match the item in that column.

You can have multiple search filters. An example, the following screenshot limits the displayed pipelines to those with a name that starts with aba and created by Me. For more information on searching in Studio, see Search Experiments Using Amazon SageMaker Studio (p. 2006).

4. Open a pipeline to view details about the pipeline. The pipeline details tab opens and displays a list of pipeline executions. You can start an execution or choose one of the other tabs for more information about the pipeline. Use the **Settings** icon (⚙️) to choose which columns to display.

5. From the pipeline details page, choose one of the following tabs to view details about the pipeline:
   - **Executions** – Details about the executions. You can start an execution from this tab or the **Graph** tab.
   - **Graph** – The DAG for the pipeline.
• **Parameters** – Includes the model approval status.

View a Pipeline Execution

This procedure shows you how to view a pipeline execution. For information on how to view a list of pipeline executions, and how to use SageMaker search to narrow the executions in the list, see View a Pipeline (p. 2847).

To view details of a pipeline execution

1. In the execution list, open an execution to view details about the execution. The execution details tab opens and displays a graph of the steps in the pipeline. You can choose one of the other tabs to view information about the pipeline execution, which is similar to that shown when viewing the pipeline details.

2. Use search to find a step in the graph. Type characters that match a step name. You can drag the graph around or use the resizing icons on the lower-left side of the graph. The inset on the lower-right side of the graph displays where you are in the graph.

3. Choose one of the steps in the graph to see details about the step. In the preceding screenshot, a training step is chosen and displays the following tabs:
• **Input** – The training inputs. If an input source is from Amazon Simple Storage Service (Amazon S3), choose the link to view the file in the Amazon S3 console.

• **Output** – The training outputs, such as metrics, charts, files, and evaluation outcome. The graphs were produced using the Tracker APIs.
**training_step**

- **Info** – The parameters and metadata associated with the step.

![Parameters and metadata]

**View Experiment Entities Created by SageMaker Pipelines**

When you create a pipeline and specify `pipeline_experiment_config`, SageMaker Pipelines creates the following SageMaker Experiments entities by default if they don't exist:

- An experiment for the pipeline
- A trial for every execution of the pipeline
- A trial component for each SageMaker job created in a pipeline step
For information on how experiments are integrated with pipelines, see Amazon SageMaker Experiments Integration (p. 2827). For more information on SageMaker Experiments, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1991).

You can get to the list of trial components associated with a pipeline from either the pipeline executions list or the experiments list.

To view the trial components list from the pipeline executions list

1. To view the pipeline executions list, follow the first four steps in View a Pipeline (p. 2847).
2. On the top right of the screen, choose the Settings icon (⚙️) to open TABLE PROPERTIES.
3. Select Experiment. If experiment integration wasn't disabled when the pipeline was created, the experiment name and trial name are displayed in the executions list.
   
   **Note**
   
   Experiments integration was introduced in v2.41.0 of the Amazon SageMaker Python SDK. Pipelines created with an earlier version of the SDK aren't integrated with experiments by default.

4. Select one or more executions, open (right-click) the selection, then choose View trial components generated by execution.

To view the trial components list from the experiments list

1. In the left sidebar of Studio, choose the Components and registries icon (.retrieve).
2. Select Experiments and trials from the dropdown list.
3. Use search to filter the list to experiments created by a pipeline.
   a. Drag the right border of the Components and registries pane to the right until you can see the Experiment type column.
   b. In the search box, enter `ex` and choose Experiment type.
   c. In Filter by values, choose Pipeline, then choose Apply.

To further narrow the search, you can add additional filters. For more information, see Search Experiments Using Amazon SageMaker Studio (p. 2006).

4. Open (right-click) an experiment name and choose Open in trial component list.
List of trial components

The following shows the list of trial components created by the pipeline.

<table>
<thead>
<tr>

Execute a Pipeline

This procedure shows you how to execute a pipeline. For information on how to view a list of pipeline executions, see View a Pipeline (p. 2847).

To start a pipeline execution

1. From the Executions or Graph tab in the execution list, choose Start an execution.
2. Enter or update the following required information:

- **Name** – Must be unique to your account in the AWS Region.
- **ProcessingInstanceType** – The instance type for processing.
- **ProcessingInstanceCount** – The number of instances to use for processing.
- **TrainingInstanceType** – The instance type for training.
- **ModelApprovalStatus** – For your convenience.
- **InputData** – The S3 URI of the input data.

3. Choose **Submit**.

- To see details of the execution or to stop the execution, choose **View details** on the status banner.
- To stop the execution, choose **Stop** on the status banner.
- To resume the execution from where it was stopped, choose **Resume** on the status banner.
Note
If your pipeline fails, the status banner will show Failed status. After troubleshooting the failed step, choose Retry on the status banner to resume running the pipeline from that step.

For a list of registered models, see Automate MLOps with SageMaker Projects (p. 2861).

Track the Lineage of a SageMaker ML Pipeline

In this tutorial, you use Amazon SageMaker Studio to track the lineage of an Amazon SageMaker ML Pipeline.

The pipeline was created by the Orchestrating Jobs with Amazon SageMaker Model Building Pipelines notebook in the Amazon SageMaker example GitHub repository. For detailed information on how the pipeline was created, see Define a Pipeline (p. 2831).

Lineage tracking in Studio is centered around a directed acyclic graph (DAG). The DAG represents the steps in a pipeline. From the DAG you can track the lineage from any step to any other step. The following diagram displays the steps in the pipeline. These steps appear as a DAG in Studio.

Prerequisites
- Access to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
- Familiarity with the SageMaker Studio user interface. For more information, see Amazon SageMaker Studio UI Overview (p. 122).
- (Recommended) A completed run of the example notebook.

To track the lineage of a pipeline
1. Sign in to SageMaker Studio.
2. In the left sidebar of Studio, choose the SageMaker Components and registries icon (网站地图).
3. In the drop-down menu, select Pipelines.
4. Use the **Search** box to filter the pipelines list. To view all available columns, drag the right border of the pane to the right. For more information, see [Search Experiments Using Amazon SageMaker Studio](#) (p. 2006).

The following screenshot shows the list filtered by a name that starts with "aba" and that was created on 12/5/20.
5. Double-click the AbalonePipeline pipeline to view the execution list and other details about the pipeline. The following screenshot shows the TABLE PROPERTIES pane open where you can choose which properties to view.

6. Choose the Settings tab and then choose Download pipeline definition file. You can view the file to see how the pipeline graph was defined.

7. On the Execution tab, double-click the first row in the execution list to view its execution graph and other details about the execution. Note that the graph matches the diagram displayed at the beginning of the tutorial.

You can drag the graph around (select an area not on the graph itself) or use the resizing icons on the lower-left side of the graph. The inset on the lower-right side of the graph displays your location in the graph.
8. On the **Graph** tab, choose the **AbaloneProcess** step to view details about the step.

9. Find the Amazon S3 paths to the training, validation, and test datasets in the **Output** tab, under **Files**.

   **Note**
   To get the full paths, right-click the path and then choose **Copy cell contents**.

```
s3://sagemaker-eu-west-1-acct-id/sklearn-abalone-process-2020-12-05-17-28-28-509/output/train
```
10. Choose the AbaloneTrain step.

11. Find the Amazon S3 path to the model artifact in the Output tab, under Files:

   s3://sagemaker-eu-west-1-acct-id/AbaloneTrain/pipelines-6locnsqz4bfu-AbaloneTrain-NtfEp10Ahu/output/model.tar.gz

12. Choose the AbaloneRegisterModel step.

13. Find the ARN of the model package in the Output tab, under Files:

   arn:aws:sagemaker:eu-west-1:acct-id:model-package/abalonemodelpackagegroupname/2

Automate MLOps with SageMaker Projects

Create end-to-end ML solutions with CI/CD by using SageMaker projects.

Use SageMaker projects to create an MLOps solution to orchestrate and manage:

- Building custom images for processing, training, and inference
- Data preparation and feature engineering
- Training models
- Evaluating models
- Deploying models
- Monitoring and updating models
Why Should You Use MLOps?

As you move from running individual artificial intelligence and machine learning (AI/ML) projects to using AI/ML to transform your business at scale, the discipline of ML Operations (MLOps) can help. MLOps accounts for the unique aspects of AI/ML projects in project management, CI/CD, and quality assurance, helping you improve delivery time, reduce defects, and make data science more productive.

MLOps refers to a methodology that is built on applying DevOps practices to machine learning workloads. For a discussion of DevOps principles, see the white paper Introduction to DevOps on AWS. To learn more about implementation using AWS services, see Practicing CI/CD on AWS and Infrastructure as Code.

Like DevOps, MLOps relies on a collaborative and streamlined approach to the machine learning development lifecycle where the intersection of people, process, and technology optimizes the end-to-end activities required to develop, build, and operate machine learning workloads.

MLOps focuses on the intersection of data science and data engineering in combination with existing DevOps practices to streamline model delivery across the machine learning development lifecycle. MLOps is the discipline of integrating ML workloads into release management, CI/CD, and operations. MLOps requires the integration of software development, operations, data engineering, and data science.

Challenges with MLOps

Although MLOps can provide valuable tools to help you scale your business, you might face certain issues as you integrate MLOps into your machine learning workloads.

Project management

- ML projects involve data scientists, a relatively new role, and one not often integrated into cross-functional teams. These new team members often speak a very different technical language than product owners and software engineers, compounding the usual problem of translating business requirements into technical requirements.

Communication and collaboration

- Building visibility on ML projects and enabling collaboration across different stakeholders such as data engineers, data scientists, ML engineers, and DevOps is becoming increasingly important to ensure successful outcomes.

Everything is code
• Use of production data in development activities, longer experimentation lifecycles, dependencies on
data pipelines, retraining deployment pipelines, and unique metrics in evaluating the performance of a
model.
• Models often have a lifecycle independent of the applications and systems integrating with those
models.
• The entire end-to-end system is reproducible through versioned code and artifacts. DevOps projects
use Infrastructure-as-Code (IaC) and Configuration-as-Code (CaC) to build environments, and
Pipelines-as-Code (PaC) to ensure consistent CI/CD patterns. The pipelines have to integrate with Big
Data and ML training workflows. That often means that the pipeline is a combination of a traditional
CI/CD tool and another workflow engine. There are important policy concerns for many ML projects,
so the pipeline may also need to enforce those policies. Biased input data produces biased results, an
increasing concern for business stakeholders.

**CI/CD**

• In MLOps, the source data is a first-class input, along with source code. That’s why MLOps calls for
versioning the source data and initiating pipeline runs when the source or inference data changes.
• Pipelines must also version the ML models, along with inputs and other outputs, in order to provide for
traceability.
• Automated testing must include proper validation of the ML model during build phases and when the
model is in production.
• Build phases may include model training and retraining, a time-consuming and resource-intensive
process. Pipelines must be granular enough to only perform a full training cycle when the source data
or ML code changes, not when related components change.
• Because machine learning code is typically a small part of an overall solution, a deployment pipeline
may also incorporate the additional steps required to package a model for consumption as an API by
other applications and systems.

**Monitoring and logging**

• The feature engineering and model training phases needed to capture model training metrics as well
as model experiments. Tuning an ML model requires manipulating the form of the input data as well
as algorithm hyperparameters, and systematically capture those experiments. Experiment tracking
helps data scientists work more effectively and gives a reproducible snapshot of their work.
• Deployed ML models require monitoring of the data passed to the model for inference, along with the
standard endpoint stability and performance metrics. The monitoring system must also capture the
quality of model output, as evaluated by an appropriate ML metric.

**Benefits of MLOps**

Adopting MLOps practices gives you faster time-to-market for ML projects by delivering the following
benefits.

• **Productivity**: Providing self-service environments with access to curated data sets lets data engineers
and data scientists move faster and waste less time with missing or invalid data.
• **Repeatability**: Automating all the steps in the MLDC helps you ensure a repeatable process, including
how the model is trained, evaluated, versioned, and deployed.
• **Reliability**: Incorporating CI/CD practices allows for the ability to not only deploy quickly but with
increased quality and consistency.
• **Auditability**: Versioning all inputs and outputs, from data science experiments to source data to
trained model, means that we can demonstrate exactly how the model was built and where it was
deployed.
• **Data and model quality:** MLOps lets us enforce policies that guard against model bias and track changes to data statistical properties and model quality over time.

**What is a SageMaker Project?**

SageMaker Projects help organizations set up and standardize developer environments for data scientists and CI/CD systems for MLOps engineers. Projects also help organizations set up dependency management, code repository management, build reproducibility, and artifact sharing.

You can provision SageMaker Projects from the AWS Service Catalog using custom or SageMaker-provided templates. For information about the AWS Service Catalog, see [What Is AWS Service Catalog](https://docs.aws.amazon.com/service-catalog/latest/adminguide/what-is.html). With SageMaker Projects, MLOps engineers and organization admins can define their own templates or use SageMaker-provided templates. The SageMaker-provided templates bootstrap the ML workflow with source version control, automated ML pipelines, and a set of code to quickly start iterating over ML use cases.

**When Should You Use a SageMaker Project?**

While notebooks are helpful for model building and experimentation, a team of data scientists and ML engineers sharing code needs a more scalable way to maintain code consistency and strict version control.

Every organization has its own set of standards and practices that provide security and governance for its AWS environment. SageMaker provides a set of first-party templates for organizations that want to quickly get started with ML workflows and CI/CD. The templates include projects that use AWS-native services for CI/CD, such as AWS CodeBuild, AWS CodePipeline, and AWS CodeCommit. The templates also offer the option to create projects that use third-party tools, such as Jenkins and GitHub. For a list of the project templates that SageMaker provides, see [Use SageMaker-Provided Project Templates (p. 2868)](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-project-templates.html).

Organizations often need tight control over the MLOps resources that they provision and manage. Such responsibility assumes certain tasks, including configuring IAM roles and policies, enforcing resource tags, enforcing encryption, and decoupling resources across multiple accounts. SageMaker Projects can support all these tasks through custom template offerings where organizations use AWS CloudFormation templates to define the resources needed for an ML workflow. Data Scientists can choose a template to bootstrap and pre-configure their ML workflow. These custom templates are created as AWS Service Catalog products and you can provision them in the Studio UI under **Organization Templates**. The [AWS Service Catalog](https://docs.aws.amazon.com/service-catalog/latest/adminguide/what-is.html) is a service that helps organizations create and manage catalogs of products that are approved for use on AWS. For more information about creating custom templates, see [Build Custom SageMaker Project Templates – Best Practices](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-project-templates.html).

SageMaker Projects can help you manage your Git repositories so that you can collaborate more efficiently across teams, ensure code consistency, and support CI/CD. SageMaker Projects can help you with the following tasks:

- Organize all entities of the ML lifecycle under one project.
- Establish a single-click approach to set up standard ML infrastructure for model training and deployment that incorporates best practices.
- Create and share templates for ML infrastructure to serve multiple use cases.
- Leverage SageMaker-provided pre-built templates to quickly start focusing on model building, or create custom templates with organization-specific resources and guidelines.
- Integrate with tools of your choice by extending the project templates. For an example, see [Create a SageMaker Project to integrate with GitLab and GitLab Pipelines](https://docs.aws.amazon.com/sagemaker/latest/dg/sagemaker-project-templates.html).
- Organize all entities of the ML lifecycle under one project.
What is in a SageMaker Project?

Customers have the flexibility to set up their projects with the resources that best serve their use case. The example below showcases the MLOps setup for an ML workflow, including model training and deployment.

A typical project with a SageMaker-provided template might include the following:

- One or more repositories with sample code to build and deploy ML solutions. These are working examples that you can clone locally and modify for your needs. You own this code and can take advantage of the version-controlled repositories for your tasks.
- A SageMaker pipeline that defines steps for data preparation, training, model evaluation, and model deployment, as shown in the following diagram.

![Diagram of SageMaker Pipelines and Model Registry]

- A CodePipeline or Jenkins pipeline that runs your SageMaker pipeline every time you check in a new version of the code. For information about CodePipeline, see What is AWS CodePipeline. For information about Jenkins, see Jenkins User Documentation.
- A model group that contains model versions. Every time you approve the resulting model version from a SageMaker pipeline run, you can deploy it to a SageMaker endpoint.

Each SageMaker project has a unique name and ID that are applied as tags to all of the SageMaker and AWS resources created in the project. With the name and ID, you can view all of the entities associated with your project. These include:

- Pipelines
- Registered models
- Deployed models (endpoints)
- Datasets
- AWS Service Catalog products
- CodePipeline and Jenkins pipelines
- CodeCommit and third-party Git repositories
Do I Need to Create a Project to Use SageMaker Pipelines?

No. SageMaker pipelines are standalone entities just like training jobs, processing jobs, and other SageMaker jobs. You can create, update, and run pipelines directly within a notebook by using the SageMaker Python SDK without using a SageMaker project.

Projects provide an additional layer to help you organize your code and adopt operational best practices that you need for a production-quality system.

SageMaker Studio Permissions Required to Use Projects

Users can view SageMaker provided project templates and create projects with those templates when you grant Projects permissions for users. You can grant these permissions when you onboard or update Amazon SageMaker Studio. There are two permissions to grant.

1. Grant Projects permissions for the Studio administrator to permit the Studio administrator to view the SageMaker-provided templates in the AWS Service Catalog console. The administrator can see what other Studio users create if you grant them permission to use SageMaker projects. The administrator can also view the AWS CloudFormation template that the SageMaker-provided project templates define in the AWS Service Catalog console. For information about using the AWS Service Catalog console, see What Is AWS Service Catalog in the AWS Service Catalog User Guide.

2. Allow Studio users who are configured to use the domain execution role to create projects. This grants Studio users permission to use the SageMaker-provided project templates to create a project from within Studio.

For users who use any role other than the domain execution role to view and use SageMaker-provided project templates, you need to grant Projects permissions to the individual user profiles.

The following procedures show how to grant Projects permissions after you onboard to Studio. For more information about onboarding to Studio, see Onboard to Amazon SageMaker Domain (p. 36).

To grant Projects permissions for the administrator and domain execution role users

1. Open the SageMaker console.
2. Choose Control Panel.
3. If you choose Quick setup to set up your SageMaker Domain, you have permissions to use project templates by default.
4. If you choose Standard setup to set up your SageMaker Domain, make sure you turn on both Enable Projects, and JumpStart templates for this Studio user and Enable Projects, and JumpStart templates for Studio users when you configure Studio settings.
5. To confirm that your SageMaker Domain has active project template permissions:
   a. Open the SageMaker console.
   b. Choose Control Panel.
   c. Choose the Settings icon in the upper-right corner of the Domain card.
   d. Choose Studio Settings in the left side panel.
   e. Under Projects and JumpStart, make sure Enable Projects, and JumpStart templates for this Studio user and Enable Projects, and JumpStart templates for Studio users are turned on.
Create an MLOps Project using Amazon SageMaker Studio

This procedure demonstrates how to create an MLOps project using Amazon SageMaker Studio.

Prerequisites

- An AWS SSO or IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 36).
- Permission to use SageMaker-provided project templates. For information, see SageMaker Studio Permissions Required to Use Projects (p. 2866).
- Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 122).

To create a project in Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the Studio sidebar, choose the SageMaker resources icon (📅).
3. Select Projects from the dropdown list.
4. Choose Create project.

The Create project tab opens displaying a list of available templates.

5. For SageMaker project templates, choose SageMaker templates. For more information about project templates, see MLops Project Templates (p. 2867).
6. Choose MLOps template for model building, training, and deployment.
7. Choose Select project template.

The Create project tab changes to display Project details.

8. Enter the following information:
   - For Project details, enter a name and description for your project.
   - Optionally, add tags, which are key-value pairs that you can use to track your projects.
9. Choose Create project and wait for the project to appear in the Projects list.

MLOps Project Templates

An Amazon SageMaker project template automates the setup and implementation of MLOps for your projects. A SageMaker project template is an AWS Service Catalog product that SageMaker makes available to Amazon SageMaker Studio users. These AWS Service Catalog products are visible in your AWS Service Catalog console after you enable permissions when you onboard or update Amazon SageMaker Studio. For information about enabling permissions to use SageMaker project templates, see SageMaker Studio Permissions Required to Use Projects (p. 2866). Use SageMaker project templates to create a project that is an end-to-end MLOps solution.

If you are an administrator, you can create custom project templates from scratch or modify one of the project templates provided by SageMaker. Studio users in your organization can use these custom project templates to create their projects.

Topics

- Use SageMaker-Provided Project Templates (p. 2868)
Use SageMaker-Provided Project Templates

Amazon SageMaker provides project templates that create the infrastructure you need to create an MLOps solution for continuous integration and continuous deployment (CI/CD) of ML models. Use these templates to process data, extract features, train and test models, register the models in the SageMaker model registry, and deploy the models for inference. You can customize the seed code and the configuration files to suit your requirements.

Important
As of July 27, 2021, SageMaker projects can use third-party Git repositories. For more information, see Update SageMaker Projects to Use Third-Party Git Repositories (p. 2873).

SageMaker project templates offer you the following choice of code repositories, workflow automation tools, and pipeline stages:

- **Code repository**: AWS CodeCommit or third-party Git repositories such as GitHub and Bitbucket
- **CI/CD workflow automation**: AWS CodePipeline or Jenkins
- **Pipeline stages**: Model building and training, model deployment, or both

Each of the following topics corresponds to a template you can choose when you create your SageMaker project. You can view the available templates in Step 1: Create the Project of the Project walkthrough.

Topics

- MLOps template for model building, training, and deployment (p. 2868)
- MLOps template for model building, training, deployment, and Amazon SageMaker Model Monitor (p. 2870)
- MLOps template for image building, model building, and model deployment (p. 2871)
- MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline (p. 2872)
- MLOps template for model building, training, and deployment with third-party Git repositories using Jenkins (p. 2872)
- Update SageMaker Projects to Use Third-Party Git Repositories (p. 2873)

MLOps template for model building, training, and deployment

This template is a combination of the following two templates, each of which can be used independently, and contains all of the resources provided in those templates.

- **Code repository**: AWS CodeCommit
- **CI/CD workflow automation**: AWS CodePipeline

MLOps template for model building and training

Use this template when you want an MLOps solution to process data, extract features, train and test models, and register the models in the SageMaker model registry.

This template provides the following resources:

- An AWS CodeCommit repository that contains sample code that creates an Amazon SageMaker Model Building Pipelines pipeline in Python code and shows how to create and update the
SageMaker pipeline. This repository also has a Python Jupyter Notebook that you can open and run in Studio.

- An AWS CodePipeline pipeline that has source and build steps. The source step points to the CodeCommit repository. The build step gets the code from that repository, creates and updates the SageMaker pipeline, starts a pipeline execution, and waits for the pipeline execution to complete.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.

The following diagram illustrates the workflow and AWS resources used by this template to help you build and train your models.

### MLOps template for model deployment

Use this template to automate the deployment of models in the SageMaker model registry to SageMaker endpoints for real-time inference. This template recognizes changes in the model registry. When a new model version is registered and approved, it automatically initiates a deployment.

The template provisions a CodeCommit repository with configuration files to specify the model deployment steps, AWS CloudFormation templates to define endpoints as infrastructure, and seed code for testing the endpoint.

This template provides the following resources:

- An AWS CodeCommit repository that contains sample code that deploys models to endpoints in staging and production environments.
- An AWS CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the CodeCommit repository, and the build step gets the code from that repository and generates CloudFormation stacks to deploy. The deploy-to-staging and
deploy-to-production steps deploy the CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.

There is also a programmatic approval step with placeholder tests in the example code in the CodeCommit repository. You can add additional tests to replace the placeholders tests.

- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.
- A CloudWatch event to initiate the pipeline when a model package version is approved or rejected.

The following diagram illustrates the workflow and AWS resources used by this template to help you deploy your models.

**MLOps template for model building, training, deployment, and Amazon SageMaker Model Monitor**

This template is an extension of the MLOps template for model building, training, and deployment. It includes both the model building, training, and deployment components of the template, and an additional Amazon SageMaker Model Monitor template that provides the following types of monitoring:

- **Data Quality** – Monitor drift in data quality.
- **Model Quality** – Monitor drift in model quality metrics, such as accuracy.
- **Bias Drift for Models in Production** – Monitor bias in a model's predictions.

- **Code repository**: AWS CodeCommit
- **CI/CD workflow automation**: AWS CodePipeline
MLOps template for Amazon SageMaker Model Monitor

You can use this template for an MLOps solution to deploy one or more of the Amazon SageMaker data quality, model quality, model bias, and model explainability monitors to monitor a deployed model on a SageMaker inference endpoint.

This template provides the following resources:

- An AWS CodeCommit repository that contains sample Python code that gets the baselines used by the monitors from the SageMaker Model Registry, and updates the template's parameters for the staging and production environments. It also contains a AWS CloudFormation template to create the Amazon SageMaker Model Monitors.
- An AWS CodePipeline pipeline that has source, build, and deploy steps. The source step points to the CodePipeline repository. The build step gets the code from that repository, gets the baseline from the Model Registry, and updates template parameters for the staging and production environments. The deploy steps deploy the configured monitors into the staging and production environments. The manual approval step, within the DeployStaging stage, requires you to verify that the production SageMaker endpoint is InService before approving and moving to the DeployProd stage.
- The template uses the same S3 bucket created by the MLOps template for model building, training, and deployment to store the monitors' outputs.
- Two Amazon EventBridge events rules initiate the Amazon SageMaker Model Monitor AWS CodePipeline every time the staging SageMaker endpoint is updated, or a code change is committed to the CodePipeline repository.

MLOps template for image building, model building, and model deployment

This template is an extension of the MLOps template for model building, training, and deployment (p. 2868). It includes both the model building, training, and deployment components of that template and the following options:

- Include processing image–building pipeline
- Include training image–building pipeline
- Include inference image–building pipeline

For each of the components selected during project creation, the following are created by using the template:

- An Amazon ECR repository
- A SageMaker Image
- A CodeCommit repository containing a Dockerfile that you can customize
- A CodePipeline that is initiated by changes to the CodePipeline repository
- A CodeBuild project that builds a Docker image and registers it in the Amazon ECR repository
- An EventBridge rule that initiates the CodePipeline on a schedule

When the CodePipeline is initiated, it builds a new Docker container and registers it with an Amazon ECR repository. When a new container is registered with the Amazon ECR repository, a new ImageVersion is added to the SageMaker image. This initiates the model building pipeline, which in turn initiates the deployment pipeline.

The newly created image is used in the model building, training, and deployment portions of the workflow where applicable.
MLOps template for model building, training, and deployment with third-party Git repositories using CodePipeline

- **Code repository**: Third-party Git. Establish the AWS CodeStar connection from your AWS account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.

- **CI/CD workflow automation**: AWS CodePipeline

This template provides the following resources:

- Associations with one or more customer-specified Git repositories.
- An AWS CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the third-party Git repository and the build step gets the code from that repository and generates CloudFormation stacks to deploy. The deploy-to-staging and deploy-to-production steps deploy the CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.

- An AWS CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your AWS account to your account on the Git repository host.

- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.

MLOps template for model building, training, and deployment with third-party Git repositories using Jenkins

Attach your own Git repository to the project for checking in and managing code versions. Connect the project to Jenkins to orchestrate your model deployment steps. Start the model deployment workflow by approving the model registered in the model registry for deployment either manually or automatically.

- **Code repository**: Third-party Git. Establish the AWS CodeStar connection from your AWS account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.

- **CI/CD workflow automation**: Jenkins

This template provides the following resources:

- Associations with one or more customer-specified Git repositories.
- Seed code to generate Jenkins pipelines that have source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the customer-specified Git repository. The build step gets the code from that repository and generates two CloudFormation stacks. The deploy steps deploy the CloudFormation stacks to their respective environments. There is an approval step between the staging step and the production step.

- An AWS CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your AWS account to your account on the Git repository host.

- An Amazon S3 bucket to store artifacts of the SageMaker project and SageMaker pipeline.
Update SageMaker Projects to Use Third-Party Git Repositories

The managed policy attached to the `AmazonSageMakerServiceCatalogProductsUseRole` role was updated on July 27, 2021 for use with the third-party Git templates. Users who onboard to Amazon SageMaker Studio after this date and enable project templates use the new policy. Users who onboarded prior to this date must update the policy to use these templates. Use one of the following options to update the policy:

- **Delete role and toggle Studio settings**
  1. In the IAM console, delete `AmazonSageMakerServiceCatalogProductsUseRole`.
  2. In the Studio control panel, choose **Edit Settings**.
  3. Toggle both settings and then choose **Submit**.
- **In the IAM console, add the following permissions to `AmazonSageMakerServiceCatalogProductsUseRole`**:

```json
{
    "Effect": "Allow",
    "Action": [
        "codestar-connections:UseConnection"
    ],
    "Resource": "arn:aws:codestar-connections:*:*:connection/*",
    "Condition": {
        "StringEqualsIgnoreCase": {
            "aws:ResourceTag/sagemaker": "true"
        }
    }
}
,
{
    "Effect": "Allow",
    "Action": [
        "s3:PutObjectAcl"
    ],
    "Resource": [
        "arn:aws:s3:::sagemaker-*"
    ]
}
```

Create Custom Project Templates

If the SageMaker-provided templates do not meet your needs (for example, you want to have more complex orchestration in the CodePipeline with multiple stages or custom approval steps), create your own templates.

We recommend starting by using SageMaker-provided templates to understand how to organize your code and resources and build on top of it. To do this, after you enable administrator access to the SageMaker templates, log in to the [https://console.aws.amazon.com/servicecatalog/](https://console.aws.amazon.com/servicecatalog/), choose **Portfolios**, then choose **Imported**. For information about AWS Service Catalog, see [Overview of AWS Service Catalog](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/what-is-servicecatalog.html) in the **AWS Service Catalog User Guide**.

Create your own project templates to customize your MLOps project. SageMaker project templates are AWS Service Catalog-provisioned products to provision the resources for your MLOps project.

To create a custom project template, complete the following steps.

1. **Create a portfolio.** For information, see [Step 3: Create an AWS Service Catalog Portfolio](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/servicecatalog-create-portfolio.html).
2. **Create a product.** A product is a CloudFormation template. You can create multiple versions of the product. For information, see [Step 4: Create an AWS Service Catalog Product](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/servicecatalog-create-product.html).
For the product to work with SageMaker projects, add the following parameters to your product template.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SageMakerProjectName:</td>
<td>String</td>
<td>Name of the project</td>
</tr>
<tr>
<td>SageMakerProjectId:</td>
<td>String</td>
<td>Service generated ID of the project</td>
</tr>
</tbody>
</table>

**Important**

We recommend that you wrap the CodeCommit repository into the SageMaker code repository for the project's repositories to be visible in VPC mode. The sample template and required addition are shown in the following code samples.

Original (sample) template:

```yaml
ModelBuildCodeCommitRepository:
  Type: AWS::CodeCommit::Repository
  Properties:
    RepositoryName: !Sub sagemaker-${SageMakerProjectName}-${SageMakerProjectId}-modelbuild
    RepositoryDescription: !Sub SageMaker Model building workflow infrastructure as code for the Project #{SageMakerProjectName}
    Code:
      S3:
        Bucket: SEEDCODE_BUCKETNAME
        Key: toolchain/model-building-workflow-v1.0.zip
        BranchName: main
```

Additional content to add in VPC mode:

```yaml
SageMakerRepository:
  Type: AWS::SageMaker::CodeRepository
  Properties:
    GitConfig:
      RepositoryUrl: !GetAtt ModelBuildCodeCommitRepository.CloneUrlHttp
      Branch: main
```

3. Add a launch constraint. A launch constraint designates an IAM role that AWS Service Catalog assumes when a user launches a product. For information, see [Step 6: Add a Launch Constraint to Assign an IAM Role](#).

4. Provision the product on [https://console.aws.amazon.com/servicecatalog/](https://console.aws.amazon.com/servicecatalog/) to test the template. If you are satisfied with your template, continue to the next step to make the template available in Studio.

5. Grant access to the AWS Service Catalog portfolio that you created in step 1 to your Studio execution role. Use either the Studio domain execution role or a user role that has Studio access. For information about adding a role to the portfolio, see [Step 7: Grant End Users Access to the Portfolio](#).

6. To make your project template available in your [Organization templates](#) list in Studio, create a tag with the following key and value to the AWS Service Catalog product you created in step 2.

   - **key**: sagemaker:studio-visibility
   - **value**: true
After you complete these steps, Studio users in your organization can create a project with the template you created by following the steps in Create an MLOps Project using Amazon SageMaker Studio (p. 2867) and choosing Organization templates when you choose a template.

View Project Resources

After you create a project, view the resources associated with the project in Amazon SageMaker Studio.

To create a project in Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. Choose Components and registries, and then choose Projects.
3. Double-click the name of the project for which you want to view details.

A tab with the project details appears.

On the product details tab, you can view the following entities associated with the project.

- Repositories: Code repositories (repos) associated with this project. If you use a SageMaker-provided template when you create your project, it creates a AWS CodeCommit repo or a third-party Git repo. For more information about CodeCommit, see What is AWS CodeCommit.
- Pipelines: SageMaker ML pipelines that define steps to prepare data, train, and deploy models. For information about SageMaker ML pipelines, see Create and Manage SageMaker Pipelines (p. 2831).
- Experiments: One or more Amazon SageMaker Autopilot experiments associated with the project. For information about Autopilot, see Automate model development with Amazon SageMaker Autopilot (p. 262).
- Model groups: Groups of model versions that were created by pipeline executions in the project. For information about model groups, see Create a Model Group (p. 2593).
- Endpoints: SageMaker endpoints that host deployed models for real-time inference. When a model version is approved, it is deployed to an endpoint.
- Settings: Settings for the project. This includes the name and description of the project, information about the project template and SourceModelPackageGroupName, and metadata about the project.

Update an MLOps Project in Amazon SageMaker Studio

This procedure demonstrates how to update an MLOps project in Amazon SageMaker Studio. You can update the Description, template version, and template parameters.

Prerequisites

- An AWS SSO or IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 36).
- Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 122).
- Add the following custom inline policies to the specified roles:

User-created role having AmazonSageMakerFullAccess

```json
{
    "Version": "2012-10-17",
    "Statement": [  
```
To update a project in Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. In the Studio sidebar, choose the SageMaker resources icon (🔎).
3. Select Projects from the dropdown list.
   A list of your projects appears.
4. You can open the Project update dialog box in one of the following ways:
   a. You can open it from the projects list.
      Right-click the target project and choose Update from the dropdown list.
   b. You can open it from the project tab.
      i. Double-click the project in the projects list.
      ii. Choose Update from the Actions menu in the upper-right corner of the project tab.
5. In the Update project dialog box, you can edit the Description, template version, and template parameters.
6. Choose Show Diff.

   A dialog box displays your original and updated project settings. Any change in your project settings can modify or delete resources in the current project. The dialog box displays these changes as well.
7. You may need to wait a few minutes for the **Update** button to become active. Choose **Update**.
8. The project update may take a few minutes to complete. Select **Settings** in the project tab and ensure the parameters have been updated correctly.

## Delete an MLOps Project using Amazon SageMaker Studio

This procedure demonstrates how to delete an MLOps project using Amazon SageMaker Studio.

### Prerequisites

**Note**

You can only delete projects in Studio that you have created. This condition is part of the service catalog permission `servicecatalog:TerminateProvisionedProduct` in the `AmazonSageMakerFullAccess` policy. If needed, you can update this policy to remove this condition.

- An AWS SSO or IAM account to sign in to Studio. For information, see [Onboard to Amazon SageMaker Domain](#).
- Basic familiarity with the Studio user interface. For information, see [Amazon SageMaker Studio UI Overview](#).

### To delete a project in Amazon SageMaker Studio

1. Sign in to Studio. For more information, see [Onboard to Amazon SageMaker Domain](#).
2. In the Studio sidebar, choose the **SageMaker resources** icon (🔍).
3. Select **Projects** from the dropdown list.
4. Select the target project from the dropdown list. If you don’t see your project, type the project name and apply the filter to find your project.
5. **You can delete a Studio project in one of the following ways:**
   a. You can delete the project from the projects list.
      
      Right-click the target project and choose **Delete** from the dropdown list.
      
      **Note**
      
      This functionality is supported in Studio version v3.17.1 or higher. For more information, see [Shut down and Update SageMaker Studio](#).
   b. You can delete a project from the Project details section.
      i. Once you've found your project, double-click it to view its details.
      ii. Choose **Delete** from the **Actions** menu.
6. Confirm your choice by choosing **Delete** from the **Delete Project** window.

## SageMaker MLOps Project Walkthrough

This walkthrough demonstrates how to use MLOps projects to create a CI/CD system to build, train, and deploy models.

### Prerequisites

To complete this walkthrough, you need:
• An AWS SSO or IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Domain (p. 36).
• Permission to use SageMaker-provided project templates. For information, see SageMaker Studio Permissions Required to Use Projects (p. 2866).
• Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 122).

Topics
• Step 1: Create the Project (p. 2878)
• Step 2: Clone the Code Repository (p. 2878)
• Step 3: Make a Change in the Code (p. 2879)
• Step 4: Approve the Model (p. 2881)
• (Optional) Step 5: Deploy the Model Version to Production (p. 2881)
• Step 6: Clean Up Resources (p. 2881)

Step 1: Create the Project
In this step, you create a SageMaker MLOps project by using a SageMaker-provided project template to build, train, and deploy models.

To create the SageMaker MLOps project
1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).
2. Choose Components and registries, and then select Projects from the dropdown list.
3. Choose Create project.

   The Create project tab appears.
4. For SageMaker project templates, choose Organization templates, then choose MLOps template for model building, training, and deployment.
5. For Project details, enter a name and description for your project.

When the project appears in the Projects list with a Status of Created, move on to the next step.

Step 2: Clone the Code Repository
After you create the project, two CodeCommit repositories are created in the project. One of the repositories contains code to build and train a model, and one contains code to deploy the model. In this step, you clone the repository to your local SageMaker project that contains the code to build and train the model to the local Studio environment so that you can work with the code.

To clone the code repository
1. Choose Components and registries, and then select Projects from the dropdown list.
2. Find the name of the project you created in the previous step and double-click on it to open the project tab for your project.
3. In the project tab, choose Repositories, and in the Local path column for the repository that ends with modelbuild, choose clone repo....
4. In the dialog box that appears, accept the defaults and choose Clone repository.
When clone of the repository is complete, the local path appears in the **Local path** column. Choose the path to open the local folder that contains the repository code in Studio.

### Step 3: Make a Change in the Code

Now make a change to the pipeline code that builds the model and check in the change to initiate a new pipeline run. The pipeline run registers a new model version.

**To make a code change**

1. In Studio, choose the file browser icon ( ), and navigate to the *pipelines/abalone* folder. Double-click *pipeline.py* to open the code file.
2. In the *pipeline.py* file, find the line that sets the training instance type.

```python
training_instance_type = ParameterString(
    name="TrainingInstanceType", default_value="ml.m5.xlarge"
)
```

Change `ml.m5.xlarge` to `ml.m5.large`, then type **Ctrl+S** to save the change.

3. Choose the **Git** icon ( ). Stage, commit, and push the change in *pipeline.py*. For information about using Git in Studio, see *Clone a Git Repository in SageMaker Studio (p. 170).*
Current Repository
sagemaker-myproject-p-kjwrgqIr05qn-modelbuild

Current Branch
master

Changes

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Description

Changed instance type

Commit
After pushing your code change, the MLOps system initiates a run of the pipeline that creates a new model version. In the next step, you approve the new model version to deploy it to production.

**Step 4: Approve the Model**

Now you approve the new model version that was created in the previous step to initiate a deployment of the model version to a SageMaker endpoint.

**To approve the model version**

1. Choose **Components and registries**, and then select **Projects** from the dropdown list.
2. Find the name of the project you created in the first step and double-click on it to open the project tab for your project.
3. In the project tab, choose **Model groups**, then double-click the name of the model group that appears.

   The model group tab appears.
4. In the model group tab, double-click **Version 2**. The **Version 2** tab opens. Choose **Update status**
5. In the model **Update model version status** dialog box, in the **Status** dropdown list, select **Approve**, then choose **Update status**.

   Approving the model version causes the MLOps system to deploy the model to staging. To view the endpoint, choose the **Endpoints** tab on the project tab.

(Optional) **Step 5: Deploy the Model Version to Production**

Now you can deploy the model version to the production environment.

**Note**
To complete this step, you need to be an administrator in your Studio domain. If you are not an administrator, skip this step.

**To deploy the model version to the production environment**

1. Log in to the CodePipeline console at https://console.aws.amazon.com/codepipeline/
2. Choose **Pipelines**, then choose the pipeline with the name `sagemaker-projectname-projectid-modeldeploy`, where `projectname` is the name of your project, and `projectid` is the ID of your project.
3. In the **DeployStaging** stage, choose **Review**.
4. In the **Review** dialog box, choose **Approve**.

   Approving the **DeployStaging** stage causes the MLOps system to deploy the model to production. To view the endpoint, choose the **Endpoints** tab on the project tab in Studio.

**Step 6: Clean Up Resources**

To stop incurring charges, clean up the resources that were created in this walkthrough. To do this, complete the following steps.

**Note**
To delete the AWS CloudFormation stack and the Amazon S3 bucket, you need to be an administrator in Studio. If you are not an administrator, ask your administrator to complete those steps.
1. In the Studio sidebar, choose the SageMaker resources icon (🔍).

2. Choose Projects from the dropdown list.

3. Select the target project from the dropdown list. If you don't see your project, type the project name and apply the filter to find your project.

4. **You can delete a Studio project in one of the following ways:**
   
a. **You can delete the project from the projects list.**
      
      Right-click the target project and choose **Delete** from the dropdown list.
      
      **Note**
      
      This functionality is supported in Studio version v3.17.1 or higher. For more information, see Shut down and Update SageMaker Studio (p. 173).

   b. **You can delete a project from the Project details section.**
      
      i. When you've found your project, double-click it to view its details in the main panel.
      
      ii. Choose **Delete** from the **Actions** menu.

5. Confirm your choice by choosing **Delete** from the **Delete Project** window.

   This deletes the AWS Service Catalog provisioned product that the project created. This includes the CodeCommit, CodePipeline, and CodeBuild resources created for the project.

6. Delete the AWS CloudFormation stacks that the project created. There are two stacks, one for staging and one for production. The names of the stacks are `sagemaker-projectname-project-id-deploy-staging` and `sagemaker-projectname-project-id-deploy-prod`, where `projectname` is the name of your project, and `project-id` is the ID of your project.

   For information about how to delete a AWS CloudFormation stack, see Deleting a stack on the AWS CloudFormation console in the AWS CloudFormation User Guide.

7. Delete the Amazon S3 bucket that the project created. The name of the bucket is `sagemaker-project-project-id`, where `project-id` is the ID of your project.

---

**Amazon SageMaker ML Lineage Tracking**

Amazon SageMaker ML Lineage Tracking creates and stores information about the steps of a machine learning (ML) workflow from data preparation to model deployment. With the tracking information, you can reproduce the workflow steps, track model and dataset lineage, and establish model governance and audit standards.

With SageMaker Lineage Tracking data scientists and model builders can do the following:

- Keep a running history of model discovery experiments.
- Establish model governance by tracking model lineage artifacts for auditing and compliance verification.

**Topics**

- Lineage Tracking Entities (p. 2883)
- Amazon SageMaker–Created Tracking Entities (p. 2885)
- Manually Create Tracking Entities (p. 2887)
- Querying Lineage Entities (p. 2890)
- Cross-Account Lineage Tracking (p. 2896)
The following diagram shows an example lineage graph that Amazon SageMaker automatically creates in an end-to-end model training and deployment ML workflow.

**Lineage Tracking Entities**

Tracking entities maintain a representation of all the elements of your end-to-end machine learning workflow. You can use this representation to establish model governance, reproduce your workflow, and maintain a record of your work history.

Amazon SageMaker automatically creates tracking entities for trial components and their associated trials and experiments when you create SageMaker jobs such as processing jobs, training jobs, and batch transform jobs. In addition to auto tracking, you can also Manually Create Tracking Entities (p. 2887) to model custom steps in your workflow. For more information, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1991).

SageMaker also automatically creates tracking entities for the other steps in a workflow so you can track the workflow from end to end. For more information, see Amazon SageMaker–Created Tracking Entities (p. 2885).

You can create additional entities to supplement those created by SageMaker. For more information, see Manually Create Tracking Entities (p. 2887).

SageMaker reuses any existing entities rather than creating new ones. For example, there can be only one artifact with a unique `SourceUri`.
Key concepts for querying lineage

- **Lineage** – Metadata that tracks the relationships between various entities in your ML workflows.
- **QueryLineage** – The action to inspect your lineage and discover relationships between entities.
- **Lineage entities** – The metadata elements of which your lineage is composed.
- **Cross-account lineage** – Your ML workflow may span more than one account. With cross-account lineage, you can configure multiple accounts to automatically create lineage associations between shared entity resources. QueryLineage then can return entities even from these shared accounts.

The following tracking entities are defined:

**Experiment entities**

- **Trial component** – A stage of a machine learning trial. Includes processing jobs, training jobs, and batch transform jobs.
- **Trial** – A combination of trial components that generally produces a model.
- **Experiment** – A grouping of trials generally focused on solving a specific use case.

**Lineage entities**

- **Trial Component** – Represents processing, training, and transform jobs in the lineage. Also part of experiment management.
- **Context** – Provides a logical grouping of other tracking or experiment entities. Conceptually, experiments and trials are contexts. Some examples are an endpoint and a model package.
- **Action** – Represents an action or activity. Generally, an action involves at least one input artifact or output artifact. Some examples are a workflow step and a model deployment.
- **Artifact** – Represents a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action. Some examples include a dataset (S3 bucket URI), or an image (Amazon ECR registry path).
- **Association** – Links other tracking or experiment entities, such as an association between the location of training data and a training job.

An association has an optional `AssociationType` property. The following values are available along with the suggested use for each type. SageMaker places no restrictions on their use:

- **ContributedTo** – The source contributed to the destination or had a part in enabling the destination. For example, the training data contributed to the training job.
- **AssociatedWith** – The source is connected to the destination. For example, an approval workflow is associated with a model deployment.
- **DerivedFrom** – The destination is a modification of the source. For example, a digest output of a channel input for a processing job is derived from the original inputs.
- **Produced** – The source generated the destination. For example, a training job produced a model artifact.
- **SameAs** – When the same lineage entity used in different accounts.

**Common properties**

- **Type property**

  The action, artifact, and context entities have a `type` property, `ActionType`, `ArtifactType`, and `ContextType`, respectively. This property is a custom string which can associate meaningful information with the entity and be used as a filter in the List APIs.

- **Source property**
The action, artifact, and context entities have a Source property. This property provides the underlying URI that the entity represents. Some examples are:

- An UpdateEndpoint action where the source is the EndpointArn.
- An image artifact for a processing job where the source is the ImageUri.
- An Endpoint context where the source is the EndpointArn.

**Metadata property**

The action and artifact entities have an optional Metadata property which can provide the following information:

- ProjectId – For example, the ID of the SageMaker MLOps project to which a model belongs.
- GeneratedBy – For example, the SageMaker pipeline execution that registered a model package version.
- Repository – For example, the repository that contains an algorithm.
- CommitId – For example, the commit ID of an algorithm version.

### Amazon SageMaker–Created Tracking Entities

Amazon SageMaker automatically creates tracking entities for SageMaker jobs, models, model packages, and endpoints if the data is available. There is no limit to the number of lineage entities created by SageMaker.

For information on how you can manually create tracking entities, see [Manually Create Tracking Entities](#). 

**Topics**

- Tracking Entities for SageMaker Jobs (p. 2885)
- Tracking Entities for Model Packages (p. 2886)
- Tracking Entities for Endpoints (p. 2886)

### Tracking Entities for SageMaker Jobs

SageMaker creates a trial component for and associated with each SageMaker job. SageMaker creates artifacts to track the job metadata and associations between each artifact and the job.

Artifacts are created for the following job properties and associated with the Amazon Resource Name (ARN) of the SageMaker job. The artifact SourceUri is listed in parentheses.

**Training Job**

- The image that contains the training algorithm (TrainingImage).
- The data source of each input channel (S3Uri).
- The location for the model (S3OutputPath).
- The location for the managed spot checkpoint data (S3Uri).

**Processing Job**

- The container to be run by the processing job (ImageUri).
- The data location for each processing input and processing output (S3Uri).
Transform Job

- The input data source to be transformed (S3Uri).
- The results of the transform (S3OutputPath).

Note
Amazon Simple Storage Service (Amazon S3) artifacts are tracked based on the Amazon S3 URI values provided to the Create API, for example `CreateTrainingJob`, and not on the Amazon S3 key and hash or etag values from each file.

Tracking Entities for Model Packages

The following entities are created:

Model Packages

- A context for each model package group.
- An artifact for each model package.
- An association between each model package artifact and the context for each model package group to which the package belongs to.
- An action for the creation of a model package version.
- An association between the model package artifact and the creation action.
- An association between the model package artifact and each model package group context to which the package belongs to.
- Inference containers
  - An artifact for the image used in each container defined in the model package.
  - An artifact for the model used in each container.
  - An association between each artifact and the model package artifact.
- Algorithms
  - An artifact for each algorithm defined in the model package.
  - An artifact for the model created by each algorithm.
  - An association between each artifact and the model package artifact.

Tracking Entities for Endpoints

The following entities are created by Amazon SageMaker:

Endpoints

- A context for each endpoint
- An action for the model deployment that created each endpoint
- An artifact for each model deployed to the endpoint
- An artifact for the image used in the model
- An artifact for the model package for the model
- An artifact for each image deployed to the endpoint
- An association between each artifact and the model deployment action
Manually Create Tracking Entities

You can manually create tracking entities for any property. For information on the tracking entities that Amazon SageMaker automatically creates, see Amazon SageMaker–Created Tracking Entities (p. 2885).

You can add tags to all entities except associations. Tags are arbitrary key-value pairs that provide custom information. You can filter or sort a list or search query by tags. For more information, see Tagging AWS resources in the AWS General Reference.

For a sample notebook that demonstrates how to create lineage entities, see the Amazon SageMaker Lineage notebook in the Amazon SageMaker example GitHub repository.

Topics

- Manually Create Entities (p. 2887)
- Manually Track a Workflow (p. 2888)
- Limits (p. 2889)

Manually Create Entities

The following procedure shows you how to create and associate artifacts between a SageMaker training job and endpoint. You perform the following steps:

Import tracking entities and associations

1. Import the lineage tracking entities.

   ```python
   import sys
   !(sys.executable) -m pip install -q sagemaker
   from sagemaker import get_execution_role
   from sagemaker.session import Session
   from sagemaker.lineage import context, artifact, association, action
   import boto3
   boto_session = boto3.Session(region_name=region)
   sagemaker_client = boto_session.client("sagemaker")
   ```

2. Create the input and output artifacts.

   ```python
   code_location_arn = artifact.Artifact.create(
       artifact_name='source-code-location',
       source_uri='s3://...',
       artifact_type='code-location'
   ).artifact_arn

   model_location_arn = artifact.Artifact.create(
       artifact_name='model-location',
       source_uri='s3://...',
       artifact_type='model-location'
   ).artifact_arn
   
   # Similar constructs for train_data_location_arn and test_data_location_arn
   ```

3. Train the model and get the trial_component_arn that represents the training job.

4. Associate the input artifacts and output artifacts with the training job (trial component).

   ```python
   input_artifacts = [code_location_arn, train_data_location_arn, test_data_location_arn]
   for artifact_arn in input_artifacts:
   ```
```python
try:
    association.Association.create(
        source_arn=artifact_arn,
        destination_arn=trial_component_arn,
        association_type='ContributedTo'
    )
except:
    logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)

output_artifacts = [model_location_arn]
for artifact_arn in output_artifacts:
    try:
        association.Association.create(
            source_arn=trial_component_arn,
            destination_arn=artifact_arn,
            association_type='Produced'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)

5. Create the inference endpoint.

```python
predictor = mnist_estimator.deploy(initial_instance_count=1,
instance_type='ml.m4.xlarge')
```

6. Create the endpoint context.

```python
from sagemaker.lineage import context

endpoint = sagemaker_client.describe_endpoint(EndpointName=predictor.endpoint_name)
endpoint_arn = endpoint['EndpointArn']

endpoint_context_arn = context.Context.create(
    context_name=predictor.endpoint_name,
    context_type='Endpoint',
    source_uri=endpoint_arn
).context_arn
```

7. Associate the training job (trial component) and endpoint context.

```python
association.Association.create(
    source_arn=trial_component_arn,
    destination_arn=endpoint_context_arn
)
```

**Manually Track a Workflow**

You can manually track the workflow created in the previous section.

Given the endpoint Amazon Resource Name (ARN) from the previous example, the following procedure shows you how to track the workflow back to the datasets used to train the model that was deployed to the endpoint. You perform the following steps:

**To track a workflow from endpoint to training data source**

1. Import the tracking entities.

```python
import sys
```
Manually Create Entities

```python
!{sys.executable} -m pip install -q sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.lineage import context, artifact, association, action
import boto3
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client("sagemaker")

2. Get the endpoint context from the endpoint ARN.

    endpoint_context_arn = sagemaker_client.list_contexts(
        SourceUri=endpoint_arn)['ContextSummaries'][0]['ContextArn']

3. Get the trial component from the association between the trial component and the endpoint context.

    trial_component_arn = sagemaker_client.list_associations(
        DestinationArn=endpoint_context_arn)['AssociationSummaries'][0]['SourceArn']

4. Get the training data location artifact from the association between the trial component and the endpoint context.

    train_data_location_artifact_arn = sagemaker_client.list_associations(
        DestinationArn=trial_component_arn, SourceType='Model')['AssociationSummaries'][0]
        ['SourceArn']

5. Get the training data location from the training data location artifact.

    train_data_location = sagemaker_client.describe_artifact(
        ArtifactArn=train_data_location_artifact_arn)['Source']['SourceUri']
    print(train_data_location)

Response:

    s3://sagemaker-sample-data-us-east-2/mxnet/mnist/train

Limits

You can create an association between any entities, experiment and lineage, except the following:

- You cannot create an association between two experiment entities. Experiment entities consist of experiments, trials, and trial components.
- You can create an association with another association.

An error occurs if you try to create an entity that already exists.

Maximum number of manually created lineage entities

- Actions: 3000
- Artifacts: 6000
- Associations: 6000
- Contexts: 500
Querying Lineage Entities

Amazon SageMaker automatically generates graphs of lineage entities as you use them. You can query this data to answer a variety of questions. For example, you can query your lineage entities to:

- Retrieve all data sets that went into the creation of a model.
- Retrieve all jobs that went into the creation of an endpoint.
- Retrieve all models that use a data set.
- Retrieve all endpoints that use a model.
- Retrieve which endpoints are derived from a certain data set.
- Retrieve the pipeline execution that created a training job.
- Retrieve the relationships between entities for investigation, governance, and reproducibility.
- Explore your lineage for visualization.

Topics
- Getting Started with Querying Lineage Entities (p. 2890)

Limitations

- Lineage querying is not available in the following Regions:
  - Asia Pacific (Osaka) – ap-northeast-3
  - Europe (Milan) – eu-south-1
  - Africa (Cape Town) – af-south
- The maximum depth of relationships to discover is currently limited to 10.
- Filtering is limited to the following properties: last modified date, created date, type, and lineage entity type.

