Docker Registry Paths and Example Code for US West (N. California) (us-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1062)
- BlazingText (algorithm) (p. 1062)
- Chainer (DLC) (p. 1063)
- Clarify (algorithm) (p. 1063)
- Data Wrangler (algorithm) (p. 1064)
- Debugger (algorithm) (p. 1064)
- DeepAR Forecasting (algorithm) (p. 1064)
- Factorization Machines (algorithm) (p. 1064)
- Hugging Face (algorithm) (p. 1065)
- IP Insights (algorithm) (p. 1068)
- Image classification (algorithm) (p. 1068)
- Inferentia MXNet (DLC) (p. 1068)
- Inferentia PyTorch (DLC) (p. 1069)
- K-Means (algorithm) (p. 1069)
- KNN (algorithm) (p. 1070)
- LDA (algorithm) (p. 1070)
- Linear Learner (algorithm) (p. 1070)
- MXNet (DLC) (p. 1071)
- MXNet Coach (DLC) (p. 1073)
- Model Monitor (algorithm) (p. 1074)
- NTM (algorithm) (p. 1074)
- Neo Image Classification (algorithm) (p. 1074)
- Neo MXNet (DLC) (p. 1075)
- Neo PyTorch (DLC) (p. 1075)
- Neo Tensorflow (DLC) (p. 1076)
- Neo XGBoost (algorithm) (p. 1076)
- Object Detection (algorithm) (p. 1076)
- Object2Vec (algorithm) (p. 1077)
- PCA (algorithm) (p. 1077)
- PyTorch (DLC) (p. 1077)
- Random Cut Forest (algorithm) (p. 1080)
- Ray PyTorch (DLC) (p. 1080)
- Scikit-learn (algorithm) (p. 1081)
- Semantic Segmentation (algorithm) (p. 1081)
Amazon SageMaker Developer Guide
Use built-in algorithms

- Seq2Seq (algorithm) (p. 1081)
- Spark (algorithm) (p. 1082)
- SparkML Serving (algorithm) (p. 1082)
- Tensorflow (DLC) (p. 1083)
- Tensorflow Coach (DLC) (p. 1091)
- Tensorflow Inferentia (DLC) (p. 1092)
- Tensorflow Ray (DLC) (p. 1092)
- VW (algorithm) (p. 1093)
- XGBoost (algorithm) (p. 1094)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-west-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.us-west-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>
<td></td>
<td>training</td>
</tr>

</tbody>
</table>

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='us-west-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='us-west-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.us-west-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>

<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='us-west-1',version='1.0',image_scope='processing')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>740489534195.dkr.ecr.us-west-1.amazonaws.com/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
Data Wrangler (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>926135532090.dkr.ecr.us-west-1.amazonaws.com/sagemaker-data-wrangler-container:&lt;tag&gt;</td>
<td>1.x</td>
<td>processing</td>
</tr>
</tbody>
</table>

Debugger (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/forecasting-deepar:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Factorization Machines (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-west-1')
```
<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

</tbody>
</table>
### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.us-west-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.5.0</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.us-west-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.us-west-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
</tbody>
</table>

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Inferencea MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.
Use built-in algorithms

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='us-west-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>710691900526.dkr.ecr.us-west-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
<tr>
<td>710691900526.dkr.ecr.us-west-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
</tbody>
</table>

**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='us-west-1', version='1.9', py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>710691900526.dkr.ecr.us-west-1.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
<tr>
<td>710691900526.dkr.ecr.us-west-1.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
<tr>
<td>710691900526.dkr.ecr.us-west-1.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
<td></td>
</tr>
</tbody>
</table>

**K-Means (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='us-west-1')
```
## Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/kmeans:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### KNN (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/knn:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### LDA (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='lda', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/lda:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Linear Learner (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='us-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>632365934929.dkr.ecr.us-west-1.amazonaws.com/linear-learner:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
**MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='us-west-1', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>

Docker Registry Paths and Example Code for US West (Oregon) (us-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1096)
• BlazingText (algorithm) (p. 1096)
• Chainer (DLC) (p. 1097)
• Clarify (algorithm) (p. 1097)
• Data Wrangler (algorithm) (p. 1097)
• Debugger (algorithm) (p. 1098)
• DeepAR Forecasting (algorithm) (p. 1098)
• Factorization Machines (algorithm) (p. 1098)
• Hugging Face (algorithm) (p. 1099)
• IP Insights (algorithm) (p. 1102)
• Image classification (algorithm) (p. 1102)
• Inferentia MXNet (DLC) (p. 1102)
• Inferentia PyTorch (DLC) (p. 1103)
• K-Means (algorithm) (p. 1103)
• KNN (algorithm) (p. 1104)
• LDA (algorithm) (p. 1104)
• Linear Learner (algorithm) (p. 1104)
• MXNet (DLC) (p. 1105)
• MXNet Coach (DLC) (p. 1107)
• Model Monitor (algorithm) (p. 1108)
• NTM (algorithm) (p. 1108)
• Neo Image Classification (algorithm) (p. 1108)
• Neo MXNet (DLC) (p. 1109)
• Neo PyTorch (DLC) (p. 1109)
• Neo Tensorflow (DLC) (p. 1110)
• Neo XGBoost (algorithm) (p. 1110)
• Object Detection (algorithm) (p. 1110)
• Object2Vec (algorithm) (p. 1111)
• PCA (algorithm) (p. 1111)
• PyTorch (DLC) (p. 1111)
• Random Cut Forest (algorithm) (p. 1114)
• Ray PyTorch (DLC) (p. 1114)
• Scikit-learn (algorithm) (p. 1115)
• Semantic Segmentation (algorithm) (p. 1115)
• Seq2Seq (algorithm) (p. 1116)
• Spark (algorithm) (p. 1116)
• SparkML Serving (algorithm) (p. 1116)
• Tensorflow (DLC) (p. 1117)
• Tensorflow Coach (DLC) (p. 1125)
• Tensorflow Inferentia (DLC) (p. 1126)
• Tensorflow Ray (DLC) (p. 1127)
• VW (algorithm) (p. 1127)
• XGBoost (algorithm) (p. 1128)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-west-2', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>

</tbody>
</table>
Use built-in algorithms

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='us-west-2')
```

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-west-2')
```

### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='us-west-2')
```
Use built-in algorithms

Docker Registry Paths and Example Code for Africa (Cape Town) (af-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1130)
- BlazingText (algorithm) (p. 1130)
- Chainer (DLC) (p. 1131)
- Clarify (algorithm) (p. 1131)
- Data Wrangler (algorithm) (p. 1132)
- Debugger (algorithm) (p. 1132)
- DeepAR Forecasting (algorithm) (p. 1132)
- Factorization Machines (algorithm) (p. 1132)
- Hugging Face (algorithm) (p. 1133)
- IP Insights (algorithm) (p. 1136)
- Image classification (algorithm) (p. 1132)
- Inferentia MXNet (DLC) (p. 1136)
- Inferentia PyTorch (DLC) (p. 1137)
- K-Means (algorithm) (p. 1137)
- KNN (algorithm) (p. 1138)
- Linear Learner (algorithm) (p. 1138)
- MXNet (DLC) (p. 1138)
- MXNet Coach (DLC) (p. 1141)
- Model Monitor (algorithm) (p. 1141)
- NTM (algorithm) (p. 1142)
- Neo Image Classification (algorithm) (p. 1142)
- Neo MXNet (DLC) (p. 1142)
- Neo PyTorch (DLC) (p. 1143)
- Neo Tensorflow (DLC) (p. 1143)
- Neo XGBoost (algorithm) (p. 1144)
- Object Detection (algorithm) (p. 1144)
- Object2Vec (algorithm) (p. 1144)
- PCA (algorithm) (p. 1145)
- PyTorch (DLC) (p. 1145)
- Random Cut Forest (algorithm) (p. 1148)
- Scikit-learn (algorithm) (p. 1148)
- **Semantic Segmentation (algorithm)** (p. 1148)
- **Seq2Seq (algorithm)** (p. 1149)
- **Spark (algorithm)** (p. 1149)
- **SparkML Serving (algorithm)** (p. 1149)
- **Tensorflow (DLC)** (p. 1150)
- **Tensorflow Coach (DLC)** (p. 1158)
- **Tensorflow Inferentia (DLC)** (p. 1159)
- **Tensorflow Ray (DLC)** (p. 1159)
- **XGBoost (algorithm)** (p. 1160)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='af-south-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

#### Semantic Segmentation (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
Use built-in algorithms

```python
image_uris.retrieve(framework='semantic-segmentation', region='af-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