Getting Started with Querying Lineage Entities

The easiest way to get started is either via the:

- Amazon SageMaker SDK for Python which has defined many common use cases.
- For a notebook that demonstrates how to use SageMaker Lineage APIs to query relationships across the lineage graph, see sagemaker-lineage-multihop-queries.ipynb.

The following examples show how to use the LineageQuery and LineageFilter APIs to construct queries to answer questions about the Lineage Graph and extract entity relationships for a few use cases.

Example Using the LineageQuery API to find entity associations

```python
from sagemaker.lineage.context import Context, EndpointContext
from sagemaker.lineage.action import Action
from sagemaker.lineage.association import Association
from sagemaker.lineage.artifact import Artifact, ModelArtifact, DatasetArtifact
from sagemaker.lineage.query import (LineageQuery,
```
# Find the endpoint context and model artifact that should be used for the lineage queries.

```python
contexts = Context.list(source_uri=endpoint_arn)
context_name = list(contexts)[0].context_name
endpoint_context = EndpointContext.load(context_name=context_name)
```

Example Find all the datasets associated with an endpoint

```python
# Define the LineageFilter to look for entities of type `ARTIFACT` and the source of type `DATASET`.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.DATASET]
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that traverses through the given context `endpoint_context` and find all datasets.

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the lineage objects corresponding to the datasets

dataset_artifacts = []
for vertex in query_result.vertices:
    dataset_artifacts.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(dataset_artifacts)
```

Example Find the models associated with an endpoint

```python
# Define the LineageFilter to look for entities of type `ARTIFACT` and the source of type `MODEL`.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.MODEL]
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that traverses through the given context `endpoint_context` and find all datasets.

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the lineage objects corresponding to the model

model_artifacts = []
for vertex in query_result.vertices:
    model_artifacts.append(vertex.to_lineage_object().source.source_uri)
```
Example Find the trial components associated with the endpoint

```python
# Define the LineageFilter to look for entities of type `TRIAL_COMPONENT` and the source of type `TRAINING_JOB`.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.TRIAL_COMPONENT],
    sources=[LineageSourceEnum.TRAINING_JOB],
)
# Providing this `LineageFilter` to the `LineageQuery` constructs a query that traverses through the given context `endpoint_context` and find all datasets.
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)
# Parse through the query results to get the ARNs of the training jobs associated with this Endpoint
trial_components = []
for vertex in query_result.vertices:
    trial_components.append(vertex.arn)
pp.pprint(trial_components)
```

Example Changing the focal point of lineage

The `LineageQuery` can be modified to have different `start_arns` which changes the focal point of lineage. In addition, the `LineageFilter` can take multiple sources and entities to expand the scope of the query.

In the following we use the model as the lineage focal point and find the endpoints and datasets associated with it.

```python
# Get the ModelArtifact
model_artifact_summary = list(Artifact.list(source_uri=model_package_arn))[0]
model_artifact = ModelArtifact.load(artifact_arn=model_artifact_summary.artifact_arn)
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)
query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that descend from the model, i.e. the endpoint
    direction=LineageQueryDirectionEnum.DESCENDANTS,
    include_edges=False,
)
associations = []
```
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that ascend from the model, i.e. the datasets
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(associations)

Example Using LineageQueryDirectionEnum.BOTH to find ascendent and descendent relationships

When the direction is set to BOTH, the query traverses the graph to find ascendant and descendant relationships. This traversal takes place not only from the starting node, but from each node that is visited. For example; if a training job is run twice and both models generated by the training job are deployed to endpoints, the result of the query with direction set to BOTH shows both endpoints. This is because the same image is used for training and deploying the model. Since the image is common to the model, the start_arn and both the endpoints, appear in the query result.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # This specifies that the query should look for associations both ascending and
    descending for the start
    direction=LineageQueryDirectionEnum.BOTH,
    include_edges=False,
)

associations = []
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(associations)

Example Directions in LineageQuery - ASCENDANTS vs. DESCENDANTS

To understand the direction in the Lineage Graph, take the following entity relationship graph - Dataset -> Training Job -> Model -> Endpoint

The endpoint is a descendant of the model, and the model is a descendant of the dataset. Similarly, the model is an ascendant of the endpoint. The direction parameter can be used to specify whether the query should return entities that are descendants or ascendants of the entity in start_arns. If the start_arns contains a model and the direction is DESCENDANTS, the query returns the endpoint. If the direction is ASCENDANTS, the query returns the dataset.

# In this example, we'll look at the impact of specifying the direction as ASCENDANT or
# DESCENDANT in a `LineageQuery`.
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[
        LineageSourceEnum.ENDPOINT,
        LineageSourceEnum.MODEL,
        LineageSourceEnum.DATASET,
        LineageSourceEnum.TRAINING_JOB,
    ],
)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

ascendant_artifacts = []

# The lineage entity returned for the Training Job is a TrialComponent which can't be
# converted to a
# lineage object using the method `to_lineage_object()` so we extract the TrialComponent
# ARN.
for vertex in query_result.vertices:
    try:
        ascendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        ascendant_artifacts.append(vertex.arn)

print("Ascendant artifacts : ")
pp.pprint(ascendant_artifacts)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.DESCENDANTS,
    include_edges=False,
)

descendant_artifacts = []

for vertex in query_result.vertices:
    try:
        descendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        # Handling TrialComponents.
        descendant_artifacts.append(vertex.arn)

print("Descendant artifacts : ")
pp.pprint(descendant_artifacts)

Example SDK helper functions to make lineage queries easier

The classes EndpointContext, ModelArtifact, and DatasetArtifact have helper functions
that are wrappers over the LineageQuery API to make certain lineage queries easier to leverage. The
following example shows how to use these helper function.

# Find all the datasets associated with this endpoint
datastes = []
dataset_artifacts = endpoint_context.dataset_artifacts()
for dataset in dataset_artifacts:
    datasets.append(dataset.source.source_uri)
print("Datasets : ", datasets)
# Find the training jobs associated with the endpoint
training_job_artifacts = endpoint_context.training_job_arns()
training_jobs = []
for training_job in training_job_artifacts:
    training_jobs.append(training_job)
print("Training Jobs : ", training_jobs)

# Get the ARN for the pipeline execution associated with this endpoint (if any)
pipeline_executions = endpoint_context.pipeline_execution_arn()
if pipeline_executions:
    for pipeline in pipeline_executions:
        print(pipeline)

# Here we use the `ModelArtifact` class to find all the datasets and endpoints associated
# with the model

dataset_artifacts = model_artifact.dataset_artifacts()
endpoint_contexts = model_artifact.endpoint_contexts()

datasets = [dataset.source.source_uri for dataset in dataset_artifacts]
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]

print("Datasets associated with this model : ")
pp.pprint(datasets)
print("Endpoints associated with this model : ")
pp.pprint(endpoints)

# Here we use the `DatasetArtifact` class to find all the endpoints hosting models that
# were trained with a particular dataset
# Find the artifact associated with the dataset

dataset_artifact_arn = list(Artifact.list(source_uri=training_data))[0].artifact_arn
dataset_artifact = DatasetArtifact.load(artifact_arn=dataset_artifact_arn)

# Find the endpoints that used this training dataset
endpoint_contexts = dataset_artifact.endpoint_contexts()
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]

print("Endpoints associated with the training dataset {}: ").format(training_data)
pp.pprint(endpoints)

### Example Getting a Lineage graph visualization

A helper class `Visualizer` is provided in the sample notebook `visualizer.py` to help plot the lineage
graph. When the query response is rendered, a graph with the lineage relationships from the StartArns
is displayed. From the StartArns the visualization shows the relationships with the other lineage
entities returned in the query_lineage API action.

```python
# Graph APIs
# Here we use the boto3 `query_lineage` API to generate the query response to plot.
from visualizer import Visualizer

query_response = sm_client.query_lineage(
    StartArns=[endpoint_context.context_arn], Direction="Ascendants", IncludeEdges=True
)

viz = Visualizer()
viz.render(query_response, "Endpoint")
```

```python
query_response = sm_client.query_lineage(
    StartArns=[model_artifact.artifact_arn], Direction="Ascendants", IncludeEdges=True
)
```
Cross-Account Lineage Tracking

Amazon SageMaker supports tracking lineage entities from a different AWS account. Other AWS accounts can share their lineage entities with you and you can access these lineage entities through direct API calls or SageMaker lineage queries.

SageMaker uses AWS Resource Access Manager to help you securely share your lineage resources. You can share your resources through the AWS RAM console.

Set Up Cross-Account Lineage Tracking

You can group and share your

Tracking entities maintain a representation of all the elements of your end-to-end machine learning workflow. You can use this representation to establish model governance, reproduce your workflow, and maintain a record of your work history.

Amazon SageMaker automatically creates tracking entities for trial components and their associated trials and experiments when you create SageMaker jobs such as processing jobs, training jobs, and batch transform jobs. In additional to auto tracking, you can also Manually Create Tracking Entities (p. 2887) to model custom steps in your workflow. For more information, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1991).

SageMaker also automatically creates tracking entities for the other steps in a workflow so you can track the workflow from end to end. For more information, see Amazon SageMaker–Created Tracking Entities (p. 2885).

You can create additional entities to supplement those created by SageMaker. For more information, see Manually Create Tracking Entities (p. 2887).

SageMaker reuses any existing entities rather than creating new ones. For example, there can be only one artifact with a unique SourceUri.

Key concepts for querying lineage

- **Lineage** – Metadata that tracks the relationships between various entities in your ML workflows.

- **QueryLineage** – The action to inspect your lineage and discover relationships between entities.

- **Lineage entities** – The metadata elements of which your lineage is composed.

- **Cross-account lineage** – Your ML workflow may span more than one account. With cross-account lineage, you can configure multiple accounts to automatically create lineage associations between shared entity resources. QueryLineage then can return entities even from these shared accounts.

The following tracking entities are defined:

**Experiment entities**

- Trial component – A stage of a machine learning trial. Includes processing jobs, training jobs, and batch transform jobs.
• Trial – A combination of trial components that generally produces a model.

• Experiment – A grouping of trials generally focused on solving a specific use case.

Lineage entities

• Trial Component – Represents processing, training, and transform jobs in the lineage. Also part of experiment management.

• Context – Provides a logical grouping of other tracking or experiment entities. Conceptually, experiments and trials are contexts. Some examples are an endpoint and a model package.

• Action – Represents an action or activity. Generally, an action involves at least one input artifact or output artifact. Some examples are a workflow step and a model deployment.

• Artifact – Represents a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action. Some examples include a dataset (S3 bucket URI), or an image (Amazon ECR registry path).

• Association – Links other tracking or experiment entities, such as an association between the location of training data and a training job. An association has an optional AssociationType property. The following values are available along with the suggested use for each type. SageMaker places no restrictions on their use:
  • ContributedTo – The source contributed to the destination or had a part in enabling the destination. For example, the training data contributed to the training job.
  • AssociatedWith – The source is connected to the destination. For example, an approval workflow is associated with a model deployment.
  • DerivedFrom – The destination is a modification of the source. For example, a digest output of a channel input for a processing job is derived from the original inputs.
  • Produced – The source generated the destination. For example, a training job produced a model artifact.
  • SameAs – When the same lineage entity used in different accounts.

Common properties

• Type property
The action, artifact, and context entities have a type property, ActionType, ArtifactType, and ContextType, respectively. This property is a custom string which can associate meaningful information with the entity and be used as a filter in the List APIs.

• Source property
The action, artifact, and context entities have a Source property. This property provides the underlying URI that the entity represents. Some examples are:
  • An UpdateEndpoint action where the source is the EndpointArn.
  • An image artifact for a processing job where the source is the ImageUri.
  • An Endpoint context where the source is the EndpointArn.

• Metadata property
The action and artifact entities have an optional Metadata property which can provide the following information:
  • ProjectId – For example, the ID of the SageMaker MLOps project to which a model belongs.
GeneratedBy – For example, the SageMaker pipeline execution that registered a model package version.

Repository – For example, the repository that contains an algorithm.

CommitId – For example, the commit ID of an algorithm version.

(p. 2883) through a lineage group in Amazon SageMaker. SageMaker supports only one default lineage group per account. SageMaker creates the default lineage group whenever a lineage entity is created in your account. Every lineage entity owned by your account is assigned to this default lineage group. To share lineage entities with another account, you share this default lineage group with that account.

Note
You can share all lineage tracking entities in a lineage group or none.

Create a resource share for your lineage entities using AWS Resource Access Manager console. For more information, see Sharing your AWS resources in the AWS Resource Access Manager User Guide.

Note
After the resource share is created, it can take a few minutes for the resource and principal associations to complete. Once the association is set, the shared account receives an invitation to join the resource share. The shared account must accept the invite to gain access to shared resources. For more information on accepting a resource share invite in AWS RAM, see Using shared AWS resources in the AWS Resource Access Manager User Guide.

Your cross-account lineage tracking resource policy

Amazon SageMaker supports only one type of resource policy. The SageMaker resource policy must allow all of the following operations:

```
"sagemaker:DescribeAction"
"sagemaker:DescribeArtifact"
"sagemaker:DescribeContext"
"sagemaker:DescribeTrialComponent"
"sagemaker:AddAssociation"
"sagemaker:DeleteAssociation"
"sagemaker:QueryLineage"
```

Example The following is a SageMaker resource policy created using AWS Resource Access Manager for creating a resource share for an accounts lineage group.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "FullLineageAccess",
      "Effect": "Allow",
      "Principal": {
        "AWS": "123456789012" #account-id
      },
      "Action": [
        "sagemaker:DescribeAction",
        "sagemaker:DescribeArtifact",
        "sagemaker:DescribeContext",
        "sagemaker:DescribeTrialComponent",
        "sagemaker:AddAssociation",
        "sagemaker:DeleteAssociation",
        "sagemaker:QueryLineage"
      ]
    }
  ]
}
```
Tracking Cross-Account Lineage Entities

With cross-account lineage tracking you can associate lineage entities in different accounts using the same `AddAssociation` API action. When you associate two lineage entities, SageMaker validates if you have permissions to perform the `AddAssociation` API action on both lineage entities. SageMaker then establishes the association. If you don't have the permissions, SageMaker does not create the association.

Once the cross-account association is established, you can access either lineage entity from the other through the `QueryLineage` API action. For more information, see Querying Lineage Entities (p. 2890).

In addition to SageMaker automatically creating lineage entities, if you have cross-account access, SageMaker connects artifacts that reference the same object or data. If the data from one account is used in lineage tracking by different accounts, SageMaker creates an artifact in each account to track that data. With cross-account lineage, whenever SageMaker creates new artifacts, SageMaker checks if there are other artifacts created for the same data that are also shared with you. SageMaker then establishes associations between the newly created artifact and each of the artifacts shared with you with the `AssociationType` set to `SameAs`. You can then use the `QueryLineage` API action to traverse the lineage entities in your own account to lineage entities shared with you but owned by a different AWS account. For more information, see Querying Lineage Entities (p. 2890).

Topics

- Accessing lineage resources from a different accounts (p. 2899)
- Authorization for querying cross-account lineage entities (p. 2899)

Accessing lineage resources from a different accounts

Once the cross-account access for sharing lineage has been set up, you can call the following SageMaker API actions directly with the ARN to describe the shared lineage entities from another account:

- `DescribeAction`
- `DescribeArtifact`
- `DescribeContext`
- `DescribeTrialComponent`

You can also manage `Associations` for lineage entities owned by different accounts that are shared with you, using the following SageMaker API actions:

- `AddAssociation`
- `DeleteAssociation`

For a notebook that demonstrates how to use SageMaker Lineage APIs to query lineage across accounts, see `sagemaker-lineage-cross-account-with-ram.ipynb`.

Authorization for querying cross-account lineage entities

Amazon SageMaker must validate that you have permissions to perform the `QueryLineage` API action on the `StartArns`. This is enforced through the resource policy attached to the `LineageGroup`. The result from this action includes all the lineage entities to which you have access, whether they are...
owned by your account or shared by another account. For more information, see Querying Lineage Entities (p. 2890).

Kubernetes Orchestration

You can orchestrate your SageMaker training and inference jobs with SageMaker Operators for Kubernetes and SageMaker Components for Kubeflow Pipelines. SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. SageMaker Components for Kubeflow Pipelines allow you to move your data processing and training jobs from the Kubernetes cluster to SageMaker’s machine learning-optimized managed service.

Contents
- SageMaker Operators for Kubernetes (p. 2900)
- SageMaker Components for Kubeflow Pipelines (p. 2939)

SageMaker Operators for Kubernetes

SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. You can install these SageMaker Operators on your Kubernetes cluster in Amazon Elastic Kubernetes Service (Amazon EKS) to create SageMaker jobs natively using the Kubernetes API and command-line Kubernetes tools such as kubectl. This guide shows you how to set up the operators. The guide also explains how to use the operators to run model training, hyperparameter tuning, and inference (real-time and batch).

There is no additional charge to use these operators. You do incur charges for any SageMaker resources that you use through these operators. The procedures and guidelines here assume you are familiar with Kubernetes and its basic commands.

- Images and SMlogs in each Region (p. 2913)
- Using Amazon SageMaker Jobs (p. 2914)

What is an operator?

Kubernetes is built on top of what is called the controller pattern. This pattern allows applications and tools to listen to a central state manager (ETCD) and act when something happens. Examples of such applications include cloud-controller-manager and controller-manager. The controller pattern allows you to create decoupled experiences and not have to worry about how other components are integrated. To add new capabilities to Kubernetes, developers can extend the Kubernetes API by creating a custom resource that contains their application-specific or domain-specific logic and components. Operators in Kubernetes allow users to natively invoke these custom resources and automate associated workflows.

Prerequisites

This guide assumes that you’ve completed the following prerequisites:
• Installed the following tools on the client machine used to access your Kubernetes cluster:
  • `kubectl` Version 1.13 or later. Use a `kubectl` version that is within one minor version of your Amazon EKS cluster control plane. For example, a 1.13 `kubectl` client works with Kubernetes 1.13 and 1.14 clusters. OpenID Connect (OIDC) is not supported in versions earlier than 1.13.
  • `eksctl` Version 0.7.0 or later
  • `AWS CLI` Version 1.16.232 or later
  • (optional) `Helm` Version 3.0 or later
  • `aws-iam-authenticator`
  • Have IAM permissions to create roles and attach policies to roles.
  • Created a Kubernetes cluster on which to run the operators. It should either be Kubernetes version 1.13 or 1.14. For automated cluster creation using `eksctl`, see Getting Started with `eksctl`. It takes 20 to 30 minutes to provision a cluster.

Permissions overview

The SageMaker Operators for Kubernetes allow you to manage jobs in SageMaker from your Kubernetes cluster. The operators access SageMaker resources on your behalf. The IAM role that the operator assumes to interact with AWS resources differs from the credentials you use to access the Kubernetes cluster. The role also differs from the role that SageMaker assumes when running your machine learning jobs. The following image explains this design and flow.
IAM role-based setup and operator deployment

The following sections describe the steps to set up and deploy the operator.
Cluster-scoped deployment

Before you can deploy your operator using an IAM role, associate an OpenID Connect (OIDC) provider with your role to authenticate with the IAM service.

Create an OpenID Connect Provider for Your Cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local CLUSTER_NAME and AWS_REGION environment variables as follows:

```
# Set the Region and cluster
export CLUSTER_NAME="<your cluster name>"
export AWS_REGION="<your region>"
```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
--region ${AWS_REGION} --approve
```

Your output should look like the following:

```
[...]
 eksctl version 0.10.1
[...]
 using region us-east-1
[...]
 IAM OpenID Connect provider is associated with cluster "my-cluster" in "us-east-1"
```

Now that the cluster has an OIDC identity provider, you can create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get the OIDC ID

To set up the ServiceAccount, obtain the OpenID Connect issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
 --query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```

In this URL, the value D48675832CA65BD10A532F5970IDCID is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:

```
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME} --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```
Create an IAM Role

1. Create a file named `trust.json` and insert the following trust relationship code block into it. Be sure to replace all `<OIDC ID>`, `<AWS account number>`, and `<EKS Cluster region>` placeholders with values corresponding to your cluster.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Federated": "arn:aws:iam::<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
         },
         "Action": "sts:AssumeRoleWithWebIdentity",
         "Condition": {
           "StringEquals": {
             "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud": "sts.amazonaws.com",
           }
         }
       }
     ]
   }
   ```

2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role enables the Amazon EKS cluster to get and refresh credentials from IAM.

```
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ABCDEFGHIJKLMNOPQRSTUVWXYZEXAMPLE   my-role
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN; you pass this value to your operator.

Attach the AmazonSageMakerFullAccess Policy to the Role

To give the role access to SageMaker, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach AmazonSageMakerFullAccess, run the following command:

```
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount `sagemaker-k8s-operator-default` should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.
Deploy the Operator

When deploying your operator, you can use either a YAML file or Helm charts.

Deploy the Operator Using YAML

This is the simplest way to deploy your operators. The process is as follows:

1. Download the installer script using the following command:

   ```bash
   ```

2. Edit the `installer.yaml` file to replace `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you’ve created.

3. Use the following command to deploy the cluster:

   ```bash
   kubectl apply -f installer.yaml
   ```

Deploy the Operator Using Helm Charts

Use the provided Helm Chart to install the operator.

1. Clone the Helm installer directory using the following command:

   ```bash
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you’ve created.

3. Install the Helm Chart using the following command:

   ```bash
   kubectl create namespace sagemaker-k8s-operator-system
   helm install --namespace sagemaker-k8s-operator-system sagemaker-operator rolebased/
   ```

   If you decide to install the operator into a namespace other than the one specified, you need to adjust the namespace defined in the IAM role `trust.json` file to match.

4. After a moment, the chart is installed with a randomly generated name. Verify that the installation succeeded by running the following command:

   ```bash
   helm ls
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>sagemaker-k8s-operator-system</td>
<td>1</td>
<td>2019-11-20</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>23:14:59.6777082 +0000 UTC</td>
</tr>
</tbody>
</table>

Verify the operator deployment

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:
kubectl get crd | grep sagemaker

Your output should look like the following:

<table>
<thead>
<tr>
<th>CRD Name</th>
<th>Created At</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchtransformjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>endpointconfigs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hostingdeployments.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hyperparametertuningjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>models.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>trainingjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
</tbody>
</table>

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

kubectl -n sagemaker-k8s-operator-system get pods

You should see a pod named sagemaker-k8s-operator-controller-manager-***** in the namespace sagemaker-k8s-operator-system as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
</tbody>
</table>

Namespace-scoped deployment

You have the option to install your operator within the scope of an individual Kubernetes namespace. In this mode, the controller only monitors and reconciles resources with SageMaker if the resources are created within that namespace. This allows for finer-grained control over which controller is managing which resources. This is useful for deploying to multiple AWS accounts or controlling which users have access to particular jobs.

This guide outlines how to install an operator into a particular, predefined namespace. To deploy a controller into a second namespace, follow the guide from beginning to end and change out the namespace in each step.

Create an OpenID Connect Provider for Your Amazon EKS cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local CLUSTER_NAME and AWS_REGION environment variables as follows:

   ```bash
   # Set the region and cluster
   export CLUSTER_NAME="<your cluster name>"
   export AWS_REGION="<your region>"
   ```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

   ```bash
   eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
   --region ${AWS_REGION} --approve
   ```

   Your output should look like the following:

   ```bash
   [+] eksctl version 0.10.1
   ```
Now that the cluster has an OIDC identity provider, create a role and give a Kubernetes ServiceAccount permission to assume the role.

**Get your OIDC ID**

To set up the ServiceAccount, first obtain the OpenID Connect issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
--query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```

In this URL, the value D48675832CA65BD10A532F5970IDCID is the OIDC ID. The OIDC ID for your cluster will be different. You need this OIDC ID value to create a role.

If your output is `None`, it means that your client version is old. To work around this, run the following command:

```
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME} --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F5970IDCID
```

**Create your IAM Role**

1. Create a file named `trust.json` and insert the following trust relationship code block into it. Be sure to replace all `<OIDC ID>`, `<AWS account number>`, `<EKS Cluster region>`, and `<Namespace>` placeholders with values corresponding to your cluster. For the purposes of this guide, `my-namespace` is used for the `<Namespace>` value.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Principal": {
         "Federated": "arn:aws:iam::<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
         "StringEquals": {
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud": "sts.amazonaws.com",
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub": "system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default"
         }
      }
   }
   ]
}
```

2907
2. Run the following command to create a role with the trust relationship defined in trust.json. This role enables the Amazon EKS cluster to get and refresh credentials from IAM.

```
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
STRINGEQUALS    sts.amazonaws.com       system:serviceaccount:my-namespace:sagemaker-k8s-operator-default
PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN. You pass this value to your operator.

**Attach the AmazonSageMakerFullAccess Policy to your Role**

To give the role access to SageMaker, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach AmazonSageMakerFullAccess, run the following command:

```
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount sagemaker-k8s-operator-default should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.

**Deploy the Operator to Your Namespace**

When deploying your operator, you can use either a YAML file or Helm charts.

**Deploy the Operator to Your Namespace Using YAML**

There are two parts to deploying an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself.

If you have not already installed the CRDs into the cluster, apply the CRD installer YAML using the following command:

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/release/rolebased/namespaced/crd.yaml
```

To install the operator onto the cluster:

1. Download the operator installer YAML using the following command:

```
```

2. Update the installer YAML to place the resources into your specified namespace using the following command:
3. Edit the `operator.yaml` file to place resources into your eks.amazonaws.com/role-arn. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you’ve created.

4. Use the following command to deploy the cluster:

   ```bash
   kubectl apply -f operator.yaml
   ```

### Deploy the Operator to Your Namespace Using Helm Charts

There are two parts needed to deploy an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself. When using helm charts you have to first create the namespace using `kubectl`.

1. Clone the Helm installer directory using the following command:

   ```bash
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer/namespaced` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you’ve created.

3. Install the Helm Chart using the following command:

   ```bash
   helm install crds crd_chart/
   ```

4. Create the required namespace and install the operator using the following command:

   ```bash
   kubectl create namespace <namespace>
   helm install --n <namespace> op operator_chart/
   ```

5. After a moment, the chart is installed with the name `sagemaker-operator`. Verify that the installation succeeded by running the following command:

   ```bash
   helm ls
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>my-namespace</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000 UTC deployed</td>
</tr>
</tbody>
</table>

### Verify the operator deployment to your namespace

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

   ```bash
   kubectl get crd | grep sagemaker
   ```
Your output should look like the following:

<table>
<thead>
<tr>
<th>Service</th>
<th>Created Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchtransformjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>endpointconfigs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hostingdeployments.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hyperparametertuningjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>models.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>trainingjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
</tbody>
</table>

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

```bash
kubectl -n my-namespace get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `my-namespace` as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>AGE 23s</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Install the SageMaker logs `kubectl` plugin

As part of the SageMaker Operators for Kubernetes, you can use the `smlogs` plugin for `kubectl`. This enables SageMaker CloudWatch logs to be streamed with `kubectl`. `kubectl` must be installed onto your PATH. The following commands place the binary in the `sagemaker-k8s-bin` directory in your home directory, and add that directory to your PATH.

```bash
export os="linux"
wget https://amazon-sagemaker-operator-for-k8s-us-east-1.s3.amazonaws.com/kubectl-smlogs-plugin/v1/${os}.amd64.tar.gz
tar xvzf ${os}.amd64.tar.gz
# Move binaries to a directory in your homedir.
mkdir ~/sagemaker-k8s-bin
cp ./kubectl-smlogs.${os}.amd64/kubectl-smlogs ~/sagemaker-k8s-bin/.
# This line adds the binaries to your PATH in your .bashrc.
echo 'export PATH=${PATH}:~/sagemaker-k8s-bin' >> ~/.bashrc
# Source your .bashrc to update environment variables:
source ~/.bashrc
```

Use the following command to verify that the `kubectl` plugin is installed correctly:

```bash
kubectl smlogs
```

If the `kubectl` plugin is installed correctly, your output should look like the following:

View SageMaker logs via Kubernetes

Usage:

```bash
smlogs [command]
```
<table>
<thead>
<tr>
<th>Aliases:</th>
<th>smlogs, SMLogs, Smlogs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available Commands:</td>
<td></td>
</tr>
<tr>
<td>BatchTransformJob</td>
<td>View BatchTransformJob logs via Kubernetes</td>
</tr>
<tr>
<td>TrainingJob</td>
<td>View TrainingJob logs via Kubernetes</td>
</tr>
<tr>
<td>help</td>
<td>Help about any command</td>
</tr>
<tr>
<td>Flags:</td>
<td></td>
</tr>
<tr>
<td>-h, --help</td>
<td>help for smlogs</td>
</tr>
<tr>
<td>Use &quot;smlogs [command] --help&quot; for more information about a command.</td>
<td></td>
</tr>
</tbody>
</table>

**Delete operators**

**Delete cluster-based operators**

Operators installed using YAML

To uninstall the operator from your cluster, make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang. Once you have deleted all SageMaker jobs, use kubectl to delete the operator from the cluster. Run the following commands to stop all jobs and delete the operator from the cluster:

```bash
# Delete all SageMaker jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com

# Delete the operator and its resources
kubectl delete -f /installer.yaml
```

You should see output like the following:

```bash
# kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
trainingjobs.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted

# kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted

# kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted

# kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted

# kubectl delete -f raw-yaml/installer.yaml
namespace "sagemaker-k8s-operator-system" deleted
customresourcedefinition.apiextensions.k8s.io "batchtransformjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "endpointconfigs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hostingdeployments.sagemaker.aws.amazon.com" deleted
"hyperparametertuningjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "models.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "trainingjobs.sagemaker.aws.amazon.com" deleted
role.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-role" deleted
```
Operators installed using Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```shell
# get the helm charts
helm ls

# delete the charts
helm delete <chart name>
```

Delete namespace-based operators

Operators installed with YAML

To uninstall the operator from your cluster, make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang. Once you have deleted all SageMaker jobs, use `kubectl` to first delete the operator from the namespace and then the CRDs from the cluster. Run the following commands to stop all jobs and delete the operator from the cluster:

```shell
# Delete all SageMaker jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com

# Delete the operator using the same yaml file that was used to install the operator
kubectl delete -f operator.yaml

# Now delete the CRDs using the CRD installer yaml

# Now you can delete the namespace if you want
kubectl delete namespace <namespace>
```

Operators installed with Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```shell
# Delete the operator
helm delete -n <namespace> op

# delete the crds
helm delete crds
```
# optionally delete the namespace
kubectl delete namespace <namespace>

## Troubleshooting

### Debugging a Failed Job

- Check the job status by running the following:

  ```
  kubectl get <CRD Type> <job name>
  ```

- If the job was created in SageMaker, you can use the following command to see the STATUS and the SageMaker Job Name:

  ```
  kubectl get <crd type> <job name>
  ```

- You can use `smlogs` to find the cause of the issue using the following command:

  ```
  kubectl smlogs <crd type> <job name>
  ```

- You can also use the `describe` command to get more details about the job using the following command. The output has an additional field that has more information about the status of the job.

  ```
  kubectl describe <crd type> <job name>
  ```

- If the job was not created in SageMaker, then use the logs of the operator's pod to find the cause of the issue as follows:

  ```
  $ kubectl get pods -A | grep sagemaker
  # Output:
  sagemaker-k8s-operator-system   sagemaker-k8s-operator-controller-manager-5cd7df4d74-wh22z   2/2     Running   0          3h33m
  $ kubectl logs -p <pod name> -c manager -n sagemaker-k8s-operator-system
  ```

## Deleting an Operator CRD

If deleting a job is not working, check if the operator is running. If the operator is not running, then you have to delete the finalizer using the following steps:

1. In a new terminal, open the job in an editor using `kubectl edit` as follows:

   ```
   kubectl edit <crd type> <job name>
   ```

2. Edit the job to delete the finalizer by removing the following two lines from the file. Save the file and the job is be deleted.

   ```
   finalizers:
   - sagemaker-operator-finalizer
   ```

## Images and SMlogs in each Region

The following table lists the available operator images and SMLogs in each region.

<table>
<thead>
<tr>
<th>Region</th>
<th>Operator Image</th>
<th>SMLog Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Northern Virginia)</td>
<td>us-west-2</td>
<td></td>

<tr>
<td>Asia Pacific (Mumbai)</td>
<td>ap-south-1</td>
<td></td>
</tr>
</tbody>
</table>

---

2913
Using Amazon SageMaker Jobs

To run an Amazon SageMaker job using the Operators for Kubernetes, you can either apply a YAML file or use the supplied Helm Charts.

All sample operator jobs in the following tutorials use sample data taken from a public MNIST dataset. In order to run these samples, download the dataset into your Amazon S3 bucket. You can find the dataset in Download the MNIST Dataset.

Contents
- TrainingJob operator (p. 2914)
- HyperParameterTuningJob operator (p. 2919)
- BatchTransformJob operator (p. 2924)
- HostingDeployment operator (p. 2927)
- ProcessingJob operator (p. 2932)
- HostingAutoscalingPolicy (HAP) Operator (p. 2935)

TrainingJob operator

Training job operators reconcile your specified training job spec to SageMaker by launching it for you in SageMaker. You can learn more about SageMaker training jobs in the SageMaker CreateTrainingJob API documentation.

Topics
- Create a TrainingJob Using a YAML File (p. 2914)
- Create a TrainingJob Using a Helm Chart (p. 2915)
- List TrainingJobs (p. 2916)
- Describe a TrainingJob (p. 2916)
- View Logs from TrainingJobs (p. 2918)
- Delete TrainingJobs (p. 2918)

Create a TrainingJob Using a YAML File

1. Download the sample YAML file for training using the following command:
2. Edit the `xgboost-mnist-trainingjob.yaml` file to replace the `roleArn` parameter with your `<sagemaker-execution-role>`, and `outputPath` with your Amazon S3 bucket that the SageMaker execution role has write access to. The `roleArn` must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see SageMaker Roles. Apply the YAML file using the following command:

```
kubectl apply -f xgboost-mnist-trainingjob.yaml
```

Create a TrainingJob Using a Helm Chart

You can use Helm Charts to run TrainingJobs.

1. Clone the GitHub repository to get the source using the following command:

```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/training-jobs/` folder and edit the `values.yaml` file to replace values like `rolearn` and `outputpath` with values that correspond to your account. The RoleARN must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see SageMaker Roles.

Create the TrainingJob

With the roles and Amazon S3 buckets replaced with appropriate values in `values.yaml`, you can create a training job using the following command:

```
helm install . --generate-name
```

Your output should look like the following:

```
NAME: chart-12345678
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES: Thanks for installing the sagemaker-k8s-trainingjob.
```

Verify Your Training Helm Chart

To verify that the Helm Chart was created successfully, run:

```
helm ls
```

Your output should look like the following:

```
NAME          NAMESPACE       REVISION        UPDATED CHART APP VERSION
LOCATION
```

2915
helm install creates a TrainingJob Kubernetes resource. The operator launches the actual training job in SageMaker and updates the TrainingJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

Note: SageMaker does not allow you to update a running training job. You cannot edit any parameter and re-apply the file/config. Either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

List TrainingJobs

Use the following command to list all jobs created using the Kubernetes operator:

```bash
cubectl get TrainingJob
```

The output listing all jobs should look like the following:

```
NAME                        STATUS       SECONDARY-STATUS   CREATION-TIME
SAGEMAKER-JOB-NAME
xgboost-mnist-from-for-s3   InProgress   Starting           2019-11-20T23:42:35Z   xgboost-
mnist-from-for-s3-examplef11eab94ede4671d5a8f
```

A training job continues to be listed after the job has completed or failed. You can remove a TrainingJob job from the list by following the Delete a Training Job steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

TrainingJob Status Values

The STATUS field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

Secondary Status Values

The secondary statuses come directly from the SageMaker official API documentation. They contain more granular information about the status of the job.

Describe a TrainingJob

You can get more details about the training job by using the describe kubectl command. This is typically used for debugging a problem or checking the parameters of a training job. To get information about your training job, use the following command:
**kubectl describe trainingjob xgboost-mnist-from-for-s3**

The output for your training job should look like the following:

<table>
<thead>
<tr>
<th>Name:</th>
<th>xgboost-mnist-from-for-s3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace:</td>
<td>default</td>

Sage Maker Training Job Name: xgboost-mnist-from-for-s3-6d7fa0af0bef11eab94eexample
Secondary Status: Downloading
Training Job Status: InProgress
Events: <none>

View Logs from TrainingJobs

Use the following command to see the logs from the kmeans-mnist training job:

```
kubectl smlogs trainingjob xgboost-mnist-from-for-s3
```

Your output should look similar to the following. The logs from instances are ordered chronologically.

```
```

Delete TrainingJobs

Use the following command to stop a training job on Amazon SageMaker:

```
kubectl delete trainingjob xgboost-mnist-from-for-s3
```

This command removes the SageMaker training job from Kubernetes. This command returns the following output:

```
trainingjob.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted
```

If the job is still in progress on SageMaker, the job stops. You do not incur any charges for SageMaker resources after your job stops or completes.

Note: SageMaker does not delete training jobs. Stopped jobs continue to show on the SageMaker console. The delete command takes about 2 minutes to clean up the resources from SageMaker.
HyperParameterTuningJob operator

Hyperparameter tuning job operators reconcile your specified hyperparameter tuning job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker hyperparameter tuning jobs in the SageMaker CreateHyperParameterTuningJob API documentation.

Topics

- Create a HyperparameterTuningJob Using a YAML File (p. 2919)
- Create a HyperparameterTuningJob using a Helm Chart (p. 2919)
- List HyperparameterTuningJobs (p. 2920)
- Describe a HyperparameterTuningJob (p. 2921)
- View Logs from HyperparameterTuningJobs (p. 2923)
- Delete a HyperparameterTuningJob (p. 2924)

Create a HyperparameterTuningJob Using a YAML File

1. Download the sample YAML file for the hyperparameter tuning job using the following command:
   
   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hpo.yaml
   ```

2. Edit the `xgboost-mnist-hpo.yaml` file to replace the `roleArn` parameter with your `sagemaker-execution-role`. For the hyperparameter tuning job to succeed, you must also change the `s3InputPath` and `s3OutputPath` to values that correspond to your account. Apply the updates YAML file using the following command:

   ```
   kubectl apply -f xgboost-mnist-hpo.yaml
   ```

Create a HyperparameterTuningJob using a Helm Chart

You can use Helm Charts to run hyperparameter tuning jobs.

1. Clone the GitHub repository to get the source using the following command:

   ```
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/hyperparameter-tuning-jobs/` folder.

3. Edit the `values.yaml` file to replace the `roleArn` parameter with your `sagemaker-execution-role`. For the hyperparameter tuning job to succeed, you must also change the `s3InputPath` and `s3OutputPath` to values that correspond to your account.

Create the HyperparameterTuningJob

With the roles and Amazon S3 paths replaced with appropriate values in `values.yaml`, you can create a hyperparameter tuning job using the following command:

```
helm install . --generate-name
```

Your output should look similar to the following:

```
NAME: chart-1574292948
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
```
Verify Chart Installation

To verify that the Helm Chart was created successfully, run the following command:

```
helm ls
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>chart-1474292948</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:35:49.9136092 +0000</td>
</tr>
<tr>
<td>UTC deployed</td>
<td>sagemaker-k8s-hyperparametertuningjob-0.1.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>STATUS</td>
<td>CHART</td>
<td>APF VERSION</td>
<td></td>
</tr>
<tr>
<td>chart-1574292948</td>

<td>1</td>
<td>2019-11-20 23:35:49.9136092 +0000</td>
</tr>
<tr>
<td>UTC deployed</td>
<td>sagemaker-k8s-trainingjob-0.1.0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rolebased-1574291698</td>
<td>default</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000</td>
</tr>
<tr>
<td>UTC deployed</td>
<td>sagemaker-k8s-operator-0.1.0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
helm install creates a HyperParameterTuningJob Kubernetes resource. The operator launches the actual hyperparameter optimization job in SageMaker and updates the HyperParameterTuningJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

**Note:** SageMaker does not allow you to update a running hyperparameter tuning job. You cannot edit any parameter and re-apply the file/config. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

List HyperparameterTuningJobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get hyperparametertuningjob
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>COMPLETED</th>
<th>INPROGRESS</th>
<th>ERRORS</th>
<th>STOPPED</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEST-TRAINING-JOB</td>
<td>Completed</td>
<td>2019-10-17T01:15:52Z</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>xgboost-mnist-hpo</td>
<td>xgboostha92f5e3cf07b11e9bf6c06d6-009-4c7a123</td>
<td>xgboostsha92f5e3cf07b11e9bf6c123</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A hyperparameter tuning job continues to be listed after the job has completed or failed. You can remove a hyperparametertuningjob from the list by following the steps in Delete a Hyperparameter Tuning Job. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

Hyperparameter Tuning Job Status Values

The **STATUS** field can be one of the following values:

- Completed
- InProgress
• Failed
• Stopped
• Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

Status Counters

The output has several counters, like COMPLETED and INPROGRESS. These represent how many training jobs have completed and are in progress, respectively. For more information about how these are determined, see TrainingJobStatusCounters in the SageMaker API documentation.

Best TrainingJob

This column contains the name of the TrainingJob that best optimized the selected metric.

To see a summary of the tuned hyperparameters, run:

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

To see detailed information about the TrainingJob, run:

```
kubectl describe trainingjobs <job name>
```

Spawned TrainingJobs

You can also track all 10 training jobs in Kubernetes launched by HyperparameterTuningJob by running the following command:

```
kubectl get trainingjobs
```

Describe a HyperparameterTuningJob

You can obtain debugging details using the describe kubectl command.

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

In addition to information about the tuning job, the SageMaker Operator for Kubernetes also exposes the best training job found by the hyperparameter tuning job in the describe output as follows:

```
Name:         xgboost-mnist-hpo
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:

  - s3DataSource:
    - s3DataDistributionType: FullyReplicated
    - s3DataType: S3Prefix
    - s3Uri: https://s3-us-east-2.amazonaws.com/my-bucket/sagemaker/xgboost-mnist/validation/

Output Data Config:
- s3OutputPath: https://s3-us-east-2.amazonaws.com/my-bucket/sagemaker/xgboost/

Resource Config:
- Instance Count: 1
- Instance Type: ml.m4.xlarge
- Volume Size in GB: 5
- Role Arn: arn:aws:iam::123456789012:role/service-role/AmazonSageMaker-ExecutionRole

Static Hyper Parameters:
- Name: base_score
  Value: 0.5
- Name: booster
  Value: gbtree
- Name: csv_weights
  Value: 0
- Name: dsplit
  Value: row
- Name: grow_policy
  Value: depthwise
- Name: lambda_bias
  Value: 0.0
- Name: max_bin
  Value: 256
Hyperparameter tuning jobs do not have logs, but all training jobs launched by them do have logs. These logs can be accessed as if they were a normal training job. For more information, see View Logs from Training Jobs.
Delete a HyperparameterTuningJob

Use the following command to stop a hyperparameter job in SageMaker.

```
kubectl delete hyperparametertuningjob xgboost-mnist-hpo
```

This command removes the hyperparameter tuning job and associated training jobs from your Kubernetes cluster and stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. SageMaker does not delete hyperparameter tuning jobs. Stopped jobs continue to show on the SageMaker Console.

Your output should look like the following:

```
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted
```

Note: The delete command takes about 2 minutes to clean up the resources from SageMaker.

BatchTransformJob operator

Batch transform job operators reconcile your specified batch transform job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker batch transform job in the SageMaker CreateTransformJob API documentation.

Topics

- Create a BatchTransformJob Using a YAML File (p. 2924)
- Create a BatchTransformJob Using a Helm Chart (p. 2924)
- List BatchTransformJobs (p. 2925)
- Describe a BatchTransformJob (p. 2926)
- View Logs from BatchTransformJobs (p. 2927)
- Delete a BatchTransformJob (p. 2927)

Create a BatchTransformJob Using a YAML File

1. Download the sample YAML file for the batch transform job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-batchtransform.yaml
```

2. Edit the file `xgboost-mnist-batchtransform.yaml` to change necessary parameters to replace `inputdataconfig` with your input data and `s3OutputPath` with your Amazon S3 buckets that the SageMaker execution role has write access to.

3. Apply the YAML file using the following command:

```
kubectl apply -f xgboost-mnist-batchtransform.yaml
```

Create a BatchTransformJob Using a Helm Chart

You can use Helm Charts to run batch transform jobs.

Get the Helm installer directory

Clone the GitHub repository to get the source using the following command:
Configure the Helm Chart

Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/batch-transform-jobs/` folder.

Edit the `values.yaml` file to replace the `inputdataconfig` with your input data and `outputPath` with your S3 buckets to which the SageMaker execution role has write access.

Create a BatchTransformJob

1. Use the following command to create a batch transform job:

   ```bash
   helm install . --generate-name
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>NAMESPACE: default</td>
<td>STATUS: deployed</td>
</tr>
<tr>
<td>REVISION: 1</td>
<td>TEST SUITE: None</td>
</tr>
<tr>
<td></td>
<td>NOTES: Thanks for installing the sagemaker-k8s-batch-transform-job.</td>
</tr>
</tbody>
</table>

2. To verify that the Helm Chart was created successfully, run the following command:

   ```bash
   helm ls
   ```

   This command creates a BatchTransformJob Kubernetes resource. The operator launches the actual transform job in SageMaker and updates the BatchTransformJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

   **Note:** SageMaker does not allow you to update a running batch transform job. You cannot edit any parameter and re-apply the file/config. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

List BatchTransformJobs

Use the following command to list all jobs created using the Kubernetes operator:

```bash
kubectl get batchtransformjob
```
NAME                                STATUS      CREATION-TIME          SAGEMAKER-JOB-NAME
xgboost-mnist-batch-transform       Completed   2019-11-18T03:44:00Z   xgboost-mnist-
a88fb19809b511eaac440aa8a9xgboost

A batch transform job will continue to be listed after the job has completed or failed. You can remove a hyperparametertuningjob from the list by following the Delete a Batch Transform Job steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

**Batch Transform Status Values**

The **STATUS** field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for **STATUS** to be **SynchronizingK8sJobWithSageMaker**. This means that the operator has not yet processed the job.

**Describe a BatchTransformJob**

You can obtain debugging details using the describe kubectl command.

```
kubectl describe batchtransformjob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
Name:         xgboost-mnist-batch-transform
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
   "apiVersion":"sagemaker.aws.amazon.com/v1","kind":"BatchTransformJob","metadata":{"annotations":{},"name":"xgboost-
mnist","namespace":"default"}
API Version:  sagemaker.aws.amazon.com/v1
Kind:         BatchTransformJob
Metadata:
   Creation Timestamp:  2019-11-18T03:44:00Z
   Finalizers:        sagemaker-operator-finalizer
   Generation:        2
   Resource Version:  21990924
   Self Link:         /apis/sagemaker.aws.amazon.com/v1/namespaces/default/batchtransformjobs/xgboost-mnist
   UID:               a88fb198-09b5-11ea-ac44-0aa8a9UIDNUM
Spec:
   Model Name:  TrainingJob-20190814SMJOb-IKEB
   Region:      us-east-1
   Transform Input:
      Content Type:  text/csv
      Data Source:
         S 3 Data Source:  
         S 3 Data Type:  S3Prefix
         S 3 Uri:        s3://my-bucket/mnist_kmeans_example/input
```
View Logs from BatchTransformJobs

Use the following command to see the logs from the xgboost-mnist batch transform job:

```bash
kubectl smlogs batchtransformjob xgboost-mnist-batch-transform
```

Delete a BatchTransformJob

Use the following command to stop a batch transform job in SageMaker.

```bash
kubectl delete batchTransformJob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted
```

This command removes the batch transform job from your Kubernetes cluster, as well as stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. Delete takes about 2 minutes to clean up the resources from SageMaker.

Note: SageMaker does not delete batch transform jobs. Stopped jobs continue to show on the SageMaker console.

HostingDeployment operator

HostingDeployment operators support creating and deleting an endpoint, as well as updating an existing endpoint, for real-time inference. The hosting deployment operator reconciles your specified hosting deployment job spec to SageMaker by creating models, endpoint-configs and endpoints in SageMaker. You can learn more about SageMaker inference in the SageMaker CreateEndpoint API documentation.

Topics

- Configure a HostingDeployment Resource (p. 2927)
- Create a HostingDeployment (p. 2928)
- List HostingDeployments (p. 2928)
- Describe a HostingDeployment (p. 2929)
- Invoking the Endpoint (p. 2930)
- Update HostingDeployment (p. 2930)
- Delete the HostingDeployment (p. 2931)

Configure a HostingDeployment Resource

Download the sample YAML file for the hosting deployment job using the following command:
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hostingdeployment.yaml

The xgboost-mnist-hostingdeployment.yaml file has the following components that can be edited as required:

- **ProductionVariants.** A production variant is a set of instances serving a single model. SageMaker load-balances between all production variants according to set weights.
- **Models.** A model is the containers and execution role ARN necessary to serve a model. It requires at least a single container.
- **Containers.** A container specifies the dataset and serving image. If you are using your own custom algorithm instead of an algorithm provided by SageMaker, the inference code must meet SageMaker requirements. For more information, see Using Your Own Algorithms with SageMaker.

**Create a HostingDeployment**

To create a HostingDeployment, use kubectl to apply the file hosting.yaml with the following command:

```
kubectl apply -f hosting.yaml
```

SageMaker creates an endpoint with the specified configuration. You incur charges for SageMaker resources used during the lifetime of your endpoint. You do not incur any charges once your endpoint is deleted.

The creation process takes approximately 10 minutes.

**List HostingDeployments**

To verify that the HostingDeployment was created, use the following command:

```
kubectl get hostingdeployments
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>SAGEMAKER-ENDPOINT-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>host-xgboost</td>
<td>Creating</td>
<td>host-xgboost-def0e83e0d5f1eaa450aSMLOGS</td>
</tr>
</tbody>
</table>

**HostingDeployment Status Values**

The status field can be one of several values:

- **SynchronizingK8sJobWithSageMaker:** The operator is preparing to create the endpoint.
- **ReconcilingEndpoint:** The operator is creating, updating, or deleting endpoint resources. If the HostingDeployment remains in this state, use kubectl describe to see the reason in the Additional field.
- **OutOfService:** Endpoint is not available to take incoming requests.
- **Creating:** CreateEndpoint is executing.
- **Updating:** UpdateEndpoint or UpdateEndpointWeightsAndCapacities is executing.
- **SystemUpdating:** Endpoint is undergoing maintenance and cannot be updated or deleted or re-scaled until it has completed. This maintenance operation does not change any customer-specified values such as VPC config, KMS encryption, model, instance type, or instance count.
- **RollingBack:** Endpoint fails to scale up or down or change its variant weight and is in the process of rolling back to its previous configuration. Once the rollback completes, endpoint returns to an InService status. This transitional status only applies to an endpoint that has autoscaling enabled and is undergoing variant weight or capacity changes as part of an
UpdateEndpointWeightsAndCapacities call or when the UpdateEndpointWeightsAndCapacities operation is called explicitly.

- **InService**: Endpoint is available to process incoming requests.
- **Deleting**: DeleteEndpoint is executing.
- **Failed**: Endpoint could not be created, updated, or re-scaled. Use DescribeEndpoint:FailureReason for information about the failure. DeleteEndpoint is the only operation that can be performed on a failed endpoint.

**Describe a HostingDeployment**

You can obtain debugging details using the describe kubectl command.

```bash
kubectl describe hostingdeployment
```

Your output should look like the following:

```
Name:         host-xgboost
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
               {
                 "apiVersion": "sagemaker.aws.amazon.com/v1",
                 "kind": "HostingDeployment",
                 "metadata": {
                   "annotations": {},
                   "name": "host-xgboost",
                   "namespace": "default"
               }
           API Version:  sagemaker.aws.amazon.com/v1
Kind:         HostingDeployment

                            xgboost-def0e83e0d5f11eaaexample/invocations
    Last Check Time:       2019-11-22T19:43:57Z
```
Model Names:
Name: xgboost-model
Value: xgboost-model-1-def0e83e0d5f11-df5cc9f0d05f11eaa45aexample
Events: <none>

The status field provides more information using the following fields:

- **Additional**: Additional information about the status of the hosting deployment. This field is optional and only gets populated in case of error.
- **Creation Time**: When the endpoint was created in SageMaker.
- **Endpoint ARN**: The SageMaker endpoint ARN.
- **Endpoint Config Name**: The SageMaker name of the endpoint configuration.
- **Endpoint Name**: The SageMaker name of the endpoint.
- **Endpoint Status**: The status of the endpoint.
- **Endpoint URL**: The HTTPS URL that can be used to access the endpoint. For more information, see [Deploy a Model on SageMaker Hosting Services](#).
- **FailureReason**: If a create, update, or delete command fails, the cause is shown here.
- **Last Check Time**: The last time the operator checked the status of the endpoint.
- **Last Modified Time**: The last time the endpoint was modified.
- **Model Names**: A key-value pair of HostingDeployment model names to SageMaker model names.

### Invoking the Endpoint

Once the endpoint status is **InService**, you can invoke the endpoint in two ways: using the AWS CLI, which does authentication and URL request signing, or using an HTTP client like cURL. If you use your own client, you need to do AWS v4 URL signing and authentication on your own.

To invoke the endpoint using the AWS CLI, run the following command. Make sure to replace the Region and endpoint-name with your endpoint's Region and SageMaker endpoint name. This information can be obtained from the output of `kubectl describe`.

```bash
# Invoke the endpoint with mock input data.
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \
  --endpoint-name <endpoint name> \
  --body $(seq 784 | xargs echo | sed 's/ /,/g') \
  >(cat) \
  --content-type text/csv > /dev/null
```

For example, if your Region is *us-east-2* and your endpoint config name is *host-xgboost-f56b6b280d7511ea824b129926example*, then the following command would invoke the endpoint:

```bash
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \
  --endpoint-name host-xgboost-f56b6b280d7511ea824b129926example \
  --body $(seq 784 | xargs echo | sed 's/ /,/g') \
  >(cat) \
  --content-type text/csv > /dev/null
```

Here, **4.95847082138** is the prediction from the model for the mock data.

### Update HostingDeployment

1. Once a HostingDeployment has a status of **InService**, it can be updated. It might take about 10 minutes for HostingDeployment to be in service. To verify that the status is **InService**, use the following command:
kubectl get hostingdeployments

2. The HostingDeployment can be updated before the status is InService. The operator waits until the SageMaker endpoint is InService before applying the update.

To apply an update, modify the hosting.yaml file. For example, change the initialInstanceCount field from 1 to 2 as follows:

```yaml
apiVersion: sagemaker.aws.amazon.com/v1
kind: HostingDeployment
metadata:
  name: host-xgboost
spec:
  region: us-east-2
  productionVariants:
    - variantName: all-traffic
      modelName: xgboost-model
      initialInstanceCount: 2
      instanceType: ml.c5.large
  models:
    - name: xgboost-model
      executionRoleArn: arn:aws:iam::123456789012:role/service-role/
      AmazonSageMaker-ExecutionRole
      primaryContainer: xgboost
      containers:
        - xgboost
      containers:
        - containerHostname: xgboost
          modelDataUrl: s3://my-bucket/inference/xgboost-mnist/model.tar.gz
          image: 123456789012.dkr.ecr.us-east-2.amazonaws.com/xgboost:latest

3. Save the file, then use kubectl to apply your update as follows. You should see the status change from InService to ReconcilingEndpoint, then Updating.

```bash
$ kubectl apply -f hosting.yaml
hostingdeployment.sagemaker.aws.amazon.com/host-xgboost configured
$ kubectl get hostingdeployments
NAME           STATUS                SAGEMAKER-ENDPOINT-NAME
host-xgboost   ReconcilingEndpoint   host-xgboost-def0e83e0d5f11eaaa450a350abcdef
$ kubectl get hostingdeployments
NAME           STATUS     SAGEMAKER-ENDPOINT-NAME
host-xgboost   Updating   host-xgboost-def0e83e0d5f11eaaa450a350abcdef
```

SageMaker deploys a new set of instances with your models, switches traffic to use the new instances, and drains the old instances. As soon as this process begins, the status becomes Updating. After the update is complete, your endpoint becomes InService. This process takes approximately 10 minutes.

**Delete the HostingDeployment**

1. Use kubectl to delete a HostingDeployment with the following command:

```bash
kubectl delete hostingdeployments host-xgboost
```

Your output should look like the following:

```bash
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted
```
2. To verify that the hosting deployment has been deleted, use the following command:

```
kubectl get hostingdeployments
No resources found.
```

Endpoints that have been deleted do not incur any charges for SageMaker resources.

**ProcessingJob operator**

ProcessingJob operators are used to launch Amazon SageMaker processing jobs. For more information on SageMaker processing jobs, see CreateProcessingJob.

**Topics**
- Create a ProcessingJob Using a YAML File (p. 2932)
- List ProcessingJobs (p. 2933)
- Describe a ProcessingJob (p. 2933)
- Delete a ProcessingJob (p. 2935)

**Create a ProcessingJob Using a YAML File**

Follow these steps to create an Amazon SageMaker processing job by using a YAML file:

1. Download the `kmeans_preprocessing.py` pre-processing script.

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/kmeans_preprocessing.py
```

2. In one of your Amazon Simple Storage Service (Amazon S3) buckets, create a `mnist_kmeans_example/processing_code` folder and upload the script to the folder.

3. Download the `kmeans-mnist-processingjob.yaml` file.

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/kmeans-mnist-processingjob.yaml
```

4. Edit the YAML file to specify your `sagemaker-execution-role` and replace all instances of `<my-bucket>` with your S3 bucket.

```
...  
metadata:  
  name: kmeans-mnist-processing  
...  
  roleArn: arn:aws:iam::<acct-id>:role/service-role/<sagemaker-execution-role>  
...  
processingOutputConfig:  
  outputs:  
    ...  
    s3Output:  
      s3Uri: s3://<my-bucket>/mnist_kmeans_example/output/  
...  
processingInputs:  
  ...  
  s3Input:  
    s3Uri: s3://<my-bucket>/mnist_kmeans_example/processing_code/kmeans_preprocessing.py
```
The `sagemaker-execution-role` must have permissions so that SageMaker can access your S3 bucket, Amazon CloudWatch, and other services on your behalf. For more information on creating an execution role, see SageMaker Roles.

5. Apply the YAML file using one of the following commands.

For cluster-scoped installation:

```bash
kubectl apply -f kmeans-mnist-processingjob.yaml
```

For namespace-scoped installation:

```bash
kubectl apply -f kmeans-mnist-processingjob.yaml -n <NAMESPACE>
```

### List ProcessingJobs

Use one of the following commands to list all the jobs created using the ProcessingJob operator. `SAGEMAKER-JOB-NAME` comes from the metadata section of the YAML file.

For cluster-scoped installation:

```bash
kubectl get ProcessingJob kmeans-mnist-processing
```

For namespace-scoped installation:

```bash
kubectl get ProcessingJob -n <NAMESPACE> kmeans-mnist-processing
```

Your output should look similar to the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>SAGEMAKER-JOB-NAME</th>
</tr>
</thead>
</table>

The output lists all jobs regardless of their status. To remove a job from the list, see Delete a Processing Job.

### ProcessingJob Status

- **SynchronizingK8sJobWithSageMaker** – The job is first submitted to the cluster. The operator has received the request and is preparing to create the processing job.
- **Reconciling** – The operator is initializing or recovering from transient errors, along with others. If the processing job remains in this state, use the `kubectl describe` command to see the reason in the Additional field.
- **InProgress | Completed | Failed | Stopping | Stopped** – Status of the SageMaker processing job. For more information, see DescribeProcessingJob.
- **Error** – The operator cannot recover by reconciling.

Jobs that have completed, stopped, or failed do not incur further charges for SageMaker resources.

### Describe a ProcessingJob

Use one of the following commands to get more details about a processing job. These commands are typically used for debugging a problem or checking the parameters of a processing job.

For cluster-scoped installation:
Amazon SageMaker Developer Guide
SageMaker Operators for Kubernetes

kubectl describe processingjob kmeans-mnist-processing

For namespace-scoped installation:
kubectl describe processingjob kmeans-mnist-processing -n <NAMESPACE>

The output for your processing job should look similar to the following.
$ kubectl describe ProcessingJob kmeans-mnist-processing
Name:
kmeans-mnist-processing
Namespace:
default
Labels:
<none>
Annotations: kubectl.kubernetes.io/last-applied-configuration:

Delete a ProcessingJob

When you delete a processing job, the SageMaker processing job is removed from Kubernetes but the job isn't deleted from SageMaker. If the job status in SageMaker is InProgress the job is stopped. Processing jobs that are stopped do not incur any charges for SageMaker resources. Use one of the following commands to delete a processing job.

For cluster-scoped installation:

```bash
kubectl delete processingjob kmeans-mnist-processing
```

For namespace-scoped installation:

```bash
kubectl delete processingjob kmeans-mnist-processing -n <NAMESPACE>
```

The output for your processing job should look similar to the following.

```
processingjob.sagemaker.aws.amazon.com "kmeans-mnist-processing" deleted
```

**Note**

SageMaker does not delete the processing job. Stopped jobs continue to show in the SageMaker console. The delete command takes a few minutes to clean up the resources from SageMaker.

HostingAutoscalingPolicy (HAP) Operator

The HostingAutoscalingPolicy (HAP) operator takes a list of resource IDs as input and applies the same policy to each of them. Each resource ID is a combination of an endpoint name and a variant name. The HAP operator performs two steps: it registers the resource IDs and then applies the scaling policy to each resource ID. Delete undoes both actions. You can apply the HAP to an existing SageMaker endpoint or you can create a new SageMaker endpoint using the HostingDeployment operator. You can read more about SageMaker autoscaling in the Application Autoscaling Policy documentation.
Note
In your kubectl commands, you can use the short form, hap, in place of hostingautoscalingpolicy.

Topics
- Create a HostingAutoscalingPolicy Using a YAML File (p. 2936)
- List HostingAutoscalingPolicies (p. 2938)
- Describe a HostingAutoscalingPolicy (p. 2938)
- Update a HostingAutoscalingPolicy (p. 2939)
- Delete a HostingAutoscalingPolicy (p. 2939)
- Update or Delete an Endpoint with a HostingAutoscalingPolicy (p. 2939)

Create a HostingAutoscalingPolicy Using a YAML File

Use a YAML file to create a HostingAutoscalingPolicy (HAP) that applies a predefined or custom metric to one or multiple SageMaker endpoints.

Amazon SageMaker requires specific values in order to apply autoscaling to your variant. If these values are not specified in the YAML spec, the HAP operator applies the following default values.

```
# Do not change
Namespace                    = "sagemaker"
# Do not change
ScalableDimension            = "sagemaker:variant:DesiredInstanceCount"
# Only one supported
PolicyType                   = "TargetTrackingScaling"
# This is the default policy name but can be changed to apply a custom policy
DefaultAutoscalingPolicyName = "SageMakerEndpointInvocationScalingPolicy"
```

Use the following samples to create a HAP that applies a predefined or custom metric to one or multiple endpoints.

Sample 1: Apply a Predefined Metric to a Single Endpoint Variant

1. Download the sample YAML file for a predefined metric using the following command:

   `wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/hap-predefined-metric.yaml`

2. Edit the YAML file to specify your `endpointName`, `variantName`, and `region`.

3. Use one of the following commands to apply a predefined metric to a single resource ID (endpoint name and variant name combination).

   For cluster-scoped installation:

   `kubectl apply -f hap-predefined-metric.yaml`

   For namespace-scoped installation:

   `kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>`

Sample 2: Apply a Custom Metric to a Single Endpoint Variant

1. Download the sample YAML file for a custom metric using the following command:
2. Edit the YAML file to specify your endpointName, variantName, and region.
3. Use one of the following commands to apply a custom metric to a single resource ID (endpoint name and variant name combination) in place of the recommended SageMakerVariantInvocationsPerInstance.

   **Note**  
   Amazon SageMaker does not check the validity of your YAML spec.

   For cluster-scoped installation:

   ```bash
   kubectl apply -f hap-custom-metric.yaml
   ```

   For namespace-scoped installation:

   ```bash
   kubectl apply -f hap-custom-metric.yaml -n <NAMESPACE>
   ```

### Sample 3: Apply a Scaling Policy to Multiple Endpoints and Variants

You can use the HAP operator to apply the same scaling policy to multiple resource IDs. A separate scaling_policy request is created for each resource ID (endpoint name and variant name combination).

1. Download the sample YAML file for a predefined metric using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/hap-predefined-metric.yaml
   ```

2. Edit the YAML file to specify your region and multiple endpointName and variantName values.
3. Use one of the following commands to apply a predefined metric to multiple resource IDs (endpoint name and variant name combinations).

   For cluster-scoped installation:

   ```bash
   kubectl apply -f hap-predefined-metric.yaml
   ```

   For namespace-scoped installation:

   ```bash
   kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>
   ```

### Considerations for HostingAutoscalingPolicies for Multiple Endpoints and Variants

The following considerations apply when you use multiple resource IDs:

- If you apply a single policy across multiple resource IDs, one PolicyARN is created per resource ID. Five endpoints have five PolicyARNs. When you run the describe command on the policy, the responses show up as one job and include a single job status.
- If you apply a custom metric to multiple resource IDs, the same dimension or value is used for all the resource ID (variant) values. For example, if you apply a customer metric for instances 1-5, and the endpoint variant dimension is mapped to variant 1, when variant 1 exceeds the metrics, all endpoints are scaled up or down.
• The HAP operator supports updating the list of resource IDs. If you modify, add, or delete resource IDs to the spec, the autoscaling policy is removed from the previous list of variants and applied to the newly specified resource ID combinations. Use the describe command to list the resource IDs to which the policy is currently applied.

**List HostingAutoscalingPolicies**

Use one of the following commands to list all HostingAutoscalingPolicies (HAPs) created using the HAP operator.

For cluster-scoped installation:

```bash
kubectl get hap
```

For namespace-scoped installation:

```bash
kubectl get hap -n <NAMESPACE>
```

Your output should look similar to the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>hap-predefined</td>
<td>Created</td>
<td>2021-07-13T21:32:21Z</td>
</tr>
</tbody>
</table>

Use the following command to check the status of your HostingAutoscalingPolicy (HAP).

```bash
kubectl get hap <job-name>
```

One of the following values is returned:

- Reconciling – Certain types of errors show the status as Reconciling instead of Error. Some examples are server-side errors and endpoints in the Creating or Updating state. Check the Additional field in status or operator logs for more details.
- Created
- Error

**To view the autoscaling endpoint to which you applied the policy**

2. In the left side panel, expand **Inference**.
3. Choose **Endpoints**.
4. Select the name of the endpoint of interest.
5. Scroll to the **Endpoint runtime settings** section.

**Describe a HostingAutoscalingPolicy**

Use the following command to get more details about a HostingAutoscalingPolicy (HAP). These commands are typically used for debugging a problem or checking the resource IDs (endpoint name and variant name combinations) of a HAP.

```bash
kubectl describe hap <job-name>
```
Update a HostingAutoscalingPolicy

The HostingAutoscalingPolicy (HAP) operator supports updates. You can edit your YAML spec to change the values and then reapply the policy. The HAP operator deletes the existing policy and applies the new policy.

Delete a HostingAutoscalingPolicy

Use one of the following commands to delete a HostingAutoscalingPolicy (HAP) policy.

For cluster-scoped installation:

```
kubectl delete hap hap-predefined
```

For namespace-scoped installation:

```
kubectl delete hap hap-predefined -n <NAMESPACE>
```

This command deletes the scaling policy and deregisters the scaling target from Kubernetes. This command returns the following output:

```
hostingautoscalingpolicies.sagemaker.aws.amazon.com "hap-predefined" deleted
```

Update or Delete an Endpoint with a HostingAutoscalingPolicy

To update an endpoint that has a HostingAutoscalingPolicy (HAP), use the `kubectl delete` command to remove the HAP, update the endpoint, and then reapply the HAP.

To delete an endpoint that has a HAP, use the `kubectl delete` command to remove the HAP before you delete the endpoint.

SageMaker Components for Kubeflow Pipelines

This document outlines how to use SageMaker Components for Kubeflow Pipelines (KFP). With these pipeline components, you can create and monitor training, tuning, endpoint deployment, and batch transform jobs in SageMaker. By running Kubeflow Pipeline jobs on SageMaker, you move data processing and training jobs from the Kubernetes cluster to SageMaker's machine learning-optimized managed service. This document assumes prior knowledge of Kubernetes and Kubeflow.

Contents

- What is Kubeflow Pipelines? (p. 2939)
- Kubeflow Pipeline components (p. 2940)
- IAM permissions (p. 2941)
- Converting Pipelines to use SageMaker (p. 2942)
- Using SageMaker Components (p. 2942)

What is Kubeflow Pipelines?

Kubeflow Pipelines (KFP) is a platform for building and deploying portable, scalable machine learning (ML) workflows based on Docker containers. The Kubeflow Pipelines platform consists of the following:

- A user interface (UI) for managing and tracking experiments, jobs, and runs.
- An engine (Argo) for scheduling multi-step ML workflows.
- A Python SDK for defining and manipulating pipelines and components.
• Notebooks for interacting with the system using the SDK.

A pipeline is a description of an ML workflow expressed as a directed acyclic graph as shown in the following diagram. Every step in the workflow is expressed as a Kubeflow Pipeline component, which is a Python module.

If your data has been preprocessed, the standard pipeline takes a subset of the data and runs hyperparameter optimization of the model. The pipeline then trains a model with the full dataset using the optimal hyperparameters. This model is used for both batch inference and endpoint creation.

For more information on Kubeflow Pipelines, see the Kubeflow Pipelines documentation.

Kubeflow Pipeline components

A Kubeflow Pipeline component is a set of code used to execute one step in a Kubeflow pipeline. Components are represented by a Python module that is converted into a Docker image. These components make it fast and easy to write pipelines for experimentation and production environments without having to interact with the underlying Kubernetes infrastructure.

What do SageMaker Components for Kubeflow Pipelines provide?

SageMaker Components for Kubeflow Pipelines offer an alternative to launching compute-intensive jobs in SageMaker. These components integrate SageMaker with the portability and orchestration of Kubeflow Pipelines. Using the SageMaker components, each of the jobs in the pipeline workflow runs on SageMaker instead of the local Kubernetes cluster. The job parameters, status, logs, and outputs from SageMaker are still accessible from the Kubeflow Pipelines UI. The following SageMaker components have been created to integrate six key SageMaker features into your ML workflows. You can create a Kubeflow Pipeline built entirely using these components, or integrate individual components into your workflow as needed.

There is no additional charge for using SageMaker Components for Kubeflow Pipelines. You incur charges for any SageMaker resources you use through these components.

Training components

Training

The Training component allows you to submit SageMaker Training jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Training Kubeflow Pipelines component.

Hyperparameter Optimization

The Hyperparameter Optimization component enables you to submit hyperparameter tuning jobs to SageMaker directly from a Kubeflow Pipelines workflow. For more information, see SageMaker hyperparameter optimization Kubeflow Pipeline component.

Processing

The Processing component enables you to submit processing jobs to SageMaker directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Processing Kubeflow Pipeline component.

Inference components

Hosting Deploy

The Deploy component enables you to deploy a model in SageMaker Hosting from a Kubeflow Pipelines workflow. For more information, see SageMaker Hosting Services - Create Endpoint Kubeflow Pipeline component.
Batch Transform component

The Batch Transform component enables you to run inference jobs for an entire dataset in SageMaker from a Kubeflow Pipelines workflow. For more information, see SageMaker Batch Transform Kubeflow Pipeline component.

Ground Truth components

Ground Truth The Ground Truth component enables you to submit SageMaker Ground Truth labeling jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Ground Truth Kubeflow Pipelines component.

Workteam

The Workteam component enables you to create SageMaker private workteam jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker create private workteam Kubeflow Pipelines component.

IAM permissions

Deploying Kubeflow Pipelines with SageMaker components requires the following three levels of IAM permissions:

• An IAM user/role to access your AWS account (your_credentials). Note: You don't need this at all if you already have access to KFP web UI and have your input data in Amazon S3, or if you already have an Amazon Elastic Kubernetes Service (Amazon EKS) cluster with KFP.

You use this user/role from your gateway node, which can be your local machine or a remote instance, to:
• Create an Amazon EKS cluster and install KFP
• Create IAM roles/users
• Create Amazon S3 buckets for your sample input data

The IAM user/role needs the following permissions:
• CloudWatchLogsFullAccess
• AWSCloudFormationFullAccess
• IAMFullAccess
• AmazonS3FullAccess
• AmazonEC2FullAccess
• AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)

• An IAM role used by KFP pods to access SageMaker (kfp-example-pod-role) The KFP pods use this permission to create SageMaker jobs from KFP components. Note: If you want to limit permissions to the KFP pods, create your own custom policy and attach it.

The role needs the following permission:
• AmazonSageMakerFullAccess

• An IAM role used by SageMaker jobs to access resources such as Amazon S3 and Amazon ECR etc. (kfp-example-sagemaker-execution-role).

Your SageMaker jobs use this role to:
• Access SageMaker resources
• Input Data from Amazon S3
• Store your output model to Amazon S3

The role needs the following permissions:
• AmazonSageMakerFullAccess
• AmazonS3FullAccess
These are all the IAM users/roles you need to run KFP components for SageMaker.

When you have run the components and have created the SageMaker endpoint, you also need a role with the sagemaker:InvokeEndpoint permission to query inference endpoints.

**Converting Pipelines to use SageMaker**

You can convert an existing pipeline to use SageMaker by porting your generic Python *processing containers* and *training containers*. If you are using SageMaker for inference, you also need to attach IAM permissions to your cluster and convert an artifact to a model.

**Using SageMaker Components**

In this tutorial, you run a pipeline using SageMaker Components for Kubeflow Pipelines to train a classification model using Kmeans with the MNIST dataset. This workflow uses Kubeflow pipelines as the orchestrator and SageMaker as the backend to run the steps in the workflow. For the full code for this and other pipeline examples, see the [Sample SageMaker Kubeflow Pipelines](#). For information on the components used, see the [KubeFlow Pipelines GitHub repository](#).

**Contents**

- Setup (p. 2942)
- Running the Kubeflow Pipeline (p. 2948)

**Setup**

To use Kubeflow Pipelines (KFP), you need an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and a gateway node to interact with that cluster. The following sections show the steps needed to set up these resources.

**Topics**

- Set up a gateway node (p. 2942)
- Set up an Amazon EKS cluster (p. 2943)
- Install Kubeflow Pipelines (p. 2943)
- Access the KFP UI (p. 2944)
- Create IAM Users/Roles for KFP pods and the SageMaker service (p. 2945)
- Add access to additional IAM users or roles (p. 2947)

**Set up a gateway node**

A gateway node is used to create an Amazon EKS cluster and access the Kubeflow Pipelines UI. Use your local machine or an Amazon EC2 instance as your gateway node. If you want to use a new Amazon EC2 instance, create one with the latest Ubuntu 18.04 DLAMI version from the AWS console using the steps in [Launching and Configuring a DLAMI](#).

Complete the following steps to set up your gateway node. Depending on your environment, you may have certain requirements already configured.

1. If you don’t have an existing Amazon EKS cluster, create a user named `your_credentials` using the steps in [Creating an IAM User in Your AWS Account](#). If you have an existing Amazon EKS cluster, use the credentials of the IAM role or user that has access to it.
2. Add the following permissions to your user using the steps in [Changing Permissions for an IAM User](#):
   - `CloudWatchLogsFullAccess`
   - `AWSCloudFormationFullAccess`
• IAMFullAccess
• AmazonS3FullAccess
• AmazonEC2FullAccess
• AmazonEKSAadminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)

3. Install the following on your gateway node to access the Amazon EKS cluster and KFP UI.
   • AWS CLI. If you are using an IAM user, configure your Access Key ID, Secret Access Key and preferred AWS Region by running: aws configure
     • aws-iam-authenticator version 0.1.31 and above
     • eksctl version above 0.15.
     • kubectl (The version needs to match your Kubernetes version within one minor version)

4. Install boto3.
   ```
   pip install boto3
   ```

Set up an Amazon EKS cluster

Run the following steps from the command line of your gateway node to set up an Amazon EKS cluster:

1. If you do not have an existing Amazon EKS cluster, complete the following substeps. If you already have an Amazon EKS cluster, skip this step.
   a. Run the following from your command line to create an Amazon EKS cluster with version 1.17 or above. Replace `<your-cluster-name>` with any name for your cluster.
      ```
      eksctl create cluster --name <your-cluster-name> --region us-east-1 --auto-kubeconfig --timeout=50m --managed --nodes=1
      ```
   b. When cluster creation is complete, verify that you have access to the cluster using the following command.
      ```
      kubectl get nodes
      ```

2. Verify that the current kubectl context is the cluster you want to use with the following command. The current context is marked with an asterisk (*) in the output.
   ```
   kubectl config get-contexts
   CURRENT NAME                  CLUSTER
   * <username>@<clustername>.us-east-1.eksctl.io  <clustername>.us-east-1.eksctl.io
   ```

3. If the desired cluster is not configured as your current default, update the default with the following command.
   ```
   aws eks update-kubeconfig --name <clustername> --region us-east-1
   ```

Install Kubeflow Pipelines

Run the following steps from the command line of your gateway node to install Kubeflow Pipelines on your cluster.

1. Install Kubeflow Pipelines on your cluster by following step 1 of Deploying Kubeflow Pipelines documentation. Your KFP version must be 1.7.0 or above.
2. Verify that the Kubeflow Pipelines service and other related resources are running.
kubectl -n kubeflow get all | grep pipeline

Your output should look like the following.

<table>
<thead>
<tr>
<th>POD/NAME</th>
<th>DEPLOYMENT</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>

</tbody>
</table>

Access the KFP UI

The Kubeflow Pipelines UI is used for managing and tracking experiments, jobs, and runs on your cluster. You can use port forwarding to access the Kubeflow Pipelines UI from your gateway node.

Set up port forwarding to the KFP UI service

Run the following from the command line of your gateway node:

1. Verify that the KFP UI service is running using the following command:

   kubectl -n kubeflow get service ml-pipeline-ui

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml-pipeline-ui</td>
<td>ClusterIP</td>
<td>10.100.38.71</td>
<td>&lt;none&gt;</td>
<td>80/TCP</td>
<td>2d22h</td>
</tr>
</tbody>
</table>

2. Run the following command to set up port forwarding to the KFP UI service. This forwards the KFP UI to port 8080 on your gateway node and allows you to access the KFP UI from your browser.
kubectl port-forward -n kubeflow service/ml-pipeline-ui 8080:80

The port forward from your remote machine drops if there is no activity. Run this command again if your dashboard is unable to get logs or updates. If the commands return an error, ensure that there is no process already running on the port you are trying to use.

Access the KFP UI service

Your method of accessing the KFP UI depends on your gateway node type.

• Local machine as the gateway node
  1. Access the dashboard in your browser as follows:

      http://localhost:8080

  2. Choose Pipelines to access the pipelines UI.

• Amazon EC2 instance as the gateway node
  1. You need to set up an SSH tunnel on your Amazon EC2 instance to access the Kubeflow dashboard from your local machine's browser.

      From a new terminal session in your local machine, run the following. Replace <public-DNS-of-gateway-node> with the IP address of your instance found on the Amazon EC2 console. You can also use the public DNS. Replace <path_to_key> with the path to the pem key used to access the gateway node.

      public_DNS_address=<public-DNS-of-gateway-node>
      key=<path_to_key>
      on Ubuntu:
      ssh -i ${key} -L 9000:localhost:8080 ubuntu@${public_DNS_address}
      or on Amazon Linux:
      ssh -i ${key} -L 9000:localhost:8080 ec2-user@${public_DNS_address}

  2. Access the dashboard in your browser.

      http://localhost:9000

  3. Choose Pipelines to access the KFP UI.

Create IAM Users/Roles for KFP pods and the SageMaker service

You now have a Kubernetes cluster with Kubeflow set up. To run SageMaker Components for Kubeflow Pipelines, the Kubeflow Pipeline pods need access to SageMaker. In this section, you create IAM users/roles to be used by Kubeflow Pipeline pods and SageMaker.

Create a KFP execution role

Run the following from the command line of your gateway node:

  1. Enable OIDC support on the Amazon EKS cluster with the following command. Replace <cluster_name> with the name of your cluster and <cluster_region> with the region your cluster is in.
eksctl utils associate-iam-oidc-provider --cluster <cluster-name> \
--region <cluster-region> --approve

2. Run the following to get the OIDC issuer URL. This URL is in the form https://oidc.eks.<region>.amazonaws.com/id/<OIDC_ID>.

```bash
aws eks describe-cluster --region <cluster-region> --name <cluster-name> --query "cluster.identity.oidc.issuer" --output text
```

3. Run the following to create a file named trust.json. Replace <OIDC_URL> with your OIDC issuer URL. Don't include https:// when in your OIDC issuer URL. Replace <AWS_account_number> with your AWS account number.

```bash
OIDC_URL="<OIDC-URL>"
AWS_ACC_NUM="<AWS-account-number>"

# Run this to create trust.json file
cat <<EOF > trust.json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::${AWS_ACC_NUM}:oidc-provider/${OIDC_URL}",
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "${OIDC_URL}:aud": "sts.amazonaws.com",
          "${OIDC_URL}:sub": "system:serviceaccount:kubeflow:pipeline-runner"
        }
      }
    }
  ]
}
EOF
```

4. Create an IAM role named kfp-example-pod-role using trust.json using the following command. This role is used by KFP pods to create SageMaker jobs from KFP components. Note the ARN returned in the output.

```bash
aws iam create-role --role-name kfp-example-pod-role --assume-role-policy-document file://trust.json
aws iam attach-role-policy --role-name kfp-example-pod-role --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam get-role --role-name kfp-example-pod-role --output text --query 'Role.Arn'
```

5. Edit your pipeline-runner service account with the following command.

```bash
kubectl edit -n kubeflow serviceaccount pipeline-runner
```

6. In the file, add the following Amazon EKS role annotation and replace <role_arn> with your role ARN.

```bash
eks.amazonaws.com/role-arn: <role-arn>
```

7. Your file should look like the following when you've added the Amazon EKS role annotation. Save the file.
Create an SageMaker execution role

The kfp-example-sagemaker-execution-role IAM role is used by SageMaker jobs to access AWS resources. For more information, see the IAM Permissions section. You provide this role as an input parameter when running the pipeline.

Run the following to create the role. Note the ARN that is returned in your output.

```bash
SAGEMAKER_EXECUTION_ROLE_NAME=kfp-example-sagemaker-execution-role

aws iam create-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --assume-role-policy-document "$TRUST"
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess
aws iam get-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --output text --query 'Role.Arn'
```

Add access to additional IAM users or roles

If you use an intuitive IDE like Jupyter or want other people in your organization to use the cluster you set up, you can also give them access. The following steps run through this workflow using SageMaker notebooks. An SageMaker notebook instance is a fully managed Amazon EC2 compute instance that runs the Jupyter Notebook App. You use the notebook instance to create and manage Jupyter notebooks to create ML workflows. You can define, compile, deploy, and run your pipeline using the KFP Python SDK or CLI. If you’re not using an SageMaker notebook to run Jupyter, you need to install the AWS CLI and the latest version of kubectl.
1. Follow the steps in Create an SageMaker Notebook Instance to create a SageMaker notebook instance if you do not already have one. Give the IAM role for this instance the S3FullAccess permission.

2. Amazon EKS clusters use IAM users and roles to control access to the cluster. The rules are implemented in a config map named aws-auth. Only the user/role that has access to the cluster will be able to edit this config map. Run the following from the command line of your gateway node to get the IAM role of the notebook instance you created. Replace `<instance-name>` with the name of your instance.

```bash
aws sagemaker describe-notebook-instance --notebook-instance-name <instance-name> --region <region> --output text --query 'RoleArn'
```

This command outputs the IAM role ARN in the `arn:aws:iam::<account-id>:role/<role-name>` format. Take note of this ARN.

3. Run the following to attach the policies the IAM role. Replace `<role-name>` with the IAM role in your ARN.

```bash
aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess
```

4. eksctl provides commands to read and edit the aws-auth config map. system:masters is one of the default user groups. You add the user to this group. The system:masters group has superuser permissions to the cluster. You can also create a group with more restrictive permissions or you can bind permissions directly to users. Replace `<IAM-Role-arn>` with the ARN of the IAM role. `<your_username>` can be any unique username.

```bash
eksctl create iamidentitymapping \    --cluster <cluster-name> \    --arn <IAM-Role-arn> \    --group system:masters \    --username <your-username> \    --region <region>
```

5. Open the Jupyter notebook on your SageMaker instance and run the following to verify that it has access to the cluster.

```bash
aws eks --region <region> update-kubeconfig --name <cluster-name>
kubectl -n kubeflow get all | grep pipeline
```

### Running the Kubeflow Pipeline

Now that setup of your gateway node and Amazon EKS cluster is complete, you can create your classification pipeline. To create your pipeline, you need to define and compile it. You then deploy it and use it to run workflows. You can define your pipeline in Python and use the KFP dashboard, KFP CLI, or Python SDK to compile, deploy, and run your workflows. The full code for the MNIST classification pipeline example is available in the Kubeflow Github repository. To use it, clone the example Python files to your gateway node.

### Topics
- Prepare datasets (p. 2949)
- Create a Kubeflow Pipeline using SageMaker Components (p. 2949)
Amazon SageMaker Developer Guide
SageMaker Components for Kubeflow Pipelines

- Compile and deploy your pipeline (p. 2949)
- Running predictions (p. 2951)
- View results and logs (p. 2953)
- Cleanup (p. 2953)

Prepare datasets

To run the pipelines, you need to upload the data extraction pre-processing script to an Amazon S3 bucket. This bucket and all resources for this example must be located in the us-east-1 Amazon Region. If you don’t have a bucket, create one using the steps in Creating a bucket.

From the mnist-kmeans-sagemaker folder of the Kubeflow repository you cloned on your gateway node, run the following command to upload the kmeans_preprocessing.py file to your Amazon S3 bucket. Change <bucket-name> to the name of the Amazon S3 bucket you created.

```bash
aws s3 cp mnist-kmeans-sagemaker/kmeans_preprocessing.py s3://<bucket-name>/mnist_kmeans_example/processing_code/kmeans_preprocessing.py
```

Create a Kubeflow Pipeline using SageMaker Components

The full code for the MNIST classification pipeline is available in the Kubeflow Github repository. To use it, clone the example Python files to your gateway node.

Input Parameters

The full MNIST classification pipeline has run-specific parameters for which you must provide values when creating a run. You must provide these parameters for each component of your pipeline. These parameters can also be updated when using other pipelines. We have provided default values for all parameters in the sample classification pipeline file.

The following are the only parameters you need to pass to run the sample pipelines. To pass these parameters, update their entries when creating a new run.

- **Role-ARN**: This must be the ARN of an IAM role that has full SageMaker access in your AWS account. Use the ARN of kfp-example-pod-role.
- **Bucket**: This is the name of the Amazon S3 bucket that you uploaded the kmeans_preprocessing.py file to.

You can adjust any of the input parameters using the KFP UI and trigger your run again.

Compile and deploy your pipeline

After defining the pipeline in Python, you must compile the pipeline to an intermediate representation before you can submit it to the Kubeflow Pipelines service. The intermediate representation is a workflow specification in the form of a YAML file compressed into a tar.gz file. You need the KFP SDK to compile your pipeline.

Install KFP SDK

Run the following from the command line of your gateway node:

1. Install the KFP SDK following the instructions in the Kubeflow pipelines documentation.
2. Verify that the KFP SDK is installed with the following command:

```bash
pip show kfp
```
3. Verify that dsl-compile has been installed correctly as follows:

```bash
which dsl-compile
```

### Compile your pipeline

You have three options to interact with Kubeflow Pipelines: KFP UI, KFP CLI, or the KFP SDK. The following sections illustrate the workflow using the KFP UI and CLI.

Complete the following from your gateway node to compile your pipeline.

1. Modify your Python file with your Amazon S3 bucket name and IAM role ARN.
2. Use the `dsl-compile` command from the command line to compile your pipeline as follows.
   Replace `<path-to-python-file>` with the path to your pipeline and `<path-to-output>` with the location where you want your tar.gz file to be.

```bash
dsl-compile --py <path-to-python-file> --output <path-to-output>
```

### Upload and run the pipeline using the KFP CLI

Complete the following steps from the command line of your gateway node. KFP organizes runs of your pipeline as experiments. You have the option to specify an experiment name. If you do not specify one, the run will be listed under **Default** experiment.

1. Upload your pipeline as follows:

   ```bash
   kfp pipeline upload --pipeline-name <pipeline-name> <path-to-output-tar.gz>
   ```

   Your output should look like the following. Take note of the **ID**.

   ```text
   Pipeline 29c3ff21-49f5-4dfe-94f6-618c0e2420fe has been submitted
   Pipeline Details
   ------------------
   ID 29c3ff21-49f5-4dfe-94f6-618c0e2420fe
   Name sm-pipeline
   Description
   Uploaded at 2020-04-30T20:22:39+00:00
   ...
   ...
   ```

2. Create a run using the following command. The KFP CLI run command currently does not support specifying input parameters while creating the run. You need to update your parameters in the Python pipeline file before compiling. Replace `<experiment-name>` and `<job-name>` with any names. Replace `<pipeline-id>` with the ID of your submitted pipeline. Replace `<your-role-arn>` with the ARN of `kfp-example-pod-role`. Replace `<your-bucket-name>` with the name of the Amazon S3 bucket you created.

   ```bash
   kfp run submit --experiment-name <experiment-name> --run-name <job-name> --pipeline-id <pipeline-id> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
   ```

   You can also directly submit a run using the compiled pipeline package created as the output of the `dsl-compile` command.
kfp run submit --experiment-name <experiment-name> --run-name <job-name> --package-file <path-to-output> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"

Your output should look like the following:

Creating experiment aws.
Run 95084a2c-f18d-4b77-a9da-eba00bf01e63 is submitted
+--------------------------------------+--------+----------+---------------------------
<table>
<thead>
<tr>
<th>run id</th>
<th>name</th>
<th>status</th>
<th>created at</th>
</tr>
</thead>
<tbody>
<tr>
<td>95084a2c-f18d-4b77-a9da-eba00bf01e63</td>
<td>sm-job</td>
<td></td>
<td>2020-04-30T20:36:41+00:00</td>
</tr>
</tbody>
</table>
+--------------------------------------+--------+----------+---------------------------

3. Navigate to the UI to check the progress of the job.

Upload and run the pipeline using the KFP UI

1. On the left panel, choose the **Pipelines** tab.
2. In the upper-right corner, choose **+UploadPipeline**.
3. Enter the pipeline name and description.
4. Choose **Upload a file** and enter the path to the tar.gz file you created using the CLI or with the Python SDK.
5. On the left panel, choose the **Pipelines** tab.
6. Find the pipeline you created.
7. Choose **+CreateRun**.
8. Enter your input parameters.
9. Choose **Run**.

Running predictions

Once your classification pipeline is deployed, you can run classification predictions against the endpoint that was created by the Deploy component. Use the KFP UI to check the output artifacts for sagemaker-deploy-model-endpoint_name. Download the .tgz file to extract the endpoint name or check the SageMaker console in the region you used.

Configure permissions to run predictions

If you want to run predictions from your gateway node, skip this section.

1. To use any other machine to run predictions, assign the sagemaker:InvokeEndpoint permission to the IAM role or IAM user used by the client machine. This permission is used to run predictions.
2. On your gateway node, run the following to create a policy file:

```bash
cat <<EoF > ./sagemaker-invoke.json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["sagemaker:InvokeEndpoint"]
    }
  ]
}

EoF
```
3. Attach the policy to the client node's IAM role or IAM user.

4. If your client machine has an IAM role attached, run the following. Replace `<your-instance-IAM-role>` with the name of the client node's IAM role. Replace `<path-to-sagemaker-invoke-json>` with the path to the policy file you created.

   ```
   aws iam put-role-policy --role-name <your-instance-IAM-role> --policy-name sagemaker-invoke-for-worker --policy-document file://<path-to-sagemaker-invoke-json>
   ```

5. If your client machine has IAM user credentials configured, run the following. Replace `<your_IAM_user_name>` with the name of the client node's IAM user. Replace `<path-to-sagemaker-invoke-json>` with the path to the policy file you created.

   ```
   aws iam put-user-policy --user-name <your-IAM-user-name> --policy-name sagemaker-invoke-for-worker --policy-document file://<path-to-sagemaker-invoke-json>
   ```

### Run predictions

1. Create a Python file from your client machine named `mnist-predictions.py` with the following content. Replace the `ENDPOINT_NAME` variable. This script loads the MNIST dataset, then creates a CSV from those digits and sends it to the endpoint for prediction. It then outputs the results.

   ```
   import boto3
   import gzip
   import io
   import json
   import numpy
   import pickle

   ENDPOINT_NAME='<endpoint-name>'
   region = boto3.Session().region_name

   # S3 bucket where the original mnist data is downloaded and stored
   downloaded_data_bucket = f"jumpstart-cache-prod-{region}"
   downloaded_data_prefix = "ip-notebooks-datasets/mnist"

   # Download the dataset
   s3 = boto3.client("s3")
   s3.download_file(downloaded_data_bucket, f"{downloaded_data_prefix}/mnist.pkl.gz", "mnist.pkl.gz")

   # Load the dataset
   with gzip.open('mnist.pkl.gz', 'rb') as f:
       train_set, valid_set, test_set = pickle.load(f, encoding='latin1')

   # Simple function to create a csv from our numpy array
   def np2csv(arr):
       csv = io.BytesIO()
       numpy.savetxt(csv, arr, delimiter=',', fmt='%.1f')
       return csv.getvalue().decode().rstrip()

   runtime = boto3.Session(region).client('sagemaker-runtime')
   ```
payload = np2csv(train_set[0][30:31])

response = runtime.invoke_endpoint(EndpointName=ENDPOINT_NAME,
    ContentType='text/csv',
    Body=payload)
result = json.loads(response['Body'].read().decode())
print(result)

2. Run the Python file as follows:

```bash
python mnist-predictions.py
```

**View results and logs**

When the pipeline is running, you can choose any component to check execution details, such as inputs and outputs. This lists the names of created resources.

If the KFP request is successfully processed and an SageMaker job is created, the component logs in the KFP UI provide a link to the job created in SageMaker. The CloudWatch logs are also provided if the job is successfully created.

If you run too many pipeline jobs on the same cluster, you may see an error message that indicates you do not have enough pods available. To fix this, log in to your gateway node and delete the pods created by the pipelines you are not using as follows:

```bash
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

**Cleanup**

When you're finished with your pipeline, you need to clean up your resources.

1. From the KFP dashboard, terminate your pipeline runs if they do not exit properly by choosing Terminete.
2. If the **Terminate** option doesn't work, log in to your gateway node and manually terminate all the pods created by your pipeline run as follows:

```bash
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

3. Using your AWS account, log in to the SageMaker service. Manually stop all training, batch transform, and HPO jobs. Delete models, data buckets, and endpoints to avoid incurring any additional costs. Terminating the pipeline runs does not stop the jobs in SageMaker.
Using Amazon Augmented AI for Human Review

When you use AI applications such as Amazon Rekognition, Amazon Textract, or your custom machine learning (ML) models, you can use Amazon Augmented AI to get human review of low-confidence predictions or random prediction samples.

What is Amazon Augmented AI?

Amazon Augmented AI (Amazon A2I) is a service that brings human review of ML predictions to all developers by removing the heavy lifting associated with building human review systems or managing large numbers of human reviewers.

Many ML applications require humans to review low-confidence predictions to ensure the results are correct. For example, extracting information from scanned mortgage application forms can require human review due to low-quality scans or poor handwriting. Building human review systems can be time-consuming and expensive because it involves implementing complex processes or workflows, writing custom software to manage review tasks and results, and managing large groups of reviewers.

Amazon A2I streamlines building and managing human reviews for ML applications. Amazon A2I provides built-in human review workflows for common ML use cases, such as content moderation and text extraction from documents. You can also create your own workflows for ML models built on SageMaker or any other tools. Using Amazon A2I, you can allow human reviewers to step in when a model is unable to make a high-confidence prediction or to audit its predictions on an ongoing basis.

Amazon A2I Use Case Examples

The following examples demonstrate how you can use Amazon A2I to integrate a human review loop into your ML application. For each of these examples, you can find a Jupyter Notebook that demonstrates that workflow in Use Cases and Examples Using Amazon A2I (p. 2975).

- **Use Amazon A2I with Amazon Textract** – Have humans review important key-value pairs in single-page documents or have Amazon Textract randomly sample and send documents from your dataset to humans for review.

- **Use Amazon A2I with Amazon Rekognition** – Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low-confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.

- **Use Amazon A2I to review real-time ML inferences** – Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker hosted endpoint and incrementally train your model using Amazon A2I output data.

- **Use Amazon A2I with Amazon Comprehend** – Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.

- **Use Amazon A2I with Amazon Transcribe** – Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.

- **Use Amazon A2I with Amazon Translate** – Have humans review low-confidence translations returned from Amazon Translate.
Use Amazon A2I to review tabular data – Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Get Started with Amazon Augmented AI

To get started using Amazon Augmented AI, review the Core Components of Amazon A2I (p. 2955) and Prerequisites to Using Augmented AI (p. 2959). Then, use the following documentation to learn how to use the Amazon A2I console and API.

- Tutorial: Get Started in the Amazon A2I Console (p. 2959)
- Tutorial: Get Started Using the Amazon A2I API (p. 2965)

You can also get started using the Amazon A2I API by following a Jupyter Notebook tutorial. See Use Cases and Examples Using Amazon A2I (p. 2975) for a list of notebooks and use cases.

Core Components of Amazon A2I

Review the following terms to familiarize yourself with the core components of Amazon A2I.

Task Types

The AI/ML workflow into which you integrate Amazon A2I defines an Amazon A2I task type.
Amazon A2I supports:

- **Two built-in task types**: Amazon Textract key-value pair extraction and Amazon Rekognition image moderation.

- **A custom task type**: Use a custom task type to integrate a human review loop into any machine learning workflow. You can use a custom task type to integrate Amazon A2I with other AWS services like Amazon Comprehend, Amazon Transcribe, and Amazon Translate, as well as your own custom machine learning workflows. To learn more, see Use Cases and Examples Using Amazon A2I (p. 2975).

Select a tab in the following table to see diagrams that illustrate how Amazon A2I works with each task type. Select the task type page using the links in the preceding list to learn more about that task type.

**Amazon Textract – Key-value pair extraction**

This image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

**Amazon Rekognition – Image moderation**

This image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.
Custom Task Type

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Human Review Workflow (Flow Definition)

You use a human review workflow to specify your human work team, to set up your worker UI using a worker task template, and to provide information about how workers should complete the review task.

For built-in task types, you also use the human review workflow to identify the conditions under which a human loop is initiated. For example, Amazon Rekognition can perform image content moderation using machine learning. You can use the human review workflow to specify that an image is sent to a human for content moderation review if Amazon Rekognition's confidence is too low.

You can use a human review workflow to create multiple human loops.
You can create a flow definition in the SageMaker console or with the SageMaker API. To learn more about both of these options, see Create a Human Review Workflow (p. 2983).

Work Team

A work team is a group of human workers to whom you send your human review tasks.

When you create a human review workflow, you specify a single work team.

Your work team can come from the Amazon Mechanical Turk workforce, a vendor-managed workforce, or your own private workforce. When you use the private workforce, you can create multiple work teams. Each work team can be used in multiple human review workflows. To learn how to create a workforce and work teams, see Create and Manage Workforces (p. 619).

Worker Task Template and Human Task UI

You use a worker task template to create a worker UI (a human task UI) for your human review tasks.

The human task UI displays your input data, such as documents or images, and instructions to workers. It also provides interactive tools that the worker uses to complete your tasks.

For built-in task types, you must use the Amazon A2I worker task template provided for that task type.

Human Loops

A human loop is used to create a single human review job. For each human review job, you can choose the number of workers that are sent a task to review a single data object. For example, if you set the number of workers per object to 3 for an image classification labeling job, three workers classify each input image. Increasing the number of workers per object can improve label accuracy.

A human loop is created using a human review workflow as follows:

- For built-in task types, the conditions specified in the human review workflow determine when the human loop is created.
- Human review tasks are sent to the work team specified in the human review workflow.
- The worker task template specified in the human review workflow is used to render the human task UI.

When do human loops get created?

When you use one of the built-in task types, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your human review workflow are met. For example:

- When you use Augmented AI with Amazon Textract, you can integrate Amazon A2I into a document review task using the API operation AnalyzeDocument. A human loop is created every time Amazon Textract returns inferences about key-value pairs that meet the conditions you specify in your human review workflow.
- When you use Augmented AI with Amazon Rekognition, you can integrate Amazon A2I into an image moderation task using the API operation DetectModerationLabels. A human loop is created every time Amazon Rekognition returns inferences about image content that meet the conditions you specify in your human review workflow.

When using a custom task type, you start a human loop using the Amazon Augmented AI Runtime API. When you call StartHumanLoop in your custom application, a task is sent to human reviewers.

To learn how to create and start a human loop, see Create and Start a Human Loop (p. 3002).
To generate these resources and create a human review workflow, Amazon A2I integrates multiple APIs, including the Amazon Augmented AI Runtime Model, the SageMaker APIs, and APIs associated with your task type. To learn more, see Use APIs in Amazon Augmented AI (p. 3038).

Note
AWS Region availability may differ when you use Augmented AI with other AWS services, such as Amazon Textract. Create Augmented AI resources in the same AWS Region that you use to interact with those AWS services. For AWS Region availability for all services, see the Region Table.

Prerequisites to Using Augmented AI

Amazon A2I uses resources in IAM, SageMaker, and Amazon S3 to create and run your human review workflows. You can create some of these resources in the Amazon A2I console when you create a human review workflow. To learn how, see Tutorial: Get Started in the Amazon A2I Console (p. 2959).

To use Amazon A2I, you need the following resources:

- One or more Amazon S3 buckets in the same AWS Region as the workflow for your input and output data. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
- An IAM role with required permissions to create a human review workflow and an IAM user or role with permission to access Augmented AI. For more information, see Permissions and Security in Amazon Augmented AI (p. 3030).
- A public, private, or vendor workforce for your human review workflows. If you plan to use a private workforce, you need to set one up ahead of time in the same AWS Region as your Amazon A2I workflow. To learn more about these workforce types, see Create and Manage Workforces (p. 619).

Important
To learn about the compliance programs that cover Amazon Augmented AI at this time, see AWS Services in Scope by Compliance Program. If you use Amazon Augmented AI in conjunction with other AWS services (such as Amazon Rekognition and Amazon Textract), note that Amazon Augmented AI may not be in scope for the same compliance programs as those other services. You are responsible for how you use Amazon Augmented AI, including understanding how the service processes or stores customer data and any impact on the compliance of your data environment. You should discuss your workload objectives and goals with your AWS account team; they can help you evaluate whether the service is a good fit for your proposed use case and architecture.

Tutorial: Get Started in the Amazon A2I Console

The following tutorial shows you how to get started using Amazon A2I in the Amazon A2I console.

The tutorial gives you the option to use Augmented AI with Amazon Textract for document review or Amazon Rekognition for image content review.

Prerequisites

To get started using Amazon A2I, complete the following prerequisites.

- Create an Amazon S3 bucket in the same AWS Region as the workflow for your input and output data. For example, if you are using Amazon A2I with Amazon Textract in us-east-1, create your bucket in us-east-1. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
- Do one of the following:
• If you want to complete the tutorial using Amazon Textract, download this sample document and place it in your Amazon S3 bucket.
• If you want to complete the tutorial using Amazon Rekognition, download this image and place it in your Amazon S3 bucket.

Note
The Amazon A2I console is embedded in the SageMaker console.

Step 1: Create a Work Team

First, create a work team in the Amazon A2I console and add yourself as a worker so that you can preview the worker review task.

Important
This tutorial uses a private work team. The Amazon A2I private workforce is configured in the Ground Truth area of the SageMaker console and is shared between Amazon A2I and Ground Truth.

To create a private workforce using worker emails

2. In the navigation pane, choose Labeling workforces under Ground Truth.
3. Choose Private, then choose Create private team.
4. Choose Invite new workers by email.
5. For this tutorial, enter your email and any others that you want to be able to preview the human task UI. You can paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an Amazon SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to Amazon SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Choose Create private team.

If you add yourself to a private work team, you receive an email from no-reply@verificationemail.com with login information. Use the link in this email to reset your password and log in to your worker portal. This is where your human review tasks appear when you create a human loop.

Step 2: Create a Human Review Workflow

In this step, you create a human review workflow. Each human review workflow is created for a specific task type. This tutorial allows you to choose between the built-in task types: Amazon Rekognition and Amazon Textract.

To create a human review workflow:

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the Human review workflows page.
2. Select Create human review workflow.
3. In Workflow settings, enter a workflow Name, S3 bucket, and the IAM role that you created for this tutorial, with the AWS managed policy AmazonAugmentedAIIIntegratedAPIAccess attached.
4. For **Task type**, select **Textract – Key-value pair extraction** or **Rekognition – Image moderation**.

5. Select the task type that you chose from the following table for instructions for that task type.

**Amazon Textract – Key-value pair extraction**

1. Select **Trigger a human review for specific form keys based on the form key confidence score or when specific form keys are missing**.

2. For **Key name**, enter **Mail Address**.

3. Set the identification confidence threshold between 0 and 99.

4. Set the qualification confidence threshold between 0 and 99.

5. Select **Trigger a human review for all form keys identified by Amazon Textract with confidence scores in a specific range**.

6. Set the identification confidence threshold between 0 and 90.

7. Set the qualification confidence threshold between 0 and 90.

This initiates a human review if Amazon Textract returns a confidence score that is less than 99 for **Mail Address** and its key, or if it returns a confidence score less than 90 for any key value pair detected in the document.

The following image shows the Amazon Textract form extraction - Conditions for invoking human review section of the Amazon A2I console. In the image, the check boxes for the two types of triggers explained in the proceeding paragraph are checked, and **Mail Address** is used as a **Key name** for the first trigger. The identification confidence threshold is defined using confidence scores for key-value pairs detect within the form and is set between 0 and 99. The qualification confidence threshold is defined using confidence scores for text contained within keys and values in a form and is set between 0 and 99.
Amazon Rekognition – Image moderation

1. Select Trigger human review for labels identified by Amazon Rekognition based on label confidence score.

2. Set the Threshold between 0 and 98.

This initiates a human review if Amazon Rekognition returns a confidence score that is less than 98 for an image moderation job.

The following image shows how you can select the Trigger human review for labels identified by Amazon Rekognition based on label confidence score option and enter a Threshold between 0 and 98 in the Amazon A2I console.
6. **Under Worker task template creation**, select **Create from a default template**.

7. Enter a **Template name**.

8. In **Task description** field, enter the following text:

   Read the instructions carefully and complete the task.

9. **Under Workers**, select **Private**.

10. Select the private team that you created.

11. Choose **Create**.

Once your human review workflow is created, it appears in the table on the **Human review workflows** page. When the **Status** is **Active**, copy and save the Workflow ARN. You need it for the next step.

**Step 3: Start a Human Loop**

You must use an API operation to start a human loop. There are a variety of language-specific SDKs that you can use to interact with these API operations. To see documentation for each of these SDKs, refer to the **See Also** section in the API documentation, as shown in the following image.

For this tutorial, you use one of the following APIs:

- If you chose the Amazon Textract task type, you use the **AnalyzeDocument** operation.
- If you chose the Amazon Rekognition task type, you use the **DetectModerationLabels** operation.
You can interact with these APIs using a SageMaker notebook instance (recommended for new users) or the AWS Command Line Interface (AWS CLI). Choose one of the following to learn more about these options:

- To learn more about and set up a notebook instance, see Use Amazon SageMaker Notebook Instances (p. 237).
- To learn more about and get started using the AWS CLI, see What Is the AWS Command Line Interface? in the AWS Command Line Interface User Guide.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

**Amazon Textract – Key-value pair extraction**

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `analyze_document` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.analyze_document(
    Document={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "document-name.pdf"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            "ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]
        }
    },
    FeatureTypes=["TABLES", "FORMS"]
)
```

**Amazon Rekognition – Image moderation**

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `detect_moderation_labels` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "image-name.png"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            "ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]
        }
    }
)
```
Step 4: View Human Loop Status in Console

When you start a human loop, you can view its status in the Amazon A2I console.

To view your human loop status

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the Human review workflows page.
2. Select the human review workflow that you used to start your human loop.
3. In the Human loops section, you can see your human loop. View its status in the Status column.

Step 5: Download Output Data

Your output data is stored in the Amazon S3 bucket you specified when you created a human review workflow.

To view your Amazon A2I output data

1. Open the Amazon S3 console.
2. Select the Amazon S3 bucket you specified when you created your human review workflow in step 2 of this example.
3. Starting with the folder that is named after your human review workflow, navigate to your output data by selecting the folder with the following naming convention:

s3://output-bucket-specified-in-human-review-workflow/human-review-workflow-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json

4. Select output.json and choose Download.

Tutorial: Get Started Using the Amazon A2I API

This tutorial explains the API operations you can use to get started using Amazon A2I.

To use a Jupyter Notebook to run these operations, select a Jupyter Notebook from Use Cases and Examples Using Amazon A2I (p. 2975) and use Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977) to learn how to use it in a SageMaker notebook instance.

To learn more about the API operations you can use with Amazon A2I, see Use APIs in Amazon Augmented AI (p. 3038).

Create a Private Work Team

You can create a private work team and add yourself as a worker so that you can preview Amazon A2I.

If you are not familiar with Amazon Cognito, we recommend that you use the SageMaker console to create a private workforce and add yourself as a private worker. For instructions, see Step 1: Create a Work Team (p. 2960).

If you are familiar with Amazon Cognito, you can use the following instructions to create a private work team using the SageMaker API. After you create a work team, note the work team ARN (WorkteamArn).

To learn more about the private workforce and other available configurations, see Use a Private Workforce (p. 624).
Create a private workforce

If you have not created a private workforce, you can do so using an Amazon Cognito user pool. Make sure that you have added yourself to this user pool. You can create a private work team using the AWS SDK for Python (Boto3) create_workforce function. For other language-specific SDKs, refer to the list in CreateWorkforce.

```python
response = client.create_workforce(
    CognitoConfig={
        "UserPool": "Pool_ID",
        "ClientId": "app-client-id"
    },
    WorkforceName="workforce-name"
)
```

Create a private work team

After you have created a private workforce in the AWS Region to configure and start your human loop, you can create a private work team using the AWS SDK for Python (Boto3) create_workteam function. For other language-specific SDKs, refer to the list in CreateWorkteam.