**Tensorflow Ray (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow',region='af-south-1',version='0.8.5',instance_type='ml.c5.4xlarge')
```
### XGBoost (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='af-south-1', version='1.2-1')
```
Docker Registry Paths and Example Code for Asia Pacific (Hong Kong) (ap-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1162)
- BlazingText (algorithm) (p. 1163)
- Chainer (DLC) (p. 1163)
- Clarify (algorithm) (p. 1163)
- Data Wrangler (algorithm) (p. 1164)
- Debugger (algorithm) (p. 1164)
- DeepAR Forecasting (algorithm) (p. 1164)
- Factorization Machines (algorithm) (p. 1165)
- Hugging Face (algorithm) (p. 1165)
- IP Insights (algorithm) (p. 1168)
- Image classification (algorithm) (p. 1168)
- Inferentia MXNet (DLC) (p. 1169)
- Inferentia PyTorch (DLC) (p. 1169)
- K-Means (algorithm) (p. 1170)
- KNN (algorithm) (p. 1170)
- Linear Learner (algorithm) (p. 1170)
- MXNet (DLC) (p. 1170)
- MXNet Coach (DLC) (p. 1173)
- Model Monitor (algorithm) (p. 1174)
- NTM (algorithm) (p. 1174)
- Neo Image Classification (algorithm) (p. 1174)
- Neo MXNet (DLC) (p. 1174)
- Neo PyTorch (DLC) (p. 1175)
- Neo Tensorflow (DLC) (p. 1176)
- Neo XGBoost (algorithm) (p. 1176)
- Object Detection (algorithm) (p. 1176)
- Object2Vec (algorithm) (p. 1177)
- PCA (algorithm) (p. 1177)
- PyTorch (DLC) (p. 1177)
- Random Cut Forest (algorithm) (p. 1180)
- Scikit-learn (algorithm) (p. 1180)
- Semantic Segmentation (algorithm) (p. 1181)
- Seq2Seq (algorithm) (p. 1181)
- Spark (algorithm) (p. 1181)
- SparkML Serving (algorithm) (p. 1182)
- Tensorflow (DLC) (p. 1182)
- Tensorflow Coach (DLC) (p. 1190)
- Tensorflow Ray (DLC) (p. 1191)
- XGBoost (algorithm) (p. 1192)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-east-1', image_scope='inference', version='0.4')
```

<table>

### Docker Registry Paths and Example Code for Asia Pacific (Mumbai) (ap-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

#### Topics
- AutoGluon (algorithm) (p. 1194)
- BlazingText (algorithm) (p. 1195)
- Chainer (DLC) (p. 1195)
- Clarify (algorithm) (p. 1196)
- Data Wrangler (algorithm) (p. 1196)
- Debugger (algorithm) (p. 1196)
- DeepAR Forecasting (algorithm) (p. 1196)
- Factorization Machines (algorithm) (p. 1197)
- Hugging Face (algorithm) (p. 1197)
- IP Insights (algorithm) (p. 1200)
- Image classification (algorithm) (p. 1201)
- Inferentia MXNet (DLC) (p. 1201)
- Inferentia PyTorch (DLC) (p. 1201)
- K-Means (algorithm) (p. 1202)
- KNN (algorithm) (p. 1202)
- LDA (algorithm) (p. 1202)
- Linear Learner (algorithm) (p. 1203)
- MXNet (DLC) (p. 1203)
- MXNet Coach (DLC) (p. 1205)
- Model Monitor (algorithm) (p. 1206)
- NTM (algorithm) (p. 1206)
- Neo Image Classification (algorithm) (p. 1206)
- Neo MXNet (DLC) (p. 1207)
• Neo PyTorch (DLC) (p. 1207)
• Neo Tensorflow (DLC) (p. 1208)
• Neo XGBoost (algorithm) (p. 1208)
• Object Detection (algorithm) (p. 1209)
• Object2Vec (algorithm) (p. 1209)
• PCA (algorithm) (p. 1209)
• PyTorch (DLC) (p. 1209)
• Random Cut Forest (algorithm) (p. 1212)
• Ray PyTorch (DLC) (p. 1212)
• Scikit-learn (algorithm) (p. 1213)
• Semantic Segmentation (algorithm) (p. 1213)
• Seq2Seq (algorithm) (p. 1214)
• Spark (algorithm) (p. 1214)
• SparkML Serving (algorithm) (p. 1214)
• Tensorflow (DLC) (p. 1215)
• Tensorflow Coach (DLC) (p. 1223)
• Tensorflow Inferentia (DLC) (p. 1224)
• Tensorflow Ray (DLC) (p. 1225)
• VW (algorithm) (p. 1225)
• XGBoost (algorithm) (p. 1226)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-south-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>

Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='ap-south-1',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```

Docker Registry Paths and Example Code for Asia Pacific (Osaka) (ap-northeast-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1228)
- BlazingText (algorithm) (p. 1228)
- Clarify (algorithm) (p. 1229)
- Debugger (algorithm) (p. 1229)
- Factorization Machines (algorithm) (p. 1229)
- Hugging Face (algorithm) (p. 1229)
- IP Insights (algorithm) (p. 1233)
- Image classification (algorithm) (p. 1233)
- Inferentia MXNet (DLC) (p. 1233)
- Inferentia PyTorch (DLC) (p. 1234)
- K-Means (algorithm) (p. 1234)
- KNN (algorithm) (p. 1234)
- Linear Learner (algorithm) (p. 1235)
- MXNet (DLC) (p. 1235)
- Model Monitor (algorithm) (p. 1236)
- NTM (algorithm) (p. 1237)
- Neo Image Classification (algorithm) (p. 1237)
- Neo MXNet (DLC) (p. 1237)
- Neo PyTorch (DLC) (p. 1238)
- Neo Tensorflow (DLC) (p. 1238)
- Neo XGBoost (algorithm) (p. 1239)
- Object Detection (algorithm) (p. 1239)
- Object2Vec (algorithm) (p. 1239)
- PCA (algorithm) (p. 1240)
- PyTorch (DLC) (p. 1240)
- Random Cut Forest (algorithm) (p. 1242)
- Scikit-learn (algorithm) (p. 1243)
- Semantic Segmentation (algorithm) (p. 1243)
- Seq2Seq (algorithm) (p. 1243)
- Tensorflow (DLC) (p. 1243)
- Tensorflow Inferentia (DLC) (p. 1249)
- XGBoost (algorithm) (p. 1250)
AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-northeast-3', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

### NTM (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ntm', region='ap-northeast-3')
```