```python
response = client.create_workteam(
    WorkteamName="work-team-name",
    WorkforceName= "workforce-name",
    MemberDefinitions=[
        {
            "CognitoMemberDefinition": {
                "UserPool": "<aws-region>_ID",
                "UserGroup": "user-group",
                "ClientId": "app-client-id"
            }
        }
    ]
)
```

Access your work team ARN as follows:

```python
workteamArn = response["WorkteamArn"]
```

List private work teams in your account

If you have already created a private work team, you can list all work teams in a given AWS Region in your account using the AWS SDK for Python (Boto3) list_workteams function. For other language-specific SDKs, refer to the list in ListWorkteams.

```python
response = client.list_workteams()
```

If you have numerous work teams in your account, you may want to use MaxResults, SortBy, and NameContains to filter your results.

Create a Human Review Workflow

You can create a human review workflow using the Amazon A2I CreateFlowDefinition operation. Before you create your human review workflow, you need to create a human task UI. You can do this with the CreateHumanTaskUi operation.
If you are using Amazon A2I with the Amazon Textract or Amazon Rekognition integrations, you can specify activation conditions using a JSON.

Create a Human Task UI

If you are creating a human review workflow to be used with Amazon Textract or Amazon Rekognition integrations, you need to use and modify pre-made worker task template. For all custom integrations, you can use your own custom worker task template. Use the following table to learn how to create a human task UI using a worker task template for the two built-in integrations. Replace the template with your own to customize this request.

Amazon Textract – Key-value pair extraction

To learn more about this template, see Custom Template Example for Amazon Textract (p. 3013).

```
<template>

<% capture s3_uri %>
</template>
```
Amazon Rekognition – Image moderation

To learn more about this template, see Custom Template Example for Amazon Rekognition (p. 3015).

```template
template = r""
<short-instructions header="Instructions">
  Review the image and choose all applicable categories. If no categories apply, choose None.
</short-instructions>
<full-instructions header="Instructions">
  <b>Nudity</b>
  Visuals depicting nude male or female person or persons

  <b>Partial Nudity</b>
  Visuals depicting covered up nudity, for example using hands or pose

  <b>Revealing Clothes</b>
  Visuals depicting revealing clothes and poses

  <b>Physical Violence</b>
  Visuals depicting violent physical assault, such as kicking or punching

  <b>Weapon Violence</b>
  Visuals depicting violence using weapons like firearms or blades, such as shooting

  <b>Weapons</b>
  Visuals depicting weapons like firearms and blades
</full-instructions>
""
Custom Integration

The following is an example template that can be used in a custom integration. This template is used in this notebook, demonstrating a custom integration with Amazon Comprehend.

```python
template = r""
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

crowd-form

crowd-classifier

name="sentiment"
categories=['"Positive", "Negative", "Neutral", "Mixed"]'
initial-value="{{ task.input.initialValue }}"
header="What sentiment does this text convey?"
>
<classification-target>
{{ task.input.taskObject }}
</classification-target>

<full-instructions header="Sentiment Analysis Instructions">
<p><strong>Positive</strong> sentiment include: joy, excitement, delight</p>
<p><strong>Negative</strong> sentiment include: anger, sarcasm, anxiety</p>
<p><strong>Neutral</strong>: neither positive or negative, such as stating a fact</p>
<p><strong>Mixed</strong>: when the sentiment is mixed</p>
</full-instructions>

<short-instructions>
Choose the primary sentiment that is expressed by the text.
</short-instructions>
</crowd-classifier>
""
```

Using the template specified above, you can create a template using the AWS SDK for Python (Boto3) `create_human_task_ui` function. For other language-specific SDKs, refer to the list in `CreateHumanTaskUi`.

```python
response = client.create_human_task_ui(
    HumanTaskUiName="human-task-ui-name",
    UiTemplate={
        "Content": template
    }
)
```

This response element contains the human task UI ARN. Save this as follows:

```python
humanTaskUiArn = response["HumanTaskUiArn"]
```

Create JSON to specify activation conditions

For Amazon Textract and Amazon Rekognition built-in integrations, you can save activation conditions in a JSON object and use this in your `CreateFlowDefinition` request.
Next, select a tab to see example activation conditions you can use for these built-in integrations. For additional information about activation condition options, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989).

Amazon Textract – Key-value pair extraction

This example specifies conditions for specific keys (such as Mail address) in the document. If Amazon Textract's confidence falls outside of the thresholds set here, the document is sent to a human for review, with the specific keys that initiated the human loop prompted to the worker.

```python
import json

humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
                "Or": [
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "MissingImportantFormKey",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"]
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Phone Number",
                            "ImportantFormKeyAliases": ["Phone number:","Phone No.:","Number:"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "*",
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "*",
                            "KeyValueBlockConfidenceGreaterThan": 0,
                            "WordBlockConfidenceGreaterThan": 0
                        }
                    }
                ]
            }
        ]
    }
)
Amazon Rekognition – Image moderation

The human loop activation conditions used here are tailored towards Amazon Rekognition content moderation; they are based on the confidence thresholds for the Suggestive and Female Swimwear Or Underwear moderation labels.

```python
import json
humanLoopActivationConditions = json.dumps(
    {
    "Conditions": [
    {
        "Or": [
        {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
                "ModerationLabelName": "Suggestive",
                "ConfidenceLessThan": 98
            }
        },
        {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
                "ModerationLabelName": "Female Swimwear Or Underwear",
                "ConfidenceGreaterThan": 98
            }
        }
    ]
    }
    }
)
```

Create a human review workflow

This section gives an example of the `CreateFlowDefinition` AWS SDK for Python (Boto3) request using the resources created in the previous sections. For other language-specific SDKs, refer to the list in `CreateFlowDefinition`. Use the tabs in the following table to see the requests to create a human review workflow for Amazon Textract and Amazon Rekognition built-in integrations.

Amazon Textract – Key-value pair extraction

If you use the built-in integration with Amazon Textract, you must specify "AWS/Textract/AnalyzeDocument/Forms/V1" for "AwsManagedHumanLoopRequestSource" in `HumanLoopRequestSource`.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "HumanLoopActivationConditions": humanLoopActivationConditions
        }
    }
)
```
Amazon SageMaker Developer Guide
Tutorial: Get Started Using the Amazon A2I API

Amazon Rekognition – Image moderation

If you use the built-in integration with Amazon Rekognition, you must specify "AWS/Rekognition/DetectModerationLabels/Image/V3" for "AwsManagedHumanLoopRequestSource" in HumanLoopRequestSource.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "HumanLoopActivationConditions": humanLoopActivationConditions
        }
    },
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {
            "Key": "string",
            "Value": "string"
        },
    ]
)`
Custom Integration

If you use a custom integration, exclude the following parameters: HumanLoopRequestSource, HumanLoopActivationConfig.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {
            "Key": "string",
            "Value": "string"
        },
    ]
)
```

After you create a human review workflow, you can retrieve the flow definition ARN from the response:

```python
humanReviewWorkflowArn = response["FlowDefinitionArn"]
```

Create a Human Loop

The API operation you use to start a human loop depends on the Amazon A2I integration you use.

- If you use the Amazon Textract built-in integration, you use the `AnalyzeDocument` operation.
- If you use the Amazon Rekognition built-in integration, you use the `DetectModerationLabels` operation.
- If you use a custom integration, you use the `StartHumanLoop` operation.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

### Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes`
Human loops are only created if Amazon Textract's confidence for document analysis task meets the activation conditions you specified in your human review workflow. You can check the response element to determine if a human loop has been created. To see everything included in this response, see HumanLoopActivationOutput.

```python
if "HumanLoopArn" in analyzeDocumentResponse["HumanLoopActivationOutput"]:  # A human loop has been started:
    print(f"A human loop has been started with ARN: {analyzeDocumentResponse["HumanLoopActivationOutput"]['HumanLoopArn']}"
```

Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call detect_moderation_labels in us-west-2. Replace the italicized red text with your resources. Include the DataAttributes parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the detect_moderation_labels documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={"S3Object":{"Bucket": "AWSDOC-EXAMPLE-BUCKET", "Name": "image-name.png"}},
    HumanLoopConfig={
        "HumanLoopName":"human-loop-name",
        "DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
    }
)
```

Human loops are only created if Amazon Rekognition's confidence for an image moderation task meets the activation conditions you specified in your human review workflow. You can check the response element to determine if a human loop has been created. To see everything included in this response, see HumanLoopActivationOutput.

```python
if "HumanLoopArn" in response["HumanLoopActivationOutput"]:  # A human loop has been started:
    print(f"A human loop has been started with ARN: {response["HumanLoopActivationOutput"]["HumanLoopArn"]}
```
Custom Integration

The following example uses the AWS SDK for Python (Boto3) to call `start_human_loop` in `us-west-2`. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `start_human_loop` documentation in the `AWS SDK for Python (Boto) API Reference`.

```python
response = client.start_human_loop(
    HumanLoopName= "human-loop-name",
    HumanLoopInput={"InputContent": inputContentJson},
    DataAttributes={"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
)
```

This example stores input content in the variable `inputContentJson`. Assume that the input content contains two elements: a text blurb and sentiment (such as Positive, Negative, or Neutral), and it is formatted as follows:

```python
inputContent = {
    "initialValue": sentiment,
    "taskObject": blurb
}
```

The keys `initialValue` and `taskObject` must correspond to the keys used in the liquid elements of the worker task template. Refer to the custom template in `Create a Human Task UI (p. 2967)` to see an example.

To create `inputContentJson`, do the following:

```python
import json
inputContentJson = json.dumps(inputContent)
```

A human loop starts each time you call `start_human_loop`. To check the status of your human loop, use `describe_human_loop`:

```python
human_loop_info = a2i.describe_human_loop(HumanLoopName="human_loop_name")
print(f"HumanLoop Status: {resp["HumanLoopStatus"]}")
print(f"HumanLoop Output Destination: {resp["HumanLoopOutput"]}")
```

Use Cases and Examples Using Amazon A2I

You can use Amazon Augmented AI to incorporate a human review into your workflow for built-in task types, Amazon Textract and Amazon Rekognition, or your own custom tasks using a custom task type.

When you create a human review workflow using one of the built-in task types, you can specify conditions, such as confidence thresholds, that initiate a human review. The service (Amazon Rekognition or Amazon Textract) creates a human loop on your behalf when these conditions are met and supplies your input data directly to Amazon A2I to send to human reviewers. To learn more about the built-in task types, use the following:
- Use Amazon Augmented AI with Amazon Textract (p. 2977)
- Use Amazon Augmented AI with Amazon Rekognition (p. 2980)

When you use a custom task type, you create and start a human loop using the Amazon A2I Runtime API. Use the custom task type to incorporate a human review workflow with other AWS services or your own custom ML application.

- For more details, see Use Amazon Augmented AI with Custom Task Types (p. 2981)

The following table outlines a variety of Amazon A2I use cases that you can explore using SageMaker Jupyter Notebooks. To get started with a Jupyter Notebook, use the instructions in Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977). For more examples, see this GitHub repository.

<table>
<thead>
<tr>
<th>Use Case</th>
<th>Description</th>
<th>Task Type</th>
</tr>
</thead>

Use Amazon A2I to review tabular data

Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Task Type

Custom

Use Amazon Augmented AI with Amazon Textract

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract’s `AnalyzeDocument` API operation. You can use `AnalyzeDocument` to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an `AnalyzeDocument` request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for review.

Use Amazon Augmented AI with Amazon Rekognition

Use Amazon Augmented AI with Custom Task Types

Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook

For an end-to-end example that demonstrates how to integrate an Amazon A2I human review loop into a machine learning workflow, you can use a Jupyter Notebook from this GitHub Repository in a SageMaker notebook instance.

To use an Amazon A2I custom task type sample notebook in an Amazon SageMaker notebook instance:

1. If you do not have an active SageMaker notebook instance, create one by following the instructions in Step 1: Create an Amazon SageMaker Notebook Instance (p. 80).
2. When your notebook instance is active, choose Open JupyterLab to the right of the notebook instance's name. It may take a few moments for JupyterLab to load.
3. Choose the button icon to clone a GitHub repository into your workspace.
4. Enter the `amazon-a2i-sample-jupyter-notebooks` repository HTTPS URL.
5. Choose CLONE.
6. Open the notebook that you would like to run.
7. Follow the instructions in the notebook to configure your human review workflow and human loop and run the cells.
8. To avoid incurring unnecessary charges, when you are done with the demo, stop and delete your notebook instance in addition to any Amazon S3 buckets, IAM roles, and CloudWatch Events resources created during the walkthrough.

Use Amazon Augmented AI with Amazon Textract

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract's `AnalyzeDocument` API operation. You can use `AnalyzeDocument` to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an `AnalyzeDocument` request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for review.

## Use Case | Description | Task Type
--- | --- | ---

Topics

- Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977)
- Use Amazon Augmented AI with Amazon Textract (p. 2977)
- Use Amazon Augmented AI with Amazon Rekognition (p. 2980)
- Use Amazon Augmented AI with Custom Task Types (p. 2981)
review when the conditions specified in your flow definition are met. For example, if you want a human to review a specific key like Full name: and their associated input values, you can create an activation condition that starts a human review any time the Full name: key is detected or when the inference confidence for that key falls within a range that you specify.

The following image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can specify when Amazon Textract sends a task to a human worker for review when creating a human review workflow or flow definition by specifying activation conditions.

You can set the following activation conditions when using the Amazon Textract task type:

- Initiate a human review for specific form keys based on the form key confidence score.
- Initiate a human review when specific form keys are missing.
- Initiate human review for all form keys identified by Amazon Textract with confidence scores in a specified range.
- Randomly send a sample of forms to humans for review.

When your activation condition depends on form key confidence scores, you can use two types of prediction confidence to initiate human loops:

- **Identification confidence** – The confidence score for key-value pairs detected within a form.
- **Qualification confidence** – The confidence score for text contained within key and value in a form.

In the image in the following section, Full Name: Jane Doe is the key-value pair, Full Name is the key, and Jane Doe is the value.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the HumanLoopActivationConditions parameter of CreateFlowDefinition API operation.
learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989) and Use Human Loop Activation Conditions JSON Schema with Amazon Textract (p. 2991).

**Note**
When using Augmented AI with Amazon Textract, create Augmented AI resources in the same AWS Region you use to call `AnalyzeDocument`.

**Get Started: Integrate a Human Review into an Amazon Textract Analyze Document Job**

To integrate a human review into an Amazon Textract text detection and analysis job, you need to create a flow definition, and then use the Amazon Textract API to integrate that flow definition into your workflow. To learn how to create a flow definition using the SageMaker console or Augmented AI API, see the following topics:

- Create a Human Review Workflow (Console) (p. 2984)
- Create a Human Review Workflow (API) (p. 2986)

After you’ve created your flow definition, see Using Augmented AI with Amazon Textract to learn how to integrate your flow definition into your Amazon Textract task.

**End-to-End Example Using Amazon Textract and Amazon A2I**

For an end-to-end example that demonstrates how to use Amazon Textract with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 2959).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Textract’s Analyze Document [Example] in a SageMaker Notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977).

**A2I Textract Worker Console Preview**

When they’re assigned a review task in an Amazon Textract workflow, workers might see a user interface similar to the following:
You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 3010).

Use Amazon Augmented AI with Amazon Rekognition

Amazon Rekognition makes it easy to add image analysis to your applications. The Amazon Rekognition DetectModerationLabels API operation is directly integrated with Amazon A2I so that you can easily create a human loop to review unsafe images, such as explicit adult or violent content. You can use DetectModerationLabels to configure a human loop using a flow definition ARN. This enables Amazon A2I to analyze predictions made by Amazon Rekognition and send results to a human for review to ensure they meet the conditions set in your flow definition.

The following image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can set the following activation conditions when using the Amazon Rekognition task type:

- Initiate human review for labels identified by Amazon Rekognition based on the label confidence score.
- Randomly send a sample of images to humans for review.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the HumanLoopActivationConditions parameter of the CreateFlowDefinition API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989) and Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition (p. 2997).

Note
When using Augmented AI with Amazon Rekognition, create Augmented AI resources in the same AWS Region you use to call DetectModerationLabels.
Get Started: Integrate a Human Review into an Amazon Rekognition Image Moderation Job

To integrate a human review into an Amazon Rekognition, see the following topics:

- Create a Human Review Workflow (Console) (p. 2984)
- Create a Human Review Workflow (API) (p. 2986)

After you've created your flow definition, see Using Augmented AI with Amazon Rekognition to learn how to integrate your flow definition into your Amazon Rekognition task.

End-to-end Demo Using Amazon Rekognition and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Rekognition with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 2959).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition [Example] in a SageMaker notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977).

A2I Rekognition Worker Console Preview

When they're assigned a review task in an Amazon Rekognition workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 3010).

Use Amazon Augmented AI with Custom Task Types

You can use Amazon Augmented AI (Amazon A2I) to incorporate a human review (human loop) into any machine learning workflow using the custom task type. This options gives you the most flexibility to customize the conditions under which your data objects are sent to humans for review, as well as the look and feel of your worker user interface.
When you use a custom task type, you create a custom human review workflow and specify the conditions under which a data object is sent for human review directly in your application.

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Use the procedures on this page to learn how to integrate Amazon A2I into any machine learning workflow using the custom task type.

**Create a human loop using a flow definition, integrate it into your application, and monitor the results**

1. Complete the Amazon A2I Prerequisites to Using Augmented AI (p. 2959). Note the following:
   - The path to the Amazon Simple Storage Service (Amazon S3) bucket or buckets where you store your input and output data.
   - The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role with required permissions attached.
   - (Optional) The ARN of your private workforce, if you plan to use one.
2. Using HTML elements, create a custom worker template which Amazon A2I uses to generate your worker task UI. To learn how to create a custom template, see Create Custom Worker Task Templates (p. 3012).
3. Use the custom worker template from step 2 to generate a worker task template in the Amazon SageMaker console. To learn how, see Create a Worker Task Template (p. 3011).

In the next step, you create a flow definition:

- If you want to create a flow definition using the SageMaker API, note the ARN of this worker task template for the next step.
- If you are creating a flow definition using the console, your template automatically appears in Worker task template section when you choose Create human review workflow.
4. When creating your flow definition, provide the path to your S3 buckets, your IAM role ARN, and your worker template.
   - To learn how to create a flow definition using the SageMaker CreateFlowDefinition API, see Create a Human Review Workflow (API) (p. 2986).
Create a Human Review Workflow

- To learn how to create a flow definition using the SageMaker console, see Create a Human Review Workflow (Console) (p. 2984).

5. Configure your human loop using the Amazon A2I Runtime API. To learn how, see Create and Start a Human Loop (p. 3002).

6. To control when human reviews are initiated in your application, specify conditions under which \texttt{StartHumanLoop} is called in your application. Human loop activation conditions, such as confidence thresholds that initiate the human loop, are not available when using Amazon A2I with custom task types. Every \texttt{StartHumanLoop} invocation results in a human review.

Once you have started a human loop, you can manage and monitor your loops using the Amazon Augmented AI Runtime API and Amazon EventBridge (also known as Amazon CloudWatch Events). To learn more, see Monitor and Manage Your Human Loop (p. 3020).

End-to-end Tutorial Using Amazon A2I Custom Task Types

For an end-to-end examples that demonstrates how to integrate Amazon A2I into a variety of ML workflows, see the table in Use Cases and Examples Using Amazon A2I (p. 2975). To get started using one of these notebooks, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2977).

Create a Human Review Workflow

Use an Amazon Augmented AI (Amazon A2I) human review workflow, or flow definition, to specify the following:

- For the Amazon Textract and Amazon Rekognition built-in task types, the conditions under which your human loop is called
- The workforce to which your tasks are sent
- The set of instructions that your workforce receives, which is called a worker task template
- The configuration of your worker tasks, including the number of workers that receive a task and time limits to complete tasks
- Where your output data is stored

You can create a human review workflow in the SageMaker console or using the SageMaker CreateFlowDefinition operation. You can build a worker task template using the console for Amazon Textract and Amazon Rekognition task types while creating your flow definition.

**Important**

Human loop activation conditions, which initiate the human loop—for example, confidence thresholds—are not available for Amazon A2I custom task types. When using the console to create a flow definition for a custom task type, you can't specify activation conditions. When using the Amazon A2I API to create a flow definition for a custom task type, you can't set the HumanLoopActivationConditions attribute of the HumanLoopActivationConditionsConfig parameter. To control when human reviews are initiated, specify conditions under which \texttt{StartHumanLoop} is called in your custom application. In this case, every \texttt{StartHumanLoop} invocation results in a human review. For more information, see Use Amazon Augmented AI with Custom Task Types (p. 2981).

**Prerequisites**

To create a human review workflow definition, you must have completed the prerequisites described in Prerequisites to Using Augmented AI (p. 2959).
If you use the API to create a flow definition for any task type, or if you use a custom task type when creating a flow definition in the console, first create a worker task template. For more information, see Create and Manage Worker Task Templates (p. 3010).

If you want to preview your worker task template while creating a flow definition for a built-in task type in the console, ensure that you grant the role that you use to create the flow definition permission to access the Amazon S3 bucket that contains your template artifacts using a policy like the one described in Enable Worker Task Template Previews (p. 3034).

Topics
- Create a Human Review Workflow (Console) (p. 2984)
- Create a Human Review Workflow (API) (p. 2986)
- JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989)

Create a Human Review Workflow (Console)

Use this procedure to create a Amazon Augmented AI (Amazon A2I) human review workflow using the SageMaker console. If you are new to Amazon A2I, we recommend that you create a private work team using people in your organization, and use this work team's ARN when creating your flow definition. To learn how to set up a private workforce and create a work team, see Create a Private Workforce (Amazon SageMaker Console) (p. 625). If you have already set up a private workforce, see Create a Work Team Using the SageMaker Console (p. 629) to learn how to add a work team to that workforce.

If you are using Amazon A2I with one of the built-in task types, you can create worker instructions using a default worker task template provided by Augmented AI while creating a human review workflow in the console. To see samples of the default templates provided by Augmented AI, see the built-in task types in Use Cases and Examples Using Amazon A2I (p. 2975).

To create flow definition (console)

2. In the navigation pane, under the Augmented AI section, choose Human review workflows and then choose Create human review workflow.
3. In Overview, do the following:
   a. For Name, enter a unique workflow name. The name must be lowercase, unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
   b. For S3 location for output, enter the S3 bucket where you want to store the human review results. The bucket must be located in the same AWS Region as the workflow.
   c. For IAM role, choose the role that has the required permissions. If you choose a built-in task type and want to preview your worker template in the console, provide a role with the type of policy described in Enable Worker Task Template Previews (p. 3034) attached.
4. For Task type, choose the task type that you want the human worker to perform.
5. If you chose the Amazon Rekognition or Amazon Textract task type, specify the conditions that invoke human review.
   a. For Amazon Rekognition image moderation tasks, choose an inference confidence score threshold interval that initiates human review.
   b. For Amazon Textract tasks, you can initiate a human review when specific form keys are missing or when form key detection confidence is low. You can also initiate a human review if, after evaluating all of the form keys in the text, confidence is lower than your required threshold for
any form key. Two variables specify your confidence thresholds: Identification confidence and Qualification confidence. To learn more about these variables, see Use Amazon Augmented AI with Amazon Textract (p. 2977).

- For both task types, you can randomly send a percentage of data objects (images or forms) and their labels to humans for review.

6. Configure and specify your worker task template:

   a. If you are using the Amazon Rekognition or Amazon Textract task type:
      
      - In the Create template section:
        
        - To create instructions for your workers using the Amazon A2I default template for Amazon Rekognition and Amazon Textract task types, choose Build from a default template.
        
        - If you choose Build from a default template, create your instructions under Worker task design:
          
          - Provide a Template name that is unique in the AWS Region you are in.
          
          - In the Instructions section, provide detailed instructions on how to complete your task. To help workers achieve greater accuracy, provide good and bad examples.
          
          - (Optional) In Additional instructions, provide your workers with additional information and instructions.

          For information on creating effective instructions, see Creating Good Worker Instructions (p. 3019).

        - To select a custom template that you've created, choose it from the Template menu and provide a Task description to briefly describe the task for your workers. To learn how to create a custom template, see Create a Worker Task Template (p. 3011).

   b. If you are using the custom task type:
      
      - In the Worker task template section, select your template from the list. All of the templates that you have created in the SageMaker console appear in this list. To learn how to create a template for custom task types, see Create and Manage Worker Task Templates (p. 3010).

7. (Optional) Preview your worker template:

   For Amazon Rekognition and Amazon Textract task types, you have the option to choose See a sample worker task to preview your worker task UI.

   If you are creating a flow definition for a custom task type, you can preview your worker task UI using the RenderUiTemplate operation. For more information, see Preview a Worker Task Template (p. 3019).

8. For Workers, choose a workforce type.

9. Choose Create.

Next Steps

After you've created a human review workflow, it appears in the console under Human review workflows. To see your flow definition's Amazon Resource Name (ARN) and configuration details, choose the workflow by selecting its name.

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (for example, the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both options, see Create and Start a Human Loop (p. 3002).
Create a Human Review Workflow (API)

To create a flow definition using the SageMaker API, you use the `CreateFlowDefinition` operation. After you complete the Prerequisites to Using Augmented AI (p. 2959), use the following procedure to learn how to use this API operation.

For an overview of the `CreateFlowDefinition` operation, and details about each parameter, see `CreateFlowDefinition`.

To create a flow definition (API)

1. For `FlowDefinitionName`, enter a unique name. The name must be unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
2. For `RoleArn`, enter the ARN of the role that you configured to grant access to your data sources.
3. For `HumanLoopConfig`, enter information about the workers and what they should see. For information about each parameter in `HumanLoopConfig`, see `HumanLoopConfig`.
4. (Optional) If you are using a built-in task type, provide conditions that initiate a human loop in `HumanLoopActivationConfig`. To learn how to create the input required for the `HumanLoopActivationConfig` parameter, see `JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989)`. If you do not specify conditions here, when you provide a flow definition to the AWS service associated with a built-in task type (for example, Amazon Textract or Amazon Rekognition), that service sends every task to a human worker for review.

If you are using a custom task type, `HumanLoopActivationConfig` is disabled. To learn how to control when tasks are sent to human workers using a custom task type, see Use Amazon Augmented AI with Custom Task Types (p. 2981).

5. (Optional) If you are using a built-in task type, specify the integration source (for example, Amazon Rekognition or Amazon Textract) in the `HumanLoopRequestSource` parameter.
6. For `OutputConfig`, indicate where in Amazon Simple Storage Service (Amazon S3) to store the output of the human loop.
7. (Optional) Use `Tags` to enter key-value pairs to help you categorize and organize a flow definition. Each tag consists of a key and a value, both of which you define.

Amazon Textract – Key-value pair extraction

The following is an example of a request to create an Amazon Textract human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use ‘AWS/Textextract/AnalyzeDocument/Forms/V1’ to create a Amazon Textract human loop. Only include `PublicWorkforceTaskPrice` if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={'AwsManagedHumanLoopRequestSource': 'AWS/Textextract/AnalyzeDocument/Forms/V1'},
    HumanLoopActivationConfig={'HumanLoopActivationConditionsConfig': '...
    HumanLoopConfig={'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/private-crowd/workteam_name',
                      'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-task-ui/template_name'},
```
Amazon Rekognition – Image moderation

The following is an example of a request to create an Amazon Rekognition human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use 'AWS/Rekognition/DetectModerationLabels/Image/V3' to create an Amazon Rekognition flow definition. Only include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
        'AwsManagedHumanLoopRequestSource': 'AWS/Rekognition/DetectModerationLabels/Image/V3'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': ' {...}'
        }
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': ['Keyword1', 'Keyword2'],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {'Key': 'KeyName',
         'Value': 'ValueName'}
    ]
)
```

Custom Workflow

The following is an example of a request to create a human review workflow (flow definition) for a custom integration. To create this type of human review workflow, omit HumanLoopRequestSource from the flow definition request. You only need to include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...'
        }
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': ['Keyword1', 'Keyword2'],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
        },
    ]
)
```
Next Steps

The return value of a successful call of the CreateFlowDefinition API operation is a flow definition Amazon Resource Name (ARN).

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (i.e. the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both of these options, see Create and Start a Human Loop (p. 3002).

JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

The HumanLoopActivationConditions is an input parameter of the CreateFlowDefinition API. This parameter is a JSON-formatted string. The JSON models the conditions under which a human loop is created when those conditions are evaluated against the response from an integrating AI service API (such as Rekognition.DetectModerationLabels or Textract.AnalyzeDocument). This response is referred to as an inference. For example, Amazon Rekognition sends an inference of a moderation label with an associated confidence score. In this example, the inference is the model's best estimate of the appropriate label for an image. For Amazon Textract, inference is made on the association between blocks of text (key-value pairs), such as the association between Name: and Sue in a form as well as content within a block of text, or word block, such as 'Name'.

The following is the schema for the JSON. At the top level, the HumanLoopActivationConditions has a JSON array, Conditions. Each member of this array is an independent condition that, if evaluated to true, results in Amazon A2I creating a human loop. Each such independent condition can be a simple condition or a complex condition. A simple condition has the following attributes:

- **ConditionType**: This attribute identifies the type of condition. Each AWS AI service API that integrates with Amazon A2I defines its own set of allowed ConditionTypes.
  - Rekognition DetectModerationLabels – This API supports the ModerationLabelConfidenceCheck and Sampling ConditionType values.
  - Textract AnalyzeDocument – This API supports the ImportantFormKeyConfidenceCheck, MissingImportantFormKey, and Sampling ConditionType values.

- **ConditionParameters** – This is a JSON object that parameterizes the condition. The set of allowed attributes of this object is dependent on the value of the ConditionType. Each ConditionType defines its own set of ConditionParameters.

A member of the Conditions array can model a complex condition. This is accomplished by logically connecting simple conditions using the And and Or logical operators and nesting the underlying simple conditions. Up to two levels of nesting are supported.

```json
{
  "$schema": "http://json-schema.org/draft-07/schema#",
  "definitions": {
    "Condition": {
      "type": "object",
      "properties": {
        "ConditionType": {
          "type": "string"
        },
        "ValueName": {
          "type": "string"
        }
      }
    }
  }
}
```
Note

Human loop activation conditions aren't available for human review workflows that are integrated with custom task types. The `HumanLoopActivationConditions` parameter is disabled for custom task types.

Topics
Use Human Loop Activation Conditions JSON Schema with Amazon Textract

When used with Amazon A2I, the AnalyzeDocument operation supports the following inputs in the ConditionType parameter:

- **ImportantFormKeyConfidenceCheck** – Use this condition to create a human loop when inference confidence is within a specified range for document form keys and word blocks. A *form key* is any word in a document that is associated with an input. The input is called a *value*. Together, form keys and values are referred to as *key-value pairs*. A *word block* refers to the words that Amazon Textract recognizes inside of a detected block of text. To learn more about Amazon Textract document blocks, see *Documents and Block Objects* in the *Amazon Textract Developer Guide*.
- **MissingImportantFormKey** – Use this condition to create a human loop when Amazon Textract did not identify the key or its associated aliases within the document.
- **Sampling** – Use this condition to specify a percentage of forms to send to humans for review, regardless of inference confidence scores. Use this condition to do the following:
  - Audit your ML model by randomly sampling all forms analyzed by your model and sending a specified percentage to humans for review.
  - Using the **ImportantFormKeyConfidenceCheck** condition, randomly sample a percentage of the inferences that met the conditions specified in **ImportantFormKeyConfidenceCheck** to start a human loop and send only the specified percentage to humans for review.

**Note**

If you send the same request to AnalyzeDocument multiple times, the result of Sampling does not change for the inference of that input. For example, if you make an AnalyzeDocument request once, and Sampling doesn't initiate a human loop, subsequent requests to AnalyzeDocument with the same configuration do not initiate a human loop.

**ImportantFormKeyConfidenceCheck Inputs and Results**

The **ImportantFormKeyConfidenceCheck** ConditionType supports the following ConditionParameters:

- **ImportantFormKey** – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers. If the value of this parameter is the special catch-all value (*), then all keys are considered to be matched to the condition. You can use this to model the case where any key-value pair satisfying certain confidence thresholds needs human review.
- **ImportantFormKeyAliases** – An array that represents alternate spellings or logical equivalents for the important form key.
- **KeyValueBlockConfidenceEquals**
- **KeyValueBlockConfidenceLessThan**
- **KeyValueBlockConfidenceLessThanEquals**
- **KeyValueBlockConfidenceGreaterThan**
- **KeyValueBlockConfidenceGreaterThanEquals**
- **WordBlockConfidenceEquals**
- **WordBlockConfidenceLessThan**
- **WordBlockConfidenceLessThanEquals**
• WordBlockConfidenceGreaterThan
• WordBlockConfidenceGreaterThanOrEquals

When you use the ImportantFormKeyConfidenceCheck ConditionType, Amazon A2I sends the key-value block and word block inferences of the key-value blocks and associated aliases that you specified in ImportantFormKey and ImportantFormKeyAliases for human review.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the Amazon SageMaker console, key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the {{ task.input.selectedAiServiceResponse.blocks }} element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract (p. 3013).

MissingImportantFormKey Inputs and Results

The MissingImportantFormKey ConditionType supports the following ConditionParameters:

• ImportantFormKey – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers.
• ImportantFormKeyAliases – An array that represents alternate spellings or logical equivalents for the important form key.

When you use the MissingImportantFormKey ConditionType, if the key in ImportantFormKey or aliases in ImportantFormKeyAliases are not included in the Amazon Textract inference, that form is sent to human for review and no predicted key-value pairs are included. For example, if Amazon Textract only identified Address and Phone in a form, but was missing the ImportantFormKey Name (in the MissingImportantFormKey condition type) that form would be sent to humans for review without any of the form keys detected (Address and Phone).

If you use the default worker task template that is provided in the SageMaker console, a task is created asking workers to identify the key in ImportantFormKey and associated value. If you use a custom worker task template, you need to include the <task.input.humanLoopContext> custom HTML element to configure this task.

Sampling Inputs and Results

The Sampling ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for RandomSamplingPercentage must be real number between 0.01 and 100. This number represents the percentage of data that qualifies for a human review and is sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all resulting inferences made by the AnalyzeDocument operation from a single request that is sent to humans for review.

If you specify the Sampling condition without any other condition type, all key-value and block inferences are sent to workers for review.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the SageMaker console, all key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the {{ task.input.selectedAiServiceResponse.blocks }} element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract (p. 3013).
Examples

While only one condition needs to evaluate to true to initiate a human loop, Amazon A2I evaluates all conditions for each object analyzed by Amazon Textract. The human reviewers are asked to review the important form keys for all the conditions that evaluated to true.

Example 1: Detect important form keys with confidence scores in a specified range that initiate a human loop

The following example shows a HumanLoopActivationConditions JSON that initiates a human loop if any one of the following three conditions is met:

- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Employee Name, Name, or EmployeeName, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block being less than 65 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Gross Pay, GrossPay, or GrossAmount, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.

```json
{
  "Conditions": [
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Employee Name",
        "ImportantFormKeyAliases": [
          "Name",
          "EmployeeName"
        ],
        "KeyValueBlockConfidenceLessThan": 60,
        "WordBlockConfidenceLessThan": 85
      }
    },
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Pay Date",
        "ImportantFormKeyAliases": [
          "PayDate",
          "DateOfPay",
          "pay-date"
        ],
        "KeyValueBlockConfidenceLessThan": 65,
        "WordBlockConfidenceLessThan": 85
      }
    },
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Gross Pay",
        "ImportantFormKeyAliases": [
          "GrossPay",
          "GrossAmount"
        ],
        "KeyValueBlockConfidenceLessThan": 60,
        "WordBlockConfidenceLessThan": 85
      }
    }
  ]
}
```
Example 2: Use ImportantFormKeyConfidenceCheck

In the following example, if Amazon Textract detects a key-value pair whose confidence for the key-value block is less than 60 and is less than 90 for any underlying word blocks, it creates a human loop. The human reviewers are asked to review all the form key-value pairs that matched the confidence value comparisons.

```
{
   "Conditions": [
       {
           "ConditionType": "ImportantFormKeyConfidenceCheck",
           "ConditionParameters": {
               "ImportantFormKey": "*",
               "KeyValueBlockConfidenceLessThan": 60,
               "WordBlockConfidenceLessThan": 90
           }
       }
   ]
}
```

Example 3: Use Sampling

In the following example, 5% of inferences resulting from an Amazon Textract AnalyzeDocument request are sent to human workers for review. All detected key-value pairs returned by Amazon Textract are sent to workers for review.

```
{
   "Conditions": [
       {
           "ConditionType": "Sampling",
           "ConditionParameters": {
               "RandomSamplingPercentage": 5
           }
       }
   ]
}
```

Example 4: Use MissingImportantFormKey

In the following example, if Mailing Address or its alias, Mailing Address:, is missing from keys detected by Amazon Textract, a human review is initiated. When using the default worker task template, the worker UI asks workers to identify the key Mailing Address or Mailing Address: and its associated value.

```
{
   "ConditionType": "MissingImportantFormKey",
   "ConditionParameters": {
       "ImportantFormKey": "Mailing Address",
       "ImportantFormKeyAliases": ["Mailing Address:"
   }
}
```

Example 5: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

In this example, 5% of key-value pairs detected by Amazon Textract whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85, are sent to workers for review.

```
Example 6: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low confidence inferences of a specified key-value pair for human review and sample high confidence inference of a key-value pair at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences less than 60, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.

- 5% of key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences greater than 90, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.
Example 7: Use Sampling and ImportantFormKeyConfidenceCheck with the Or operator

In the following example, the Amazon Textract AnalyzeDocument operation returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85. Additionally, 5% of all other forms initiate a human loop. For each form randomly chosen, all key-value pairs detected for that form are sent to humans for review.

```json
{
    "Conditions": [
        {
            "Or": [
                {
                    "ConditionType": "Sampling",
                    "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                    }
                },
                {
                    "ConditionType": "ImportantFormKeyConfidenceCheck",
                    "ConditionParameters": {
                        "ImportantFormKey": "Pay Date",
                        "ImportantFormKeyAliases": [
                            "PayDate",
                            "DateOfPay",
                            "pay-date"
                        ],
                        "KeyValueBlockConfidenceLessThan": 65,
                        "WordBlockConfidenceLessThan": 85
                    }
                }
            ]
        }
    ]
}
```
Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

When used with Amazon A2I, the Amazon Rekognition DetectModerationLabels operation supports the following inputs in the ConditionType parameters:

- **ModerationLabelConfidenceCheck** – Use this condition type to create a human loop when inference confidence is low for one or more specified labels.
- **Sampling** – Use this condition to specify a percentage of all inferences to send to humans for review. Use this condition to do the following:
  - Audit your ML model by randomly sampling all of your model's inferences and sending a specified percentage to humans for review.
  - Using the **ModerationLabelConfidenceCheck** condition, randomly sample a percentage of the inferences that met the conditions specified in **ModerationLabelConfidenceCheck** to start a human loop and send only the specified percentage to humans for review.

**Note**
If you send the same request to DetectModerationLabels multiple times, the result of Sampling does not change for the inference of that input. For example, if you make a DetectModerationLabels request once, and Sampling does not initiate a human loop, subsequent requests to DetectModerationLabels with the same configuration don't initiate a human loop.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the Amazon SageMaker console, inferences sent for human review by these activation conditions are included in the worker UI when a worker opens your task. If you use a custom worker task template, you need to include the `<task.input.selectedAiServiceResponse.blocks>` custom HTML element to access these inferences. For an example of a custom template that uses this HTML element, see Custom Template Example for Amazon Rekognition (p. 3015).

**ModerationLabelConfidenceCheck Inputs**

For the **ModerationLabelConfidenceCheck** ConditionType, the following ConditionParameters are supported:

- **ModerationLabelName** – The exact (case-sensitive) name of a **ModerationLabel** detected by the Amazon Rekognition DetectModerationLabels operation. You can specify the special catch-all value (*) to denote any moderation label.
- **ConfidenceEquals**
- **ConfidenceLessThan**
- **ConfidenceLessThanEquals**
- **ConfidenceGreaterThan**
- **ConfidenceGreaterThanEquals**

When you use the **ModerationLabelConfidenceCheck** ConditionType, Amazon A2I sends label inferences for the labels that you specified in **ModerationLabelName** for human review.

**Sampling Inputs**

The **Sampling** ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for the RandomSamplingPercentage parameter should be a real number between 0.01 and
100. This number represents the percentage of inferences that qualifies for a human review that are sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all inferences that result from a single DetectModerationLabel request that are sent to humans for review.

Examples

Example 1: Use ModerationLabelConfidenceCheck with the And operator

The following example of a HumanLoopActivationConditions condition initiates a human loop when one or more of the following conditions are met:

• Amazon Rekognition detects the Graphic Male Nudity moderation label with a confidence between 90 and 99.
• Amazon Rekognition detects the Graphic Female Nudity moderation label with a confidence between 80 and 99.

Note the use of the Or and And logical operators to model this logic.

Although only one of the two conditions under the Or operator needs to evaluate to true for a human loop to be created, Amazon Augmented AI evaluates all conditions. Human reviewers are asked to review the moderation labels for all the conditions that evaluated to true.

```json
{
   "Conditions": [{
      "Or": [{
         "And": [{
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
               "ModerationLabelName": "Graphic Male Nudity",
               "ConfidenceLessThanEquals": 99
            }
         }, {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
               "ModerationLabelName": "Graphic Male Nudity",
               "ConfidenceGreaterThanEquals": 90
            }
         }
      }, {
         "ConditionType": "ModerationLabelConfidenceCheck",
         "ConditionParameters": {
            "ModerationLabelName": "Graphic Female Nudity",
            "ConfidenceLessThanEquals": 99
         }
      }, {
         "ConditionType": "ModerationLabelConfidenceCheck",
         "ConditionParameters": {
            "ModerationLabelName": "Graphic Female Nudity",
            "ConfidenceGreaterThanEquals": 80
         }
      }
   }
   ]
}
```
Example 2: Use `ModerationLabelConfidenceCheck` with the catch-all value (*)

In the following example, if any moderation label with a confidence greater than or equal to 75 is detected, a human loop is initiated. Human reviewers are asked to review all moderation labels with confidence scores greater than or equal to 75.

```json
{
  "Conditions": [
    {
      "ConditionType": "ModerationLabelConfidenceCheck",
      "ConditionParameters": {
        "ModerationLabelName": "*",
        "ConfidenceGreaterThanEquals": 75
      }
    }
  ]
}
```

Example 3: Use Sampling

In the following example, 5% of Amazon Rekognition inferences from a `DetectModerationLabels` request are sent to human workers. When using the default worker task template provided in the SageMaker console, all moderation labels returned by Amazon Rekognition are sent to workers for review.

```json
{
  "Conditions": [
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use Sampling and `ModerationLabelConfidenceCheck` with the And operator

In this example, 5% of Amazon Rekognition inferences of the Graphic Male Nudity moderation label with a confidence greater than 50 are sent workers for review. When using the default worker task template provided in the SageMaker console, only the inferences of the Graphic Male Nudity label are sent to workers for review.

```json
{
  "Conditions": [
    {
      "And": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
          }
        }
      ]
    }
  ]
}
```
Example 5: Use Sampling and ModerationLabelConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low-confidence inferences of a specified label for human review and sample high-confidence inferences of a label at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Inferences for the Graphic Male Nudity moderation label the with confidence scores less than 60 are always sent for human review. Only the Graphic Male Nudity label is sent to workers to review.
- 5% of all inferences for the Graphic Male Nudity moderation label the with confidence scores greater than 90 are sent for human review. Only the Graphic Male Nudity label is sent to workers to review.

```json
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceLessThan": 60
          }
        },
        {
          "And": [
            {
              "ConditionType": "Sampling",
              "ConditionParameters": {
                "RandomSamplingPercentage": 5
              }
            },
            {
              "ConditionType": "ModerationLabelConfidenceCheck",
              "ConditionParameters": {
                "ModerationLabelName": "Graphic Male Nudity",
                "ConfidenceGreaterThan": 90
              }
            }
          ]
        }
      ]
    }
  ]
}
```

Example 6: Use Sampling and ModerationLabelConfidenceCheck with the Or operator

In the following example, a human loop is created if the Amazon Rekognition inference response contains the Graphic Male Nudity label with inference confidence greater than 50. Additionally, 5% of all other inferences initiate a human loop.

```json
{
  "Conditions": [
    {
      "ConditionType": "ModerationLabelConfidenceCheck",
      "ConditionParameters": {
        "ModerationLabelName": "Graphic Male Nudity",
        "ConfidenceGreaterThan": 50
      }
    },
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```
Delete a Human Review Workflow

When you delete a human review workflow or you delete your AWS account while a human loop is in process, your human review workflow status changes to Deleting. Amazon A2I automatically stops and deletes all associated human loops if workers have not started tasks created by those human loops. If human workers are already working on a task, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human review workflow's status is Deleting. If these tasks are completed, the results are stored in the Amazon S3 bucket specified in your flow definition.

Deleting a flow definition does not remove any worker answers from your S3 bucket. If the tasks are completed, but you deleted your AWS account, the results are stored in the Augmented AI service bucket for 30 days and then permanently deleted.

After all human loops have been deleted, the human review workflow is permanently deleted. When a human review workflow has been deleted, you can reuse its name to create a new human review workflow.

You might want to delete a human review workflow for any of the following reasons:

- You have sent data to a set of human reviewers and you want to delete all non-started human loops because you do not want those workers to work on those tasks any longer.
- The worker task template used to generate your worker UI does not render correctly or is not functioning as expected.

After you delete a human review workflow, the following changes occur:

- The human review workflow no longer appears on the Human review workflows page in the Augmented AI area of the Amazon SageMaker console.
- When you use the human review workflow name as input to the API operations DescribeFlowDefinition or DeleteFlowDefinition, Augmented AI returns a ResourceNotFound error.
- When you use ListFlowDefinitions, deleted human review workflows aren't included in the results.
- When you use the human review workflow ARN as input to the Augmented AI Runtime API operation ListHumanLoops, Augmented AI returns a ResourceNotFoundException.
Delete a Flow Definition Using the Console or the SageMaker API

You can delete a human review workflow on the Human review workflows page in the Augmented AI area of the SageMaker console or by using the SageMaker API.

Flow definitions can only be deleted if their status is Active.

Delete a human review workflow (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the Augmented AI section, choose Human review workflows.
3. Select the hyperlinked name of the human review workflow that you want to delete.
4. On the Summary page of your human review workflow, choose Delete.
5. In the dialog box asking you to confirm that you want to delete your human review workflow, choose Delete.

You're automatically redirected to the Human review workflows page. While your human review workflow is being deleted, the status Deleting appears in the status column for that workflow. After it's deleted, it doesn't appear in the list of workflows on this page.

Delete a human review workflow (API)

You can delete a human review workflow (flow definition) using the SageMaker DeleteFlowDefinition API operation. This API operation is supported through the AWS CLI and a variety of language specific SDKs. The following table shows example requests using SDK for Python (Boto3) and the AWS CLI to delete the human review workflow, example-flow-definition.

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3) to delete the human review workflow. For more information, see delete_flow_definition in the AWS SDK for Python (Boto) API Reference.

```python
import boto3

sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.delete_flow_definition(FlowDefinitionName='example-flow-definition')
```

AWS CLI

The following request example uses the AWS CLI to delete the human review workflow. For more information, see delete-flow-definition in the AWS CLI Command Reference.

```
$ aws sagemaker delete-flow-definition --flow-definition-name 'example-flow-definition'
```

If the action is successful, Augmented AI sends back an HTTP 200 response with an empty HTTP body.

Create and Start a Human Loop

A human loop starts your human review workflow and sends data review tasks to human workers. When you use one of the Amazon A2I built-in task types, the corresponding AWS service creates and
starts a human loop on your behalf when the conditions specified in your flow definition are met. If no conditions are specified in your flow definition, a human loop is created for each object. When using Amazon A2I for a custom task, a human loop starts when your application calls StartHumanLoop.

Use the following instructions to configure a human loop with Amazon Rekognition or Amazon Textract built-in task types and custom task types.

**Prerequisites**

To create and start a human loop, you must attach the AmazonAugmentedAIFullAccess policy to the AWS Identity and Access Management (IAM) user or role that configures or starts the human loop. This is the identity that you use to configure the human loop using HumanLoopConfig for built-in task types. For custom task types, this is the identity that you use to call StartHumanLoop.

Additionally, when using a built-in task type, your IAM user or role must have permission to invoke API operations of the AWS service associated with your task type. For example, if you are using Amazon Rekognition with Augmented AI, you must attach permissions required to call DetectModerationLabels. For examples of identity-based policies you can use to grant these permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples. You can also use the more general policy AmazonAugmentedAIIntegratedAPIAccess to grant these permissions. For more information, see Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 3033).

To create and start a human loop, you need a flow definition ARN. To learn how to create a flow definition (or human review workflow), see Create a Human Review Workflow (p. 2983).

**Important**
Amazon A2I requires all S3 buckets that contain human loop input image data to have a CORS policy attached. To learn more about this change, see CORS Permission Requirement (p. 3031).

**Create and Start a Human Loop for a Built-in Task Type**

To start a human loop using a built-in task type, use the corresponding service's API to provide your input data and to configure the human loop. For Amazon Textract, you use the AnalyzeDocument API operation. For Amazon Rekognition, you use the DetectModerationLabels API operation. You can use the AWS CLI or a language-specific SDK to create requests using these API operations.

**Important**
When you create a human loop using a built-in task type, you can use DataAttributes to specify a set of ContentClassifiers related to the input provided to the StartHumanLoop operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA. Include the FreeOfPersonallyIdentifiableInformation content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the 'FreeOfAdultContent' classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.

After you start your ML job using your built-in task type's AWS service API, Amazon A2I monitors the inference results of that service. For example, when running a job with Amazon Rekognition, Amazon A2I checks the inference confidence score for each image and compares it to the confidence thresholds specified in your flow definition. If the conditions to start a human review task are satisfied, or if you didn't specify conditions in your flow definition, a human review task is sent to workers.
Create an Amazon Textract Human Loop

Amazon A2I integrates with Amazon Textract so that you can configure and start a human loop using the Amazon Textract API. To send a document file to Amazon Textract for document analysis, you use the Amazon Textract AnalyzeDocument API operation. To add a human loop to this document analysis job, you must configure the parameter HumanLoopConfig.

When you configure your human loop, the flow definition you specify in FlowDefinitionArn of HumanLoopConfig must be located in the same AWS Region as the bucket identified in Bucket of the Document parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see analyze_document in the AWS SDK for Python (Boto) API Reference.

```python
import boto3
textract = boto3.client('textract', aws_region)
response = textract.analyze_document(
    Document={'S3Object': {'Bucket': bucket_name, 'Name': document_name}},
    FeatureTypes=['TABLES', "FORMS"],
    HumanLoopConfig={
        'HumanLoopName': 'human_loop_name',
        'DataAttributes': {'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']}
    }
)
```

AWS CLI

The following request example uses the AWS CLI. For more information, see analyze-document in the AWS CLI Command Reference.

```bash
# aws textract analyze-document
    --document '{"S3Object":{"Bucket":"bucket_name","Name":"document_name"}}' \
    --human-loop-config
    HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws-region:aws_account_number:flow-definition/flow_def_name",DataAttributes='{"ContentClassifiers':["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}', \
    --feature-types ['"TABLES", "FORMS"]'
```

```bash
# aws textract analyze-document
    --document '{"S3Object":{"Bucket":"bucket_name","Name":"document_name"}}' \
    --human-loop-config \
    '{"HumanLoopName":"human_loop_name","FlowDefinitionArn":"arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name","DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}}', \
    --feature-types ['"TABLES", "FORMS"]'
```
Create and Start a Human Loop for a Built-in Task Type

After you run `AnalyzeDocument` with a human loop configured, Amazon A2I monitors the results from `AnalyzeDocument` and checks it against the flow definition's activation conditions. If the Amazon Textract inference confidence score for one or more key-value pairs meets the conditions for review, Amazon A2I starts a human review loop and includes the `HumanLoopActivationOutput` object in the `AnalyzeDocument` response.

Create an Amazon Rekognition Human Loop

Amazon A2I integrates with Amazon Rekognition so that you can configure and start a human loop using the Amazon Rekognition API. To send images to Amazon Rekognition for content moderation, you use the Amazon Rekognition `DetectModerationLabels` API operation. To configure a human loop, set the `HumanLoopConfig` parameter when you configure `DetectModerationLabels`.

When you configure your human loop, the flow definition you specify in `FlowDefinitionArn` of `HumanLoopConfig` must be located in the same AWS Region as the S3 bucket identified in `Bucket` of the `Image` parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see `detect_moderation_labels` in the AWS SDK for Python (Boto) API Reference.

```python
import boto3
rekognition = boto3.client("rekognition", aws_region)
response = rekognition.detect_moderation_labels( 
    Image={'S3Object': {'Bucket': bucket_name, 'Name': image_name}}, 
    HumanLoopConfig={ 
        'HumanLoopName': 'human_loop_name', 
        'FlowDefinitionArn': 'arn:aws:sagemaker:' + aws_region + ':aws_account_number:flow-definition/' + flow_def_name, 
        'DataAttributes': {'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']} 
    })
```  

AWS CLI

The following request example uses the AWS CLI. For more information, see `detect-moderation-labels` in the AWS CLI Command Reference.

```bash
$ aws rekognition detect-moderation-labels \
  --image "S3Object={Bucket='bucket_name',Name='image_name'}" \
  --human-loop-config \
  HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name",DataAttributes='{"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"]}"

$ aws rekognition detect-moderation-labels \
  --image "S3Object={Bucket='bucket_name',Name='image_name'}" \
  --human-loop-config \
  "{"HumanLoopName": "human_loop_name", "FlowDefinitionArn": "arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name", "DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"]}}"
```
After you run `DetectModerationLabels` with a human loop configured, Amazon A2I monitors the results from `DetectModerationLabels` and checks it against the flow definition’s activation conditions. If the Amazon Rekognition inference confidence score for an image meets the conditions for review, Amazon A2I starts a human review loop and includes the response element `HumanLoopActivationOutput` in the `DetectModerationLabels` response.

**Create and Start a Human Loop for a Custom Task Type**

To configure a human loop for a custom human review task, use the `StartHumanLoop` operation within your application. This section provides an example of a human loop request using the AWS SDK for Python (Boto3) and the AWS Command Line Interface (AWS CLI). For documentation on other language-specific SDKs that support `StartHumanLoop`, use the See Also section of `StartHumanLoop` in the Amazon Augmented AI Runtime API documentation. Refer to Use Cases and Examples Using Amazon A2I (p. 2975) to see examples that demonstrate how to use Amazon A2I with a custom task type.

**Prerequisites**

To complete this procedure, you need:

- Input data formatted as a string representation of a JSON-formatted file
- The Amazon Resource Name (ARN) of your flow definition

**To configure the human loop**

1. For `DataAttributes`, specify a set of `ContentClassifiers` related to the input provided to the `StartHumanLoop` operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

   To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA, and include the `FreeOfPersonallyIdentifiableInformation` content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the 'FreeOfAdultContent' classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.

2. For `FlowDefinitionArn`, enter the Amazon Resource Name (ARN) of your flow definition.

3. For `HumanLoopInput`, enter your input data as a string representation of a JSON-formatted file. Structure your input data and custom worker task template so that your input data is properly displayed to human workers when you start your human loop. See Preview a Worker Task Template (p. 3019) to learn how to preview your custom worker task template.