### Neo Image Classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo', region='ap-northeast-3')
```

### Neo MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='ap-northeast-3', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```
Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch',region='ap-northeast-3',version='1.6',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Docker Registry Paths and Example Code for Asia Pacific (Seoul) (ap-northeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1252)
- BlazingText (algorithm) (p. 1253)
- Chainer (DLC) (p. 1253)
- Clarify (algorithm) (p. 1253)
- Data Wrangler (algorithm) (p. 1254)
- Debugger (algorithm) (p. 1254)
- DeepAR Forecasting (algorithm) (p. 1254)
- Factorization Machines (algorithm) (p. 1255)
- Hugging Face (algorithm) (p. 1255)
- IP Insights (algorithm) (p. 1258)
- Image classification (algorithm) (p. 1258)
- Inferentia MXNet (DLC) (p. 1259)
- Inferentia PyTorch (DLC) (p. 1259)
- K-Means (algorithm) (p. 1260)
- KNN (algorithm) (p. 1260)
- LDA (algorithm) (p. 1260)
- Linear Learner (algorithm) (p. 1261)
- MXNet (DLC) (p. 1261)
- MXNet Coach (DLC) (p. 1263)
- Model Monitor (algorithm) (p. 1264)
- NTM (algorithm) (p. 1264)
- Neo Image Classification (algorithm) (p. 1264)
- Neo MXNet (DLC) (p. 1265)
- Neo PyTorch (DLC) (p. 1265)
- Neo Tensorflow (DLC) (p. 1266)
- Neo XGBoost (algorithm) (p. 1266)
- Object Detection (algorithm) (p. 1267)
- Object2Vec (algorithm) (p. 1267)
Use built-in algorithms

- PCA (algorithm) (p. 1267)
- PyTorch (DLC) (p. 1267)
- Random Cut Forest (algorithm) (p. 1270)
- Ray PyTorch (DLC) (p. 1271)
- Scikit-learn (algorithm) (p. 1271)
- Semantic Segmentation (algorithm) (p. 1271)
- Seq2Seq (algorithm) (p. 1272)
- Spark (algorithm) (p. 1272)
- SparkML Serving (algorithm) (p. 1272)
- Tensorflow (DLC) (p. 1273)
- Tensorflow Coach (DLC) (p. 1281)
- Tensorflow Inferentia (DLC) (p. 1282)
- Tensorflow Ray (DLC) (p. 1283)
- VW (algorithm) (p. 1283)
- XGBoost (algorithm) (p. 1284)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-northeast-2', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

</tbody>
</table>
### BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='ap-northeast-2')
```

### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='ap-northeast-2', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

### Docker Registry Paths and Example Code for Asia Pacific (Singapore) (ap-southeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics

- AutoGluon (algorithm) (p. 1286)
- BlazingText (algorithm) (p. 1287)
- Chainer (DLC) (p. 1287)
- Clarify (algorithm) (p. 1287)
- Data Wrangler (algorithm) (p. 1288)
- Debugger (algorithm) (p. 1288)
- DeepAR Forecasting (algorithm) (p. 1288)
- Factorization Machines (algorithm) (p. 1289)
- Hugging Face (algorithm) (p. 1289)
- IP Insights (algorithm) (p. 1292)
- Image classification (algorithm) (p. 1292)
- Inferentia MXNet (DLC) (p. 1293)
- Inferentia PyTorch (DLC) (p. 1293)
- K-Means (algorithm) (p. 1294)
- KNN (algorithm) (p. 1294)
- LDA (algorithm) (p. 1294)
- Linear Learner (algorithm) (p. 1294)
- MXNet (DLC) (p. 1295)
- MXNet Coach (DLC) (p. 1297)
- Model Monitor (algorithm) (p. 1298)
- NTM (algorithm) (p. 1298)
- Neo Image Classification (algorithm) (p. 1298)
- Neo MXNet (DLC) (p. 1299)
- Neo PyTorch (DLC) (p. 1299)
- Neo Tensorflow (DLC) (p. 1300)
- Neo XGBoost (algorithm) (p. 1300)
- Object Detection (algorithm) (p. 1301)
- Object2Vec (algorithm) (p. 1301)
- PCA (algorithm) (p. 1301)
- PyTorch (DLC) (p. 1301)
- Random Cut Forest (algorithm) (p. 1304)
• Ray PyTorch (DLC) (p. 1304)

**Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow',region='ap-southeast-1',version='1.12.0',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Docker Registry Paths and Example Code for Asia Pacific (Sydney) (ap-southeast-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- AutoGluon (algorithm) (p. 1320)
- BlazingText (algorithm) (p. 1321)
- Chainer (DLC) (p. 1321)
- Clarify (algorithm) (p. 1321)
- Data Wrangler (algorithm) (p. 1322)
- Debugger (algorithm) (p. 1322)
- DeepAR Forecasting (algorithm) (p. 1322)
- Factorization Machines (algorithm) (p. 1323)
- Hugging Face (algorithm) (p. 1323)
- IP Insights (algorithm) (p. 1326)
- Image classification (algorithm) (p. 1326)
- Inferentia MXNet (DLC) (p. 1327)
- Inferentia PyTorch (DLC) (p. 1327)
- K-Means (algorithm) (p. 1328)
- KNN (algorithm) (p. 1328)
- LDA (algorithm) (p. 1328)
- Linear Learner (algorithm) (p. 1328)
- MXNet (DLC) (p. 1329)
- MXNet Coach (DLC) (p. 1331)
- Model Monitor (algorithm) (p. 1332)
- NTM (algorithm) (p. 1332)
- Neo Image Classification (algorithm) (p. 1332)
- Neo MXNet (DLC) (p. 1333)
- Neo PyTorch (DLC) (p. 1333)
- Neo Tensorflow (DLC) (p. 1334)
- Neo XGBoost (algorithm) (p. 1334)
- Object Detection (algorithm) (p. 1335)
- Object2Vec (algorithm) (p. 1335)
- PCA (algorithm) (p. 1335)
- PyTorch (DLC) (p. 1335)
- Random Cut Forest (algorithm) (p. 1338)
• Ray PyTorch (DLC) (p. 1338)
• Scikit-learn (algorithm) (p. 1339)
• Semantic Segmentation (algorithm) (p. 1339)
• Seq2Seq (algorithm) (p. 1340)
• Spark (algorithm) (p. 1340)
• SparkML Serving (algorithm) (p. 1340)
• Tensorflow (DLC) (p. 1341)
• Tensorflow Coach (DLC) (p. 1349)
• Tensorflow Inferentia (DLC) (p. 1350)
• Tensorflow Ray (DLC) (p. 1351)
• VW (algorithm) (p. 1351)
• XGBoost (algorithm) (p. 1352)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='ap-southeast-2',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/autogluon-training:&lt;tag&gt;</td>
<td>0.4.0</td>
<td>training</td>

<tr>
<td>763104351884.dkr.ecr.ap-southeast-2.amazonaws.com/autogluon-inference:&lt;tag&gt;</td>
<td>0.3.1</td>
<td>inference</td>
</tr>
</tbody>
</table>
**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='ap-southeast-2')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>544295431143.dkr.ecr.ap-southeast-2.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='ap-southeast-2', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>

</thead>
<tbody>
<tr>
<td>007051062584.dkr.ecr.ap-1.0-southeast-2.amazonaws.com/</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
### Data Wrangler (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='ap-southeast-2')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-clarify-processing:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='ap-southeast-2')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

**Tensorflow Coach (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow',region='ap-southeast-2',version='1.0.0',image_scope='training',instance_type='ml.c5.4xlarge')
```
### Use built-in algorithms

#### Registry path | Version | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
520713654638.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.1-<tag> | | training | CPU, GPU | py3
520713654638.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.11.0-<tag> | | training | CPU, GPU | py3
520713654638.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.11-<tag> | | training | CPU, GPU | py3
520713654638.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.10.1-<tag> | | training | CPU, GPU | py3
520713654638.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-rl-tensorflow:coach0.10-<tag> | | training | CPU, GPU | py3

#### Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-tensorflow', region='ap-southeast-2', version='1.15.0', instance_type='ml.inf1.6xlarge')
```