4. For `HumanLoopName`, enter a name for the human loop. The name must be unique within the Region in your account and can have up to 63 characters. Valid characters are a-z, 0-9, and - (hyphen).

**To start a human loop**

- To start a human loop, submit a request similar to the following examples using your preferred language-specific SDK.

**AWS SDK for Python (Boto3)**

The following request example uses the SDK for Python (Boto3). For more information, see Boto 3 Augmented AI Runtime in the AWS SDK for Python (Boto) API Reference.
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')

response = a2i_runtime_client.start_human_loop(
    HumanLoopName='human_loop_name',
    HumanLoopInput={
        'InputContent': '{"InputContent": "{"prompt": "What is the answer?"}"}
    },
    DataAttributes={
        'ContentClassifiers': [
            'FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent',
        ]
    }
)

AWS CLI

The following request example uses the AWS CLI. For more information, see start-human-loop in the AWS CLI Command Reference.

```
$ aws sagemaker-a2i-runtime start-human-loop
    --human-loop-name 'human_loop_name'
    --human-loop-input '{"InputContent": "{"prompt": "What is the answer?"}"}'
    --data-attributes
    ContentClassifiers="FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"
```

When you successfully start a human loop by invoking StartHumanLoop directly, the response includes a HumanLoopARN and a HumanLoopActivationResults object which is set to NULL. You can use this the human loop name to monitor and manage your human loop.

**Next Steps:**

After starting a human loop, you can manage and monitor it with the Amazon Augmented AI Runtime API and Amazon CloudWatch Events. To learn more, see Monitor and Manage Your Human Loop (p. 3020).

**Delete a Human Loop**

When you delete a human loop, the status changes to Deleting. When the human loop is deleted, the associated human review task is no longer available to workers. You might want to delete a human loop in one of the following circumstances:

- The worker task template used to generate your worker user interface does not render correctly or is not functioning as expected.
- A single data object was accidentally sent to workers multiple times.
- You no longer need a data object reviewed by a human.

If the status of a human loop is InProgress, you must stop the human loop before deleting it. When you stop a human loop, the status changes to Stopping while it is being stopped. When the status changes to Stopped, you can delete the human loop.
If human workers are already working on a task when you stop the associated human loop, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human loop's status is Stopping. If these tasks are completed, the results are stored in the Amazon S3 bucket URI specified in your human review workflow. If the worker leaves the task without submitting work, it is stopped and the worker can't return to the task. If no worker has started working on the task, it is stopped immediately.

If you delete the AWS account used to create the human loop, it is stopped and deleted automatically.

Human Loop Data Retention and Deletion

When a human worker completes a human review task, the results are stored in the Amazon S3 output bucket you specified in the human review workflow used to create the human loop. Deleting or stopping a human loop does not remove any worker answers from your S3 bucket.

Additionally, Amazon A2I temporarily stores human loop input and output data internally for the following reasons:

- If you configure your human loops so that a single data object is sent to multiple workers for review, Amazon A2I does not write output data to your S3 bucket until all workers have completed the review task. Amazon A2I stores partial answers—answers from individual workers—internally so that it can write full results to your S3 bucket.
- If you report a low-quality human review result, Amazon A2I can investigate and respond to your issue.
- If you lose access to or delete the output S3 bucket specified in the human review workflow used to create a human loop, and the task has already been sent to one or more workers, Amazon A2I needs a place to temporarily store human review results.

Amazon A2I deletes this data internally 30 days after a human loop's status changes to one of the following: Deleted, Stopped, or Completed. In other words, data is deleted 30 days after the human loop has been completed, stopped, or deleted. Additionally, this data is deleted after 30 days if you close the AWS account used to create associated human loops.

Stop and Delete a Flow Definition Using the Console or the Amazon A2I API

You can stop and delete a human loop in the Augmented AI console or by using the SageMaker API. When the human loop has been deleted, the status changes to Deleted.

Delete a human loop (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the Augmented AI section, choose Human review workflows.
3. Choose the hyperlinked name of the human review workflow you used to create the human loop you want to delete.
4. In the Human loops section at the bottom of the page, select the human loop you want to stop and delete.
5. If the human loop status is Completed, Stopped, or Failed, select Delete.

   If the human loop Status is InProgress, select Stop. When the status changes to Stopped, select Delete.
Delete a human loop (API)

1. Check the status of your human loop using the Augmented AI Runtime API operation DescribeHumanLoop. See examples using this operation in the following table.

   **AWS SDK for Python (Boto3)**

   The following example uses the SDK for Python (Boto3) to describe the human loop named *example-human-loop*. For more information, see describe_human_loop in the *AWS SDK for Python (Boto) API Reference*.

   ```python
   import boto3
   a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
   response = a2i_runtime_client.describe_human_loop(HumanLoopName='example-human-loop')
   human_loop_status = response['HumanLoopStatus']
   print(f'example-human-loop status is: {human_loop_status}')
   ```

   **AWS CLI**

   The following example uses the AWS CLI to describe the human loop named *example-human-loop*. For more information, see describe-human-loop in the *AWS CLI Command Reference*.

   ```bash
   $ aws sagemaker-a2i-runtime describe-human-loop --human-loop-name 'example-human-loop'
   ```

2. If the flow definition status is Completed, Stopped, or Failed, delete the flow definition using the Augmented AI Runtime API operation DeleteHumanLoop.

   **AWS SDK for Python (Boto3)**

   The following example uses the SDK for Python (Boto3) to delete the human loop named *example-human-loop*. For more information, see delete_human_loop in the *AWS SDK for Python (Boto) API Reference*.

   ```python
   import boto3
   a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
   response = a2i_runtime_client.delete_human_loop(HumanLoopName='example-human-loop')
   ```

   **AWS CLI**

   The following example uses the AWS CLI to delete the human loop named *example-human-loop*. For more information, see delete-human-loop in the *AWS CLI Command Reference*.

   ```bash
   $ aws sagemaker-a2i-runtime delete-human-loop --human-loop-name 'example-human-loop'
   ```

   If the human loop status is InProgress, stop the human loop using StopHumanLoop and then use DeleteHumanLoop to delete it.

   **AWS SDK for Python (Boto3)**

   The following example uses the SDK for Python (Boto3) to describe the human loop named *example-human-loop*. For more information, see stop_human_loop in the *AWS SDK for Python (Boto) API Reference*.

   ```python
   ```

3009
Create and Manage Worker Task Templates

You can create a task user interface for your workers by creating a worker task template. A worker task template is an HTML file that is used to display your input data and instructions to help workers complete your task.

For Amazon Rekognition or Amazon Textract task types, you can customize a pre-made worker task template using a graphical user interface (GUI) and avoid interacting with HTML code. For this option, use the instructions in Create a Human Review Workflow (Console) (p. 2984) to create a human review workflow and customize your worker task template in the Amazon SageMaker console. Once you create a template using these instructions, it appears on the worker task templates page of the Augmented AI console.

If you are creating a human review workflow for a custom task type, you must create a custom worker task template using HTML code. For more information, see Create Custom Worker Task Templates (p. 3012).

If you create your template using HTML, you must use this template to generate an Amazon A2I human task UI Amazon Resource Name (ARN) in the Amazon A2I console. This ARN has the following format: arn:aws:sagemaker:<aws-region>:<aws-account-number>:human-task-ui/<template-name>. This ARN is associated with a worker task template resource that you can use in one or more human review workflows (flow definitions).

Generate a human task UI ARN using a worker task template by following the instructions found in Create a Worker Task Template (p. 3011) or by using the CreateHumanTaskUi API operation.

Topics

- Create and Delete Worker Task Templates (p. 3010)
- Create Custom Worker Task Templates (p. 3012)
- Creating Good Worker Instructions (p. 3019)

Create and Delete Worker Task Templates

You can use a worker template to customize the interface and instructions that your workers see when working on your tasks. Use the instructions on this page to create a worker task template in the Augmented AI area of the Amazon SageMaker console. A starter template is provided for Amazon Textract and Amazon Rekognition tasks. To learn how to customize your template using HTML crowd elements, see Create Custom Worker Task Templates (p. 3012).

When you create a worker template in the worker task templates page of the Augmented AI area of the SageMaker console, a worker task template ARN is generated. Use this ARN as the input to
HumanTaskUiArn when you create a flow definition using the API operation CreateFlowDefinition. You can choose this template when creating a human review workflow on the human review workflows page of the console.

If you are creating a worker task template resource for an Amazon Textract or Amazon Rekognition task type, you can preview the worker UI that is generated from your template on the worker task templates console page. You must attach the policy described in Enable Worker Task Template Previews (p. 3034) to the IAM role that you use to preview the template.

Create a Worker Task Template

You can create a worker task template using the SageMaker console and using the SageMaker API operation CreateHumanTaskUi.

Create a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i/.
2. Under Amazon Augmented AI in the left navigation pane, choose Worker task templates.
3. Choose Create template.
4. In Template name, enter a unique name.
5. (Optional) Enter an IAM role that grants Amazon A2I the permissions necessary to call services on your behalf.
6. In Template type, choose a template type from the dropdown list. If you are creating a template for a Textract-form extraction or Rekognition-image moderation task, choose the appropriate option.
7. Enter your custom template elements as follows:
   • If you selected the Amazon Textract or Amazon Rekognition task template, the Template editor autopopulates with a default template that you can customize.
   • If you are using a custom template, enter your predefined template in the editor.
8. (Optional) To complete this step, you must provide an IAM role ARN with permission to read Amazon S3 objects that get rendered on your user interface in Step 5.

You can only preview your template if you are creating templates for Amazon Textract or Amazon Rekognition.

Choose See preview to preview the interface and instructions that workers see. This is an interactive preview. After you complete the sample task and choose Submit, you see the resulting output from the task that you just performed.

If you are creating a worker task template for a custom task type, you can preview your worker task UI using RenderUiTemplate. For more information, see Preview a Worker Task Template (p. 3019).

9. When you're satisfied with your template, choose Create.

After you've created your template, you can select that template when you create a human review workflow in the console. Your template also appears in the Amazon Augmented AI section of the SageMaker console under Worker task templates. Choose your template to view its ARN. Use this ARN when using the CreateFlowDefinition API operation.

Create a worker task template using a worker task template (API)

To generate a worker task template using the SageMaker API operation CreateHumanTaskUi, specify a name for your UI in HumanTaskUiName and input your HTML template in Content under UiTemplate. Find documentation on language-specific SDKs that support this API operation in the See Also section of the CreateHumanTaskUi.
Delete a Worker Task Template

Once you have created a worker task template, you can delete it using the SageMaker console or the SageMaker API operation `DeleteHumanTaskUi`.

When you delete a worker task template, you are not able to use human review workflows (flow definitions) created using that template to start human loops. Any human loops that have already been created using the worker task template that you delete continue to be processed until completion and are not impacted.

Delete a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i/.
2. Under Amazon Augmented AI in the left navigation pane, choose Worker task templates.
3. Select the template that you want to delete.
4. Select Delete.
5. A modal appears to confirm your choice. Select Delete.

Delete a worker task template (API)

To delete a worker task template using the SageMaker API operation `DeleteHumanTaskUi`, specify a name of your UI in `HumanTaskUiName`.

Create Custom Worker Task Templates

Crowd HTML Elements are web components that provide a number of task widgets and design elements that you can tailor to the question you want to ask. You can use these crowd elements to create a custom worker template and integrate it with an Amazon Augmented AI (Amazon A2I) human review workflow to customize the worker console and instructions.

For a list of all HTML crowd elements available to Amazon A2I users, see Crowd HTML Elements Reference (p. 645). For examples of templates, see the AWS GitHub repository, which contains over 60 sample custom task templates.

Develop Templates Locally

When in the console to test how your template processes incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding the following code to the top of your HTML file.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

This loads the necessary code to render the custom HTML elements. Use this code if you want to develop your template's look and feel in your preferred editor instead of in the console.

This code won't parse your variables. You might want to replace them with sample content while developing locally.

Use External Assets

Amazon Augmented AI custom templates enable you to embed external scripts and style sheets. For example, the following header embeds a `text/css` style sheet name stylesheet located at https://www.example.com/my-enhancement-styles.css into the custom template.
Example

```html
<script src="https://www.example.com/my-enhancement-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding type for remote scripts is `application/javascript; CHARSET=UTF-8`.

The MIME and encoding type for remote stylesheets is `text/css; CHARSET=UTF-8`.

**Track Your Variables**

When building a custom template, you must add variables to it to represent the pieces of data that might change from task to task, or worker to worker. If you're starting with one of the sample templates, you need to make sure you're aware of the variables it already uses.

For example, for a custom template that integrates an Augmented AI human review loop with an Amazon Textract text review task, `{{ task.input.selectedAiServiceResponse.blocks }}` is used for initial-value input data. For Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition, `{{ task.input.selectedAiServiceResponse.moderationLabels }}` is used. For a custom task type, you need to determine the input parameter for your task type.

Use `{{ task.input.customInputValuesForStartHumanLoop }}` where you specify `customInputValuesForStartHumanLoop`.

**Custom Template Example for Amazon Textract**

All custom templates begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements.

For an Amazon Textract document analysis task, use the `<crowd-textract-analyze-document>` element. It uses the following attributes:

- `src` – Specifies the URL of the image file to be annotated.
- `initialValue` – Sets initial values for attributes found in the worker UI.
- `blockTypes (required)` – Determines the kind of analysis that the workers can do. Only `KEY_VALUE_SET` is currently supported.
- `keys (required)` – Specifies new keys and the associated text value that the worker can add.
- `no-key-edit (required)` – Prevents the workers from editing the keys of annotations passed through `initialValue`.
- `no-geometry-edit` – Prevents workers from editing the polygons of annotations passed through `initialValue`.

For children of the `<crowd-textract-analyze-document>` element, you must have two Regions. You can use arbitrary HTML and CSS elements in these Regions.

- `<full-instructions>` – Instructions that are available from the View full instructions link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- `<short-instructions>` – A brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.
An Amazon Textract template would look similar to the following.

**Example**

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/{{ task.input.aiServiceRequest.document.s3Object.bucket }}/{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they don't match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="['KEY_VALUE_SET']">
    <short-instructions header="Instructions">
      <style>
        .instructions { white-space: pre-wrap; }
        .instructionsImage { display: inline-block; max-width: 100%; }
      </style>
      <p class='instructions'>Choose a key-value block to highlight the corresponding key-value pair in the document.

      If it is a valid key-value pair, review the content for the value. If the content is incorrect, correct it.

      The text of the value is incorrect, correct it.
      <img class='instructionsImage' src="https://example-site/correct-value-text.png" />

      A wrong value is identified, correct it.
      <img class='instructionsImage' src="https://example-site/correct-value.png" />

      If it is not a valid key-value relationship, choose No.
      <img class='instructionsImage' src="https://example-site/not-a-key-value-pair.png" />

      If you can’t find the key in the document, choose Key not found.
      <img class='instructionsImage' src="https://example-site/key-is-not-found.png" />

      If the content of a field is empty, choose Value is blank.
      <img class='instructionsImage' src="https://example-site/value-is-blank.png" />

      <b>Examples</b>
      Key and value are often displayed next to or below to each other.
      <img class='instructionsImage' src="https://example-site/sample-key-value-pair-1.png" />

      Key and value displayed in one line.
      <img class='instructionsImage' src="https://example-site/sample-key-value-pair-2.png" />

      Key and value displayed in two lines.
      <img class='instructionsImage' src="https://example-site/sample-key-value-pair-2.png" />

      If the content of the value has multiple lines, enter all the text without a line break. Include all value text even if it extends beyond the highlight box.
      <img class='instructionsImage' src="https://assets.crowd.aws/images/a2i-console/multiple-lines.png"/>
    </short-instructions>
  </crowd-textract-analyze-document>
</crowd-form>
```
Custom Template Example for Amazon Rekognition

All custom templates begin and end with the `<crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements. For an Amazon Rekognition custom task template, use the `<crowd-rekognition-detect-moderation-labels>` element. This element supports the following attributes:

- **categories** – An array of strings or an array of objects where each object has a name field.
  - If the categories come in as objects, the following applies:
    - The displayed categories are the value of the name field.
    - The returned answer contains the full objects of any selected categories.
  - If the categories come in as strings, the following applies:
    - The returned answer is an array of all the strings that were selected.
- **exclusion-category** – By setting this attribute, you create a button underneath the categories in the UI. When a user selects the button, all categories are deselected and disabled. If the worker selects the button again, you re-enable users to choose categories. If the worker submits the task by selecting Submit after you select the button, that task returns an empty array.

For children of the `<crowd-rekognition-detect-moderation-labels>` element, you must have two Regions.

- `<full-instructions>` – Instructions that are available from the View full instructions link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- `<short-instructions>` – Brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.

A template using these elements would look similar to the following.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/{{ task.input.aiServiceRequest.image.s3Object.bucket }}/{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-rekognition-detect-moderation-labels categories='[
    {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
      {
        name: "{{ label.name }}",
        parentName: "{{ label.parentName }}",
      },
    {% endfor %}
  ]' src="{{ s3_uri | grant_read_access }}"
    header="Review the image and choose all applicable categories."
  >
    <short-instructions header="Instructions">
      <style>
        .instructions {
          white-space: pre-wrap;
        }
      </style>
      
      
    </short-instructions>
  </crowd-rekognition-detect-moderation-labels>
</crowd-form>
```
Review the image and choose all applicable categories. If no categories apply, choose None.

- **Nudity**
  - Visuals depicting nude male or female person or persons

- **Graphic Male Nudity**
  - Visuals depicting full frontal male nudity, often close ups

- **Graphic Female Nudity**
  - Visuals depicting full frontal female nudity, often close ups

- **Sexual Activity**
  - Visuals depicting various types of explicit sexual activities and pornography

- **Illustrated Nudity or Sexual Activity**
  - Visuals depicting animated or drawn sexual activity, nudity, or pornography

- **Adult Toys**
  - Visuals depicting adult toys, often in a marketing context

- **Female Swimwear or Underwear**
  - Visuals depicting female person wearing only swimwear or underwear

- **Male Swimwear Or Underwear**
  - Visuals depicting male person wearing only swimwear or underwear

- **Partial Nudity**
  - Visuals depicting covered up nudity, for example using hands or pose

- **Revealing Clothes**
  - Visuals depicting revealing clothes and poses, such as deep cut dresses

- **Graphic Violence or Gore**
  - Visuals depicting prominent blood or bloody injuries

- **Physical Violence**
  - Visuals depicting violent physical assault, such as kicking or punching

- **Weapon Violence**
  - Visuals depicting violence using weapons like firearms or blades, such as shooting

- **Weapons**
  - Visuals depicting weapons like firearms and blades

- **Self Injury**
  - Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns using sharp objects

- **Emaciated Bodies**
  - Visuals depicting extremely malnourished human bodies

- **Corpses**
  - Visuals depicting human dead bodies

- **Hanging**
  - Visuals depicting death by hanging

</short-instructions>
</full-instructions>
Add Automation with Liquid

The custom template system uses Liquid for automation. Liquid is an open-source inline markup language. For more information and documentation, see the Liquid homepage.

In Liquid, the text between single curly braces and percent symbols is an instruction or tag that performs an operation like control flow or iteration. Text between double curly braces is a variable or object that outputs its value. The following list includes two types of liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you are redirected to the Liquid documentation.

- **Control flow**: Includes programming logic operators like if/else, unless, and case/when.
- **Iteration**: Enables you to run blocks of code repeatedly using statements like for loops.

For example, the following code example demonstrates how you can use the Liquid for tag to create a for loop. This example loops through the moderationLabels returned from Amazon Rekognition and displays the moderationLabels attributes name and parentName for workers to review:

```liquid
{% for label in task.input.selectedAiServiceResponse.moderationLabels %}
  {
    name: &quot;{{ label.name }}&quot;,
    parentName: &quot;{{ label.parentName }}&quot;,
  },
{% endfor %}
```

Use Variable Filters

In addition to the standard Liquid filters and actions, Amazon Augmented AI (Amazon A2I) offers additional filters. You apply filters by placing a pipe (|) character after the variable name, and then specifying a filter name. To chain filters, use the following format.

Example

```liquid
{{ <content> | <filter> | <filter> }}
```

Autoescape and Explicit Escape

By default, inputs are HTML-escaped to prevent confusion between your variable text and HTML. You can explicitly add the escape filter to make it more obvious to someone reading the source of your template that escaping is being done.

**escape_once**

escape_once ensures that if you've already escaped your code, it doesn't get re-escaped again. For example, it ensures that &amp; doesn't become &amp;amp;.

**skip_autoescape**

skip_autoescape is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

Note

Use skip_autoescape sparingly. As a best practice for templates, avoid passing in functional code or markup with skip_autoescape unless you are absolutely sure that you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a cross-site scripting attack.
to_json

to_json encodes data that you provide to JavaScript Object Notation (JSON). If you provide an object, it serializes it.

grant_read_access

grant_read_access takes an Amazon Simple Storage Service (Amazon S3) URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

Example Example of the to_json and grant_read_access filters

Input

| auto-escape: {{ "Have you read 'James & the Giant Peach'?' }} |
| explicit escape: {{ "Have you read 'James & the Giant Peach'?' | escape }} |
| explicit escape_once: {{ "Have you read 'James &; the Giant Peach'?' | escape_once }} |
| skip_autoescape: {{ "Have you read 'James & the Giant Peach'?' | skip_autoescape }} |
| to_json: {{ jsObject | to_json }} |
| grant_read_access: {{ "s3://examplebucket/myphoto.png" | grant_read_access }} |

Example

Output

| auto-escape: Have you read &amp;#39;James &amp; the Giant Peach&amp;#39;? |
| explicit escape: Have you read &amp;#39;James &amp; the Giant Peach&amp;#39;? |
| explicit escape_once: Have you read &amp;#39;James &amp; the Giant Peach&amp;#39;? |
| skip_autoescape: Have you read 'James & the Giant Peach'?
| to_json: { "point_number": 8, "coords": [ 59, 76 ] } |
| grant_read_access: https://s3.amazonaws.com/examplebucket/myphoto.png?<access token and other params> |

Example Example of an automated classification template.

To automate this simple text classification sample, include the Liquid tag {{ task.input.source }}. This example uses the crowd-classifier (p. 659) element.

<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="["positive", "negative", "neutral", "cannot determine"]"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      {{ task.input.source }}
    </classification-target>

    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author of the tweet is trying to express.
      If none seems to match, choose "other."
    </full-instructions>

    <short-instructions>
      Pick the term that best describes the sentiment of the tweet.
    </short-instructions>
</crowd-form>
Preview a Worker Task Template

To preview a custom worker task template, use the SageMaker RenderUiTemplate operation. You can use the RenderUiTemplate operation with the AWS CLI or your preferred AWS SDK. For documentation on the supported language specific SDKs for this API operation, see the See Also section of the RenderUiTemplate.

Prerequisites

To preview your worker task template, the AWS Identity and Access Management (IAM) role Amazon Resource Name (ARN), or RoleArn, that you use must have permission to access to the S3 objects that are used by the template. To learn how to configure your role or user see Enable Worker Task Template Previews (p. 3034).

To preview your worker task template using the RenderUiTemplate operation:

1. Provide a RoleArn of the role with required policies attached to preview your custom template.
2. In the Input parameter of Task, provide a JSON object that contains values for the variables defined in the template. These are the variables that are substituted for the task.input.source variable. For example, if you define a task.input.text variable in your template, you can supply the variable in the JSON object as text: sample text.
3. In the Content parameter of UiTemplate, insert your template.

Once you've configured RenderUiTemplate, use your preferred SDK or the AWS CLI to submit a request to render your template. If your request was successful, the response includes RenderedContent, a Liquid template that renders the HTML for the worker UI.

Important
To preview your template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. For a sample policy that you can attach to your IAM role to grant these permissions, see Enable Worker Task Template Previews (p. 3034).

Creating Good Worker Instructions

Creating good instructions for your human review jobs improves your worker's accuracy in completing their task. You can modify the default instructions that are provided in the console when creating a human review workflow, or you can use the console to create a custom worker template and include your instructions in this template. The instructions are shown to the worker on the UI page where they complete their labeling task.

Create Good Worker Instructions

There are three kinds of instructions in the Amazon Augmented AI console:

- **Task Description** – The description should provide a succinct explanation of the task.
- **Instructions** – These instructions are shown on the same webpage where workers complete a task. These instructions should provide an easy reference to show the worker the correct way to complete the task.
- **Additional Instructions** – These instructions are shown in a dialog box that appears when a worker chooses View full instructions. We recommend that you provide detailed instructions for completing the task, and include several examples showing edge cases and other difficult situations for labeling objects.
Add Example Images to Your Instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions, do the following:

1. Place the cursor where the image should go in the instructions editor.
2. Choose the image icon in the editor toolbar.
3. Enter the URL of your image.

If your instruction image is in an S3 bucket that isn't publicly accessible, do the following:

- For the image URL, enter: `{{ 'https://s3.amazonaws.com/your-bucket-name/image-file-name' | grant_read_access }}`.

This renders the image URL with a short-lived, one-time access code that's appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview. See grant_read_access (p. 3018) for more information about the grant_read_access element.

Monitor and Manage Your Human Loop

Once you've started a human review loop, you can check the results of tasks sent to the loop and manage it using the Amazon Augmented AI Runtime API. Additionally, Amazon A2I integrates with Amazon EventBridge (also known as Amazon CloudWatch Events) to alert you when a human review loop status changes to Completed, Failed, or Stopped. This event delivery is guaranteed at least once, which means all events created when human loops finish are successfully delivered to EventBridge.

Use the procedures below to learn how to use the Amazon A2I Runtime API to monitor and manage your human loops. See Use Amazon CloudWatch Events in Amazon Augmented AI (p. 3035) to learn how Amazon A2I integrates with Amazon EventBridge.

To check your output data:

1. Check the results of your human loop by calling the DescribeHumanLoop operation. The result of this API operation contains information about the reason for and outcome of the loop activation.
2. Check the output data from your human loop in Amazon Simple Storage Service (Amazon S3). In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

   ```s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json```

   You can integrate this structure with AWS Glue or Amazon Athena to partition and analyze your output data. For more information, see Managing Partitions for ETL Output in AWS Glue.

   To learn more about Amazon A2I output data format, see Amazon A2I Output Data (p. 3021).

To stop and delete your human loop:

1. Once a human loop has been started, you can stop your human loop by calling the StopHumanLoop operation using the HumanLoopName. If a human loop was successfully stopped, the server sends back an HTTP 200 response.
2. To delete a human loop for which the status equals Failed, Completed, or Stopped, use the `DeleteHumanLoop` operation.

**To list human loops:**

1. You can list all active human loops by calling the `ListHumanLoops` operation. You can filter human loops by the creation date of the loop using the `CreationTimeAfter` and `CreateTimeBefore` parameters.
2. If successful, `ListHumanLoops` returns `HumanLoopSummaries` and `NextToken` objects in the response element. `HumanLoopSummaries` contains information about a single human loop. For example, it lists a loop's status and, if applicable, its failure reason.

Use the string returned in `NextToken` as an input in a subsequent call to `ListHumanLoops` to see the next page of human loops.

**Amazon A2I Output Data**

When your machine learning workflow sends Amazon A2I a data object, a human loop is created and human reviewers receive a task to review that data object. The output data from each human review task is stored in the Amazon Simple Storage Service (Amazon S3) output bucket you specify in your human review workflow. In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

`s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json`

The content of your output data depends on the type of task type (built-in or custom) and the type of workforce you use. Your output data always includes the response from the human worker. Additionally, output data may include metadata about the human loop, the human reviewer (worker), and the data object.

Use the following sections to learn more about Amazon A2I output data format for different task types and workforces.

**Output Data From Built-In Task Types**

Amazon A2I built-in task types include Amazon Textract and Amazon Rekognition. In addition to human responses, the output data from one of these tasks includes details about the reason the human loop was created and information about the integrated service used to create the human loop. Use the following table to learn more about the output data schema for all built-in task types. The value for each of these parameters depends on the service you use with Amazon A2I. Refer to the second table in this section for more information about these service-specific values.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Example Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>awsManagedHumanLoopRequestSource</code></td>
<td>String</td>
<td>AWS/Rekognition/DetectModerationLabels/Image/V3 or AWS/Texttract/AnalyzeDocument/Forms/V1</td>
<td>The API operation and associated AWS services that requested that Amazon A2I create the a human loop. This is the API operation you use to configure your</td>

</table>
### Output Data From Built-In Task Types

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Example Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>humanTaskActivationConditionResults</td>
<td>JSON object</td>
<td>{ &quot;Conditions&quot;: [...] }</td>
<td>A JSON object in inputContent that contains the reason a human loop was created. This includes a list of the activation conditions (Conditions) included in your human review workflow (flow definition), and the evaluation result for each condition—this result is either true or false. To learn more about activation conditions, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2989).</td>
</tr>
</tbody>
</table>

Select a tab on the following table to learn about the task type–specific parameters and see an example output-data code block for each of the built-in task types.

### Amazon Textract Task Type Output Data

When you use the Amazon Textract built-in integration, you see 'AWS/Textract/AnalyzeDocument/Forms/V1' as the value for awsManagedHumanLoopRequestSource in your output data.

The answerContent parameter contains a Block object that includes human responses for all blocks sent to Amazon A2I.

The aiServiceResponse parameter also includes a Block object with Amazon Textract's response to the original request sent using to AnalyzeDocument.

To learn more about the parameters you see in the block object, refer to Block in the Amazon Textract Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Textract document analysis inferences.

```json
{
    "awsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1",
    "humanAnswers": [
        {
            "answerContent": {
                "AWS/Textract/AnalyzeDocument/Forms/V1": {
                    "blocks": [...] |
                }
            },
            "submissionTime": "2020-09-28T19:17:59.880Z",
            "workerId": "111122223333",
        }
    ],
```
"workerMetadata": {

  "Conditions": [ 
    { 
      "EvaluationResult": true,
      "Or": [ 
        { 
          "ConditionParameters": { 
            "ImportantFormKey": "Mail address",
            "ImportantFormKeyAliases": [ 
              "Mail Address:",
              "Mail address:",
              "Mailing Add:",
              "Mailing Addresses"
            ],
            "KeyValueBlockConfidenceLessThan": 100,
            "WordBlockConfidenceLessThan": 100
          },
          "ConditionType": "ImportantFormKeyConfidenceCheck",
          "EvaluationResult": true
        }
      ]
    }
  ]
}
Amazon Rekognition Task Type Output Data

When you use the Amazon Textract built-in integration, you see the string 'AWS/Rekognition/DetectModerationLabels/Image/V3' as the value for `awsManagedHumanLoopRequestSource` in your output data.

The `answerContent` parameter contains a `moderationLabels` object that contains human responses for all moderation labels sent to Amazon A2I.

The `aiServiceResponse` parameter also includes a `moderationLabels` object with Amazon Rekognition's response to the original request sent to `DetectModerationLabels`.

To learn more about the parameters you see in the block object, refer to `ModerationLabel` in the Amazon Rekognition Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Rekognition image moderation inferences.

```json
{
  "awsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3",
  "humanAnswers": [
    {
      "answerContent": {
        "AWS/Rekognition/DetectModerationLabels/Image/V3": {
          "moderationLabels": [...]}
      }
    },
    "submissionTime": "2020-09-28T19:22:35.508Z",
    "workerId": "ef7294f850a3d9d1",
    "workerMetadata": {
      "identityData": {
        "identityProviderType": "Cognito",
        "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
      }
    }
  ],
  "humanLoopName": "human-loop-name",
  "inputContent": {
    "aiServiceRequest": {
      "humanLoopConfig": {
```
Output Data From Custom Task Types

When you add Amazon A2I to a custom human review workflow, you see the following parameters in the output data returned from human review tasks.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowDefinitionArn</td>
<td>String</td>
<td>The Amazon Resource Number (ARN) of the human review</td>
</tr>
<tr>
<td>humanLoopName</td>
<td></td>
<td></td>
</tr>
<tr>
<td>image</td>
<td></td>
<td></td>
</tr>
<tr>
<td>aiServiceResponse</td>
<td></td>
<td></td>
</tr>
<tr>
<td>moderationLabels</td>
<td></td>
<td></td>
</tr>
<tr>
<td>moderationModelVersion</td>
<td></td>
<td></td>
</tr>
<tr>
<td>humanTaskActivationConditionResults</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Conditions</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EvaluationResult</td>
<td>true</td>
<td></td>
</tr>
<tr>
<td>Or</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ConditionParameters</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ConfidenceLessThan</td>
<td>98</td>
<td></td>
</tr>
<tr>
<td>ModerationLabelName</td>
<td>&quot;Suggestive&quot;</td>
<td></td>

### Output Data From Custom Task Types

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflow (flow definition) used to create the human loop.</td>
<td>humanAnswers List of JSON objects</td>
<td>A list of JSON objects that contain worker responses in answerContent. The value in this parameter is determined by the output received from your worker task template. If you are using a private workforce, worker metadata is included. To learn more, see Track Worker Activity (p. 3029).</td>
</tr>
<tr>
<td>humanLoopName</td>
<td>String</td>
<td>The name of the human loop.</td>
</tr>
<tr>
<td>inputContent</td>
<td>JSON Object</td>
<td>The input content sent to Amazon A2I in the request to StartHumanLoop.</td>
</tr>
</tbody>
</table>

The following is an example of output data from a custom integration with Amazon A2I and Amazon Transcribe. In this example, the inputContent consists of:

- A path to an .mp4 file in Amazon S3 and the video title
- The transcription returned from Amazon Transcribe (parsed from Amazon Transcribe output data)
- A start and end time used by the worker task template to clip the .mp4 file and show workers a relevant portion of the video

```json
{
   "humanAnswers": [
      {
         "answerContent": {
            "transcription": "use lambda to turn your notebook"
         },
         "submissionTime": "2020-06-18T17:08:26.246Z",
         "workerId": "ef7294f850a3d9d1",
         "workerMetadata": {
            "identityData": {
               "identityProviderType": "Cognito",
               "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
            }
         }
      }
   ],
   "humanLoopName": "human-loop-name",
   "inputContent": {
      "audioPath": "s3://DOC-EXAMPLE-BUCKET1/a2i_transcribe_demo/Fully-Managed Notebook Instances with Amazon SageMaker - a Deep Dive.mp4",
      "end_time": 950.27,
      "original_words": "but definitely use Lambda to turn your ",
      "start_time": 948.51
   }
}
```
Track Worker Activity

Amazon A2I provides information that you can use to track individual workers in task output data. To identify the worker that worked on the human review task, use the following from the output data in Amazon S3:

- **acceptanceTime** is the time that the worker accepted the task. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- **submissionTime** is the time that the worker submitted their annotations using the Submit button. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- **timeSpentInSeconds** reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- **workerId** is unique to each worker.
- If you use a **private workforce**, in workerMetadata, you see the following.
  - The **identityProviderType** is the service used to manage the private workforce.
  - The **issuer** is the Amazon Cognito user pool or OpenID Connect (OIDC) Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique **sub** identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) associated with this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the **identityProviderType**.

```
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentIn Seconds": 40.543,
"workerId": "a12b3defg4h5i67",
"workerMetadata": {  
  "identityData": {  
    "identityProviderType": "Cognito",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"  
  }  
}
```

The following is an example of the output you may see if you use your own OIDC IdP to create a private workforce:

```
"workerMetadata": {  
  "identityData": {  
    "identityProviderType": "Oidc",
    "issuer": "https://example-oidc-ipd.com/adfs",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"  
  }  
}
```
Permissions and Security in Amazon Augmented AI

When using Amazon Augmented AI (Amazon A2I) to create a human review workflow for your ML/AI application, you create and configure resources in Amazon SageMaker such as a human workforce and worker task templates. To configure and start a human loop, you either integrate Amazon A2I with other AWS services such as Amazon Textract or Amazon Rekognition, or use the Amazon Augmented AI Runtime API. To create a human review workflow and start a human loop, you must attach certain policies to your AWS Identity and Access Management (IAM) role or user. Specifically:

- When you start a human loop using image input data on or after January 12th, 2020, you must add a CORS header policy to the Amazon S3 bucket that contains your input data. See CORS Permission Requirement (p. 3031) to learn more.
- When you create a flow definition, you need to provide a role that grants Amazon A2I permission to access Amazon S3 both for reading objects that are rendered in a human task UI and for writing the results of the human review. This role must also have a trust policy attached to give SageMaker permission to assume the role. This allows Amazon A2I to perform actions in accordance with permissions that you attach to the role. See Add Permissions to the IAM Role Used to Create a Flow Definition (p. 3031) for example policies that you can modify and attach to the role you use to create a flow definition. These are the policies that are attached to the IAM role that is created in the Human review workflows section of the Amazon A2I area of the SageMaker console.

- To create and start human loops, you either use an API operation from a built-in task type (such as DetectModerationLabel or AnalyzeDocument) or the Amazon A2I Runtime API operation StartHumanLoop in a custom ML application. You need to attach the AmazonAugmentedAIInvocationFullAccess managed policy to the IAM user that invokes these API operations to grant permission to these services to use Amazon A2I operations. To learn how, see Create an IAM User That Can Invoke Amazon A2I API Operations (p. 3033). This policy does not grant permission to invoke the API operations of the AWS service associated with built-in task types. For example, AmazonAugmentedAIInvocationFullAccess does not grant permission to call the Amazon Rekognition DetectModerationLabel API operation or Amazon Textract AnalyzeDocument API operation. You can use the more general policy, AmazonAugmentedAIInvocationFullAccess, to grant these permissions. For more information, see Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 3033). This is a good option when you want to grant an IAM user broad permissions to use Amazon A2I and integrated AWS services' API operations.

- To preview your custom worker task UI template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. See a policy example in Enable Worker Task Template Previews (p. 3034).

Topics

- CORS Permission Requirement (p. 3031)
- Add Permissions to the IAM Role Used to Create a Flow Definition (p. 3031)
- Create an IAM User That Can Invoke Amazon A2I API Operations (p. 3033)
- Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 3033)
CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, images would always display in browsers exactly how they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called orientation value. This has important implications for the entire machine learning (ML) community. For example, if the EXIF orientation is not considered, applications that are used to annotate images may display images in unexpected orientations and result in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web's Same-Origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a human loop, you must add a CORS header policy to the S3 buckets that contain your input images.

**Important**

If you do not add a CORS configuration to the S3 buckets that contains your input data, human review tasks for those input data objects fail.

You can add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json
{
  "AllowedHeaders": [],
  "AllowedMethods": ["GET"],
  "AllowedOrigins": ["*"],
  "ExposeHeaders": []
}
```

**XML**

```xml
<CORSConfiguration>
  <CORSRule>
    <AllowedOrigin>*</AllowedOrigin>
    <AllowedMethod>GET</AllowedMethod>
  </CORSRule>
</CORSConfiguration>
```

Add Permissions to the IAM Role Used to Create a Flow Definition

To create a flow definition, attach the policies in this section to the role that you use when creating a human review workflow in the SageMaker console, or when using the CreateFlowDefinition API operation.
Add Permissions to the IAM Role
Used to Create a Flow Definition

- If you are using the console to create a human review workflow, enter the role Amazon Resource Name (ARN) in the IAM role field when creating a human review workflow in the console.
- When creating a flow definition using the API, attach these policies to the role that is passed to the RoleArn parameter of the CreateFlowDefinition operation.

When you create a human review workflow (flow definition), Amazon A2I invokes Amazon S3 to complete your task. To grant Amazon A2I permission to retrieve and store your files in your Amazon S3 bucket, create the following policy and attach it to your role. For example, if the images, documents, and other files that you are sending for human review are stored in an S3 bucket named my_input_bucket, and if you want the human reviews to be stored in a bucket named my_output_bucket, create the following policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObject"
         ],
         "Resource": [
            "arn:aws:s3:::my_input_bucket/*"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:PutObject"
         ],
         "Resource": [
            "arn:aws:s3:::my_output_bucket/*"
         ]
      }
   ]
}
```

In addition, the IAM role must have the following trust policy to give SageMaker permission to assume the role. To learn more about IAM trust policies, see Resource-Based Policies section of Policies and Permissions in the AWS Identity and Access Management documentation.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowSageMakerToAssumeRole",
         "Effect": "Allow",
         "Principal": {
            "Service": "sagemaker.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

For more information about creating and managing IAM roles and policies, see the following topics in the AWS Identity and Access Management User Guide:

- To create an IAM role, see Creating a Role to Delegate Permissions to an IAM User.
- To learn how to create IAM policies, see Creating IAM Policies.
To learn how to attach an IAM policy to a role, see Adding and Removing IAM Identity Permissions.

Create an IAM User That Can Invoke Amazon A2I API Operations

To use Amazon A2I to create and start human loops for Amazon Rekognition, Amazon Textract, or the Amazon A2I runtime API, you must use an IAM user that has permissions to invoke Amazon A2I operations. To do this, use the IAM console to attach the AmazonAugmentedAIFullAccess managed policy to a new or existing IAM user.

This policy grants permission to an IAM user to invoke API operations from the SageMaker API for flow definition creation and management and the Amazon Augmented AI Runtime API for human loop creation and management. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

AmazonAugmentedAIFullAccess does not grant permissions to use Amazon Rekognition or Amazon Textract API operations.

**Note**

You can also attach the AmazonAugmentedAIFullAccess policy to an IAM role that is used to create and start a human loop.

To create the required IAM user

2. Choose Users and choose an existing user, or create a new user by choosing Add user. To learn how to create a new user, see Creating an IAM User in Your AWS Account in the AWS Identity and Access Management User Guide.
   - If you chose to attach the policy to an existing user, choose Add permissions.
   - While creating a new user, follow the next step on the Set permissions page.
3. Choose Attach existing policies directly.
4. In the Search bar, enter AmazonAugmentedAIFullAccess and check the box next to that policy.
   To enable this IAM user to create a flow definition with the public work team, also attach the AmazonSageMakerMechanicalTurkAccess managed policy.
5. After attaching the policy or policies:
   a. If you are using an existing user, choose Next: Review, and then choose Add permissions.
   b. If you are creating a new user, choose Next: Tags and complete the process of creating your user.

For more information, see Adding and Removing IAM Identity Permissions in the AWS Identity and Access Management User Guide.

Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations

To create an IAM user that has permission to invoke the API operations used by the built-in task types (that is, DetectModerationLabels for Amazon Rekognition and AnalyzeDocument for Amazon...
Textract) and permission to use all Amazon A2I API operations, attach the IAM managed policy, 
AmazonAugmentedAIIntegratedAPIAccess. You may want to use this policy when you want to grant 
broad permissions to an IAM user using Amazon A2I with more than one task type. To learn more about 
these API operations, see Use APIs in Amazon Augmented AI.

**Note**
You can also attach the AmazonAugmentedAIIntegratedAPIAccess policy to an IAM role 
that is used to create and start a human loop.

**To create the required IAM user**

2. Choose Users and choose an existing user, or create a new user by choosing Add user. To learn how 
to create a new user, see Creating an IAM User in Your AWS Account in the AWS Identity and Access 
Management User Guide.
   - If you chose to attach the policy to an existing user, choose Add permissions.
   - If you are creating a new user, follow the next step on the Set permissions page.
3. Choose Attach existing policies directly.
4. In the Search bar, enter AmazonAugmentedAIIntegratedAPIAccess and select the box next to 
that policy.

To allow this IAM user to create a flow definition using Amazon Mechanical Turk, also attach the 
AmazonSageMakerMechanicalTurkAccess managed policy.

5. After attaching the policy or policies:
   - If you are using an existing user, choose Next: Review, and then choose Add permissions.
   - If you are creating a new user, choose Next: Tags and complete the process of creating your 
user.

For more information, see Adding and Removing IAM Identity Permissions in the AWS Identity and Access 
Management User Guide.

**Enable Worker Task Template Previews**

To customize the interface and instructions that your workers see when working on your tasks, you 
create a worker task template. You can create the template using the CreateHumanTaskUi operation or 
the SageMaker console.

To preview your template, you need an IAM role with the following permissions to read Amazon S3 
objects that get rendered on your user interface.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObject"
         ],
         "Resource": [
            "arn:aws:s3:::my_input_bucket/*"
         ]
      }
   ]
}
```
For Amazon Rekognition and Amazon Textract task types, you can preview your template using the Amazon Augmented AI section of the SageMaker console. For custom task types, you preview your template by invoking the `RenderUiTemplate` operation. To preview your template, follow the instructions for your task type:

- Amazon Rekognition and Amazon Textract task types – In the SageMaker console, use the role's Amazon Resource Name (ARN) in the procedure documented in Create a Worker Task Template (p. 3011).
- Custom task types – In the `RenderUiTemplate` operation, use the role's ARN in the `RoleArn` parameter.

### Using Amazon A2I with AWS KMS Encrypted Buckets

If you specify an AWS Key Management Service (AWS KMS) customer managed key to encrypt output data in `OutputConfig` of `CreateFlowDefinition`, you must add an IAM policy similar to the following to that key. This policy gives the IAM execution role that you use to create your human loops permission to use this key to perform all of the actions listed in "Action". To learn more about these actions, see AWS KMS permissions in the AWS Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in "Principal" with the ARN of the execution role you use to create the human review workflow (flow definition). When you create a labeling job using `CreateFlowDefinition`, this is the ARN you specify for `RoleArn`. Note that you cannot provide a `KmsKeyId` when you create a flow definition in the console.

```json
{
  "Sid": "AllowUseOfKmsKey",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt",
    "kms:GenerateDataKey",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```

### Additional Permissions and Security Resources

- the section called “Control Access to SageMaker Resources by Using Tags” (p. 3090).
- the section called “SageMaker Identity-Based Policies” (p. 3068)
- the section called “Control Creation of SageMaker Resources with Condition Keys” (p. 3081)
- the section called “Amazon SageMaker API Permissions Reference” (p. 3114)
- `Security` (p. 3057)

### Use Amazon CloudWatch Events in Amazon Augmented AI

Amazon Augmented AI uses Amazon CloudWatch Events to alert you when a human review loop status changes to `Completed`, `Failed`, or `Stopped`. This event delivery is guaranteed at least once, which
means all events created when human loops finish are successfully delivered to CloudWatch Events (Amazon EventBridge). When a review loop changes to one of these states, Augmented AI sends an event to CloudWatch Events similar to the following.

```
{
    "version": "0",
    "id": "12345678-1111-2222-3333-12345EXAMPLE",
    "detail-type": "SageMaker A2I HumanLoop Status Change",
    "source": "aws.sagemaker",
    "account": "1111111111111",
    "time": "2019-11-14T17:49:25Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:sagemaker:us-east-1:111111111111:human-loop/humanloop-nov-14-1"
    ],
    "detail": {
        "creationTime": "2019-11-14T17:37:36.740Z",
        "failureCode": null,
        "failureReason": null,
        "flowDefinitionArn": "arn:aws:sagemaker:us-east-1:111111111111:flow-definition/flowdef-nov-12",
        "humanLoopName": "humanloop-nov-14-1",
        "humanLoopOutput": {
            "outputS3Uri": "s3://customer-output-bucket-specified-in-flow-definition/flowdef-nov-12/2019/11/14/17/37/36/humanloop-nov-14-1/output.json"
        }
    }
}
```

The details in the JSON output include the following:

**creationTime**

The timestamp when Augmented AI created the human loop.

**failureCode**

A failure code denoting a specific type of failure.

**failureReason**

The reason why a human loop has failed. The failure reason is only returned when the human review loop status is failed.

**flowDefinitionArn**

The Amazon Resource Name (ARN) of the flow definition, or human review workflow.

**humanLoopArn**

The Amazon Resource Name (ARN) of the human loop.

**humanLoopName**

The name of the human loop.

**humanLoopOutput**

An object containing information about the output of the human loop.

**outputS3Uri**

The location of the Amazon S3 object where Augmented AI stores your human loop output.
humanLoopStatus

The status of the human loop.

## Send Events from Your Human Loop to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or events, for your Amazon A2I human loops, use the AWS Command Line Interface (AWS CLI) `put-rule` command. When using the `put-rule` command, specify the following to receive human loop statuses:

- "source": ["aws.sagemaker"]
- "detail-type": ["SageMaker A2I HumanLoop Status Change"]

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace "A2IHumanLoopStatusChanges" with a unique CloudWatch Events rule name and "arn:aws:iam::111122223333:role/MyRoleForThisRule" with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached. Replace `region` with the AWS Region in which you want to create the rule.

```bash
aws events put-rule --name "A2IHumanLoopStatusChanges" --event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker A2I HumanLoop Status Change"]}") --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule" --region "region"
```

To learn more about the `put-rule` request, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

## Set Up a Target to Process Events

To process events, you need to set up a target. For example, if you want to receive an email when a human loop status changes, use a procedure in Setting Up Amazon SNS Notifications in the Amazon CloudWatch User Guide to set up an Amazon SNS topic and subscribe your email to it. Once you have created a topic, you can use it to create a target.

### To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose Rules.
3. Choose the rule to which you want to add a target.
4. Choose Actions, and then choose Edit.
5. Under Targets, choose Add Target and choose the AWS service you want to act when a human loop status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose Configure details.
8. For Name, enter a name and, optionally, provide details about the purpose of the rule in Description.
9. Make sure that the check box next to State is selected so that your rule is listed as Enabled.
10. Choose Update rule.
Use Human Review Output

After you receive human review results, you can analyze the results and compare them to machine learning predictions. The JSON that is stored in the Amazon S3 bucket contains both the machine learning predictions and the human review results.

More Information

Automating Amazon SageMaker with Amazon EventBridge (p. 3205)

Use APIs in Amazon Augmented AI

You can create a human review workflow or a worker task template programmatically. The APIs you use depend on whether you are creating a Amazon Rekognition, Amazon Textract, or custom task type. This topic provides links to API reference documentation for each task type and programming task.

The following APIs can be used with Augmented AI:

Amazon Augmented AI

Use the Augmented AI API to start, stop, and delete human review loops. You can also list all human review loops and return information about human review loops in your account.

Learn more about human review loop APIs in the Amazon Augmented AI Runtime API Reference.

Amazon Rekognition

Use the **HumanLoopConfig** parameter of the **DetectModerationLabels** API to initiate a human review workflow using Amazon Rekognition.

Amazon SageMaker

Use the Amazon SageMaker API to create a **FlowDefinition**, also known as a *human review workflow*. You can also create a **HumanTaskUi** or *worker task template*.

For more information, see the **CreateFlowDefinition** or the **CreateHumanTaskUi** API documentation.

Amazon Textract

Use the **HumanLoopConfig** parameter of the **AnalyzeDocument** API to initiate a human review workflow using Amazon Textract.

Programmatic Tutorials

The following tutorials provide example code and step-by-step instructions for creating human review workflows and worker task templates programmatically.

- Tutorial: Get Started Using the Amazon A2I API (p. 2965)
- Create a Human Review Workflow (API) (p. 2986)
- Create and Start a Human Loop (p. 3002)
- Using Amazon Augmented AI with Amazon Rekognition in the *Amazon Rekognition Developer Guide*
- Using Amazon Augmented AI with Amazon Textract AnalyzeDocument in the *Amazon Textract Developer Guide*
Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace

Amazon SageMaker integrates with AWS Marketplace, enabling developers to charge other SageMaker users for the use of their algorithms and model packages. AWS Marketplace is a curated digital catalog that makes it easy for customers to find, buy, deploy, and manage third-party software and services that customers need to build solutions and run their businesses. AWS Marketplace includes thousands of software listings in popular categories, such as security, networking, storage, machine learning, business intelligence, database, and DevOps. It simplifies software licensing and procurement with flexible pricing options and multiple deployment methods.

For information, see AWS Marketplace Documentation.

Topics

- SageMaker Algorithms (p. 3039)
- SageMaker Model Packages (p. 3039)
- Sell Amazon SageMaker Algorithms and Model Packages (p. 3053)
- Find and Subscribe to Algorithms and Model Packages on AWS Marketplace (p. 3056)
- Use Algorithm and Model Package Resources (p. 3046)

SageMaker Algorithms

An algorithm enables you to perform end-to-end machine learning. It has two logical components: training and inference. Buyers can use the training component to create training jobs in SageMaker and build a machine learning model. SageMaker saves the model artifacts generated by the algorithm during training to an Amazon S3 bucket. For more information, see Train a Model with Amazon SageMaker (p. 9).

Buyers use the inference component with the model artifacts generated during a training job to create a deployable model in their SageMaker account. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 11).

SageMaker Model Packages

Buyers use a model package to build a deployable model in SageMaker. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 11). As a seller, you can build your model artifacts by training in SageMaker, or you can use your own model artifacts from a model that you trained outside of SageMaker. You can charge buyers for inference.
Use your own algorithms and models with the AWS Marketplace

The following sections show how to create algorithm and model package resources that you can use locally and publish to the AWS Marketplace.

Topics
- Create Algorithm and Model Package Resources (p. 3040)
- Use Algorithm and Model Package Resources (p. 3046)

Create Algorithm and Model Package Resources

After your training and/or inference code is packaged in Docker containers, create algorithm and model package resources that you can use in your Amazon SageMaker account and, optionally, publish on AWS Marketplace.

Topics
- Create an Algorithm Resource (p. 3040)
- Create a Model Package Resource (p. 3043)

Create an Algorithm Resource

To create an algorithm resource that you can use to run training jobs in Amazon SageMaker and publish on AWS Marketplace specify the following information:

- The Docker containers that contains the training and, optionally, inference code.
- The configuration of the input data that your algorithm expects for training.
- The hyperparameters that your algorithm supports.
- Metrics that your algorithm sends to Amazon CloudWatch during training jobs.
- The instance types that your algorithm supports for training and inference, and whether it supports distributed training across multiple instances.
- Validation profiles, which are training jobs that SageMaker uses to test your algorithm's training code and batch transform jobs that SageMaker runs to test your algorithm's inference code.

To ensure that buyers and sellers can be confident that products work in SageMaker, we require that you validate your algorithms before listing them on AWS Marketplace. You can list products in the AWS Marketplace only if validation succeeds. To validate your algorithms, SageMaker uses your validation profile and sample data to run the following validations tasks:
1. Create a training job in your account to verify that your training image works with SageMaker.
2. If you included inference code in your algorithm, create a model in your account using the algorithm's inference image and the model artifacts produced by the training job.
3. If you included inference code in your algorithm, create a transform job in your account using the model to verify that your inference image works with SageMaker.

When you list your product on AWS Marketplace, the inputs and outputs of this validation process persist as part of your product and are made available to your buyers. This helps buyers understand and evaluate the product before they buy it. For example, buyers can inspect the input data that you used, the outputs generated, and the logs and metrics emitted by your code. The more comprehensive your validation specification, the easier it is for customers to evaluate your product.
Note
In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Training jobs and Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. If any issues are found, you will have to create the algorithm again.

Note
To publish your algorithm on AWS Marketplace, at least one validation profile is required.

You can create an algorithm by using either the SageMaker console or the SageMaker API.