#### Registry path | Version | Job types (image scope) | Processor types | Python versions
---|---|---|---|---
355873309152.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-neo-tensorflow:<tag> | | inference | inf | py3
355873309152.dkr.ecr.ap-southeast-2.amazonaws.com/sagemaker-neo-tensorflow:<tag> | | inference | inf | py3
Tensorflow Ray (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ray-tensorflow', region='ap-southeast-2', version='0.8.5', instance_type='ml.c5.4xlarge')
```

Docker Registry Paths and Example Code for Asia Pacific (Tokyo) (ap-northeast-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1354)
- BlazingText (algorithm) (p. 1355)
- Chainer (DLC) (p. 1355)
- Clarify (algorithm) (p. 1355)
- Data Wrangler (algorithm) (p. 1356)
- Debugger (algorithm) (p. 1356)
- DeepAR Forecasting (algorithm) (p. 1356)
- Factorization Machines (algorithm) (p. 1357)
- Hugging Face (algorithm) (p. 1357)
- IP Insights (algorithm) (p. 1360)
- Image classification (algorithm) (p. 1360)
- Inference MXNet (DLC) (p. 1361)
- Inference PyTorch (DLC) (p. 1361)
- K-Means (algorithm) (p. 1362)
- KNN (algorithm) (p. 1362)
- LDA (algorithm) (p. 1362)
- Linear Learner (algorithm) (p. 1362)
- MXNet (DLC) (p. 1363)
- MXNet Coach (DLC) (p. 1365)
- Model Monitor (algorithm) (p. 1366)
- NTM (algorithm) (p. 1366)
- Neo Image Classification (algorithm) (p. 1366)
- Neo MXNet (DLC) (p. 1367)
- Neo PyTorch (DLC) (p. 1367)
- Neo Tensorflow (DLC) (p. 1368)
- Neo XGBoost (algorithm) (p. 1368)
- Object Detection (algorithm) (p. 1369)
- Object2Vec (algorithm) (p. 1369)
- PCA (algorithm) (p. 1369)
- PyTorch (DLC) (p. 1369)
- Random Cut Forest (algorithm) (p. 1372)
• Ray PyTorch (DLC) (p. 1373)
• Scikit-learn (algorithm) (p. 1373)
• Semantic Segmentation (algorithm) (p. 1373)
• Seq2Seq (algorithm) (p. 1374)
• Spark (algorithm) (p. 1374)
• SparkML Serving (algorithm) (p. 1374)
• Tensorflow (DLC) (p. 1375)
• Tensorflow Coach (DLC) (p. 1383)
• Tensorflow Inferentia (DLC) (p. 1384)
• Tensorflow Ray (DLC) (p. 1385)
• VW (algorithm) (p. 1385)
• XGBoost (algorithm) (p. 1386)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ap-northeast-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify', region='ap-northeast-1', version='1.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>377024640650.dkr.ecr.ap-1.0</td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>
### Data Wrangler (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='data-wrangler', region='ap-northeast-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

**SparkML Serving (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
```
**Use built-in algorithms**

```python
image_uris.retrieve(framework='sparkml-serving', region='ap-northeast-1', version='2.4')
```

Docker Registry Paths and Example Code for Canada (Central) (ca-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1388)
- BlazingText (algorithm) (p. 1389)
- Chainer (DLC) (p. 1389)
- Clarify (algorithm) (p. 1389)
- Data Wrangler (algorithm) (p. 1390)
- Debugger (algorithm) (p. 1390)
- DeepAR Forecasting (algorithm) (p. 1390)
- Factorization Machines (algorithm) (p. 1391)
- Hugging Face (algorithm) (p. 1391)
- IP Insights (algorithm) (p. 1394)
- Image classification (algorithm) (p. 1394)
- Inferentia MXNet (DLC) (p. 1395)
- Inferentia PyTorch (DLC) (p. 1395)
- K-Means (algorithm) (p. 1396)
- KNN (algorithm) (p. 1396)
- LDA (algorithm) (p. 1396)
- Linear Learner (algorithm) (p. 1396)
- MXNet (DLC) (p. 1397)
- MXNet Coach (DLC) (p. 1399)
- Model Monitor (algorithm) (p. 1400)
- NTM (algorithm) (p. 1400)
- Neo Image Classification (algorithm) (p. 1400)
- Neo MXNet (DLC) (p. 1401)
- Neo PyTorch (DLC) (p. 1401)
- Neo Tensorflow (DLC) (p. 1402)
- Neo XGBoost (algorithm) (p. 1402)
- Object Detection (algorithm) (p. 1403)
- Object2Vec (algorithm) (p. 1403)
- PCA (algorithm) (p. 1403)
- PyTorch (DLC) (p. 1403)
- Random Cut Forest (algorithm) (p. 1406)
Use built-in algorithms

- Ray PyTorch (DLC) (p. 1406)
- Scikit-learn (algorithm) (p. 1407)
- Semantic Segmentation (algorithm) (p. 1407)
- Seq2Seq (algorithm) (p. 1408)
- Spark (algorithm) (p. 1408)
- SparkML Serving (algorithm) (p. 1408)
- Tensorflow (DLC) (p. 1409)
- Tensorflow Coach (DLC) (p. 1417)
- Tensorflow Inferentia (DLC) (p. 1418)
- Tensorflow Ray (DLC) (p. 1419)
- VW (algorithm) (p. 1419)
- XGBoost (algorithm) (p. 1420)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='ca-central-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