Topics
• Create an Algorithm Resource (Console) (p. 3041)
• Create an Algorithm Resource (API) (p. 3043)

Create an Algorithm Resource (Console)

To create an algorithm resource (console)
2. From the left menu, choose Training.
3. From the dropdown menu, choose Algorithms, then choose Create algorithm.
4. On the Training specifications page, provide the following information:
   a. For Algorithm name, type a name for your algorithm. The algorithm name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
   b. Type a description for your algorithm. This description appears in the SageMaker console and in the AWS Marketplace.
   c. For Training image, type the path in Amazon ECR where your training container is stored.
   d. For Support distributed training, Choose Yes if your algorithm supports training on multiple instances. Otherwise, choose No.
   e. For Support instance types for training, choose the instance types that your algorithm supports.
   f. For Channel specification, specify up to 8 channels of input data for your algorithm. For example, you might specify 3 input channels named train, validation, and test. For each channel, specify the following information:
      i. For Channel name, type a name for the channel. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
      ii. To require the channel for your algorithm, choose Channel required.
      iii. Type a description for the channel.
      iv. For Supported input modes, choose Pipe mode if your algorithm supports streaming the input data, and File mode if your algorithm supports downloading the input data as a file. You can choose both.
      v. For Supported content types, type the MIME type that your algorithm expects for input data.
      vi. For Supported compression type, choose Gzip if your algorithm supports Gzip compression. Otherwise, choose None.
vii. Choose **Add channel** to add another data input channel, or choose **Next** if you are done adding channels.

5. **On the Tuning specifications** page, provide the following information:

   a. **For Hyperparameter specification**, specify the hyperparameters that your algorithm supports by editing the JSON object. For each hyperparameter that your algorithm supports, construct a JSON block similar to the following:

   ```json
   {
     "DefaultValue": "5",
     "Description": "The first hyperparameter",
     "IsRequired": true,
     "IsTunable": false,
     "Name": "intRange",
     "Range": {
       "IntegerParameterRangeSpecification": {
         "MaxValue": "10",
         "MinValue": "1"
       },
       "Type": "Integer"
     }
   }
   ```

   In the JSON, supply the following:

   i. **For DefaultValue**, specify a default value for the hyperparameter, if there is one.

   ii. **For Description**, specify a description for the hyperparameter.

   iii. **For IsRequired**, specify whether the hyperparameter is required.

   iv. **For IsTunable**, specify `true` if this hyperparameter can be tuned when a user runs a hyperparameter tuning job that uses this algorithm. For information, see Perform Automatic Model Tuning with SageMaker (p. 2186).

   v. **For Name**, specify a name for the hyperparameter.

   vi. **For Range**, specify one of the following:

      - **IntegerParameterRangeSpecification** - the values of the hyperparameter are integers. Specify minimum and maximum values for the hyperparameter.

      - **ContinuousParameterRangeSpecification** - the values of the hyperparameter are floating-point values. Specify minimum and maximum values for the hyperparameter.

      - **CategoricalParameterRangeSpecification** - the values of the hyperparameter are categorical values. Specify a list of all of the possible values.

   vii. **For Type**, specify `Integer`, `Continuous`, or `Categorical`. The value must correspond to the type of Range that you specified.

   b. **For Metric definitions**, specify any training metrics that you want your algorithm to emit. SageMaker uses the regular expression that you specify to find the metrics by parsing the logs from your training container during training. Users can view these metrics when they run training jobs with your algorithm, and they can monitor and plot the metrics in Amazon CloudWatch. For information, see Monitor and Analyze Training Jobs Using Amazon CloudWatch Metrics (p. 2383). For each metric, provide the following information:

   i. **For Metric name**, type a name for the metric.

   ii. **For Regex**, type the regular expression that SageMaker uses to parse training logs so that it can find the metric value.

   iii. **For Objective metric support** choose `Yes` if this metric can be used as the objective metric for a hyperparameter tuning job. For information, see Perform Automatic Model Tuning with SageMaker (p. 2186).
iv. Choose Add metric to add another metric, or choose Next if you are done adding metrics.

6. On the Inference specifications page, provide the following information if your algorithm supports inference:
   a. For Location of inference image, type the path in Amazon ECR where your inference container is stored.
   b. For Container DNS host name, type the name of a DNS host for your image.
   c. For Supported instance types for real-time inference, choose the instance types that your algorithm supports for models deployed as hosted endpoints in SageMaker. For information, see Deploy Models for Inference (p. 2391).
   d. For Supported instance types for batch transform jobs, choose the instance types that your algorithm supports for batch transform jobs. For information, see Use Batch Transform (p. 2565).
   e. For Supported content types, type the type of input data that your algorithm expects for inference requests.
   f. For Supported response MIME types, type the MIME types that your algorithm supports for inference responses.
   g. Choose Next.

7. On the Validation specifications page, provide the following information:
   a. For Publish this algorithm on AWS Marketplace, choose Yes to publish the algorithm on AWS Marketplace.
   b. For Validate this resource, choose Yes if you want SageMaker to run training jobs and/or batch transform jobs that you specify to test the training and/or inference code of your algorithm.
      
      **Note**
      To publish your algorithm on AWS Marketplace, your algorithm must be validated.
   c. For IAM role, choose an IAM role that has the required permissions to run training jobs and batch transform jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3097).
   d. For Validation profile, specify the following:
      - A name for the validation profile.
      - A Training job definition. This is a JSON block that describes a training job. This is in the same format as the TrainingJobDefinition input parameter of the CreateAlgorithm API.
      - A Transform job definition. This is a JSON block that describes a batch transform job. This is in the same format as the TransformJobDefinition input parameter of the CreateAlgorithm API.
   e. Choose Create algorithm.

Create an Algorithm Resource (API)

To create an algorithm resource by using the SageMaker API, call the CreateAlgorithm API.

Create a Model Package Resource

To create a model package resource that you can use to create deployable models in Amazon SageMaker and publish on AWS Marketplace specify the following information:

- The Docker container that contains the inference code, or the algorithm resource that was used to train the model.
• The location of the model artifacts. Model artifacts can either be packaged in the same Docker container as the inference code or stored in Amazon S3.

• The instance types that your model package supports for both real-time inference and batch transform jobs.

• Validation profiles, which are batch transform jobs that SageMaker runs to test your model package's inference code.

Before listing model packages on AWS Marketplace, you must validate them. This ensures that buyers and sellers can be confident that products work in Amazon SageMaker. You can list products on AWS Marketplace only if validation succeeds.

The validation procedure uses your validation profile and sample data to run the following validations tasks:

1. Create a model in your account using the model package's inference image and the optional model artifacts that are stored in Amazon S3.

   **Note**
   A model package is specific to the region in which you create it. The S3 bucket where the model artifacts are stored must be in the same region where your created the model package.

2. Create a transform job in your account using the model to verify that your inference image works with SageMaker.

3. Create a validation profile.

   **Note**
   In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. After fixing issues, recreate the algorithm. When the status of the algorithm is COMPLETED, find it in the SageMaker console and start the listing process.

   **Note**
   To publish your model package on AWS Marketplace, at least one validation profile is required.

You can create an model package either by using the SageMaker console or by using the SageMaker API.

**Topics**

- Create a Model Package Resource (Console) (p. 3044)
- Create a Model Package Resource (API) (p. 3046)

**Create a Model Package Resource (Console)**

**To create a model package in the SageMaker console:**

2. From the left menu, choose **Inference**.
3. Choose **Model packages**, then choose **Create model package**.
4. On the Inference specifications page, provide the following information:
   a. For **Model package name**, type a name for your model package. The model package name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
b. Type a description for your model package. This description appears in the SageMaker console and in the AWS Marketplace.

c. For **Inference specification options**, choose **Provide the location of the inference image and model artifacts** to create a model package by using an inference container and model artifacts. Choose **Provide the algorithm used for training and its model artifacts** to create a model package from an algorithm resource that you created or subscribe to from AWS Marketplace.

d. If you chose **Provide the location of the inference image and model artifacts** for **Inference specification options**, provide the following information for **Container definition** and **Supported resources**:

   i. For **Location of inference image**, type the path to the image that contains your inference code. The image must be stored as a Docker container in Amazon ECR.

   ii. For **Location of model data artifacts**, type the location in S3 where your model artifacts are stored.

   iii. For **Container DNS host name**, type the name of the DNS host to use for your container.

   iv. For **Supported instance types for real-time inference**, choose the instance types that your model package supports for real-time inference from SageMaker hosted endpoints.

   v. For **Supported instance types for batch transform jobs**, choose the instance types that your model package supports for batch transform jobs.

   vi. **Supported content types**, type the content types that your model package expects for inference requests.

   vii. For **Supported response MIME types**, type the MIME types that your model package uses to provide inferences.

e. If you chose **Provide the algorithm used for training and its model artifacts** for **Inference specification options**, provide the following information:

   i. For **Algorithm ARN**, type the Amazon Resource Name (ARN) of the algorithm resource to use to create the model package.

   ii. For **Location of model data artifacts**, type the location in S3 where your model artifacts are stored.

f. Choose **Next**.

5. On the **Validation and scanning** page, provide the following information:

   a. For **Publish this model package on AWS Marketplace**, choose **Yes** to publish the model package on AWS Marketplace.

   b. For **Validate this resource**, choose **Yes** if you want SageMaker to run batch transform jobs that you specify to test the inference code of your model package.

   **Note**
   To publish your model package on AWS Marketplace, your model package must be validated.

   c. For **IAM role**, choose an IAM role that has the required permissions to run batch transform jobs in SageMaker, or choose **Create a new role** to allow SageMaker to create a role that has the **AmazonSageMakerFullAccess** managed policy attached. For information, see **SageMaker Roles** (p. 3097).

   d. For **Validation profile**, specify the following:

      - A name for the validation profile.
      - A **Transform job definition**. This is a JSON block that describes a batch transform job. This is in the same format as the **TransformJobDefinition** input parameter of the **CreateAlgorithm** API.

6. Choose **Create model package**.
Create a Model Package Resource (API)

To create a model package by using the SageMaker API, call the `CreateModelPackage` API.

Use Algorithm and Model Package Resources

You can create algorithms and model packages as resources in your Amazon SageMaker account, and you can find and subscribe to algorithms and model packages on AWS Marketplace.

Use algorithms to:

- Run training jobs. For information, see Use an Algorithm to Run a Training Job (p. 3047).
- Run hyperparameter tuning jobs. For information, see Use an Algorithm to Run a Hyperparameter Tuning Job (p. 3049).
- Create model packages. After you use an algorithm resource to run a training job or a hyperparameter tuning job, you can use the model artifacts that these jobs output along with the algorithm to create a model package. For information, see Create a Model Package Resource (p. 3043).

**Note**

If you subscribe to an algorithm on AWS Marketplace, you must create a model package before you can use it to get inferences by creating hosted endpoint or running a batch transform job.
• Create models that you can use to get real-time inference or run batch transform jobs. For information, see Use a Model Package to Create a Model (p. 3052).
• Create hosted endpoints to get real-time inference. For information, see Deploy the Model to SageMaker Hosting Services (p. 90).
• Create batch transform jobs. For information, see (Optional) Make Prediction with Batch Transform (p. 91).

Topics
• Use an Algorithm to Run a Training Job (p. 3047)
• Use an Algorithm to Run a Hyperparameter Tuning Job (p. 3049)
• Use a Model Package to Create a Model (p. 3052)

Use an Algorithm to Run a Training Job

You can create use an algorithm resource to create a training job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics
• Use an Algorithm to Run a Training Job (Console) (p. 3047)
• Use an Algorithm to Run a Training Job (API) (p. 3048)
• Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK) (p. 3048)

Use an Algorithm to Run a Training Job (Console)

To use an algorithm to run a training job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create training job.

   The algorithm you chose will automatically be selected.
5. On the Create training job page, provide the following information:

   a. For Job name, type a name for the training job.
   b. For IAM role, choose an IAM role that has the required permissions to run training jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3097).
   c. For Resource configuration, provide the following information:
      i. For Instance type, choose the instance type to use for training.
      ii. For Instance count, type the number of ML instances to use for the training job.
      iii. For Additional volume per instance (GB), type the size of the ML storage volume that you want to provision. ML storage volumes store model artifacts and incremental states.
      iv. For Encryption key, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instance, specify the key.
      v. For Stopping condition, specify the maximum amount of time in seconds, minutes, hours, or days, that you want the training job to run.
d. For **VPC**, choose a Amazon VPC that you want to allow your training container to access. For more information, see *Give SageMaker Training Jobs Access to Resources in Your Amazon VPC* (p. 3175).

e. For **Hyperparameters**, specify the values of the hyperparameters to use for the training job.

f. For **Input data configuration**, specify the following values for each channel of input data to use for the training job. You can see what channels the algorithm you’re using for training support, and the content type, supported compression type, and supported input modes for each channel, under **Channel specification** section of the **Algorithm summary** page for the algorithm.

i. For **Channel name**, type the name of the input channel.

ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.

iii. For **Compression type**, choose the data compression type to use, if any.

iv. For **Record wrapper**, choose RecordIO if the algorithm expects data in the RecordIO format.

v. For **S3 data type, S3 data distribution type, and S3 location**, specify the appropriate values. For information about what these values mean, see *S3DataSource*.

vi. For **Input mode**, choose **File** to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose **Pipe** to stream data directly from Amazon S3 to the container.

vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

g. For **Output location**, specify the following values:

i. For **S3 output path**, choose the S3 location where the training job stores output, such as model artifacts.

   **Note**  
   You use the model artifacts stored at this location to create a model or model package from this training job.

ii. For **Encryption key**, if you want SageMaker to use an AWS KMS key to encrypt output data at rest in the S3 location.

h. For **Tags**, specify one or more tags to manage the training job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

i. Choose **Create training job** to run the training job.

### Use an Algorithm to Run a Training Job (API)

To use an algorithm to run a training job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) as the **AlgorithmName** field of the **AlgorithmSpecification** object that you pass to **CreateTrainingJob**. For information about training models in SageMaker, see *Train a Model with Amazon SageMaker* (p. 9).

### Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a training job, create an **AlgorithmEstimator** object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the **algorithm_arn** argument. Then call the **fit** method of the estimator. For example:

```python
from sagemaker import AlgorithmEstimator

data_path = os.path.join(DATA_DIR, 'marketplace', 'training')
```
Use an Algorithm to Run a Hyperparameter Tuning Job

A hyperparameter tuning job finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose. For more information, see Perform Automatic Model Tuning with SageMaker (p. 2186).

You can create use an algorithm resource to create a hyperparameter tuning job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics

- Use an Algorithm to Run a Hyperparameter Tuning Job (Console) (p. 3049)
- Use an Algorithm to Run a Hyperparameter Tuning Job (API) (p. 3051)
- Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK) (p. 3051)

Use an Algorithm to Run a Hyperparameter Tuning Job (Console)

To use an algorithm to run a hyperparameter tuning job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create hyperparameter tuning job.

The algorithm you chose will automatically be selected.
5. On the Create hyperparameter tuning job page, provide the following information:
   a. For Warm start, choose Enable warm start to use the information from previous hyperparameter tuning jobs as a starting point for this hyperparameter tuning job. For more information, see Run a Warm Start Hyperparameter Tuning Job (p. 2207).
      i. Choose Identical data and algorithm if your input data is the same as the input data for the parent jobs of this hyperparameter tuning job, or choose Transfer learning to use additional or different input data for this hyperparameter tuning job.
      ii. For Parent hyperparameter tuning job(s), choose up to 5 hyperparameter tuning jobs to use as parents to this hyperparameter tuning job.
   b. For Hyperparameter tuning job name, type a name for the tuning job.
   c. For IAM role, choose an IAM role that has the required permissions to run hyperparameter tuning jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3097).
d. For **VPC**, choose a Amazon VPC that you want to allow the training jobs that the tuning job launches to access. For more information, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3175).

e. Choose **Next**.

f. For **Objective metric**, choose the metric that the hyperparameter tuning job uses to determine the best combination of hyperparameters, and choose whether to minimize or maximize this metric. For more information, see View the Best Training Job (p. 2205).

g. For **Hyperparameter configuration**, choose ranges for the tunable hyperparameters that you want the tuning job to search, and set static values for hyperparameters that you want to remain constant in all training jobs that the hyperparameter tuning job launches. For more information, see Define Hyperparameter Ranges (p. 2189).

h. Choose **Next**.

i. For **Input data configuration**, specify the following values for each channel of input data to use for the hyperparameter tuning job. You can see what channels the algorithm you're using for hyperparameter tuning supports, and the content type, supported compression type, and supported input modes for each channel, under **Channel specification** section of the **Algorithm summary** page for the algorithm.

   i. For **Channel name**, type the name of the input channel.

   ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.

   iii. For **Compression type**, choose the data compression type to use, if any.

   iv. For **Record wrapper**, choose RecordIO if the algorithm expects data in the RecordIO format.

   v. For **S3 data type**, **S3 data distribution type**, and **S3 location**, specify the appropriate values. For information about what these values mean, see **S3DataSource**.

   vi. For **Input mode**, choose File to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose Pipe to stream data directly from Amazon S3 to the container.

   vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

j. For **Output location**, specify the following values:

   i. For **S3 output path**, choose the S3 location where the training jobs that this hyperparameter tuning job launches store output, such as model artifacts.

   **Note**

   You use the model artifacts stored at this location to create a model or model package from this hyperparameter tuning job.

   ii. For **Encryption key**, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

k. For **Resource configuration**, provide the following information:

   i. For **Instance type**, choose the instance type to use for each training job that the hyperparameter tuning job launches.

   ii. For **Instance count**, type the number of ML instances to use for each training job that the hyperparameter tuning job launches.

   iii. For **Additional volume per instance (GB)**, type the size of the ML storage volume that you want to provide each training job that the hyperparameter tuning job launches. ML storage volumes store model artifacts and incremental states.

   iv. For **Encryption key**, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instances, specify the key.
l. For **Resource limits**, provide the following information:

   i. For **Maximum training jobs**, specify the maximum number of training jobs that you want the hyperparameter tuning job to launch. A hyperparameter tuning job can launch a maximum of 500 training jobs.

   ii. For **Maximum parallel training jobs**, specify the maximum number of concurrent training jobs that the hyperparameter tuning job can launch. A hyperparameter tuning job can launch a maximum of 10 concurrent training jobs.

   iii. For **Stopping condition**, specify the maximum amount of time in seconds, minutes, hours, or days, that you want each training job that the hyperparameter tuning job launches to run.

m. For **Tags**, specify one or more tags to manage the hyperparameter tuning job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

n. Choose **Create jobs** to run the hyperparameter tuning job.

### Use an Algorithm to Run a Hyperparameter Tuning Job (API)

To use an algorithm to run a hyperparameter tuning job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) of the algorithm as the `AlgorithmName` field of the `AlgorithmSpecification` object that you pass to `CreateHyperParameterTuningJob`. For information about hyperparameter tuning in SageMaker, see Perform Automatic Model Tuning with SageMaker (p. 2186).

### Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a hyperparameter tuning job, create an `AlgorithmEstimator` object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the `algorithm_arn` argument. Then initialize a `HyperparameterTuner` object with the `AlgorithmEstimator` you created as the value of the `estimator` argument. Finally, call the `fit` method of the `AlgorithmEstimator`. For example:

```python
from sagemaker import AlgorithmEstimator
from sagemaker.tuner import HyperparameterTuner
data_path = os.path.join(DATA_DIR, 'marketplace', 'training')
algo = AlgorithmEstimator(
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=sagemaker_session,
    base_job_name='test-marketplace')
train_input = algo.sagemaker_session.upload_data(
    path=data_path, key_prefix='integ-test-data/marketplace/train')
algo.set_hyperparameters(max_leaf_nodes=10)
tuner = HyperparameterTuner(estimator=algo, base_tuning_job_name='some-name',
                           objective_metric_name='validation:accuracy',
                           hyperparameter_ranges=hyperparameter_ranges,
                           max_jobs=2, max_parallel_jobs=2)
tuner.fit({'training': train_input}, include_cls_metadata=False)
tuner.wait()
```
Use a Model Package to Create a Model

Use a model package to create a deployable model that you can use to get real-time inferences by creating a hosted endpoint or to run batch transform jobs. You can create a deployable model from a model package by using the Amazon SageMaker console, the low-level SageMaker API, or the Amazon SageMaker Python SDK.

Topics
- Use a Model Package to Create a Model (Console) (p. 3052)
- Use a Model Package to Create a Model (API) (p. 3052)
- Use a Model Package to Create a Model (Amazon SageMaker Python SDK) (p. 3053)

Use a Model Package to Create a Model (Console)

To create a deployable model from a model package (console)

2. Choose Model packages.
3. Choose a model package that you created from the list on the My model packages tab or choose a model package that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create model.
5. For Model name, type a name for the model.
6. For IAM role, choose an IAM role that has the required permissions to call other services on your behalf, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 3097).
7. For VPC, choose a Amazon VPC that you want to allow the model to access. For more information, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3178).
8. Leave the default values for Container input options and Choose model package.
9. For environment variables, provide the names and values of environment variables you want to pass to the model container.
10. For Tags, specify one or more tags to manage the model. Each tag consists of a key and an optional value. Tag keys must be unique per resource.
11. Choose Create model.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Use a Model Package to Create a Model (API)

To use a model package to create a deployable model by using the SageMaker API, specify the name or the Amazon Resource Name (ARN) of the model package as the ModelPackageName field of the ContainerDefinition object that you pass to the CreateModel API.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosted endpoints in SageMaker, see Deploy Models for Inference.
Use a Model Package to Create a Model (Amazon SageMaker Python SDK)

To use a model package to create a deployable model by using the SageMaker Python SDK, initialize a ModelPackage object, and pass the Amazon Resource Name (ARN) of the model package as the model_package_arn argument. For example:

```python
from sagemaker import ModelPackage
model = ModelPackage(role='SageMakerRole',
                      model_package_arn='training-job-scikit-decision-trees-1542660466-6f92',
                      sagemaker_session=sagemaker_session)
```

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Sell Amazon SageMaker Algorithms and Model Packages

Selling Amazon SageMaker algorithms and model packages is a three-step process:

1. Develop your algorithm or model, and package it in a Docker container. For information, see Develop Algorithms and Models in Amazon SageMaker (p. 3054).

2. Create an algorithm or model package resource in SageMaker. For information, see Create Algorithm and Model Package Resources (p. 3040).

3. Register as a seller on AWS Marketplace and list your algorithm or model package on AWS Marketplace. For information about registering as a seller, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. For information about listing and monetizing your algorithms and model packages, see Listing Algorithms and Model Packages in AWS Marketplace for Machine Learning in the User Guide for AWS Marketplace Providers.
Topics

- Develop Algorithms and Models in Amazon SageMaker (p. 3054)
- Create Algorithm and Model Package Resources (p. 3040)
- List Your Algorithm or Model Package on AWS Marketplace (p. 3055)

Develop Algorithms and Models in Amazon SageMaker

Before you can create algorithm and model package resources to use in Amazon SageMaker or list on AWS Marketplace, you have to develop them and package them in Docker containers.

Note

When algorithms and model packages are created for listing on AWS Marketplace, SageMaker scans the containers for security vulnerabilities on supported operating systems. Only the following operating system versions are supported:

- Debian: 6.0, 7, 8, 9, 10
- CentOS: 5, 6, 7
- Oracle Linux: 5, 6, 7
- Alpine: 3.3, 3.4, 3.5
- Amazon Linux

Develop Algorithms in SageMaker

An algorithm should be packaged as a docker container and stored in Amazon ECR to use it in SageMaker. The Docker container contains the training code used to run training jobs and, optionally, the inference code used to get inferences from models trained by using the algorithm.

For information about developing algorithms in SageMaker and packaging them as containers, see Using Docker containers with SageMaker (p. 2744). For a complete example of how to create an algorithm container, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/scikitBringYourOwn/scikitBringYourOwn.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named scikitBringYourOwn.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks (p. 250).

Always thoroughly test your algorithms before you create algorithm resources to publish on AWS Marketplace.

Note

When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.
Develop Models in SageMaker

A deployable model in SageMaker consists of inference code, model artifacts, an IAM role that is used to access resources, and other information required to deploy the model in SageMaker. Model artifacts are the results of training a model by using a machine learning algorithm. The inference code must be packaged in a Docker container and stored in Amazon ECR. You can either package the model artifacts in the same container as the inference code, or store them in Amazon S3.

You create a model by running a training job in SageMaker, or by training a machine learning algorithm outside of SageMaker. If you run a training job in SageMaker, the resulting model artifacts are available in the ModelArtifacts field in the response to a call to the DescribeTrainingJob operation. For information about how to develop a SageMaker model container, see Use Your Own Inference Code (p. 2782). For a complete example of how to create a model container from a model trained outside of SageMaker, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/xgboost Bring_Your_Own_Model/xgboost Bring_Your_Own_Model.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named xgboost Bring_Your_Own_Model.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks (p. 250).

Always thoroughly test your models before you create model packages to publish on AWS Marketplace.

Note
When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.

List Your Algorithm or Model Package on AWS Marketplace

After creating and validating your algorithm or model in Amazon SageMaker, list your product on AWS Marketplace. The listing process makes your products available in the AWS Marketplace and the SageMaker console.

To list products on AWS Marketplace, you must be a registered seller. To register, use the self-registration process from the AWS Marketplace Management Portal (AMMP). For information, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. When you start the product listing process from the Amazon SageMaker console, we check your seller registration status. If you have not registered, we direct you to do so.

To start the listing process, do one of the following:

- From the SageMaker console, choose the product, choose Actions, and choose Publish new ML Marketplace listing. This carries over your product reference, the Amazon Resource Name (ARN), and directs you to the AMMP to create the listing.

- Go to ML listing process, manually enter the Amazon Resource Name (ARN), and start your product listing. This process carries over the product metadata that you entered when creating the product in SageMaker. For an algorithm listing, the information includes the supported instance types and hyperparameters. In addition, you can enter a product description, promotional information, and support information as you would with other AWS Marketplace products.
Find and Subscribe to Algorithms and Model Packages on AWS Marketplace

With AWS Marketplace, you can browse and search for hundreds of machine learning algorithms and models in a broad range of categories, such as computer vision, natural language processing, speech recognition, text, data, voice, image, video analysis, fraud detection, predictive analysis, and more.

To find algorithms on AWS Marketplace

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose **Algorithms**, then choose **Find algorithms**.

   This takes you to the AWS Marketplace algorithms page. For information about finding and subscribing to algorithms on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

To find model packages on AWS Marketplace

2. Choose **Model packages**, then choose **Find model packages**.

   This takes you to the AWS Marketplace model packages page. For information about finding and subscribing to model packages on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

Use Algorithms and Model Packages

For information about using algorithms and model packages that you subscribe to in SageMaker, see Use Algorithm and Model Package Resources (p. 3046).

**Note**

When you create a training job, inference endpoint, and batch transform job from an algorithm or model package that you subscribe to on AWS Marketplace, the training and inference containers do not have access to the internet. Because the containers do not have access to the internet, the seller of the algorithm or model package does not have access to your data.
Security in Amazon SageMaker

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon SageMaker, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using SageMaker. The following topics show you how to configure SageMaker to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your SageMaker resources.

**Topics**
- Access Control (p. 3057)
- Data Protection in Amazon SageMaker (p. 3059)
- Identity and Access Management for Amazon SageMaker (p. 3064)
- Logging and Monitoring (p. 3157)
- Compliance Validation for Amazon SageMaker (p. 3157)
- Resilience in Amazon SageMaker (p. 3158)
- Infrastructure Security in Amazon SageMaker (p. 3158)

Access Control

Amazon SageMaker Studio notebooks and SageMaker notebook instances differ in their runtime environments. The following topics describe how to control root access to these notebooks.

**Topics**
- Access control and SageMaker Studio notebooks (p. 3057)
- Control root access to a SageMaker notebook instance (p. 3059)

Access control and SageMaker Studio notebooks

Amazon SageMaker Studio uses filesystem and container permissions for access control and isolation of Studio users and notebooks. This is one of the major differences between Studio notebooks and SageMaker notebook instances. This topic describes how permissions are set up to avoid security threats, what SageMaker does by default, and how the customer can customize the permissions. For more information about Studio notebooks and their runtime environment, see Use Amazon SageMaker Studio Notebooks (p. 127).

**SageMaker app permissions**
A run-as user is a POSIX user/group which is used to run the JupyterServer app and KernelGateway apps inside the container.

The run-as user for the JupyterServer app is sagemaker-user (1000) by default. This user has sudo permissions to enable the installation of dependencies such as yum packages.

The run-as user for the KernelGateway apps is root (0) by default. This user is able to install dependencies using pip/apt-get/conda.

Due to user remapping, neither user is able to access resources or make changes to the host instance.

**User remapping**

SageMaker performs user-remapping to map a user inside the container to a user on the host instance outside the container. The range of user IDs (0 - 65535) in the container are mapped to non-privileged user IDs above 65535 on the instance. For example, sagemaker-user (1000) inside the container might map to user (200001) on the instance, where the number in parentheses is the user ID. If the customer creates a new user/group inside the container, it won't be privileged on the host instance regardless of the user/group ID. The root user of the container is also mapped to a non-privileged user on the instance. For more information, see [Isolate containers with a user namespace](#).

**Custom image permissions**

Customers can bring their own custom SageMaker images. These images can specify a different run-as user/group to launch the KernelGateway app. The customer can implement fine grained permission control inside the image, for example, to disable root access or perform other actions. The same user remapping applies here. For more information, see [Bring your own SageMaker image](#).

**Container isolation**

Docker keeps a list of default capabilities that the container can use. SageMaker doesn't add additional capabilities. SageMaker adds specific route rules to block requests to Amazon EFS and the instance metadata service (IMDS) from the container. Customers can't change these route rules from the container. For more information, see [Runtime privilege and Linux capabilities](#).

**App metadata access**

Metadata used by running apps are mounted to the container with read-only permission. Customers aren't able to modify this metadata from the container. For the available metadata, see [Get Notebook and App Metadata](#).

**User isolation on EFS**

When you onboard to Studio, SageMaker creates an Amazon Elastic File System (EFS) volume for your domain that is shared by all Studio users in the domain. Each user gets their own private home directory on the EFS volume. This home directory is used to store the user's notebooks, Git repositories, and other data. To prevent other users in the domain from accessing the user's data, SageMaker creates a globally unique user ID for the user's profile and applies it as a POSIX user/group ID for the user's home directory.

**EBS access**

An Amazon Elastic Block Store (Amazon EBS) volume is attached to the host instance and shared across all images. It's used for the root volume of the notebooks and stores temporary data that's generated inside the container. The storage isn't persisted when the instance running the notebooks is deleted. The root user inside the container can't access the EBS volume.

**IMDS access**

Due to security concerns, access to the Amazon Elastic Compute Cloud (Amazon EC2) Instance Metadata Service (IMDS) is unavailable in SageMaker Studio. For more information on IMDS, see [Instance metadata and user data](#).
Control root access to a SageMaker notebook instance

By default, when you create a notebook instance, users that log into that notebook instance have root access. Data science is an iterative process that might require the data scientist to test and use different software tools and packages, so many notebook instance users need to have root access to be able to install these tools and packages. Because users with root access have administrator privileges, users can access and edit all files on a notebook instance with root access enabled.

If you don’t want users to have root access to a notebook instance, when you call CreateNotebookInstance or UpdateNotebookInstance operations, set the RootAccess field to Disabled. You can also disable root access for users when you create or update a notebook instance in the Amazon SageMaker console. For information, see Step 1: Create an Amazon SageMaker Notebook Instance (p. 80).

Note
Lifecycle configurations need root access to be able to set up a notebook instance. Because of this, lifecycle configurations associated with a notebook instance always run with root access even if you disable root access for users.

Note
For security reasons, Rootless Docker is installed on root-disabled notebook instances instead of regular Docker. For more information, see Run the Docker daemon as a non-root user (Rootless mode)

Data Protection in Amazon SageMaker

The AWS shared responsibility model applies to data protection in Amazon SageMaker. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers’ email addresses, into tags or free-form fields such as a Name field. This includes when you work with Amazon SageMaker or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form fields used for names may be used for billing or
diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics

- Protect Data at Rest Using Encryption (p. 3060)
- Protecting Data in Transit with Encryption (p. 3061)
- Key Management (p. 3063)
- Internetwork Traffic Privacy (p. 3064)

Protect Data at Rest Using Encryption

To protect your Amazon SageMaker Studio notebooks and SageMaker notebook instances, along with your model-building data and model artifacts, SageMaker encrypts the notebooks, as well as output from Training and Batch Transform jobs. SageMaker encrypts these by default using the AWS Managed Key for Amazon S3. This AWS Managed Key for Amazon S3 cannot be shared for cross-account access. For cross-account access, specify your customer managed key while creating SageMaker resources so that it can be shared for cross-account access. For more information on AWS KMS, see What is AWS Key Management Service?

Topics

- Studio notebooks (p. 3060)
- Notebook instances and SageMaker jobs (p. 3060)

Studio notebooks

In Amazon SageMaker Studio, your SageMaker Studio notebooks and data can be stored in the following locations:

- An S3 bucket – When you onboard to Studio and enable shareable notebook resources, SageMaker shares notebook snapshots and metadata in an Amazon Simple Storage Service (Amazon S3) bucket.
- An EFS volume – When you onboard to Studio, SageMaker attaches an Amazon Elastic File System (Amazon EFS) volume to your domain for storing your Studio notebooks and data files. The EFS volume persists after the domain is deleted.
- An EBS volume – When you open a notebook in Studio, an Amazon Elastic Block Store (Amazon EBS) is attached to the instance that the notebook runs on. The EBS volume persists for the duration of the instance.

SageMaker uses the AWS Key Management Service (AWS KMS) to encrypt the S3 bucket and both volumes. By default, it uses an AWS managed key. For more control, you can specify your own customer managed key when you onboard to Studio or through the SageMaker API. For more information, see Onboard to Amazon SageMaker Domain (p. 36) and CreateDomain.

In the CreateDomain API, you use the S3KmsKeyId parameter to specify the customer managed key for shareable notebooks. You use the KmsKeyId parameter to specify the customer managed key for the EFS and EBS volumes. The same customer managed key is used for both volumes. The customer managed key for shareable notebooks can be the same customer managed key as used for the volumes or a different customer managed key.

Notebook instances and SageMaker jobs

To encrypt the machine learning (ML) storage volume that is attached to notebooks, processing jobs, training jobs, hyperparameter tuning jobs, batch transform jobs, and endpoints, you can pass a AWS KMS
key to SageMaker. If you don’t specify a KMS key, SageMaker encrypts storage volumes with a transient key and discards it immediately after encrypting the storage volume. For notebook instances, if you don’t specify a KMS key, SageMaker encrypts both OS volumes and ML data volumes with a system-managed KMS key.

You can use an AWS managed AWS KMS key to encrypt all instance OS volumes. You can encrypt all ML data volumes for all SageMaker instances with a AWS KMS key that you specify. ML storage volumes are mounted as follows:

- Notebooks - /home/ec2-user/SageMaker
- Processing - /opt/ml/processing and /tmp/
- Training - /opt/ml/ and /tmp/
- Batch - /opt/ml/ and /tmp/
- Endpoints - /opt/ml/ and /tmp/

Processing, batch transform, and training job containers and their storage are ephemeral in nature. When the job completes, output is uploaded to Amazon S3 using AWS KMS encryption with an optional AWS KMS key that you specify and the instance is torn down. If a AWS KMS Key is not provided in the job request, the output is encrypted by default using your AWS Managed Key for Amazon S3.

**Note**
The key policy for an AWS Managed Key for Amazon S3 cannot be edited, so cross-account permissions cannot be granted for these key policies. If the output Amazon S3 bucket for the request is from another account, specify your own AWS KMS Customer Key in the job request and ensure that the job’s execution role has permissions to encrypt data with it.

**Important**
Sensitive data that needs to be encrypted with a KMS key for compliance reasons should be stored in the ML storage volume or in Amazon S3, both of which can be encrypted using a KMS key you specify.

When you open a notebook instance, SageMaker saves it and any files associated with it in the SageMaker folder in the ML storage volume by default. When you stop a notebook instance, SageMaker creates a snapshot of the ML storage volume. Any customizations to the operating system of the stopped instance, such as installed custom libraries or operating system level settings, are lost. Consider using a lifecycle configuration to automate customizations of the default notebook instance. When you terminate an instance, the snapshot and the ML storage volume are deleted. Any data that you need to persist beyond the lifespan of the notebook instance should be transferred to an Amazon S3 bucket.

**Note**
Certain Nitro-based SageMaker instances include local storage, depending on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can’t use a KMS key on an instance type with local storage. For a list of instance types that support local instance storage, see [Instance Store Volumes](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instancedata-volume-types.html). For more information about storage volumes on Nitro-based instances, see [Amazon EBS and NVMe on Linux Instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/nvme-on-linux-instances.html). For more information about local instance storage encryption, see [SSD Instance Store Volumes](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-store-ssd.html).

### Protecting Data in Transit with Encryption

All inter-network data in transit supports TLS 1.2 encryption.

Amazon SageMaker ensures that machine learning (ML) model artifacts and other system artifacts are encrypted in transit and at rest. Requests to the SageMaker API and console are made over a secure (SSL) connection. You pass AWS Identity and Access Management roles to SageMaker to provide permissions to access resources on your behalf for training and deployment. You can use encrypted Amazon S3 buckets for model artifacts and data, as well as pass a AWS KMS key to SageMaker instances to encrypt the attached ML storage volumes.
Some intra-network data in-transit (inside the service platform) is unencrypted. This includes:

- Command and control communications between the service control plane and training job instances (not customer data).
- Communications between nodes in distributed processing jobs (intra-network).
- Communications between nodes in distributed training jobs (intra-network).

There are no inter-node communications for batch processing.

You can choose to encrypt communication between nodes in a training cluster. For information about how to do this, see Protect Communications Between ML Compute Instances in a Distributed Training Job (p. 3062). Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

FIPS validated endpoints are available for the SageMaker API and request router for hosted models (runtime). For information about FIPS compliant endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Protect Communications Between ML Compute Instances in a Distributed Training Job

By default, Amazon SageMaker runs training jobs in an Amazon Virtual Private Cloud (Amazon VPC) to help keep your data secure. You can add another level of security to protect your training containers and data by configuring a private VPC. Distributed ML frameworks and algorithms usually transmit information that is directly related to the model such as weights, not the training dataset. When performing distributed training, you can further protect data that is transmitted between instances. This can help you to comply with regulatory requirements. To do this, use inter-container traffic encryption.

Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. Enabling inter-container traffic encryption doesn't affect training jobs with a single compute instance. However, for training jobs with several compute instances, the effect on training time depends on the amount of communication between compute instances. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

You can enable inter-container traffic encryption for training jobs or hyperparameter tuning jobs. You can use SageMaker APIs or console to enable inter-container traffic encryption.

For information about running training jobs in a private VPC, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3175).

Enable Inter-Container Traffic Encryption (API)

Before enabling inter-container traffic encryption on training or hyperparameter tuning jobs with APIs, you need to add inbound and outbound rules to your private VPC's security group.

To enable inter-container traffic encryption (API)

1. Add the following inbound and outbound rules in the security group for your private VPC:

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port Range</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>500</td>
<td>Self Security Group ID</td>
</tr>
</tbody>
</table>
2. When you send a request to the `CreateTrainingJob` or `CreateHyperParameterTuningJob` API, specify `True` for the `EnableInterContainerTrafficEncryption` parameter.

**Note**

For the ESP 50 protocol, the AWS Security Group Console might display the port range as "All". However, Amazon EC2 ignores the specified port range because it is not applicable for the ESP 50 IP protocol.

### Enable Inter-Container Traffic Encryption (Console)

#### Enable Inter-container Traffic Encryption in a Training Job

**To enable inter-container traffic encryption in a training job**

1. Open the Amazon SageMaker console at `https://console.aws.amazon.com/sagemaker/`
2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you have created.
5. Choose **Enable inter-container traffic encryption**.

After you enable inter-container traffic encryption, finish creating the training job. For more information, see [Step 4: Train a Model (p. 86)](#).

#### Enable Inter-container Traffic Encryption in a Hyperparameter Tuning Job

**To enable inter-container traffic encryption in a hyperparameter tuning job**

1. Open the Amazon SageMaker console at `https://console.aws.amazon.com/sagemaker/`
2. In the navigation pane, choose **Training**, then choose **Hyperparameter tuning jobs**.
3. Choose **Create hyperparameter tuning job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you have created.
5. Choose **Enable inter-container traffic encryption**.

After enabling inter-container traffic encryption, finish creating the hyperparameter tuning job. For more information, see [Configure and Launch a Hyperparameter Tuning Job (p. 2198)](#).

### Key Management

Customers can specify AWS KMS keys, including bring your own keys (BYOK), to use for envelope encryption with Amazon S3 input/output buckets and machine learning (ML) Amazon EBS volumes. ML volumes for notebook instances and for processing, training, and hosted model Docker containers can be optionally encrypted by using AWS KMS customer-owned keys. All instance OS volumes are encrypted with an AWS-managed AWS KMS key.

**Note**

Certain Nitro-based instances include local storage, dependent on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't request a `VolumeKmsKeyId` when using an instance type with local storage.

For a list of instance types that support local instance storage, see [Instance Store Volumes](#).

For more information about local instance storage encryption, see [SSD Instance Store Volumes](#).
Internetwork Traffic Privacy

This topic describes how Amazon SageMaker secures connections from the service to other locations. Internetwork communications support TLS 1.2 encryption between all components and clients. Instances can be connected to Customer VPC, providing access to S3 VPC endpoints or customer repositories. Internet egress can be managed through this interface by the customer if service platform internet egress is disabled for notebooks. For training and hosting, egress through the service platform is not available when connected to the customer's VPC.

By default, API calls made to published endpoints traverse the public network to the request router. SageMaker supports Amazon Virtual Private Cloud interface endpoints powered by AWS PrivateLink for private connectivity between the customer's VPC and the request router to access hosted model endpoints. For information about Amazon VPC, see Connect to SageMaker Through a VPC Interface Endpoint (p. 3163)

Identity and Access Management for Amazon SageMaker

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use SageMaker resources. IAM is an AWS service that you can use with no additional charge.

Topics
- Audience (p. 3064)
- Authenticating with Identities (p. 3065)
- Managing Access Using Policies (p. 3067)
- How Amazon SageMaker Works with IAM (p. 3068)
- Amazon SageMaker Identity-Based Policy Examples (p. 3071)
- Cross-Service Confused Deputy Prevention (p. 3093)
- SageMaker Roles (p. 3097)
- Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference (p. 3114)
- AWS Managed Policies for Amazon SageMaker (p. 3131)
- Troubleshooting Amazon SageMaker Identity and Access (p. 3155)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in SageMaker.

Service user – If you use the SageMaker service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more SageMaker features to do your
work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in SageMaker, see Troubleshooting Amazon SageMaker Identity and Access (p. 3155).

Service administrator – If you're in charge of SageMaker resources at your company, you probably have full access to SageMaker. It's your job to determine which SageMaker features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with SageMaker, see How Amazon SageMaker Works with IAM (p. 3068).

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to SageMaker. To view example SageMaker identity-based policies that you can use in IAM, see Amazon SageMaker Identity-Based Policy Examples (p. 3071).

Authenticating with Identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don't use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

IAM Users and Groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.
An IAM group is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM Roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon SageMaker in the Service Authorization Reference.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.
Managing Access Using Policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. You can sign in as the root user or an IAM user, or you can assume an IAM role. When you then make a request, AWS evaluates the related identity-based or resource-based policies. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-Based Policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

Resource-Based Policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

Access Control Lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.
Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

**Other Policy Types**

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.

**Multiple Policy Types**

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

**How Amazon SageMaker Works with IAM**

Before you use IAM to manage access to SageMaker, you should understand what IAM features are available to use with SageMaker. To get a high-level view of how SageMaker and other AWS services work with IAM, see AWS Services That Work with IAM in the IAM User Guide.

**Topics**

- SageMaker Identity-Based Policies (p. 3068)

**SageMaker Identity-Based Policies**

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. SageMaker supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the IAM User Guide.

**Actions**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.
The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as permission-only actions that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called dependent actions.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in SageMaker use the following prefix before the action: \texttt{sagemaker:}. For example, to grant someone permission to run a SageMaker training job with the SageMaker CreateTrainingJob API operation, you include the \texttt{sagemaker:CreateTrainingJob} action in their policy. Policy statements must include either an \texttt{Action} or \texttt{NotAction} element. SageMaker defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

\begin{verbatim}
"Action": [
  "sagemaker:action1",
  "sagemaker:action2"
]
\end{verbatim}

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:

\begin{verbatim}
"Action": "sagemaker:Describe*"
\end{verbatim}

To see a list of SageMaker actions, see Actions, resources, and condition keys for Amazon SageMaker in the Service Authorization Reference.

**Resources**

SageMaker does not support specifying resource ARNs in a policy.

**Condition Keys**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The Condition element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

SageMaker defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see AWS Global Condition Context Keys in the IAM User Guide.
SageMaker supports a number of service-specific condition keys that you can use for fine-grained access control for the following operations:

- CreateProcessingJob
- CreateTrainingJob
- CreateModel
- CreateEndpointConfig
- CreateTransformJob
- CreateHyperParameterTuningJob
- CreateLabelingJob
- CreateNotebookInstance
- UpdateNotebookInstance

To see a list of SageMaker condition keys, see Condition keys for Amazon SageMaker in the IAM User Guide. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon SageMaker.

For examples of using SageMaker condition keys, see the following: Control Creation of SageMaker Resources with Condition Keys (p. 3081).

Examples

To view examples of SageMaker identity-based policies, see Amazon SageMaker Identity-Based Policy Examples (p. 3071).

SageMaker Resource-Based Policies

SageMaker does not support resource-based policies.

Authorization Based on SageMaker Tags

You can attach tags to SageMaker resources or pass tags in a request to SageMaker. To control access based on tags, you provide tag information in the condition element of a policy using the sagemaker:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information about tagging SageMaker resources, see Control Access to SageMaker Resources by Using Tags (p. 3090).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Control Access to SageMaker Resources by Using Tags (p. 3090).

SageMaker IAM Roles

An IAM role is an entity within your AWS account that has specific permissions.

Using Temporary Credentials with SageMaker

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

SageMaker supports using temporary credentials.

Service-Linked Roles

SageMaker partially supports service-linked roles. Service-linked roles are currently available for SageMaker Studio and SageMaker training jobs.
Service Roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

SageMaker supports service roles.

Choosing an IAM Role in SageMaker

When you create a notebook instance, processing job, training job, hosted endpoint, or batch transform job resource in SageMaker, you must choose a role to allow SageMaker to access SageMaker on your behalf. If you have previously created a service role or service-linked role, then SageMaker provides you with a list of roles to choose from. It’s important to choose a role that allows access to the AWS operations and resources you need. For more information, see SageMaker Roles (p. 3097).

Amazon SageMaker Identity-Based Policy Examples

By default, IAM users and roles don’t have permission to create or modify SageMaker resources. They also can’t perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. To learn how to attach policies to an IAM user or group, see Adding and Removing IAM Identity Permissions in the IAM User Guide.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the IAM User Guide.

Topics

- Policy Best Practices (p. 3071)
- Using the SageMaker Console (p. 3072)
- Allow Users to View Their Own Permissions (p. 3080)
- Control Creation of SageMaker Resources with Condition Keys (p. 3081)
- Control Access to the SageMaker API by Using Identity-based Policies (p. 3088)
- Limit Access to SageMaker API and Runtime Calls by IP Address (p. 3089)
- Limit Access to a Notebook Instance by IP Address (p. 3090)
- Control Access to SageMaker Resources by Using Tags (p. 3090)
- Require the Presence or Absence of Tags for API Calls (p. 3092)

Policy Best Practices

Identity-based policies are very powerful. They determine whether someone can create, access, or delete SageMaker resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started using AWS managed policies – To start using SageMaker quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.

- Grant least privilege – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as
necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.

- **Enable MFA for sensitive operations** – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

- **Use policy conditions for extra security** – To the extent that it’s practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Using the SageMaker Console

To access the Amazon SageMaker console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the SageMaker resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won’t function as intended for entities (IAM users or roles) with that policy.

To ensure that those entities can still use the SageMaker console, also attach the following AWS managed policy to the entities. For more information, see Adding Permissions to a User in the IAM User Guide:

You don’t need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you’re trying to perform.

**Topics**

- Permissions Required to Use the Amazon SageMaker Console (p. 3072)
- Permissions Required to Use the Amazon SageMaker Ground Truth Console (p. 3074)
- Permissions Required to Use the Amazon Augmented AI (Preview) Console (p. 3075)

Permissions Required to Use the Amazon SageMaker Console

The permissions reference table lists the Amazon SageMaker API operations and shows the required permissions for each operation. For more information about Amazon SageMaker API operations, see Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference (p. 3114).

To use the Amazon SageMaker console, you need to grant permissions for additional actions. Specifically, the console needs permissions that allow the `ec2` actions to display subnets, VPCs, and security groups. Optionally, the console needs permission to create `execution roles` for tasks such as `CreateNotebook`, `CreateTrainingJob`, and `CreateModel`. Grant these permissions with the following permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerApis",
            "Effect": "Allow",
            "Action": [
                "sagemaker:*"
            ],
            "Resource": "*"
        },
        {
            "Sid": "VpcConfigurationForCreateForms",
            "Effect": "Allow",
```
"Action": [  
  "ec2:DescribeVpcs",
  "ec2:DescribeSubnets",
  "ec2:DescribeSecurityGroups"
],
"Resource": "*"
},
{
  "Sid":"KmsKeysForCreateForms",
  "Effect":"Allow",
  "Action":[
    "kms:DescribeKey",
    "kms:ListAliases"
  ],
  "Resource":"*"
},
{
  "Sid": "AccessAwsMarketplaceSubscriptions",
  "Effect": "Allow",
  "Action": [  
    "aws-marketplace:ViewSubscriptions"
  ],
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": [  
    "codecommit:BatchGetRepositories",
    "codecommit:CreateRepository",
    "codecommit:GetRepository",
    "codecommit:ListRepositories",

    "iam:CreatePolicy",
    "iam:AttachRolePolicy"
  ],
  "Resource": "*"
},
{
  "Sid": "DescribeECRMetaData",
  "Effect": "Allow",
  "Action": [
    "ecr:Describe*"
  ],
  "Resource": "*"
},
{
  "Sid": "PassRoleForExecutionRoles",
  "Effect": "Allow",
  "Action": [  
    "iam:PassRole"
  ],
  "Resource": "*",
  "Condition": {  
    "StringEquals": {  

Permissions Required to Use the Amazon SageMaker Ground Truth Console

To use the Amazon SageMaker Ground Truth console, you need to grant permissions for additional resources. Specifically, the console needs permissions for the AWS Marketplace to view subscriptions, Amazon Cognito operations to manage your private workforce, Amazon S3 actions for access to your input and output files, and AWS Lambda actions to list and invoke functions. Grant these permissions with the following permissions policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "GroundTruthConsole",
        "Effect": "Allow",
        "Action": [
          "aws-marketplace:DescribeListings",
          "aws-marketplace:ViewSubscriptions",
          "cognito-idp:AdminAddUserToGroup",
          "cognito-idp:AdminCreateUser",
          "cognito-idp:AdminDeleteUser",
          "cognito-idp:AdminDisableUser",
          "cognito-idp:AdminEnableUser",
          "cognito-idp:AdminRemoveUserFromGroup",
          "cognito-idp:CreateGroup",
          "cognito-idp:CreateUserPool",
          "cognito-idp:CreateUserPoolClient",
          "cognito-idp:CreateUserPoolDomain",
          "cognito-idp:DescribeUserPool",
          "cognito-idp:DescribeUserPoolClient",
          "cognito-idp:DescribeUserPoolClient",
          "cognito-idp:ListGroups",
          "cognito-idp:ListIdentityProviders",
          "cognito-idp:ListUsers",
          "cognito-idp:ListUsersInGroup",
          "cognito-idp:ListUserPoolClients",
          "cognito-idp:ListUserPools",
          "cognito-idp:UpdateUserPool",
          "cognito-idp:UpdateUserPoolClient",
          "groundtruthlabeling:DescribeConsoleJob",
          "groundtruthlabeling:ListDatasetObjects",
          "groundtruthlabeling:RunFilterOrSampleManifestJob",
          "groundtruthlabeling:RunGenerateManifestByCrawlingJob",
          "lambda:InvokeFunction",
          "lambda:ListFunctions",
          "s3:GetObject",
          "s3:PutObject",
          "s3:SelectObjectContent"
        ],
        "Resource": "*"
      }
    ]
}
```
Permissions Required to Use the Amazon Augmented AI (Preview) Console

To use the Augmented AI console, you need to grant permissions for additional resources. Grant these permissions with the following permissions policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*Algorithm",
        "sagemaker:*Algorithms",
        "sagemaker:*App",
        "sagemaker:*Apps",
        "sagemaker:*AutoMLJob",
        "sagemaker:*AutoMLJobs",
        "sagemaker:*CodeRepositories",
        "sagemaker:*CodeRepository",
        "sagemaker:*CompilationJob",
        "sagemaker:*CompilationJobs",
        "sagemaker:*Endpoint",
        "sagemaker:*EndpointConfig",

Identity-Based Policy Examples

Allow Users to View Their Own Permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
        "iam:GetUserPolicy",
        "iam:ListGroupsForUser",
        "iam:ListAttachedUserPolicies",
        "iam:ListUserPolicies",
        "iam:PassRole"
      ],
      "Resource": "arn:aws:iam::*:role/*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": [
            "sagemaker.amazonaws.com",
            "glue.amazonaws.com",
            "robomaker.amazonaws.com",
            "states.amazonaws.com"
          ]
        }
      }
    }
  ]
}
```
Control Creation of SageMaker Resources with Condition Keys

Control fine-grained access to allow the creation of SageMaker resources by using SageMaker-specific condition keys. For information about using condition keys in IAM policies, see IAM JSON Policy Elements: Condition in the IAM User Guide.

The condition keys, along with related API actions, and links to relevant documentation are listed in Condition Keys for SageMaker in the IAM User Guide.

The following examples show how to use the SageMaker condition keys to control access.

Topics
- Control Access to SageMaker Resources by Using File System Condition Keys (p. 3081)
- Restrict Training to a Specific VPC (p. 3083)
- Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows (p. 3084)
- Enforce Encryption of Input Data (p. 3085)
- Enforce Encryption of Notebook Instance Storage Volume (p. 3085)
- Enforce Network Isolation for Training Jobs (p. 3086)
- Enforce a Specific Instance Type for Training Jobs (p. 3086)
- Enforce a Specific EI Accelerator for Training Jobs (p. 3087)
- Enforce Disabling Internet Access and Root Access for Creating Notebook Instances (p. 3087)

Control Access to SageMaker Resources by Using File System Condition Keys

SageMaker training provides a secure infrastructure for the training algorithm to run in, but for some cases you may want increased defense in depth. For example, you minimize the risk of running untrusted code in your algorithm, or you have specific security mandates in your organization. For these scenarios, you can use the service-specific condition keys in the Condition element of an IAM policy to scope down the user to specific file systems, directories, access modes (read-write, read-only) and security groups.

Topics
- Restrict an IAM User to Specific Directories and Access Modes (p. 3082)
- Restrict an IAM User to a Specific File System (p. 3082)
Restrict an IAM User to Specific Directories and Access Modes

The policy below restricts an IAM user to the /sagemaker/xgboost-dm/train and /sagemaker/xgboost-dm/validation directories of an EFS file system to ro (read-only) AccessMode:

Note

When a directory is allowed, all of its subdirectories are also accessible by the training algorithm. POSIX permissions are ignored.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AccessToElasticFileSystem",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateTrainingJob", "sagemaker:CreateHyperParameterTuningJob"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "sagemaker:FileSystemId": "fs-12345678",
               "sagemaker:FileSystemAccessMode": "ro",
               "sagemaker:FileSystemType": "EFS",
               "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/train"
            }
         }
      },
      {
         "Sid": "AccessToElasticFileSystemValidation",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateTrainingJob", "sagemaker:CreateHyperParameterTuningJob"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "sagemaker:FileSystemId": "fs-12345678",
               "sagemaker:FileSystemAccessMode": "ro",
               "sagemaker:FileSystemType": "EFS",
               "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/validation"
            }
         }
      }
   ]
}
```

Restrict an IAM User to a Specific File System

To prevent a malicious algorithm using a user space client from accessing any file system directly in your account, you can restrict networking traffic by allowing ingress from a specific security group. In the following example, the IAM user can only use the specified security group to access the file system:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AccessToLustreFileSystem",
         "Effect": "Allow",
         "Action": ["sagemaker:CreateTrainingJob", "sagemaker:CreateHyperParameterTuningJob"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "sagemaker:FileSystemId": "fs-12345678",
               "sagemaker:FileSystemAccessMode": "ro",
               "sagemaker:FileSystemType": "EFS",
               "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/train"
            }
         }
      }
   ]
}
```
Although the above example can restrict an algorithm to a specific file system, it does not prevent an algorithm from accessing any directory within that file system using the user space client. To mitigate this, you can:

- Ensure that the file system only contains data that you trust your IAM users to access
- Create an IAM role that restricts your IAM users to launching training jobs with algorithms from approved ECR repositories

For more information on how to use roles with SageMaker, see SageMaker Roles.

### Restrict Training to a Specific VPC

Restrict an AWS user to creating training jobs from within a Amazon VPC. When a training job is created within a VPC, you can use VPC flow logs to monitor all traffic to and from the training cluster. For information about using VPC flow logs, see VPC Flow Logs in the Amazon Virtual Private Cloud User Guide.

The following policy enforces that a training job is created by an IAM user calling CreateTrainingJob from within a VPC:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFromVpc",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "sagemaker:VpcSubnets": ["subnet-a1234"],
          "sagemaker:VpcSecurityGroupIds": ["sg12345", "sg-67890"]
        },
        "Null": {
          "sagemaker:VpcSubnets": "false",
          "sagemaker:VpcSecurityGroupIds": "false"
        }
      }
    }
  ]
}
```
Identity-Based Policy Examples

Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows

Amazon SageMaker Ground Truth and Amazon Augmented AI work teams fall into one of three workforce types: public (with Amazon Mechanical Turk), private, and vendor. To restrict IAM user access to a specific work team using one of these types or the work team ARN, use the `sagemaker:WorkteamType` and/or the `sagemaker:WorkteamArn` condition keys. For the `sagemaker:WorkteamType` condition key, use string condition operators. For the `sagemaker:WorkteamArn` condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the `sagemaker:WorkteamType` and `sagemaker:WorkteamArn` condition keys with appropriate condition operators and valid condition values.