Docker Registry Paths and Example Code for China (Beijing) (cn-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1422)
- BlazingText (algorithm) (p. 1422)
- Chainer (DLC) (p. 1423)
- Clarify (algorithm) (p. 1423)
- Data Wrangler (algorithm) (p. 1423)
- Debugger (algorithm) (p. 1424)
- DeepAR Forecasting (algorithm) (p. 1424)
- Factorization Machines (algorithm) (p. 1424)
- Hugging Face (algorithm) (p. 1425)
- IP Insights (algorithm) (p. 1428)
- Image classification (algorithm) (p. 1428)
- Inferentia MXNet (DLC) (p. 1428)
- Inferentia PyTorch (DLC) (p. 1429)
- K-Means (algorithm) (p. 1429)
- KNN (algorithm) (p. 1430)
- Linear Learner (algorithm) (p. 1430)
- MXNet (DLC) (p. 1430)
- MXNet Coach (DLC) (p. 1433)
- Model Monitor (algorithm) (p. 1433)
- NTM (algorithm) (p. 1434)
- Neo Image Classification (algorithm) (p. 1434)
- Neo MXNet (DLC) (p. 1434)
- Neo PyTorch (DLC) (p. 1435)
- Neo Tensorflow (DLC) (p. 1435)
- Neo XGBoost (algorithm) (p. 1436)
- Object Detection (algorithm) (p. 1436)
- Object2Vec (algorithm) (p. 1436)
- PCA (algorithm) (p. 1437)
- PyTorch (DLC) (p. 1437)
- Random Cut Forest (algorithm) (p. 1440)
Use built-in algorithms

- Scikit-learn (algorithm) (p. 1440)
- Semantic Segmentation (algorithm) (p. 1441)
- Seq2Seq (algorithm) (p. 1441)
- Spark (algorithm) (p. 1441)
- SparkML Serving (algorithm) (p. 1442)
- Tensorflow (DLC) (p. 1442)
- Tensorflow Coach (DLC) (p. 1450)
- Tensorflow Inferentia (DLC) (p. 1451)
- Tensorflow Ray (DLC) (p. 1451)
- XGBoost (algorithm) (p. 1452)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='cn-north-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>727897471807.dkr.ecr.cn-north-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>
<td>0.4.0</td>
<td>inference</td>
</tr>
<tr>
<td>727897471807.dkr.ecr.cn-north-1.amazonaws.com.cn/autogluon-inference:&lt;tag&gt;</td>

</tr>
</tbody>
</table>

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='cn-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>390948362332.dkr.ecr.cn-north-1.amazonaws.com.cn/blazingtext:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='cn-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>422961961927.dkr.ecr.cn-north-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
<td></td>
</tr>
<tr>

## Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

### Topics
- AutoGluon (algorithm) (p. 1454)
- BlazingText (algorithm) (p. 1454)
- Chainer (DLC) (p. 1455)
- Clarify (algorithm) (p. 1455)
- Data Wrangler (algorithm) (p. 1456)
- Debugger (algorithm) (p. 1456)
- DeepAR Forecasting (algorithm) (p. 1456)
- Factorization Machines (algorithm) (p. 1456)
- Hugging Face (algorithm) (p. 1457)
- IP Insights (algorithm) (p. 1460)
- Image classification (algorithm) (p. 1460)
- Inferentia MXNet (DLC) (p. 1460)
- Inferentia PyTorch (DLC) (p. 1461)
- K-Means (algorithm) (p. 1461)
- KNN (algorithm) (p. 1462)
- Linear Learner (algorithm) (p. 1462)
- MXNet (DLC) (p. 1462)
- MXNet Coach (DLC) (p. 1465)
- Model Monitor (algorithm) (p. 1465)
- NTM (algorithm) (p. 1466)
- Neo Image Classification (algorithm) (p. 1466)
- Neo MXNet (DLC) (p. 1466)
- Neo PyTorch (DLC) (p. 1467)
- Neo Tensorflow (DLC) (p. 1467)
- Neo XGBoost (algorithm) (p. 1468)
- Object Detection (algorithm) (p. 1468)
- Object2Vec (algorithm) (p. 1468)
- PCA (algorithm) (p. 1469)
- PyTorch (DLC) (p. 1469)
- Random Cut Forest (algorithm) (p. 1472)
- Scikit-learn (algorithm) (p. 1472)
- Semantic Segmentation (algorithm) (p. 1473)
- Seq2Seq (algorithm) (p. 1473)
- Spark (algorithm) (p. 1473)
- SparkML Serving (algorithm) (p. 1474)
- Tensorflow (DLC) (p. 1474)
- Tensorflow Coach (DLC) (p. 1482)
- Tensorflow Inferentia (DLC) (p. 1483)
- Tensorflow Ray (DLC) (p. 1483)
- XGBoost (algorithm) (p. 1484)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='cn-northwest-1',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>inference</td>
</tr>
</tbody>
</table>