The following example uses the `sagemaker:WorkteamType` condition key with the `StringEquals` condition operator to restrict access to a public work team. It accepts condition values in the following format: `workforcetype-crowd`, where `workforcetype` can equal `public`, `private`, or `vendor`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:WorkteamType": "public-crowd"
                }
            }
        }
    ]
}
```

The following policies show how to restrict access to a public work team using the `sagemaker:WorkteamArn` condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the `ArnLike` condition operator. The second shows how to use it with the `ArnEquals` condition operator and the work team ARN.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/*
                }
            }
        }
    ]
}
```
Identity-Based Policy Examples

Enforce Encryption of Input Data

The following policy restricts an IAM user to specify an AWS KMS key to encrypt input data when creating training, hyperparameter tuning, and labeling jobs by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceEncryption",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob",
        "sagemaker:CreateLabelingJob",
        "sagemaker:CreateFlowDefinition"
      ],
      "Resource": "*",
      "Condition": {
        "ArnEquals": {
          "sagemaker:VolumeKmsKey": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
      }
    }
  ]
}
```

Enforce Encryption of Notebook Instance Storage Volume

The following policy restricts an IAM user to specify an AWS KMS key to encrypt the attached storage volume when creating or updating a notebook instance by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceEncryption",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateNotebookInstance",
        "sagemaker:UpdateNotebookInstance"
      ],
      "Resource": "*",
      "Condition": {
        "ArnEquals": {
          "sagemaker:VolumeKmsKey": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
      }
    }
  ]
}
```
"Effect": "Allow",
"Action": [
  "sagemaker:CreateNotebookInstance"
],
"Resource": "*",
"Condition": {
  "ArnLike": {
    "sagemaker:VolumeKmsKey": "*key/volume-kms-key-12345"
  }
}

Enforce Network Isolation for Training Jobs

The following policy restricts an IAM user to enable network isolation when creating training jobs by using the `sagemaker:NetworkIsolation` condition key:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceIsolation",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "Bool": {
          "sagemaker:NetworkIsolation": "true"
        }
      }
    }
  ]
}
```

Enforce a Specific Instance Type for Training Jobs

The following policy restricts an IAM user to use a specific instance type when creating training jobs by using the `sagemaker:InstanceTypes` condition key:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceInstanceType",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringLike": {
          "sagemaker:InstanceTypes": ["ml.c5.*"]
        }
      }
    }
  ]
}
```
Enforce a Specific EI Accelerator for Training Jobs

The following policy restricts an IAM user to use a specific elastic inference (EI) accelerator, if an accelerator is provided, when creating or updating notebook instances and when creating endpoint configurations by using the `sagemaker:AcceleratorTypes` condition key:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnforceAcceleratorType",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateNotebookInstance",
        "sagemaker:UpdateNotebookInstance",
        "sagemaker:CreateEndpointConfig"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "sagemaker:AcceleratorTypes": ["ml.eia1.medium"]
        }
      }
    }
  ]
}
```

Enforce Disabling Internet Access and Root Access for Creating Notebook Instances

You can disable both internet access and root access to notebook instances to help make them more secure. For information about controlling root access to a notebook instance, see Control root access to a SageMaker notebook instance (p. 3059). for information about disabling internet access for a notebook instance, see Connect a Notebook Instance in a VPC to External Resources (p. 3161).

The following policy requires an IAM user to disable network access when creating instance, and disable root access when creating or updating a notebook instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "LockDownCreateNotebookInstance",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateNotebookInstance"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:DirectInternetAccess": "Disabled",
          "sagemaker:RootAccess": "Disabled"
        },
        "Null": {
          "sagemaker:VpcSubnets": "false",
          "sagemaker:VpcSecurityGroupIds": "false"
        }
      }
    }
  ]
}
```
Control Access to the SageMaker API by Using Identity-based Policies

To control access to SageMaker API calls and calls to SageMaker hosted endpoints, use identity-based IAM policies.

Topics

- Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC (p. 3088)

Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC

If you set up an interface endpoint in your VPC, individuals outside the VPC can still connect to the SageMaker API and runtime over the internet unless you attach an IAM policy that restricts access to calls coming from within the VPC to all users and groups that have access to your SageMaker resources. For information about creating a VPC interface endpoint for the SageMaker API and runtime, see Connect to SageMaker Through a VPC Interface Endpoint (p. 3163).

**Important**

If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the SageMaker API or runtime.

**Note**

This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
    "Id": "api-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnableAPIAccess",
            "Effect": "Allow",
            "Action": [ "sagemaker:*" ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:RootAccess": "Enabled"
                }
            }
        }
    ]
}
```
If you want to restrict access to the API to only calls made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
  "Id": "api-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "EnableAPIAccess",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedNotebookInstanceUrl"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:sourceVpce": [
            "vpce-111bbccc",
            "vpce-111bbddd"
          ]
        }
      }
    }
  ]
}
```

## Limit Access to SageMaker API and Runtime Calls by IP Address

To allow access to SageMaker API calls and runtime invocations only from IP addresses in a list that you specify, attach an IAM policy that denies access to the API unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the API or runtime. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the API call, use the `IpAddress` condition operator and the `aws:SourceIp` condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to the `CreateTrainingJob` only from IP addresses in the ranges `192.0.2.0-192.0.2.255` and `203.0.113.0-203.0.113.255`:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:CreateTrainingJob",
      "Resource": "*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "192.0.2.0/24",
            "203.0.113.0/24"
          ]
        }
      }
    }
  ]
}
```
Limit Access to a Notebook Instance by IP Address

To allow access to a notebook instance only from IP addresses in a list that you specify, attach an IAM policy that denies access to CreatePresignedNotebookInstanceUrl unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the notebook instance. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the notebook instance, use the IpAddress condition operator and the aws:SourceIp condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to a notebook instance only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
         "Resource": "*",
         "Condition": {
            "IpAddress": {
               "aws:SourceIp": [
                  "192.0.2.0/24",
                  "192.0.2.24",
                  "203.0.113.0/24"
               ]
            }
         }
      }
   ]
}
```

The policy restricts access to both the call to CreatePresignedNotebookInstanceUrl and to the URL that the call returns. The policy also restricts access to opening a notebook instance in the console and is enforced for every HTTP request and WebSocket frame that attempts to connect to the notebook instance.

**Note**

Using this method to filter by IP address is incompatible when connecting to SageMaker through a VPC interface endpoint. For information about restricting access to a notebook instance when connecting through a VPC interface endpoint, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 3169).

Control Access to SageMaker Resources by Using Tags

Control access to groups of SageMaker resources by attaching tags to the resources and specifying ResourceTypeTag conditions in IAM policies.

**Note**

Tag-based policies don't work to restrict the following API calls:

- ListAlgorithms
• ListCodeRepositories
• ListCompilationJobs
• ListEndpointConfigs
• ListEndpoints
• ListFlowDefinitions
• ListHumanTaskUis
• ListHyperparameterTuningJobs
• ListLabelingJobs
• ListLabelingJobsForWorkteam
• ListModelPackages
• ListModels
• ListNotebookInstanceLifecycleConfigs
• ListNotebookInstances
• ListSubscribedWorkteams
• ListTags
• ListProcessingJobs
• ListTrainingJobs
• ListTrainingJobsForHyperParameterTuningJob
• ListTransformJobs
• ListWorkteams
• Search

For example, suppose you’ve defined two different IAM groups, named DevTeam1 and DevTeam2, in your AWS account. Suppose also that you’ve created 10 notebook instances, 5 of which are used for one project, and 5 of which are used for a second project. You want to allow members of DevTeam1 to make API calls on notebook instances used for the first project, and members of DevTeam2 to make API calls on notebook instances used for the second project.

To control access to API calls (example)

1. Add a tag with the key Project and value A to the notebook instances used for the first project. For information about adding tags to SageMaker resources, see AddTags.
2. Add a tag with the key Project and value B to the notebook instances used for the second project.
3. Create an IAM policy with a ResourceTag condition that denies access to the notebook instances used for the second project, and attach that policy to DevTeam1. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of Project and a value of B:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:*",
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": "sagemaker:*",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:ResourceTag/Project": "B"
        }
      }
    }
  ]
}
```
For information about creating IAM policies and attaching them to identities, see Controlling Access Using Policies in the AWS Identity and Access Management User Guide.

4. Create an IAM policy with a ResourceTag condition that denies access to the notebook instances used for the first project, and attach that policy to DevTeam2. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of Project and a value of A:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:*",
      "Resource": "*"
    },
    {
      "Effect": "Deny",
      "Action": "sagemaker:*",
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:ResourceTag/Project": "A"
        }
      }
    },
    {
      "Effect": "Deny",
      "Action": ["sagemaker:AddTags", "sagemaker:DeleteTags"],
      "Resource": "*"
    }
  ]
}
```

### Require the Presence or Absence of Tags for API Calls

Require the presence or absence of specific tags or specific tag values by using RequestTag condition keys in an IAM policy. For example, if you want to require that every endpoint created by any member of an IAM group to be created with a tag with the key environment and value dev, create a policy as follows:

```json
{
  "Version": "2012-10-17",
  "Statement": [
```
Cross-Service Confused Deputy Prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In AWS, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the calling service) calls another service (the called service). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, AWS provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

Limit Permissions With Global Condition Keys

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition keys in resource policies to limit the permissions that Amazon SageMaker gives another service to the resource. If you use both global condition keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition key with the full ARN of the resource. If you don't know the full ARN of the resource or if you are specifying multiple resources, use the `aws:SourceArn` global condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws:sagemaker::*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition keys in SageMaker to prevent the confused deputy problem.

```json
{
   "Version": "2012-10-17",
   "Statement": {
      "Sid": "ConfusedDeputyPreventionExamplePolicy",
      "Effect": "Allow",
      "Principal": {
         "Service": "sagemaker.amazonaws.com"
      },
      "Action": "service:ActionName",
      "Resource": ["arn:aws:service:::ResourceName/*"],
      "Condition": {
         "ArnLike": {
            "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:"*
         },
         "StringEquals": {
            "aws:SourceAccount": "123456789012"
         }
      }
   }
}
```
Cross-Service Confused Deputy Prevention for SageMaker Inference

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker real-time, serverless, and asynchronous inference. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": { "Service": "sagemaker.amazonaws.com" },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
      }
    }
  }
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific model or endpoint. The ARN must be in the format provided above. The asterisk in the ARN template does not stand for wildcard and should not be changed.

Cross-Service Confused Deputy Prevention for SageMaker Marketplace

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Marketplace resources created by account number 123456789012 in region `us-west-2`. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": { "Service": "sagemaker.amazonaws.com" },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
        }
      }
    }
  ]
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific algorithm or model package. The ARN must be in the format provided above. The asterisk in the ARN template does stand
for wildcard and covers all training jobs, models, and batch transform jobs from validation steps, as well as algorithm and model packages published to SageMaker Marketplace.

**Cross-Service Confused Deputy Prevention for SageMaker Studio**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Studio created by account number `123456789012` in region `us-west-2`. Note that because the account number is part of the `aws:SourceArn` value, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:sagemaker:us-west-2:123456789012:*"
        }
      }
    }
  ]
}
```

Do not replace the `aws:SourceArn` in this template with the full ARN of a specific Studio app, user profile, or domain. The ARN must be in the format provided above. The asterisk in the ARN template does not stand for wildcard and should not be changed.

**Cross-Service Confused Deputy Prevention for SageMaker Pipelines**

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker Pipelines using pipeline execution records from one or more pipelines. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:partition:sagemaker:region:123456789012:pipelinemypipeline/*"
        }
      }
    }
  ]
}
```
Do not replace the `aws:SourceArn` in this template with the full ARN of a specific pipeline execution. The ARN must be in the format provided above. The `partition` placeholder should designate either an AWS commercial partition (aws) or an AWS in China partition (aws-cn), depending on where the pipeline is executing. Similarly, the `region` placeholder in the ARN can be any valid region where SageMaker Pipelines is available.

The asterisk in the ARN template does stand for wildcard and covers all pipeline executions of a pipeline named `mypipeline`. If you want to allow the `AssumeRole` permissions for all pipelines in account 123456789012 rather than one specific pipeline, then the `aws:SourceArn` would be `arn:aws:sagemaker:*:123456789012:processing-job/*`.

### Cross-Service Confused Deputy Prevention for SageMaker Processing Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker processing jobs created by account number 123456789012 in region `us-west-2`. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                }
            }
        }
    ]
}
```

You can replace the `aws:SourceArn` in this template with the full ARN of one specific processing job to further limit permissions.

### Cross-Service Confused Deputy Prevention for SageMaker Training Jobs

The following example shows how you can use the `aws:SourceArn` global condition key to prevent the cross-service confused deputy problem for SageMaker training jobs created by account number 123456789012 in region `us-west-2`. Note that because the account number is in the ARN, you do not need to specify an `aws:SourceAccount` value.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                }
            }
        }
    ]
}
```
You can replace the `aws:SourceArn` in this template with the full ARN of one specific training job to further limit permissions.

Next Up

For more information on managing execution roles, see SageMaker Roles.

SageMaker Roles

As a managed service, Amazon SageMaker performs operations on your behalf on the AWS hardware that is managed by SageMaker. SageMaker can perform only operations that the user permits. A SageMaker user can grant these permissions with an IAM role (referred to as an execution role).

To create and use a locally available execution role, you can use the following procedures.

Get execution role

You can find the IAM execution role in the following ways:

From the notebook

When you run a notebook within SageMaker (from the SageMaker console or SageMaker Studio) you can access the execution role with the following code:

```python
sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

Note

The execution role is available only when running a notebook within SageMaker. If you run `get_execution_role` in a notebook not on SageMaker, expect a "region" error.

From the SageMaker console

Under Notebook > Notebook instances, select the notebook. The ARN is given in the Permissions and encryption section.

Create execution role

Use the following procedure to create an execution role with the IAM managed policy, `AmazonSageMakerFullAccess`, attached. If your use case requires more granular permissions, use other sections on this page to create an execution role that meets your business needs.

Important

The IAM managed policy, `AmazonSageMakerFullAccess`, used in the following procedure only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to add an additional policy to an execution role to grant it access to other Amazon S3 buckets and objects, see Add Additional Amazon S3 Permissions to a SageMaker Execution Role (p. 3098).

To create a new role

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. Select **Roles** and then select **Create role**.
3. Select **SageMaker**.
4. Select **Next: Permissions**.
5. The IAM managed policy, `AmazonSageMakerFullAccess` is automatically attached to this role. To see the permissions included in this policy, select the sideways arrow next to the policy name. Select **Next: Tags**.
6. (Optional) Add tags and select **Next: Review**.
7. Give the role a name in the text field under **Role name** and select **Create role**.
8. On the **Roles** section of the IAM console, select the role you just created. If needed, use the text box to search for the role using the role name you entered in step 7.
9. On the role summary page, make note of the ARN.

With a known ARN for your role, you can programmatically check the role when running the notebook locally or on SageMaker. Replace `RoleName` with your known ARN:

```python
try:
    role = sagemaker.get_execution_role()
except ValueError:
    iam = boto3.client('iam')
    role = iam.get_role(RoleName='AmazonSageMaker-ExecutionRole-20201200T100000')['Role']

Add Additional Amazon S3 Permissions to a SageMaker Execution Role

When you use a SageMaker feature with resources in Amazon S3, such as input data, the execution role you specify in your request (for example `CreateTrainingJob`) is used to access these resources.

If you attach the IAM managed policy, `AmazonSageMakerFullAccess`, to an execution role, that role has permission to perform certain Amazon S3 actions on buckets or objects with `SageMaker`, `Sagemaker`, `sagemaker`, or `aws-glue` in the name. It also has permission to perform the following actions on any Amazon S3 resource:

```
"s3:CreateBucket",
"s3:GetBucketLocation",
"s3:ListBucket",
"s3:ListAllMyBuckets",
"s3:GetBucketCors",
"s3:PutBucketCors"
```

To give an execution role permissions to access one or more specific buckets in Amazon S3, you can attach a policy similar to the following to the role. This policy grants an IAM role permission to perform all actions that `AmazonSageMakerFullAccess` allows but restricts this access to the buckets `DOC-EXAMPLE-BUCKET1` and `DOC-EXAMPLE-BUCKET2`. Refer to the security documentation for the specific SageMaker feature you are using to learn more about the Amazon S3 permissions required for that feature.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
```
Passing Roles

Actions like passing a role between services are a common function within SageMaker. You can find more details on Actions, Resources, and Condition Keys for SageMaker in the IAM User Guide.

You pass the role (iam:PassRole) when making these API calls: CreateAutoMLJob, CreateCompilationJob, CreateDomain, CreateFlowDefinition, CreateHyperParameterTuningJob, CreateImage, CreateLabelingJob, CreateModel, CreateMonitoringSchedule, CreateNotebookInstance, CreateProcessingJob, CreateTrainingJob, CreateUserProfile, RenderUiTemplate, and UpdateImage.

You attach the following trust policy to the IAM role which grants SageMaker principal permissions to assume the role, and is the same for all of the execution roles:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The permissions that you need to grant to the role vary depending on the API that you call. The following sections explain these permissions.
Note
Instead of managing permissions by crafting a permission policy, you can use the AWS-managed AmazonSageMakerFullAccess permission policy. The permissions in this policy are fairly broad, to allow for any actions you might want to perform in SageMaker. For a listing of the policy including information about the reasons for adding many of the permissions, see AmazonSageMakerFullAccess (p. 3132). If you prefer to create custom policies and manage permissions to scope the permissions only to the actions you need to perform with the execution role, see the following topics.

For more information about IAM roles, see IAM Roles in the IAM User Guide.

Topics
- CreateAutoMLJob API: Execution Role Permissions (p. 3100)
- CreateDomain API: Execution Role Permissions (p. 3102)
- CreateImage and UpdateImage APIs: Execution Role Permissions (p. 3102)
- CreateNotebookInstance API: Execution Role Permissions (p. 3103)
- CreateHyperParameterTuningJob API: Execution Role Permissions (p. 3106)
- CreateProcessingJob API: Execution Role Permissions (p. 3108)
- CreateTrainingJob API: Execution Role Permissions (p. 3110)
- CreateModel API: Execution Role Permissions (p. 3113)

CreateAutoMLJob API: Execution Role Permissions

For an execution role that you can pass in a CreateAutoMLJob API request, you can attach the following minimum permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iam:PassRole"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "iam:PassedToService": "sagemaker.amazonaws.com"
            }
         }
      },
      {
         "Effect": "Allow",
         "Action": [
            "sagemaker:DescribeEndpointConfig",
            "sagemaker:DescribeModel",
            "sagemaker:InvokeEndpoint",
            "sagemaker:ListTags",
            "sagemaker:DescribeEndpoint",
            "sagemaker:CreateModel",
            "sagemaker:CreateEndpointConfig",
            "sagemaker:CreateEndpoint",
            "sagemaker:DeleteModel",
            "sagemaker:DeleteEndpointConfig",
            "sagemaker:DeleteEndpoint",
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents"
         ]
      }
   ]
}
```
If you specify a private VPC for your AutoML job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
    ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```
{
    "Effect": "Allow",
    "Action": ["kms:Decrypt"]
}
```

If you specify a KMS key in the output configuration of your AutoML job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": ["kms:Encrypt"]
}
```

If you specify a volume KMS key in the resource configuration of your AutoML job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": ["kms:CreateGrant"]
}
```
CreateDomain API: Execution Role Permissions

The execution role for AWS SSO domains and the user/execution role for IAM domains need the following permissions when you pass an AWS KMS customer managed key as the KmsKeyId in the CreateDomain API request. The permissions are enforced during the CreateApp API call.

For an execution role that you can pass in the CreateDomain API request, you can attach the following permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "kms:CreateGrant",
            "kms:DescribeKey"
         ],
         "Resource": "arn:aws:kms:region:account-id:key/kms-key-id"
      }
   ]
}
```

Alternatively, if the permissions are specified in a KMS policy, you can attach the following policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Allow use of the key",
         "Effect": "Allow",
         "Principal": {
            "AWS": [
               "arn:aws:iam::account-id:role/ExecutionRole"
            ]
         },
         "Action": [
            "kms:CreateGrant",
            "kms:DescribeKey"
         ],
         "Resource": "*"
      }
   ]
}
```

CreateImage and UpdateImage APIs: Execution Role Permissions

For an execution role that you can pass in a CreateImage or UpdateImage API request, you can attach the following permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ecr:BatchGetImage",
            "ecr:GetDownloadUrlForLayer"
         ],
         "Resource": "*"
      }
   ]
}
```
SageMaker Roles

CreateNotebookInstance API: Execution Role Permissions

The permissions that you grant to the execution role for calling the CreateNotebookInstance API depend on what you plan to do with the notebook instance. If you plan to use it to invoke SageMaker APIs and pass the same role when calling the CreateTrainingJob and CreateModel APIs, attach the following permissions policy to the role:

```
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "sagemaker:*",
         "ecr:GetAuthorizationToken",
         "ecr:GetDownloadUrlForLayer",
         "ecr:BatchGetImage",
         "ecr:BatchCheckLayerAvailability",
         "ecr:GetRepositoryPolicy",
         "ecr:CompleteLayerUpload",
         "ecr:BatchDeleteImage",
         "ecr:UploadLayerPart",
         "ecr:DeleteRepositoryPolicy",
         "ecr:InitiateLayerUpload",
         "ecr:DeleteRepository",
         "ecr:PutImage",
         "ecr:CreateRepository",
         "cloudwatch:PutMetricData",
         "cloudwatch:GetMetricData",
         "cloudwatch:GetMetricStatistics",
         "cloudwatch:ListMetrics",
         "logs:CreateLogGroup",
         "logs:CreateLogStream",
         "logs:DescribeLogStreams",
         "logs:PutLogEvents",
         "s3:CreateBucket",
         "s3:ListBucket",
         "s3:GetBucketLocation",
         "s3:GetObject",
         "s3:PutObject",
         "s3:DeleteObject",
         "robomaker:CreateSimulationApplication",
         "robomaker:DescribeSimulationApplication",
         "robomaker:DeleteSimulationApplication",
         "robomaker:CreateSimulationJob",
         "robomaker:DescribeSimulationJob",
```
To tighten the permissions, limit them to specific Amazon S3 and Amazon ECR resources, by restricting "Resource": "*", as follows:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:*",
                "ecr:GetAuthorizationToken",
                "cloudwatch:PutMetricData",
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:PutLogEvents",
                "logs:GetLogEvents"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "sagemaker.amazonaws.com"
                }
            }
        }
    ]
}
```
If you plan to access other resources, such as Amazon DynamoDB or Amazon Relational Database Service, add the relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to the specific bucket that you specify as `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope `s3:GetObject`, `s3:PutObject`, and `s3:DeleteObject` permissions as follows:
  - Scope to the following values that you specify in a `CreateTrainingJob` request:
    - `InputDataConfig.DataSource.S3DataSource.S3Uri`
    - `OutputDataConfig.S3OutputPath`
  - Scope to the following values that you specify in a `CreateModel` request:
    - `PrimaryContainer.ModelDataUrl`
    - `SupplementalContainers.ModelDataUrl`
- Scope `ecr` permissions as follows:
  - Scope to the `AlgorithmSpecification.TrainingImage` value that you specify in a `CreateTrainingJob` request.
• Scope to the `PrimaryContainer.Image` value that you specify in a `CreateModel` request:

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/aws-monitoring-resource-summary.html) in the Amazon CloudWatch User Guide.

**CreateHyperParameterTuningJob API: Execution Role Permissions**

For an execution role that you can pass in a `CreateHyperParameterTuningJob` API request, you can attach the following permission policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": "*"
    }
  ]
}
```

Instead of the specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": ["*"
```
If the training container associated with the hyperparameter tuning job needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy. In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateHyperParameterTuningJob` request:
  - `InputDataConfig.DataSource.S3DataSource.S3Uri`
  - `OutputDataConfig.S3OutputPath`
- Scope Amazon ECR permissions to the registry path (`AlgorithmSpecification.TrainingImage`) that you specify in a `CreateHyperParameterTuningJob` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your hyperparameter tuning job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ]
}
```
If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ]
}
```

If you specify a KMS key in the output configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt"
    ]
}
```

If you specify a volume KMS key in the resource configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant"
    ]
}
```

**CreateProcessingJob API: Execution Role Permissions**

For an execution role that you can pass in a `CreateProcessingJob` API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListBucket",
                "ecr:GetAuthorizationToken",
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "*"
        }
    ]
}
```
Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "ecr:GetAuthorizationToken"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::inputbucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::inputbucket/object",
                "arn:aws:s3:::outputbucket/path"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "arn:aws:ecr:region::repository/my-repo"
        }
    ]
}``

If `CreateProcessingJob.AppSpecification.ImageUri` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `ProcessingInputs` in a `CreateProcessingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the objects that will be downloaded or uploaded in the `ProcessingInputs` and `ProcessingOutputConfig` in a `CreateProcessingJob` request.
- Scope Amazon ECR permissions to the registry path (`AppSpecification.ImageUri`) that you specify in a `CreateProcessingJob` request.
The cloudwatch and logs actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
    ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [ "kms:Decrypt"
]
}
```

If you specify a KMS key in the output configuration of your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [ "kms:Encrypt"
]
}
```

If you specify a volume KMS key in the resource configuration of your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [ "kms:CreateGrant"
]
}
```

**CreateTrainingJob API: Execution Role Permissions**

For an execution role that you can pass in a CreateTrainingJob API request, you can attach the following permission policy to the role:

```
{
    "Version": "2012-10-17",
    "Statement": [
```
Instead of the specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:PutObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket/object",
        "arn:aws:s3:::outputbucket/path"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*
    }
  ]
}
```
If `CreateTrainingJob.AlgorithmSpecifications.TrainingImage` needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateTrainingJob` request:
  - `InputDataConfig.DataSource.S3DataSource.S3Uri`
  - `OutputDataConfig.S3OutputPath`
- Scope Amazon ECR permissions to the registry path (`AlgorithmSpecification.TrainingImage`) that you specify in a `CreateTrainingJob` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see [CloudWatch Resources and Operations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch_resources.html) in the Amazon CloudWatch User Guide.

If you specify a private VPC for your training job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}
```

If you specify a KMS key in the output configuration of your training job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}
```
If you specify a volume KMS key in the resource configuration of your training job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant"
  ]
}
```

CreateModel API: Execution Role Permissions

For an execution role that you can pass in a `CreateModel` API request, you can attach the following permission policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "s3:ListBucket",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    }
  ]
}
```

Instead of specifying "Resource": "*", you can scope these permissions to specific Amazon S3 and Amazon ECR resources:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
If `CreateModel.PrimaryContainer.Image` need to access other data sources, such as Amazon DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope S3 permissions to objects that you specify in the `PrimaryContainer.ModelDataUrl` in a `CreateModel` request.
- Scope Amazon ECR permissions to a specific registry path that you specify as the `PrimaryContainer.Image` and `SecondaryContainer.Image` in a `CreateModel` request.

The `cloudwatch` and `logs` actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your model, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ],
  "Resource": ["arn:aws:ecr:region::repository/my-repo",
               "arn:aws:s3:::inputbucket/object"
  ]
}
```

Amazon SageMaker API Permissions Reference

When you are setting up access control and writing a permissions policy that you can attach to an IAM identity (an identity-based policy), use the following as a reference. The each Amazon SageMaker API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's `Action` field, and you specify the resource value in the policy's `Resource` field.
**Note**
Except for the ListTags API, resource-level restrictions are not available on List- calls. Any user calling a List- API will see all resources of that type in the account.

To express conditions in your Amazon SageMaker policies, you can use AWS-wide condition keys. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.

### Amazon SageMaker API Operations and Required Permissions for Actions

<table>

API Operation: **UpdateWorkteam**

Required Permissions (API Action): sagemaker:UpdateWorkteam

AWS Managed Policies for Amazon SageMaker

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) to which the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the ReadOnlyAccess AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.

**Important**
We recommend that you use the most restricted policy that allows you to perform your use case.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon SageMaker:
• **AmazonSageMakerFullAccess** – Grants full access to Amazon SageMaker resources and the supported operations. This does not provide unrestricted Amazon S3 access, but supports buckets and objects with specific `sagemaker` tags. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services.

• **AmazonSageMakerReadOnly** – Grants read-only access to Amazon SageMaker resources.

The following AWS managed policies can be attached to users in your account but are not recommended:

• **AdministratorAccess** – Grants all actions for all AWS services and for all resources in the account.

• **DataScientist** – Grants a wide range of permissions to cover most of the use cases (primarily for analytics and business intelligence) encountered by data scientists.

You can review these permissions policies by signing in to the IAM console and searching for them.

You can also create your own custom IAM policies to allow permissions for Amazon SageMaker actions and resources as you need them. You can attach these custom policies to the IAM users or groups that require them.

**Topics**

- **AmazonSageMakerFullAccess** (p. 3132)
- **AmazonSageMakerReadOnly** (p. 3141)
- **AWS Managed Policies for SageMaker projects and JumpStart** (p. 3142)
- **AWS Managed Policies for SageMaker Pipelines** (p. 3150)
- **AWS Managed Policies for Amazon SageMaker Ground Truth** (p. 3151)
- **SageMaker Updates to AWS Managed Policies** (p. 3154)

**AmazonSageMakerFullAccess**

This policy grants administrative permissions that allow a principal full access to all Amazon SageMaker resources and operations. The policy also provides select access to related services. This policy allows all IAM roles to be passed to Amazon SageMaker, but only allows IAM roles with "AmazonSageMaker" in them to be passed to the AWS Glue, AWS Step Functions, and AWS RoboMaker services. This policy does not include permissions to create an Amazon SageMaker domain. For information on the policy needed to create a domain, see **Create an IAM Administrator User and Group** (p. 35).

**Permissions details**

This policy includes the following permissions.

• **application-autoscaling** – Allows principals to automatically scale a SageMaker real-time inference endpoint.

• **athena** – Allows principals to query a list of data catalogs, databases, and table metadata from Amazon Athena.

• **aws-marketplace** – Allows principals to view AWS AI Marketplace subscriptions. You need this if you want to access SageMaker software subscribed in AWS Marketplace.

• **cloudformation** – Allows principals to get AWS CloudFormation templates for using SageMaker JumpStart solutions and Pipelines. SageMaker JumpStart creates resources necessary to run end-to-end machine learning solutions that tie SageMaker to other AWS services. SageMaker Pipelines creates new projects that are backed by AWS Service Catalog.

• **cloudwatch** – Allows principals to post CloudWatch metrics, interact with alarms, and upload logs to CloudWatch Logs in your account.
- `codebuild` – Allows principals to store AWS CodeBuild artifacts for SageMaker Pipeline and Projects.
- `codecommit` – Needed for AWS CodeCommit integration with SageMaker notebook instances.
- `cognito-identity` – Needed for Amazon SageMaker Ground Truth to define private workforce and work teams.
- `ec2` – Needed for SageMaker to manage Amazon EC2 resources and network interfaces when you specify an Amazon VPC for your SageMaker jobs, models, endpoints, and notebook instances.
- `ecr` – Needed to pull and store Docker artifacts for Amazon SageMaker Studio (custom images), training, processing, batch inference, and inference endpoints. This is also required to use your own container in SageMaker. Additional permissions for SageMaker JumpStart solutions are required to create and remove custom images on behalf of users.
- `elastic-inference` – Allows principals to connect to Amazon Elastic Inference for using SageMaker notebook instances and endpoints.
- `elasticfilesystem` – Allows principals to access Amazon Elastic File System. This is needed for SageMaker to use data sources in Amazon Elastic File System for training machine learning models.
- `fsx` – Allows principals to access Amazon FSx. This is needed for SageMaker to use data sources in Amazon FSx for training machine learning models.
- `glue` – Needed for inference pipeline pre-processing from within SageMaker notebook instances.
- `groundtruthlabeling` – Needed for Ground Truth labeling jobs. The `groundtruthlabeling` endpoint is accessed by the Ground Truth console.
- `iam` – Needed to give the SageMaker console access to available IAM roles and create service-linked roles.
- `kms` – Needed to give the SageMaker console access to available AWS KMS keys and retrieve them for any specified AWS KMS aliases in jobs and endpoints.
- `lambda` – Allows principals to invoke and get a list of AWS Lambda functions.
- `logs` – Needed to allow SageMaker jobs and endpoints to publish log streams.
- `redshift` – Allows principals to access Amazon Redshift cluster credentials.
- `redshift-data` – Allows principals to use data from Amazon Redshift to run, describe, and cancel statements; get statement results; and list schemas and tables.
- `robomaker` – Allows principals to have full access to create, get descriptions, and delete AWS RoboMaker simulation applications and jobs. This is also needed to run reinforcement learning examples on notebook instances.
- `s3` – Allows principals to have full access to Amazon S3 resources pertaining to SageMaker, but not all of Amazon S3.
- `secretsmanager` – Allows principals to have full access to AWS Secrets Manager. The principals can securely encrypt, store, and retrieve credentials for databases and other services. This is also needed for SageMaker notebook instances with SageMaker code repositories that use GitHub.
- `servicecatalog` – Allows principals to use AWS Service Catalog. The principals can create, get a list of, update, or terminate provisioned products, such as servers, databases, websites, or applications deployed using AWS resources. This is needed for SageMaker JumpStart and Projects to find and read service catalog products and launch AWS resources in user accounts.
- `sns` – Allows principals to get a list of Amazon SNS topics. This is needed for endpoints with Async Inference enabled for notifying users that their inference has completed.
- `states` – Needed for SageMaker JumpStart and Pipelines to use a service catalog to create step function resources.
- `tag` – Needed for SageMaker Pipelines to render in Studio. Studio needs resources tagged with particular `sagemaker:project-id` tag-key. This requires the `tag:GetResources` permission.

Amazon SageMaker Developer Guide
AWS Managed Policies for SageMaker

This policy grants read-only access to Amazon SageMaker via the AWS Management Console and SDK.

Permissions details

This policy includes the following permissions.

- application-autoscaling – Allows users to browse descriptions of scalable SageMaker real-time inference endpoints.
- aws-marketplace – Allows users to view AWS AI Marketplace subscriptions.
- cloudwatch – Allows users to receive CloudWatch alarms.
- cognito-idp – Needed for Amazon SageMaker Ground Truth to browse descriptions and lists of private workforce and work teams.
- ecr – Needed to read Docker artifacts for training and inference.

AWS Managed Policies for SageMaker projects and JumpStart

These AWS managed policies add permissions to use built-in Amazon SageMaker project templates and JumpStart solutions. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

SageMaker projects and JumpStart use AWS Service Catalog to provision AWS resources in customers' accounts. Some created resources need to assume an execution role. For example, if AWS Service Catalog creates a CodePipeline pipeline on behalf of a customer for a SageMaker machine learning CI/CD project, then that pipeline requires an IAM role.

The AmazonSageMakerServiceCatalogProductsLaunchRole role has the permissions required to launch the SageMaker portfolio of products from AWS Service Catalog. The AmazonSageMakerServiceCatalogProductsUseRole role has the permissions required to use the SageMaker portfolio of products from AWS Service Catalog. The AmazonSageMakerServiceCatalogProductsLaunchRole role passes an AmazonSageMakerServiceCatalogProductsUseRole role to the provisioned AWS Service Catalog product resources.

Topics
- AWS managed policy: AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy (p. 3142)
- Amazon SageMaker updates to AWS Service Catalog AWS managed policies (p. 3149)

AWS managed policy: AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy

This service role policy is used by the AWS Service Catalog service to provision products from the Amazon SageMaker portfolio. The policy grants permissions to a set of related AWS services including AWS CodePipeline, AWS CodeBuild, AWS CodeCommit, AWS Glue, Amazon CloudFront, and others.

The AmazonSageMakerAdmin-ServiceCatalogProductsServiceRolePolicy policy is intended to be used by the AmazonSageMakerServiceCatalogProductsLaunchRole role created from the SageMaker console. The policy adds permissions to provision AWS resources for SageMaker projects and JumpStart using AWS Service Catalog to a customer's account.

Permissions details

This policy includes the following permissions.

- apigateway – Allows the role to call API Gateway endpoints that are tagged with sagemaker:launch-source.
- cloudformation – Allows AWS Service Catalog to create, update and delete CloudFormation stacks.
- codebuild – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeBuild projects.
- codecommit – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodeCommit repositories.
• codepipeline – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create, update and delete CodePipelines.
• codestar-connections – Allows the role to pass AWS CodeStar connections.
• cognito-idp – Allows the role to create, update, and delete groups and user pools. Also allows tagging resources.
• ecr – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete Amazon ECR repositories. Also allows tagging resources.
• events – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to create and delete EventBridge rules. Used for tying together the various components of the CICD pipeline.
• firehose – Allows the role to interact with Kinesis Data Firehose streams.
• glue – Allows the role to interact with AWS Glue.
• iam – Allows the role to pass roles prepended with AmazonSageMakerServiceCatalog. This is needed when Projects provisions a AWS Service Catalog product, as a role needs to be passed to AWS Service Catalog.
• lambda – Allows the role to interact with AWS Lambda.
• logs – Allows the role to create, delete and access log streams.
• s3 – Allows the role assumed by AWS Service Catalog and passed to CloudFormation to access Amazon S3 buckets where the Project template code is stored.
• sagemaker – Allows the role to interact with various SageMaker services. This is done both in CloudFormation during template provisioning, as well as in CodeBuild during CICD pipeline execution.
• states – Allows the role to create, delete, and update Step Functions prepended with sagemaker.

### AWS Managed Policies for SageMaker Pipelines

These AWS managed policies add permissions required to use SageMaker Pipelines. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

**Topics**

- AWS managed policy: AmazonSageMakerPipelinesIntegrations (p. 3150)
- Amazon SageMaker updates to SageMaker Pipelines managed policies (p. 3151)

**AWS managed policy: AmazonSageMakerPipelinesIntegrations**

This AWS managed policy grants permissions commonly needed to use Callback steps and Lambda steps in SageMaker Pipelines. The policy is added to the `AmazonSageMaker-ExecutionRole` that is created when you onboard to Amazon SageMaker Studio. The policy can be attached to any role used for authoring or executing a pipeline.

This policy grants appropriate AWS Lambda, Amazon Simple Queue Service (Amazon SQS), and IAM permissions needed when building pipelines that invoke Lambda functions or include callback steps, which can be used for manual approval steps or running custom workloads.

The Amazon SQS permissions allow you to create the Amazon SQS queue needed for receiving callback messages, and also to send messages to that queue.

The Lambda permissions allow you to create, update, and delete the Lambda functions used in the pipeline steps, and also to invoke those Lambda functions.

**Permissions details**

This policy includes the following permissions.

- **lambda** – Create, delete, and invoke Lambda functions; update Lambda function code. These permissions are limited to functions whose name includes "sagemaker".
- **sqs** – Create an Amazon SQS queue; send an Amazon SQS message. These permissions are limited to queues whose name includes "sagemaker".
- **iam** – Pass an IAM role to the AWS Lambda service.

AWS Managed Policies for Amazon SageMaker Ground Truth

These AWS managed policies add permissions required to use SageMaker Ground Truth. The policies are available in your AWS account and are used by execution roles created from the SageMaker console.

Topics
- AWS managed policy: AmazonSageMakerGroundTruthExecution (p. 3151)
- Amazon SageMaker updates to SageMaker Ground Truth managed policies (p. 3154)

AWS managed policy: AmazonSageMakerGroundTruthExecution

This AWS managed policy grants permissions commonly needed to use SageMaker Ground Truth.
Permissions details

This policy includes the following permissions.

- **lambda** – Allows principals to invoke Lambda functions whose name includes "sagemaker" (case-insensitive), "GtRecipe", or "LabelingFunction".
- **s3** – Allows principals to add and retrieve objects from Amazon S3 buckets. These objects are limited to those whose case-insensitive name contains "groundtruth" or "sagemaker", or are tagged with "SageMaker".
- **cloudwatch** – Allows principals to post CloudWatch metrics.
- **logs** – Allows principals to create and access log streams, and post log events.
- **sqs** – Allows principals to create Amazon SQS queues, and send and receive Amazon SQS messages. These permissions are limited to queues whose name includes "GroundTruth".
- **sns** – Allows principals to subscribe to and publish messages to Amazon SNS topics whose case-insensitive name contains "groundtruth" or "sagemaker".

Troubleshooting Amazon SageMaker Identity and Access

Use the following information to help you diagnose and fix common issues that you might encounter when working with SageMaker and IAM.

Topics

- I Am Not Authorized to Perform an Action in SageMaker (p. 3155)
- I Am Not Authorized to Perform iam:PassRole (p. 3155)
- I Want to View My Access Keys (p. 3156)
- I’m an Administrator and Want to Allow Others to Access SageMaker (p. 3156)
- I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources (p. 3156)

I Am Not Authorized to Perform an Action in SageMaker

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a training job but does not have sagemaker:sagemaker:DescribeTrainingJob permissions.

```plaintext
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: sagemaker:DescribeTrainingJob on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the TrainingJob resource using the sagemaker:DescribeTrainingJob action.

I Am Not Authorized to Perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to SageMaker.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in SageMaker. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.
In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I Want to View My Access Keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can't view your secret access key again. If you lose your secret key, you must create a new access key pair.

Access keys consist of two parts: an access key ID (for example, `AKIAIOSFODNN7EXAMPLE`) and a secret access key (for example, `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

Important
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

I'm an Administrator and Want to Allow Others to Access SageMaker

To allow others to access SageMaker, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in SageMaker.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether SageMaker supports these features, see How Amazon SageMaker Works with IAM (p. 3068).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
Logging and Monitoring

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. You can also set alarms that watch for certain thresholds and send notifications or take actions when those thresholds are met. For more information, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190).

Amazon CloudWatch Logs enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. You can collect and track metrics, create customized dashboards, and set alerts that notify you or take actions when a specified metric reaches a threshold that you specify. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201).

AWS CloudTrail provides a record of actions taken by a user, role, or an AWS service in SageMaker. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3202).

Note
CloudTrail does not monitor calls to runtime_InvokeEndpoint.

You can create rules in Amazon CloudWatch Events to react to status changes in status in a SageMaker training, hyperparameter tuning, or batch transform job. For more information, see Automating Amazon SageMaker with Amazon EventBridge (p. 3205).

Compliance Validation for Amazon SageMaker

Third-party auditors assess the security and compliance of Amazon SageMaker as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using Amazon SageMaker is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.

- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.

- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.

- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.
Resilience in Amazon SageMaker

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon SageMaker offers several features to help support your data resiliency and backup needs.

Infrastructure Security in Amazon SageMaker

As a managed service, Amazon SageMaker is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Amazon SageMaker through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

SageMaker Scans AWS Marketplace Training and Inference Containers for Security Vulnerabilities

To meet our security requirements, algorithms and model packages listed in AWS Marketplace are scanned for Common Vulnerabilities and Exposures (CVE). CVE is a list of publicly known information about security vulnerability and exposure. The National Vulnerability Database (NVD) provides CVE details such as severity, impact rating, and fix information. Both CVE and NVD are available for public consumption and free for security tools and services to use. For more information, see http://cve.mitre.org/about/faqs.html#what_is_cve.

Connect to Resources From Within a VPC

Amazon SageMaker Studio and SageMaker notebook instances allow direct internet access by default. This allows you to download popular packages and notebooks, customize your development
environment, and work efficiently. However, this could provide an additional avenue for unauthorized access to your data. For example, if you install malicious code on your computer in the form of a publicly available notebook or a publicly available source code library, it could access your data. You can choose to restrict which traffic can access the internet by launching your Amazon SageMaker Studio and SageMaker notebook instances in an Amazon Virtual Private Cloud (Amazon VPC) of your choosing.

An Amazon Virtual Private Cloud is a virtual network dedicated to your AWS account. With an Amazon VPC, you can control the network access and internet connectivity of your Amazon SageMaker Studio and notebook instances. You can disable direct internet access to add an additional layer of security.

The following topics describe how to connect your SageMaker Studio instances and notebook instances to resources in a VPC.

Topics
- Connect SageMaker Studio Notebooks in a VPC to External Resources (p. 3159)
- Connect a Notebook Instance in a VPC to External Resources (p. 3161)

Connect SageMaker Studio Notebooks in a VPC to External Resources

The following topic gives information on how to connect Studio Notebooks in a VPC to external resources.

Default communication with the internet

By default, SageMaker Studio provides a network interface that allows communication with the internet through a VPC managed by SageMaker. Traffic to AWS services like Amazon S3 and CloudWatch goes through an internet gateway, as does traffic that accesses the SageMaker API and SageMaker runtime. Traffic between the domain and your Amazon EFS volume goes through the VPC that you specified when you onboarded to Studio or called the CreateDomain API. The following diagram shows the default configuration.

VPC only communication with the internet

To prevent SageMaker from providing internet access to your Studio notebooks, you can disable internet access by specifying the VPC only network access type when you onboard to Studio or call
the `CreateDomain` API. As a result, you won't be able to run a Studio notebook unless your VPC has an interface endpoint to the SageMaker API and runtime, or a NAT gateway with internet access, and your security groups allow outbound connections. The following diagram shows a configuration for using VPC-only mode.

![Diagram showing VPC-only configuration](image)

**Requirements to use VPC only mode**

When you choose `VpcOnly`, follow these steps:

1. Ensure your subnets have one IP address for each instance. For more information, see VPC and subnet sizing for IPv4.
   
   **Note**
   
   You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

2. Set up one or more security groups with inbound and outbound rules that together allow the following traffic:
   
   - **NFS traffic over TCP on port 2049** between the domain and the Amazon EFS volume.
   - **TCP traffic within the security group**. This is required for connectivity between the JupyterServer app and the KernelGateway apps. You must allow access to at least ports in the range 8192–65535.

3. If you want to allow internet access, you must use a **NAT gateway** with access to the internet, for example through an internet gateway.

4. If you don't want to allow internet access, create **interface VPC endpoints** (AWS PrivateLink) to allow Studio to access the following services with the corresponding service names. You must also associate the security groups for your VPC with these endpoints.
   
   - **SageMaker API**: com.amazonaws.us-east-1.sagemaker.api
   - **SageMaker runtime**: com.amazonaws.us-east-1.sagemaker.runtime. This is required to run Studio notebooks and to train and host models.
   - **Amazon S3**: com.amazonaws.us-east-1.s3.
   - **To use SageMaker Projects**: com.amazonaws.us-east-1.servicecatalog.
   - **Any other AWS services you require.**
Note
For a customer working within VPC mode, company firewalls can cause connection issues with SageMaker Studio or between JupyterServer and the KernelGateway. Make the following checks if you encounter one of these issues when using SageMaker Studio from behind a firewall.

- Check that the Studio URL is in your networks allowlist.
- Check that the websocket connections are not blocked. Jupyter uses websocket under the hood. If the KernelGateway application is InService, JupyterServer may not be able to connect to the KernelGateway. You should see this problem when opening System Terminal as well.

- VPC with public and private subnets (NAT)

Connect a Notebook Instance in a VPC to External Resources

The following topic gives information on how to connect your notebook instance in a VPC to external resources.

Default communication with the internet

When your notebook allows direct internet access, SageMaker provides a network interface that allows the notebook to communicate with the internet through a VPC managed by SageMaker. Traffic within your VPC's CIDR goes through elastic network interface created in your VPC. All the other traffic goes through the network interface created by SageMaker, which is essentially through the public internet. Traffic to gateway VPC endpoints like Amazon S3 and DynamoDB goes through the public internet, while traffic to interface VPC interface endpoints still goes through your VPC. If you want to use gateway VPC endpoints, you might want to disable direct internet access.

VPC communication with the internet

To disable direct internet access, you can specify a VPC for your notebook instance. By doing so, you prevent SageMaker from providing internet access to your notebook instance. As a result, the notebook instance can't train or host models unless your VPC has an interface endpoint (AWS PrivateLink) or a NAT gateway and your security groups allow outbound connections.

For information about creating a VPC interface endpoint to use AWS PrivateLink for your notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 3169). For information about setting up a NAT gateway for your VPC, see VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide. For more information about security groups, see Security Groups for Your VPC. For more information about networking configurations in each networking mode and configuring network on premise, see Understanding Amazon SageMaker notebook instance networking configurations and advanced routing options.

Security and Shared Notebook Instances

A SageMaker notebook instance is designed to work best for an individual user. It is designed to give data scientists and other users the most power for managing their development environment.

A notebook instance user has root access for installing packages and other pertinent software. We recommend that you exercise judgement when granting individuals access to notebook instances that are attached to a VPC that contains sensitive information. For example, you might grant a user access to a notebook instance with an IAM policy, as shown in the following example:
Run Training and Inference Containers in Internet-Free Mode

SageMaker training and deployed inference containers are internet-enabled by default. This allows containers to access external services and resources on the public internet as part of your training and inference workloads. However, this could provide an avenue for unauthorized access to your data. For example, a malicious user or code that you accidentally install on the container (in the form of a publicly available source code library) could access your data and transfer it to a remote host.

If you use an Amazon VPC by specifying a value for the `VpcConfig` parameter when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`, you can protect your data and resources by managing security groups and restricting internet access from your VPC. However, this comes at the cost of additional network configuration, and has the risk of configuring your network incorrectly. If you do not want SageMaker to provide external network access to your training or inference containers, you can enable network isolation.

### Network Isolation

You can enable network isolation when you create your training job or model by setting the value of the `EnableNetworkIsolation` parameter to `True` when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`.

**Note**

Network isolation is required to run training jobs and models using resources from AWS Marketplace.

If you enable network isolation, the containers can't make any outbound network calls, even to other AWS services such as Amazon S3. Additionally, no AWS credentials are made available to the container runtime environment. In the case of a training job with multiple instances, network inbound and outbound traffic is limited to the peers of each training container. SageMaker still performs download and upload operations against Amazon S3 using your SageMaker execution role in isolation from the training or inference container.

The following managed SageMaker containers do not support network isolation because they require access to Amazon S3:

- Chainer
- SageMaker Reinforcement Learning

### Network isolation with a VPC

Network isolation can be used in conjunction with a VPC. In this scenario, the download and upload of customer data and model artifacts are routed through your VPC subnet. However, the training and
inference containers themselves continue to be isolated from the network, and do not have access to any resource within your VPC or on the internet.

**Connect to SageMaker Through a VPC Interface Endpoint**

You can connect directly to the SageMaker API or to the SageMaker Runtime through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the internet. When you use a VPC interface endpoint, communication between your VPC and the SageMaker API or Runtime is conducted entirely and securely within the AWS network.

The SageMaker API and Runtime support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.

The VPC interface endpoint connects your VPC directly to the SageMaker API or Runtime without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. The instances in your VPC don't need public IP addresses to communicate with the SageMaker API or Runtime.

You can create an interface endpoint to connect to SageMaker or to SageMaker Runtime with either the AWS console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint.

After you have created a VPC endpoint, you can use the following example CLI commands that use the endpoint-url parameter to specify interface endpoints to the SageMaker API or Runtime:

```bash
aws sagemaker list-notebook-instances --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com

aws sagemaker list-training-jobs --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com

aws sagemaker-runtime invoke-endpoint --endpoint-url VPC_Endpoint_ID.runtime.sagemaker.Region.vpce.amazonaws.com \
  --endpoint-name Endpoint_Name \
  --body "Endpoint_Body" \
  --content-type "Content_Type" \n  Output_File
```

If you enable private DNS hostnames for your VPC endpoint, you don't need to specify the endpoint URL. The SageMaker API DNS hostname that the CLI and SageMaker SDK use by default (https://api.sagemaker.Region.amazon.com) resolves to your VPC endpoint. Similarly, the SageMaker Runtime DNS hostname that the CLI and SageMaker Runtime SDK use by default (https://runtime.sagemaker.Region.amazonaws.com) resolves to your VPC endpoint.

The SageMaker API and Runtime support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available. SageMaker supports making calls to all of its Operations inside your VPC. The result AuthorizedUrl from the CreatePresignedNotebookInstanceUrl is not supported by AWS PrivateLink. For information about how to enable AWS PrivateLink for the authorized URL that users use to connect to a notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 3169).

To learn more about AWS PrivateLink, see the AWS PrivateLink documentation. Refer to VPC Pricing for the price of VPC endpoints. To learn more about VPC and endpoints, see Amazon VPC. For information about how to use identity-based AWS Identity and Access Management policies to restrict access to the SageMaker API and runtime, see Control Access to the SageMaker API by Using Identity-based Policies (p. 3088).
Create a VPC Endpoint Policy for SageMaker

You can create a policy for Amazon VPC endpoints for SageMaker to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

**Note**

VPC endpoint policies aren't supported for Federal Information Processing Standard (FIPS) SageMaker runtime endpoints for `runtime_InvokeEndpoint`.

The following example VPC endpoint policy specifies that all users who have access to the VPC interface endpoint are allowed to invoke the SageMaker hosted endpoint named `myEndpoint`.

```
{
  "Statement": [
    {
      "Action": "sagemaker:InvokeEndpoint",
      "Effect": "Allow",
      "Principal": "*"
    }
  ]
}
```

In this example, the following are denied:

- Other SageMaker API actions, such as `sagemaker:CreateEndpoint` and `sagemaker:CreateTrainingJob`.
- Invoking SageMaker hosted endpoints other than `myEndpoint`.

**Note**

In this example, users can still take other SageMaker API actions from outside the VPC. For information about how to restrict API calls to those from within the VPC, see Control Access to the SageMaker API by Using Identity-based Policies (p. 3088).

Create a VPC Endpoint Policy for Amazon SageMaker Feature Store

To create a VPC Endpoint for Amazon SageMaker Feature Store, use the following endpoint template, substituting your `VPC_Endpoint_ID.api` and `Region`:

```
VPC_Endpoint_ID.api.featurestore-runtime.sagemaker.Region.vpce.amazonaws.com
```

Connect to SageMaker Studio Through an Interface VPC Endpoint

You can connect to Amazon SageMaker Studio from your Amazon Virtual Private Cloud (Amazon VPC) through an interface endpoint in your VPC instead of connecting over the internet. When you use an interface VPC endpoint (interface endpoint), communication between your VPC and Studio is conducted entirely and securely within the AWS network.
SageMaker Studio supports interface endpoints that are powered by AWS PrivateLink. Each interface endpoint is represented by one or more Elastic network interfaces with private IP addresses in your VPC subnets.

You can create an interface endpoint to connect to Studio with either the AWS console or the AWS Command Line Interface (AWS CLI). For instructions, see Creating an interface endpoint. Make sure that you create interface endpoints for all of the subnets in your VPC from which you want to connect to Studio.

When you create an interface endpoint, ensure that the security groups on your endpoint allow inbound access for HTTPS traffic from the security groups associated with SageMaker Studio. For more information, see Control access to services with VPC endpoints.

Note
In addition to creating an interface endpoint to connect to SageMaker Studio, create an interface endpoint to connect to the Amazon SageMaker API. When users call CreatePresignedDomainUrl to get the URL to connect to Studio, that call goes through the interface endpoint used to connect to the SageMaker API.

When you create the interface endpoint, specify `aws.sagemaker.Region.studio` as the service name. After you create the interface endpoint, enable private DNS for your endpoint. Anyone who uses the SageMaker API, the AWS CLI, or the console to connect to SageMaker Studio from within the VPC connects to Studio through the interface endpoint instead of the public internet. You also need to set up a custom DNS with private hosted zones for the Amazon VPC endpoint so SageMaker Studio can access the SageMaker API using the `api.sagemaker.$region.amazonaws.com` endpoint rather than using the VPC endpoint URL. For instructions on setting up a private hosted zone, see Working with private hosted zones.

Studio supports interface endpoints in all AWS Regions where both Amazon SageMaker and Amazon VPC are available.

Topics
- Create a VPC Endpoint Policy for SageMaker Studio (p. 3165)
- Allow Access Only from Within Your VPC (p. 3166)

Create a VPC Endpoint Policy for SageMaker Studio

You can attach an Amazon VPC endpoint policy to the interface VPC endpoints that you use to connect to SageMaker Studio. The endpoint policy controls access to Studio. You can specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

To use a VPC endpoint with SageMaker Studio, your endpoint policy must allow the CreateApp operation on the KernelGateway app type. This allows traffic that is routed to through the VPC endpoint to call the CreateApp API. The following example VPC endpoint policy shows how to allow the CreateApp operation.

```
{
  "Statement": [
    {
      "Action": "sagemaker:CreateApp",
      "Effect": "Allow",
      "Principal": "*"
    }
  ]
}
```
For more information, see Controlling access to services with VPC endpoints.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the user profiles in the SageMaker Studio domain with the specified domain ID. Access to other domains is denied.

```json
{
    "Statement": [
        {
            "Action": "sagemaker:CreatePresignedDomainUrl",
            "Effect": "Allow",
            "Principal": "*"
        }
    ]
}
```

**Allow Access Only from Within Your VPC**

Users outside your VPC can connect to SageMaker Studio over the internet even if you set up an interface endpoint in your VPC.

To allow access to only connections made from within your VPC, create an AWS Identity and Access Management (IAM) policy to that effect. Add that policy to every IAM user, group, or role used to access Studio. This feature is only supported in IAM mode, and is not supported in SSO mode. The following examples demonstrate how to create such policies.

**Important**

If you apply an IAM policy similar to one of the following examples, users can't access SageMaker Studio or the specified SageMaker APIs through the SageMaker console. To access Studio, users must use a presigned URL or call the SageMaker APIs directly.

**Example 1: Allow connections only within the subnet of an interface endpoint**

The following policy allows connections only to callers within the subnet where you created the interface endpoint.

```json
{
    "Id": "sagemaker-studio-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceVpc": "vpc-111bbaaa"
                }
            }
        }
    ]
}
```

**Example 2: Allow connections only through interface endpoints using aws:sourceVpce**
The following policy allows connections only to those made through the interface endpoints specified by the `aws:sourceVpce` condition key. For example, the first interface endpoint could allow access through the SageMaker Studio Control Panel. The second interface endpoint could allow access through the SageMaker API.

```json
{
    "Id": "sagemaker-studio-example-2",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:sourceVpce": [
                        "vpce-111bbccc",
                        "vpce-111bbddd"
                    ]
                }
            }
        }
    ]
}
```

This policy includes the `DescribeUserProfile` action. Typically you call `DescribeUserProfile` to make sure that the status of the user profile is `InService` before you try to connect to the domain. For example:

```
aws sagemaker describe-user-profile
  --domain-id domain-id
  --user-profile-name profile-name
```

Response:

```json
{
    "DomainId": "domain-id",
    "UserProfileName": "profile-name",
    "HomeEfsFileSystemUid": "200001",
    "Status": "InService",
    "LastModifiedDate": 1605418785.555,
    "CreationTime": 1605418477.297
}
```

```
aws sagemaker create-presigned-domain-url
  --domain-id domain-id
  --user-profile-name profile-name
```

Response:

```json
{
    "AuthorizedUrl": "https://domain-id.studio.us-west-2.sagemaker.aws/auth?token=AuthToken"
}
```
For both of these calls, if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the following example shows a call to `create-presigned-domain-url`:

```
aws sagemaker create-presigned-domain-url
  --domain-id domain-id
  --user-profile-name profile-name
  --endpoint-url vpc-endpoint-id.api.sagemaker.Region.vpce.amazonaws.com
```

Example 3: Allow connections from IP addresses using `aws:SourceIp`

The following policy allows connections only from the specified range of IP addresses using the `aws:SourceIp` condition key.

```
{
    "Id": "sagemaker-studio-example-3",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": [
                        "192.0.2.0/24",
                        "203.0.113.0/24"
                    ]
                }
            }
        }
    ]
}
```

Example 4: Allow connections from IP addresses through an interface endpoint using `aws:VpcSourceIp`

If you are accessing SageMaker Studio through an interface endpoint, you can use the `aws:VpcSourceIp` condition key to allow connections only from the specified range of IP addresses within the subnet where you created the interface endpoint as shown in the following policy:

```
{
    "Id": "sagemaker-studio-example-4",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable SageMaker Studio Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedDomainUrl",
                "sagemaker:DescribeUserProfile"
            ],
            "Resource": "*",
            "Condition": {
                "IpAddress": {
                    "aws:SourceIp": [
                        "192.0.2.0/24",
                        "203.0.113.0/24"
                    ]
                }
            }
        }
    ]
}
```
Connect to SageMaker Through a VPC Interface Endpoint

You can connect to your notebook instance from your VPC through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the public internet. When you use a VPC interface endpoint, communication between your VPC and the notebook instance is conducted entirely and securely within the AWS network.

SageMaker notebook instances support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.

Note
Before you create an interface VPC endpoint to connect to a notebook instance, create an interface VPC endpoint to connect to the SageMaker API. That way, when users call CreatePresignedNotebookInstanceUrl to get the URL to connect to the notebook instance, that call also goes through the interface VPC endpoint. For information, see Connect to SageMaker Through a VPC Interface Endpoint (p. 3163).

You can create an interface endpoint to connect to your notebook instance with either the AWS console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint. Make sure that you create an interface endpoint for all of the subnets in your VPC from which you want to connect to the notebook instance.

When you create the interface endpoint, specify `aws.sagemaker.region.notebook` as the service name. After you create a VPC endpoint, enable private DNS for your VPC endpoint. Anyone using the SageMaker API, the AWS CLI, or the console to connect to the notebook instance from within the VPC connects to the notebook instance through the VPC endpoint instead of the public internet.

SageMaker notebook instances support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available.

Topics
- Connect Your Private Network to Your VPC (p. 3169)
- Create a VPC Endpoint Policy for SageMaker Notebook Instances (p. 3170)
- Restrict Access to Connections from Within Your VPC (p. 3170)

Connect Your Private Network to Your VPC

To connect to your notebook instance through your VPC, you either have to connect from an instance that is inside the VPC, or connect your private network to your VPC by using an AWS Virtual Private Network (AWS VPN) or AWS Direct Connect. For information about AWS VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.
Create a VPC Endpoint Policy for SageMaker Notebook Instances

You can create a policy for Amazon VPC endpoints for SageMaker notebook instances to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the notebook instance named myNotebookInstance.

```json
{
    "Statement": [
        {
            "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
            "Effect": "Allow",
            "Principal": "*"
        }
    ]
}
```

Access to other notebook instances is denied.

Restrict Access to Connections from Within Your VPC

Even if you set up an interface endpoint in your VPC, individuals outside the VPC can connect to the notebook instance over the internet.

**Important**

If you apply an IAM policy similar to one of the following, users can’t access the specified SageMaker APIs or the notebook instance through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the notebook instance.

**Note**

This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
    "Id": "notebook-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable Notebook Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedNotebookInstanceUrl",
                "sagemaker:DescribeNotebookInstance"
            ],
            "Resource": "*",
```
If you want to restrict access to the notebook instance to only connections made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```
{
    "Id": "notebook-example-1",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable Notebook Access",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePresignedNotebookInstanceUrl",
                "sagemaker:DescribeNotebookInstance"
            ],
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:sourceVpce": [
                        "vpce-111bbccc",
                        "vpce-111bbddd"
                    ]
                }
            }
        }
    ]
}
```

Both of these policy examples assume that you have also created an interface endpoint for the SageMaker API. For more information, see Connect to SageMaker Through a VPC Interface Endpoint (p. 3163). In the second example, one of the values for `aws:SourceVpce` is the ID of the interface endpoint for the notebook instance. The other is the ID of the interface endpoint for the SageMaker API.

The policy examples here include `DescribeNotebookInstance`, because typically you would call `DescribeNotebookInstance` to make sure that the `NotebookInstanceStatus` is `InService` before you try to connect to it. For example:

```
aws sagemaker describe-notebook-instance --notebook-instance-name myNotebookInstance
```

```
{
    "NotebookInstanceName": "myNotebookInstance",
    "NotebookInstanceStatus": "InService",
    "Url": "mynotebookinstance.notebook.us-west-2.sagemaker.aws",
    "InstanceType": "ml.m4.xlarge",
    "RoleArn": "arn:aws:iam::1234567890ab:role/service-role/AmazonSageMaker-ExecutionRole-12345678T123456",
    "LastModifiedTime": 1540334777.501
}
```
Give SageMaker Access to Resources in your Amazon VPC

SageMaker runs the following job types in an Amazon Virtual Private Cloud by default.

- Processing
- Training
- Model hosting
- Batch transform
- Amazon SageMaker Clarify
- SageMaker Compilation

However, containers for these jobs access AWS resources—such as the Amazon Simple Storage Service (Amazon S3) buckets where you store training data and model artifacts—over the internet.

To control access to your data and job containers, we recommend that you create a private VPC and configure it so that they aren't accessible over the internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your job containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your job containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create jobs by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your job...
containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

Topics
- Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC (p. 3173)
- Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 3175)
- Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 3178)
- Give Batch Transform Jobs Access to Resources in Your Amazon VPC (p. 3181)
- Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC (p. 3184)
- Give SageMaker Compilation Jobs Access to Resources in Your Amazon VPC (p. 3187)

Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC

To control access to your data and processing jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your processing containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your processing containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for processing jobs.

Configure a Processing Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the NetworkConfig.VpcConfig request parameter of the CreateProcessingJob API, or provide this information when you create a processing job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your processing containers. The network interfaces provide your processing containers with a network connection within your VPC that is not connected to the internet. They also enable your processing job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateProcessingJob:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Processing

When configuring the private VPC for your SageMaker processing jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 3174)
- Create an Amazon S3 VPC Endpoint (p. 3174)
Give SageMaker Access to Resources in your Amazon VPC

- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3174)
- Configure Route Tables (p. 3175)
- Configure the VPC Security Group (p. 3175)
- Connect to Resources Outside Your VPC (p. 3175)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a processing job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that processing containers don't have access to the internet, they can’t connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your processing containers to access the buckets where you store your data. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint.
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. For VPC, choose the VPC you want to use for this endpoint.
5. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3174).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Processing Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the processing container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Effect": "Deny",
```
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your processing jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed processing, you must allow communication between the different containers in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For more information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, processing jobs that use that VPC do not have access to resources outside your VPC. If your processing job needs access to resources outside your VPC, provide access with one of the following options:

- If your processing job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your processing job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give SageMaker Training Jobs Access to Resources in Your Amazon VPC

**Note**

For training jobs, you can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.
Configure a Training Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the `VpcConfig` request parameter of the `CreateTrainingJob` API, or provide this information when you create a training job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your training containers. The network interfaces provide your training containers with a network connection within your VPC that is not connected to the internet. They also enable your training job to connect to resources in your private VPC.

The following is an example of the `VpcConfig` parameter that you include in your call to `CreateTrainingJob`:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Training

When configuring the private VPC for your SageMaker training jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 3176)
- Create an Amazon S3 VPC Endpoint (p. 3176)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3177)
- Configure Route Tables (p. 3177)
- Configure the VPC Security Group (p. 3178)
- Connect to Resources Outside Your VPC (p. 3178)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a training job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that training containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your training data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your training containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, search for `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3177).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Training Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRepositoryAccess",
      "Principal": "*",
      "Action": ["s3:GetObject"],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::packages.*.amazonaws.com/*",
        "arn:aws:s3:::repo.*.amazonaws.com/*"
      ]
    }
  ]
}
```

```
{
  "Statement": [
    {
      "Sid": "AmazonLinux2AMIRepositoryAccess",
      "Principal": "*",
      "Action": ["s3:GetObject"],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
      ]
    }
  ]
}
```

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your training jobs resolve by
configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed training, you must allow communication between the different containers in the same training job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, training jobs that use that VPC do not have access to resources outside your VPC. If your training job needs access to resources outside your VPC, provide access with one of the following options:

- If your training job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

- If your training job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC

Configure a Model for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

Note
You must create at least two subnets in different availability zones in your private VPC, even if you have only one hosting instance.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Hosting

When configuring the private VPC for your SageMaker models, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
Ensure That Subnets Have Enough IP Addresses (p. 3179)
Create an Amazon S3 VPC Endpoint (p. 3179)
Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 3179)
Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies (p. 3180)
Configure Route Tables (p. 3180)
Connect to Resources Outside Your VPC (p. 3181)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each model instance. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an Amazon S3 VPC endpoint:
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint.
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the AWS Region where your VPC resides.
4. For VPC, choose the VPC that you want to use for this endpoint.
5. For Configure route tables, choose the route tables for the endpoint to use. The VPC service automatically adds a route to each route table that you choose that points Amazon S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the Amazon S3 service by any user or service within the VPC. To restrict access further, choose Custom. For more information, see Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 3179).

Use a Custom Endpoint Policy to Restrict Access to Amazon S3

The default endpoint policy allows full access to Amazon Simple Storage Service (Amazon S3) for any user or service in your VPC. To further restrict access to Amazon S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3.

You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Model Container with a Custom Endpoint Policy

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the model container. If you don't want users to install packages from those repositories, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRepositoryAccess",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": "arn:aws:s3:::aws-elastic映射表/AMIScript*",
      "Effect": "Deny",
      "Condition": {
        "StringNotLike": {
          "aws:SourceIp": ["10.0.0.0/8", "172.16.0.0/12", "192.168.0.0/16"]
        }
      }
    }
  ]
}
```
Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker to create an elastic network interface and attach it to model containers running in a VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for VPC access.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeVpcs",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:CreateNetworkInterface"
      ],
      "Resource": "*"
    }
  ]
}
```

For more information about the SageMakerFullAccess managed policy, see AmazonSageMakerFullAccess (p. 3132).

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings,
ensure that the URLs that you use to specify the locations of the data in your models resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

**Connect to Resources Outside Your VPC**

If you configure your VPC so that it doesn't have internet access, models that use that VPC do not have access to resources outside your VPC. If your model needs access to resources outside your VPC, provide access with one of the following options:

- If your model needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your model needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

**Give Batch Transform Jobs Access to Resources in Your Amazon VPC**

To control access to your data and batch transform jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. You specify your private VPC configuration when you create a model by specifying subnets and security groups. You then specify the same model when you create a batch transform job. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your model containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

This document explains how to add Amazon VPC configurations for batch transform jobs.

**Configure a Batch Transform Job for Amazon VPC Access**

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. Then specify the same model in the ModelName request parameter of the CreateTransformJob API, or in the Model name field when you create a transform job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your transform job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

```json
VpcConfig: {
    "Subnets": ["subnet-0123456789abcdef0","subnet-0123456789abcdef1","subnet-0123456789abcdef2"],
    "SecurityGroupIds": ["sg-0123456789abcdef0"]
}
```
If you are creating a model using the CreateModel API operation, the IAM execution role that you use to create your model must include the permissions described in CreateModel API: Execution Role Permissions (p. 3113), including the following permissions required for a private VPC.

When creating a model in the console, if you select Create a new role in the Model Settings section, the AmazonSageMakerFullAccess policy used to create the role already contains these permissions. If you select Enter a custom IAM role ARN or Use existing role, the role ARN that you specify must have an execution policy attached with the following permissions.

```json
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
    ]
}
```

 Configure Your Private VPC for SageMaker Batch Transform

When configuring the private VPC for your SageMaker batch transform jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

**Topics**

- Ensure That Subnets Have Enough IP Addresses (p. 3182)
- Create an Amazon S3 VPC Endpoint (p. 3182)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3183)
- Configure Route Tables (p. 3183)
- Configure the VPC Security Group (p. 3184)
- Connect to Resources Outside Your VPC (p. 3184)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a transform job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

**To create an S3 VPC endpoint:**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**
3. For **Service Name**, choose `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. For **VPC**, choose the VPC you want to use for this endpoint.
5. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.

6. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3183).

### Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

### Restrict Package Installation on the Model Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [{
        "Sid": "AmazonLinuxAMIMRepositoryAccess",
        "Principal": "*",
        "Action": [
            "s3:GetObject"
        ],
        "Effect": "Deny",
        "Resource": [
            "arn:aws:s3:::packages.*.amazonaws.com/**",
            "arn:aws:s3:::repo.*.amazonaws.com/**"
        ]
    }
}

{
    "Statement": [{
        "Sid": "AmazonLinux2AMIRepositoryAccess",
        "Principal": "*",
        "Action": [
            "s3:GetObject"
        ],
        "Effect": "Deny",
        "Resource": [
            "arn:aws:s3:::amazonlinux.*.amazonaws.com/**"
        ]
    }
}
```

### Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your batch transform jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.
Configure the VPC Security Group

In distributed batch transform, you must allow communication between the different containers in the same batch transform job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, batch transform jobs that use that VPC do not have access to resources outside your VPC. If your batch transform job needs access to resources outside your VPC, provide access with one of the following options:

- If your batch transform job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your batch transform job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give Amazon SageMaker Clarify Jobs Access to Resources in Your Amazon VPC

To control access to your data and SageMaker Clarify jobs, we recommend that you create a private Amazon VPC and configure it so that your jobs aren't accessible over the public internet. For information about creating and configuring an Amazon VPC for processing jobs, see Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC.

This document explains how to add additional Amazon VPC configurations that meet the requirements for SageMaker Clarify jobs.

Topics
- Configure a SageMaker Clarify Job for Amazon VPC Access (p. 3184)
- Configure Your Private Amazon VPC for SageMaker Clarify jobs (p. 3186)

Configure a SageMaker Clarify Job for Amazon VPC Access

You need to specify subnets and security groups when configuring your private Amazon VPC for SageMaker Clarify jobs and to enable the job to get inferences from the SageMaker model when computing post-training bias metrics and feature contributions that help explain model predictions.

Topics
- SageMaker Clarify Job Amazon VPC Subnets and Security Groups (p. 3184)
- Configure a Model Amazon VPC for Inference (p. 3185)

SageMaker Clarify Job Amazon VPC Subnets and Security Groups

Subnets and security groups in your private Amazon VPC can be assigned to a SageMaker Clarify job in various ways, depending on how you create the job.

- SageMaker console: Provide this information when you create the job in the SageMaker Dashboard. From the Processing menu, choose Processing jobs, then choose Create processing job. Select the
**VPC** option in the **Network** panel and provide the subnets and security groups using the dropdown lists. Make sure network isolation option provided in this panel is set to disabled.

- **SageMaker API**: Use the `NetworkConfig.VpcConfig` request parameter of the `CreateProcessingJob` API, as shown in the following example:

```json
"NetworkConfig": {
"VpcConfig": {
"Subnets": [
"subnet-0123456789abcdef0",
"subnet-0123456789abcdef1",
"subnet-0123456789abcdef2"
],
"SecurityGroupIds": [
"sg-0123456789abcdef0"
]
}
}
```

- **SageMaker Python SDK**: Use the `NetworkConfig` parameter of the `SageMakerClarifyProcessor` API or `Processor` API, as shown in the following example:

```python
from sagemaker.network import NetworkConfig
network_config = NetworkConfig(
    subnets=[
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2",
    ],
    security_group_ids=[
        "sg-0123456789abcdef0",
    ],
)
```

SageMaker uses the information to create network interfaces and attach them to the SageMaker Clarify job. The network interfaces provide a SageMaker Clarify job with a network connection within your Amazon VPC that is not connected to the public internet. They also enable the SageMaker Clarify job to connect to resources in your private Amazon VPC.

**Configure a Model Amazon VPC for Inference**

In order to compute post-training bias metrics and explainability, the SageMaker Clarify job needs to get inferences from the SageMaker model that is specified by the `model_name` parameter of the analysis configuration for the SageMaker Clarify processing job. Alternatively, if you use the SageMakerClarifyProcessor API in the SageMaker Python SDK, the job needs to get the `model_name` specified by the `ModelConfig` class. To accomplish this, the SageMaker Clarify job creates an ephemeral endpoint with the model, known as a **shadow endpoint**, and then applies the Amazon VPC configuration of the model to the shadow endpoint.

**Note**

The network isolation option of both the SageMaker Clarify job and the model must be disabled (by default the option is disabled) so that the SageMaker Clarify job can communicate with the shadow endpoint.

To specify subnets and security groups in your private Amazon VPC to the SageMaker model, use the `VpcConfig` request parameter of the `CreateModel` API or provide this information when you create the model using the SageMaker dashboard in the console. The following is an example of the `VpcConfig` parameter that you include in your call to `CreateModel`:

```json
"VpcConfig": {
```
You can specify the number of instances of the shadow endpoint to launch with the `initial_instance_count` parameter of the analysis configuration for the SageMaker Clarify processing job. Alternatively, if you use the `SageMakerClarifyProcessor` API in the SageMaker Python SDK, the job needs to get the `instance_count` specified by the ModelConfig class.

**Note**
Even if you only request one instance when creating the shadow endpoint, you need at least two subnets in the model's ModelConfig in distinct availability zones. Otherwise the shadow endpoint creation fails with the following error:

```
ClientError: Error hosting endpoint sagemaker-clarify-endpoint-XXX: Failed. Reason: Unable to locate at least 2 availability zone(s) with the requested instance type YYY that overlap with SageMaker subnets.
```

If your model requires model files in Amazon S3, then the model Amazon VPC needs to have an Amazon S3 VPC endpoint. For more information about creating and configuring an Amazon VPC for SageMaker models, see [Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC](p. 3178).

### Configure Your Private Amazon VPC for SageMaker Clarify jobs

In general, you can follow the steps in Configure Your Private VPC for SageMaker Processing to configure your private Amazon VPC for SageMaker Clarify jobs. Here are some highlights and special requirements for SageMaker Clarify jobs.

**Topics**
- Connect to Resources Outside Your Amazon VPC (p. 3186)
- Configure the Amazon VPC Security Group (p. 3187)

**Connect to Resources Outside Your Amazon VPC**

If you configure your Amazon VPC so that it does not have public internet access, then some additional setup is required to grant SageMaker Clarify jobs access to resources and services outside of your Amazon VPC. For example, an Amazon S3 VPC endpoint is required because a SageMaker Clarify job needs to load a dataset from an S3 bucket as well as save the analysis results to an S3 bucket. For more information, see [Create an Amazon S3 VPC Endpoint](p. 3178) for the creation guide. In addition, if a SageMaker Clarify job needs to get inferences from the shadow endpoint, then it needs to call several more AWS services.

- **Create an Amazon SageMaker API service VPC endpoint**: The SageMaker Clarify job needs to call the Amazon SageMaker API service to manipulate the shadow endpoint, or to describe a SageMaker model for Amazon VPC validation. You can follow the guidance provided in the Securing all Amazon SageMaker API calls with AWS PrivateLink blog to create an Amazon SageMaker API VPC endpoint that allows the SageMaker Clarify job to make the service calls. Note that the service name of Amazon SageMaker API service is `com.amazonaws.region.sagemaker.api`, where `region` is the name of the Region where your Amazon VPC resides.

- **Create an Amazon SageMaker Runtime VPC Endpoint**: The SageMaker Clarify job needs to call the Amazon SageMaker runtime service, which routes the invocations to the shadow endpoint. The setup steps are similar to those for the Amazon SageMaker API service. Note that the service name
of Amazon SageMaker Runtime service is 
com.amazonaws.region.sagemaker.runtime, where 
region is the name of the Region where your Amazon VPC resides.

Configure the Amazon VPC Security Group

SageMaker Clarify jobs support distributed processing when two or more processing instances are specified in one of the following ways:

- **SageMaker console**: The Instance count is specified in the Resource configuration part of the Job settings panel on the Create processing job page.
- **SageMaker API**: The InstanceCount is specified when you create the job with the CreateProcessingJob API.
- **SageMaker Python SDK**: The instance_count is specified when using the SageMakerClarifyProcessor API or the Processor API.

In distributed processing, you must allow communication between the different instances in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security group rules.

Give SageMaker Compilation Jobs Access to Resources in Your Amazon VPC

**Note**
For compilation jobs, you can configure only subnets with a default tenancy VPC in which your job runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

Configure a Compilation Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateCompilationJob API, or provide this information when you create a compilation job in the SageMaker console. SageMaker Neo uses this information to create network interfaces and attach them to your compilation jobs. The network interfaces provide compilation jobs with a network connection within your VPC that is not connected to the internet. They also enable your compilation job to connect to resources in your private VPC. The following is an example of the VpcConfig parameter that you include in your call to CreateCompilationJob:

```json
VpcConfig: {
  "Subnets": [
    "subnet-0123456789abcdef0",
    "subnet-0123456789abcdef1",
    "subnet-0123456789abcdef2"
  ],
  "SecurityGroupIds": [
    "sg-0123456789abcdef0"
  ]
}
```

Configure Your Private VPC for SageMaker Compilation

When configuring the private VPC for your SageMaker compilation jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

**Topics**
- Ensure That Subnets Have Enough IP Addresses (p. 3188)
- Create an Amazon S3 VPC Endpoint (p. 3188)
• Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3188)
• Configure Route Tables (p. 3189)
• Configure the VPC Security Group (p. 3189)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a compilation job.
For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC to block access to the internet, SageMaker Neo can't connect to the Amazon S3 buckets that contain your models unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your SageMaker Neo compilation jobs to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, search for com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 3177).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies. The following is a sample customized policy:

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Deny",
        "Principal": { "AWS": "*" },
        "Action": "s3:GetObject",
        "Resource": [ "arn:aws:s3:::your-sample-bucket", "arn:aws:s3:::your-sample-bucket/" ],
        "Condition": {
            "StringNotEquals": { "aws:SourceVpce": [ "*" ] }
        }
    }]
}
```
Add Permissions for Compilation Job Running in a Amazon VPC to Custom IAM Policies

The SageMakerFullAccess managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker Neo to create an elastic network interface and attach it to compilation job running in a Amazon VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for Amazon VPC access.

```json
```

For more information about the SageMakerFullAccess managed policy, see AmazonSageMakerFullAccess (p. 3132).

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your compilation jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In your security group for the compilation job, you must allow outbound communication to your Amazon S3 Amazon VPC endpoints and the subnet CIDR ranges used for the compilation job. For information, see Security Group Rules and Control access to services with Amazon VPC endpoints.
Monitor Amazon SageMaker

Monitoring is an important part of maintaining the reliability, availability, and performance of SageMaker and your other AWS solutions. AWS provides the following monitoring tools to watch SageMaker, report when something is wrong, and take automatic actions when appropriate:

- **Amazon CloudWatch** monitors your AWS resources and the applications that you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For example, you can have CloudWatch track CPU usage or other metrics of your Amazon EC2 instances and automatically launch new instances when needed. For more information, see the Amazon CloudWatch User Guide.

- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. Create CloudWatch Events rules react to a status change in a SageMaker training, hyperparameter tuning, or batch transform job.

Topics
- Monitor Amazon SageMaker with Amazon CloudWatch (p. 3190)
- Log Amazon SageMaker Events with Amazon CloudWatch (p. 3201)
- Log Amazon SageMaker API Calls with AWS CloudTrail (p. 3202)
- Automating Amazon SageMaker with Amazon EventBridge (p. 3205)

Monitor Amazon SageMaker with Amazon CloudWatch

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. However, the Amazon CloudWatch console limits the search to metrics that were updated in the last 2 weeks. This limitation ensures that the most current jobs are shown in your namespace. To graph metrics without using a search, specify its exact name in the source view. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met. For more information, see the Amazon CloudWatch User Guide.

SageMaker Metrics and Dimensions
- SageMaker Endpoint Invocation Metrics (p. 3191)
- SageMaker Multi-Model Endpoint Metrics (p. 3192)
- SageMaker Jobs and Endpoint Metrics (p. 3194)
- SageMaker Ground Truth Metrics (p. 3197)
- SageMaker Feature Store Metrics (p. 3199)
- SageMaker Pipelines Metrics (p. 3199)
# SageMaker Endpoint Invocation Metrics

The `AWS/SageMaker` namespace includes the following request metrics from calls to `InvokeEndpoint`

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the `Amazon CloudWatch API Reference`.

## Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of <code>InvokeEndpoint</code> requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocations</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of invocations sent to a model, normalized by <code>InstanceCount</code> in each ProductionVariant. ( \frac{1}{\text{numberOfInstances}} ) is sent as the value on each request, where <code>numberOfInstances</code> is the number of active instances for the ProductionVariant behind the endpoint at the time of the request. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The interval of time added to the time taken to respond to a client request by SageMaker overheads. This interval is measured from the time SageMaker receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. Overhead latency can vary depending on multiple factors, including request and response payload sizes, request frequency, and authentication/authorization of the request.</td>
</tr>
</tbody>
</table>
### Multi-Model Endpoint Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelSetupTime</td>
<td>The time it takes to launch new compute resources for a serverless endpoint. The time can vary depending on the model size, how long it takes to download the model, and the start-up time of the container.</td>
</tr>
<tr>
<td>Units: Microseconds</td>
<td>Valid statistics: Average, Min, Max, Sample Count, Percentiles</td>
</tr>
</tbody>
</table>

### Dimensions for Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

### SageMaker Multi-Model Endpoint Metrics

The **AWS/SageMaker** namespace includes the following model loading metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the [Amazon CloudWatch API Reference](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_GetMetricStatistics.html).

#### Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelLoadingWaitTime</td>
<td>The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference.</td>
</tr>
<tr>
<td>Units: Microseconds</td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelUnloadingTime</td>
<td>The interval of time that it took to unload the model through the container's UnloadModel API call.</td>
</tr>
<tr>
<td>Units: Microseconds</td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelDownloadingTime</td>
<td>The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3).</td>
</tr>
<tr>
<td>Units: Microseconds</td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>
## Multi-Model Endpoint Metrics

### Metric | Description
--- | ---
ModelLoadingTime | The interval of time that it took to load the model through the container's `LoadModel` API call.  
Units: Microseconds  
Valid statistics: Average, Sum, Min, Max, Sample Count

ModelCacheHit | The number of `InvokeEndpoint` requests sent to the multi-model endpoint for which the model was already loaded.  
The Average statistic shows the ratio of requests for which the model was already loaded.  
Units: None  
Valid statistics: Average, Sum, Sample Count

### Dimensions for Multi-Model Endpoint Model Loading Metrics

| Dimension | Description |
--- | --- |
EndpointName, VariantName | Filters endpoint invocation metrics for a `ProductionVariant` of the specified endpoint and variant.

The `/aws/sagemaker/Endpoints` namespaces include the following instance metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the Amazon CloudWatch API Reference.

### Multi-Model Endpoint Model Instance Metrics

| Metric | Description |
--- | --- |
LoadedModelCount | The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance.  
The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.  
The Sum statistic tells you the total number of models loaded across all instances in the endpoint.  
The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint.  
Units: None  
Valid statistics: Average, Sum, Min, Max, Sample Count

## SageMaker Jobs and Endpoint Metrics

The `/aws/sagemaker/ProcessingJobs`, `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` namespaces include the following metrics for the training jobs and endpoint instances.

Metrics are available at a 1-minute frequency.

**Note**
Amazon CloudWatch supports high-resolution custom metrics and its finest resolution is 1 second. However, the finer the resolution, the shorter the lifespan of the CloudWatch metrics. For the 1-second frequency resolution, the CloudWatch metrics are available for 3 hours. For more information about the resolution and the lifespan of the CloudWatch metrics, see `GetMetricStatistics` in the Amazon CloudWatch API Reference.

**Tip**
If you want to profile your training job with a finer resolution down to 100-millisecond (0.1 second) granularity and store the training metrics indefinitely in Amazon S3 for custom analysis at any time, consider using Amazon SageMaker Debugger. SageMaker Debugger provides built-in rules to automatically detect common training issues; it detects hardware resource utilization issues (such as CPU, GPU, and I/O bottlenecks) and non-converging model issues (such as overfit, vanishing gradients, and exploding tensors). SageMaker Debugger also provides visualizations through Studio and its profiling report. To explore the Debugger visualizations, see SageMaker Debugger Insights Dashboard Walkthrough, Debugger Profiling Report Walkthrough, and Analyze Data Using the SMDebug Client Library.

### Processing Job, Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>

<tbody>
<tr>
<td>FeatureGroupName, OperationName</td>
<td>Filters feature store runtime operation metrics of the specified feature group.</td>
</tr>
</tbody>
</table>

### SageMaker Pipelines Metrics

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline executions.

Two categories of Pipelines execution metrics are available:
• **Execution Metrics across All Pipelines** – Account level pipeline execution metrics (for all pipelines in the current account)
• **Execution Metrics by Pipeline** – Pipeline execution metrics per pipeline

Metrics are available at a 1-minute frequency.

**Pipelines Execution Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExecutionStarted</td>
<td>The number of pipeline executions that started.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionFailed</td>
<td>The number of pipeline executions that failed.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionSucceeded</td>
<td>The number of pipeline executions that succeeded.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionStopped</td>
<td>The number of pipeline executions that stopped.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>ExecutionDuration</td>
<td>The duration in milliseconds that the pipeline execution ran.</td>
</tr>
<tr>
<td></td>
<td>Units: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
</tbody>
</table>

**Dimensions for Execution Metrics by Pipeline**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PipelineName</td>
<td>Filters pipeline execution metrics for a specified pipeline.</td>
</tr>
</tbody>
</table>

**Pipelines Step Metrics**

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline steps.

Metrics are available at a 1-minute frequency.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StepStarted</td>
<td>The number of steps that started.</td>
</tr>
</tbody>
</table>
### Metric Description

<table>
<thead>
<tr>

### Log Amazon SageMaker Events with Amazon CloudWatch

To help you debug your compilation jobs, processing jobs, training jobs, endpoints, transform jobs, notebook instances, and notebook instance lifecycle configurations, anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` is also sent to Amazon CloudWatch Logs. In addition to debugging, you can use these for progress analysis.

#### Logs

The following table lists all of the logs provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/CompilationJobs</td>
<td>[compilation-job-name]</td>
</tr>
</tbody>
</table>
### Log Group Name | Log Stream Name
--- | ---
/aws/sagemaker/Endpoints/[EndpointName] | [production-variant-name]/[instance-id]
 | [production-variant-name]/[instance-id]/[container-name provided in SageMaker model] (For Inference Pipelines)
/aws/sagemaker/groundtruth/WorkerActivity | aws/sagemaker/groundtruth/worker-activity/[requester-AWS-Id]-[region]/[timestamp]
/aws/sagemaker/LabelingJobs | [labeling-job-name]
/aws/sagemaker/NotebookInstances | [notebook-instance-name]/[LifecycleConfigHook]
 | [notebook-instance-name]/jupyter.log
/aws/sagemaker/ProcessingJobs | [processing-job-name]/[hostname]-[epoch_timestamp]
/aws/sagemaker/studio | [domain-id]/[user-profile-name]/[app-type]/[app-name]
 | [domain-id]/domain-shared/rstudioserverpro/default
/aws/sagemaker/TrainingJobs | [training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]
/aws/sagemaker/TransformJobs | [transform-job-name]/[instance-id]-[epoch_timestamp]
 | [transform-job-name]/[instance-id]-[epoch_timestamp]/data-log
 | [transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in SageMaker model] (For Inference Pipelines)

**Note**
1. The /aws/sagemaker/NotebookInstances/[LifecycleConfigHook] log stream is created when you create a notebook instance with a lifecycle configuration. For more information, see [Customize a Notebook Instance Using a Lifecycle Configuration Script](p. 243).
2. For Inference Pipelines, if you don't provide container names, the platform uses **container-1, container-2**, and so on, corresponding to the order provided in the SageMaker model.

For more information about logging events with CloudWatch logging, see [What is Amazon CloudWatch Logs?](in the [Amazon CloudWatch User Guide](.)

## Log Amazon SageMaker API Calls with AWS CloudTrail

Amazon SageMaker is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in SageMaker. CloudTrail captures all API calls for SageMaker, with the exception of `InvokeEndpoint` and `InvokeEndpointAsync`, as events. The calls captured include calls from the SageMaker console and code calls to the SageMaker API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for SageMaker. If you don't configure a trail, you can still view the most recent events in the CloudTrail...
console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/Creating-A-CloudTrail-Trail.html).

By default, log data is stored in CloudWatch Logs indefinitely. However, you can configure how long to store log data in a log group. For information, see [Change Log Data Retention in CloudWatch Logs](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/EnableLogsRetentionPolicy.html) in the *Amazon CloudWatch Logs User Guide*.

**SageMaker Information in CloudTrail**

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon SageMaker, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailOverview.html).

For an ongoing record of events in your AWS account, including events for Amazon SageMaker, create a trail. A **trail** enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for Creating a Trail](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailOverview.html)
- [CloudTrail Supported Services and Integrations](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailSupportedServices.html)
- [Configuring Amazon SNS Notifications for CloudTrail](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailSNS.html)
- [Receiving CloudTrail Log Files from Multiple Regions](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailSNS.html) and [Receiving CloudTrail Log Files from Multiple Accounts](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailSNS.html)

All SageMaker actions, with the exception of **InvokeEndpoint** and **InvokeEndpointAsync**, are logged by CloudTrail and are documented in the **Operations**. For example, calls to the **CreateTrainingJob**, **CreateEndpoint** and **CreateNotebookInstance** actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/CloudTrailOverview.html).

**Operations Performed by Automatic Model Tuning**

SageMaker supports logging non-API service events to your CloudTrail log files for automatic model tuning jobs. These events are related to your tuning jobs but, are not the direct result of a customer request to the public AWS API. For example, when you create a hyperparameter tuning job by calling **CreateHyperParameterTuningJob**, SageMaker creates training jobs to evaluate various combinations of hyperparameters to find the best result. Similarly, when you call **StopHyperParameterTuningJob** to stop a hyperparameter tuning job, SageMaker might stop any of the associated running training jobs. Non-API events for your tuning jobs are logged to CloudTrail to help you improve governance, compliance, and operational and risk auditing of your AWS account.
Log entries that result from non-API service events have an eventType of AwsServiceEvent instead of AwsApiCall.

Understanding SageMaker Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following examples a log entry for the CreateEndpoint action, which creates an endpoint to deploy a trained model.

```
{"eventVersion":"1.05",
"userIdentity": {
"type":"IAMUser",
"principalId":"AIXDAYQEXAMPLEUMLYNGL",
"arn":"arn:aws:iam::123456789012:user/intern",
"accountId":"123456789012",
"accessKeyId":"ASXIAGXEXAMPLEQULKNXY",
"userName":"intern"
},
"eventTime":"2018-01-02T13:39:06Z",
"eventSource":"sagemaker.amazonaws.com",
"eventName":"CreateEndpoint",
"awsRegion":"us-west-2",
"sourceIP_ADDRESS":"127.0.0.1",
"userAgent":"USER_AGENT",
"requestParameters": {
"endpointName":"ExampleEndpoint",
"endpointConfigName":"ExampleEndpointConfig"
},
"responseElements": {
"endpointArn":"arn:aws:sagemaker:us-west-2:123456789012:endpoint/exampleendpoint"
},
"requestID":"6b1b42b9-EXAMPLE",
"eventID":"a6f85b21-EXAMPLE",
"eventType":"AwsApiCall",
"recipientAccountId":"444455556666"
}
```

The following example is a log entry for the CreateModel action, which creates one or more containers to host a previously trained model.

```
{"eventVersion": "1.05",
"userIdentity": {
"type": "IAMUser",
"principalId": "AIXDAYQEXAMPLEUMLYNGL",
"arn": "arn:aws:iam::123456789012:user/intern",
"accountId": "123456789012",
"accessKeyId": "ASXIAGXEXAMPLEQULKNXY",
"userName": "intern"
},
"eventTime": "2018-01-02T13:39:06Z",
"eventSource": "sagemaker.amazonaws.com",
"eventName": "CreateModel",
"awsRegion": "us-west-2",
"sourceIP_address": "127.0.0.1",
"userAgent": "USER_AGENT",
"requestParameters": {
"modelName": "ExampleModel",
"modelConfigName": "ExampleModelConfig"
},
"responseElements": {
"modelArn": "arn:aws:sagemaker:us-west-2:123456789012:model/examplemodel"
},
"requestID": "6b1b42b9-EXAMPLE",
"eventID": "a6f85b21-EXAMPLE",
"eventType": "AwsApiCall",
"recipientAccountId": "444455556666"
}
```
Automating Amazon SageMaker with Amazon EventBridge

Amazon EventBridge monitors status change events in Amazon SageMaker. EventBridge enables you to automate SageMaker and respond automatically to events such as a training job status change or endpoint status change. Events from SageMaker are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you, and what automated actions to take when an event matches a rule. For an example of how to create a rule, see Schedule a Pipeline with Amazon EventBridge (p. 2825).

Some examples of the actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an AWS SMS queue

**SageMaker events monitored by EventBridge**

- Training job state change (p. 3206)
- Hyperparameter tuning job state change (p. 3207)
- Transform job state change (p. 3208)
- Endpoint state change (p. 3209)
- Feature group state change (p. 3210)
- Model package state change (p. 3210)
- Pipeline execution state change (p. 3211)
- Pipeline step state change (p. 3212)
- SageMaker image state change (p. 3213)
- SageMaker image version state change (p. 3213)
- Endpoint deployment state change (p. 3214)
Training job state change

Indicates a change in the status of a SageMaker training job.

If the value of TrainingJobStatus is Failed, the event contains the FailureReason field, which provides a description of why the training job failed.

```json
{
  "version": "0",

}
```
Transform job state change

Indicates a change in the status of a SageMaker batch transform job.

If the value of TransformJobStatus is Failed, the event contains the FailureReason field, which provides a description of why the training job failed.

```json
{
  "version": "0",
  "id": "844e2571-85d4-695f-b930-0153b71dcb42",
  "detail-type": "SageMaker Transform Job State Change",

    }
  }
}
```
**Endpoint state change**

Indicates a change in the status of a SageMaker hosted real-time inference endpoint.

The following shows an event with an endpoint in the **IN_SERVICE** state.

```json
{
    "version": "0",
    "id": "d2921b5a-b0ad-cace-a8e3-0f159d018e06",
    "detail-type": "SageMaker Endpoint State Change",

    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "EndpointName": "MyEndpoint",
        "EndpointConfigName": "MyEndpointConfig",
        "ProductionVariants": [
            {
                "DesiredWeight": 1.0,
                "DesiredInstanceCount": 1.0
            }
        ],
        "EndpointStatus": "IN_SERVICE",
        "CreationTime": 159241199203.0,
        "LastModifiedTime": 1592411994287.0,
        "Tags": {
        }
    }
}
```
Feature group state change

Indicates a change either in the FeatureGroupStatus or the OfflineStoreStatus of a SageMaker feature group.

```
{
  "version": "0",
  "id": "93201303-abdb-36a4-1b9b-4c1c3e3671c0",

      }
    },
    "RoleArn": "arn:aws:iam::123456789012:role/SageMakerRole",
    "FeatureGroupStatus": "Active",
    "Tags": {}
  }
}
```
Pipeline execution state change

Indicates a change in the status of a SageMaker pipeline execution.
Pipeline step state change

Indicates a change in the status of a SageMaker pipeline step.

If there is a cache hit, the event contains the `cacheHitResult` field.

If the value of `currentStepStatus` is `Failed`, the event contains the `failureReason` field, which provides a description of why the step failed.

```json
{
  "version": "0",

  }
}
```
SageMaker image state change

Indicates a change in the status of a SageMaker image.

```json
{
  "version": "0",
  "id": "cee033a3-17d8-49f8-865f-b9ebf485d9ee",
  "detail-type": "SageMaker Image State Change",
  "source": "aws.sagemaker",

  "region": "us-east-1",
  "resources": ["arn:aws:sagemaker:us-west-2:123456789012:image/cee033a3-17d8-49f8-865f-b9ebf485d9ee"],
  "detail": {
    "ImageName": "cee033a3-17d8-49f8-865f-b9ebf485d9ee",
    "ImageArn": "arn:aws:sagemaker:us-west-2:123456789012:image/cee033a3-17d8-49f8-865f-b9ebf485d9ee",
    "ImageStatus": "Creating",
    "Version": 1.0,
    "Tags": {} 
  }
}
```

SageMaker image version state change

Indicates a change in the status of a SageMaker image version.

```json
{
  "version": "0",
  "id": "07fc4615-ebd7-15fc-1746-243411f09f04",
  "detail-type": "SageMaker Image Version State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "2021-04-29T01:29:59Z",
  "region": "us-east-1",
  "resources": ["arn:aws:sagemaker:us-west-2:123456789012:image-version/07800032-2d29-48b7-8f82-5129225b2a85"],
  "detail": {
    "ImageArn": "arn:aws:sagemaker:us-west-2:123456789012:image-version/07800032-2d29-48b7-8f82-5129225b2a85",
    "ImageVersionStatus": "Creating",
    "Version": 1.0,
    "Tags": {} 
  }
}
```

For more information about the status values and their meanings for SageMaker jobs, endpoints, and pipelines, see the following links:

- AlgorithmStatus
- EndpointStatus
- FeatureGroupStatus
- HyperParameterTuningJobStatus
- LabelingJobStatus
- ModelPackageStatus
For more information, see the Amazon EventBridge User Guide.

Important

The following examples may not work for all endpoints. For a list of features that may exclude your endpoint, see the Exclusions (p. 2590) page.

Indicates a state change for an endpoint deployment. The following example shows an endpoint updating with a blue/green canary deployment.

```json
{
  "version": "0",
  "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
  "detail-type": "SageMaker Endpoint Deployment State Change",
  "source": "aws.sagemaker",
  "account": "123456789012",
  "time": "2021-10-25T01:52:12Z",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "EndpointName": "sample-endpoint",
    "EndpointConfigName": "sample-endpoint-config-1",
    "ProductionVariants": [
      {
        "VariantName": "AllTraffic",
        "CurrentWeight": 1,
        "DesiredWeight": 1,
        "CurrentInstanceCount": 3,
        "DesiredInstanceCount": 3
      }
    ],
    "EndpointStatus": "UPDATING",
    "CreationTime": 1635195148181,
    "LastModifiedTime": 1635195148181,
    "Tags": {},
    "PendingDeploymentSummary": {
      "EndpointConfigName": "sample-endpoint-config-2",
      "StartTime": Timestamp,
      "ProductionVariants": [
        {
          "VariantName": "AllTraffic",
          "CurrentWeight": 1,
          "DesiredWeight": 1,
          "CurrentInstanceCount": 3,
          "DesiredInstanceCount": 3
        }
      ]
    }
  }
}
```
The following example indicates a state change for an endpoint deployment, which is being updated with new capacity on an existing endpoint configuration.

```json
{
    "version": "0",
    "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
    "detail-type": "SageMaker Endpoint Deployment State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-10-25T01:52:12Z",
    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "EndpointName": "sample-endpoint",
        "EndpointConfigName": "sample-endpoint-config-1",
        "ProductionVariants": [
            {
                "VariantName": "AllTraffic",
                "CurrentWeight": 1,
                "DesiredWeight": 1,
                "CurrentInstanceCount": 3,
                "DesiredInstanceCount": 6,
                "VariantStatus": [
                    {
                        "Status": "Updating",
                        "StatusMessage": "Scaling out desired instance count to 6.",
                        "StartTime": 1635195269181,
                    }
                ],
                "EndpointStatus": "UPDATING",
                "CreationTime": 1635195148181,
                "LastModifiedTime": 1635195148181,
                "Tags": {}
            }
        ]
    }
}
```

The following secondary deployment statuses are also available for endpoints (found in the `VariantStatus` object.

- **Creating**: creating instances for the production variant.
  
  **Example message**: "Launching X instance(s)."

- **Deleting**: terminating instances for the production variant.
  
  **Example message**: "Terminating X instance(s)."

- **Updating**: updating capacity for the production variant.
  
  **Example messages**: "Launching X instance(s).", "Scaling out desired instance count to X."
• **ActivatingTraffic**: turning on traffic for the production variant.

  **Example message**: "Activating traffic on canary capacity of X instance(s)."

• **Baking**: waiting period to monitor the CloudWatch alarms in the auto-rollback configuration.

  **Example message**: "Baking for X seconds (TerminationWaitInSeconds) with traffic enabled on full capacity of Y instance(s)."
API Reference Guide for Amazon SageMaker

Overview

Amazon SageMaker provides APIs, SDKs, and a command line interface that you can use to create and manage notebook instances and train and deploy models.

- Amazon SageMaker Python SDK (Recommended)
- Amazon SageMaker API Reference
- Amazon Augmented AI API Reference
- AWS Command Line Interface
- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto)
- AWS SDK for Ruby
- Amazon SageMaker Spark

You can also get code examples from the Amazon SageMaker example notebooks GitHub repository.

- Example notebooks

Programming Model for Amazon SageMaker

Making API calls directly from code is cumbersome, and requires you to write code to authenticate your requests. Amazon SageMaker provides the following alternatives:

- **Use the SageMaker console**—With the console, you don’t write any code. You use the console UI to start model training or deploy a model. The console works well for simple jobs, where you use a built-in training algorithm and you don’t need to preprocess training data.

- **Modify the example Jupyter notebooks**—SageMaker provides several Jupyter notebooks that train and deploy models using specific algorithms and datasets. Start with a notebook that has a suitable algorithm and modify it to accommodate your data source and specific needs.

- **Write model training and inference code from scratch**—SageMaker provides multiple AWS SDK languages (listed in the overview) and the [Amazon SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/), a high-level Python library that you can use in your code to start model training jobs and deploy the resulting models.
• **The SageMaker Python SDK**—This Python library simplifies model training and deployment. In addition to authenticating your requests, the library abstracts platform specifics by providing simple methods and default parameters. For example:

  - To deploy your model, you call only the `deploy()` method. The method creates a SageMaker model artifact, an endpoint configuration, then deploys the model on an endpoint.

  - If you use a custom framework script for model training, you call the `fit()` method. The method creates a .gzip file of your script, uploads it to an Amazon S3 location, and then runs it for model training, and other tasks. For more information, see Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 13).

• **The AWS SDKs**—The SDKs provide methods that correspond to the SageMaker API (see Operations). Use the SDKs to programmatically start a model training job and host the model in SageMaker. SDK clients authenticate your requests by using your access keys, so you don't need to write authentication code. They are available in multiple languages and platforms. For more information, see the preceeding list in the overview.

In Get Started with Amazon SageMaker (p. 34), you train and deploy a model using an algorithm provided by SageMaker. That exercise shows how to use both of these libraries. For more information, see Get Started with Amazon SageMaker (p. 34).

• **Integrate SageMaker into your Apache Spark workflow**—SageMaker provides a library for calling its APIs from Apache Spark. With it, you can use SageMaker-based estimators in an Apache Spark pipeline. For more information, see Use Apache Spark with Amazon SageMaker (p. 14).

<td>Studio Notebooks (p. 3219)</td>
<td>SageMaker Studio Notebooks</td>
<td>April 28, 2020</td>
</tr>
<tr>
<td>Configuring notebook instances (p. 3219)</td>
<td>You can use shell scripts to configure notebook instances when you create or start them. For more information, see Customize a Notebook Instance.</td>
<td>May 1, 2018</td>
</tr>
<tr>
<td>Application Auto Scaling support (p. 3219)</td>
<td>Amazon SageMaker now supports Application Auto Scaling for production variants. For information, see Automatically Scaling SageMaker Models</td>
<td>February 28, 2018</td>
</tr>
<tr>
<td>TensorFlow 1.5 and MXNet 1.0 support (p. 3219)</td>
<td>Amazon SageMaker Deep Learning containers now support TensorFlow 1.5 and Apache MXNet 1.0.</td>
<td>February 27, 2018</td>
</tr>
<tr>
<td>BlazingText algorithm (p. 3219)</td>
<td>Amazon SageMaker now supports the BlazingText algorithm.</td>
<td>January 18, 2018</td>
</tr>
<tr>
<td>KMS encryption (p. 3219)</td>
<td>Amazon SageMaker now supports KMS encryption for hosting instances and training model artifacts at rest.</td>
<td>January 17, 2018</td>
</tr>
<tr>
<td>CloudTrail support (p. 3219)</td>
<td>Amazon SageMaker now supports logging with AWS CloudTrail.</td>
<td>January 11, 2018</td>
</tr>
<tr>
<td>DeepAR Forecasting algorithm (p. 3219)</td>
<td>Amazon SageMaker now supports the <strong>DeepAR</strong> algorithm for time series forecasting.</td>
<td>January 8, 2018</td>
</tr>