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext',region='cn-northwest-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>387376663083.dkr.ecr.cn-northwest-1.amazonaws.com.cn/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='chainer',region='cn-northwest-1',version='5.0.0',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>423003514399.dkr.ecr.cn-northwest-1.amazonaws.com.cn/sagemaker-chainer:&lt;tag&gt;</td>

Docker Registry Paths and Example Code for Europe (Ireland) (eu-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1520)
- BlazingText (algorithm) (p. 1521)
- Chainer (DLC) (p. 1521)
- Clarify (algorithm) (p. 1521)
- Data Wrangler (algorithm) (p. 1522)
- Debugger (algorithm) (p. 1522)
- DeepAR Forecasting (algorithm) (p. 1522)
- Factorization Machines (algorithm) (p. 1523)
- Hugging Face (algorithm) (p. 1523)
- IP Insights (algorithm) (p. 1526)
- Image classification (algorithm) (p. 1526)
- Inferentia MXNet (DLC) (p. 1527)
- Inferentia PyTorch (DLC) (p. 1527)
- K-Means (algorithm) (p. 1528)
- KNN (algorithm) (p. 1528)
- LDA (algorithm) (p. 1528)
- Linear Learner (algorithm) (p. 1528)
- MXNet (DLC) (p. 1529)
- MXNet Coach (DLC) (p. 1531)
- Model Monitor (algorithm) (p. 1532)
- NTM (algorithm) (p. 1532)
- Neo Image Classification (algorithm) (p. 1532)
- Neo MXNet (DLC) (p. 1533)
- Neo PyTorch (DLC) (p. 1533)
- Neo Tensorflow (DLC) (p. 1534)
- Neo XGBoost (algorithm) (p. 1534)
- Object Detection (algorithm) (p. 1535)
- Object2Vec (algorithm) (p. 1535)
- PCA (algorithm) (p. 1535)
- PyTorch (DLC) (p. 1535)
- Random Cut Forest (algorithm) (p. 1538)
• Ray PyTorch (DLC) (p. 1539)
• Scikit-learn (algorithm) (p. 1539)
• Semantic Segmentation (algorithm) (p. 1539)
• Seq2Seq (algorithm) (p. 1540)
• Spark (algorithm) (p. 1540)
• SparkML Serving (algorithm) (p. 1540)
• Tensorflow (DLC) (p. 1541)
• Tensorflow Coach (DLC) (p. 1549)
• Tensorflow Inferentia (DLC) (p. 1550)
• Tensorflow Ray (DLC) (p. 1551)
• VW (algorithm) (p. 1551)
• XGBoost (algorithm) (p. 1552)

AutoGluon (algorithm)

**Neo Image Classification (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification-neo',region='eu-west-1')
```
Use built-in algorithms

### Neo MXNNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-mxnet', region='eu-west-1', version='1.8', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

### Neo PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='neo-pytorch', region='eu-west-1', version='1.6', image_scope='inference', instance_type='ml.c5.4xlarge')
```
### Use built-in algorithms

Docker Registry Paths and Example Code for Europe (London) (eu-west-2)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1554)
- BlazingText (algorithm) (p. 1555)
- Chainer (DLC) (p. 1555)
- Clarify (algorithm) (p. 1555)
- Data Wrangler (algorithm) (p. 1556)
- Debugger (algorithm) (p. 1556)
- DeepAR Forecasting (algorithm) (p. 1556)
- Factorization Machines (algorithm) (p. 1557)
- Hugging Face (algorithm) (p. 1557)
- IP Insights (algorithm) (p. 1560)
- Image classification (algorithm) (p. 1560)
- Inferentia MXNet (DLC) (p. 1561)
- Inferentia PyTorch (DLC) (p. 1561)
- K-Means (algorithm) (p. 1562)
- KNN (algorithm) (p. 1562)
- LDA (algorithm) (p. 1562)
- Linear Learner (algorithm) (p. 1562)
- MXNet (DLC) (p. 1563)
- MXNet Coach (DLC) (p. 1565)
- Model Monitor (algorithm) (p. 1566)
- NTM (algorithm) (p. 1566)
- Neo Image Classification (algorithm) (p. 1566)
- Neo MXNet (DLC) (p. 1567)
- Neo PyTorch (DLC) (p. 1567)
- Neo Tensorflow (DLC) (p. 1568)
- Neo XGBoost (algorithm) (p. 1568)
- Object Detection (algorithm) (p. 1569)
- Object2Vec (algorithm) (p. 1569)
- PCA (algorithm) (p. 1569)
- PyTorch (DLC) (p. 1569)
- Random Cut Forest (algorithm) (p. 1572)
Use built-in algorithms

- Ray PyTorch (DLC) (p. 1572)
- Scikit-learn (algorithm) (p. 1573)
- Semantic Segmentation (algorithm) (p. 1573)
- Seq2Seq (algorithm) (p. 1574)
- Spark (algorithm) (p. 1574)
- SparkML Serving (algorithm) (p. 1574)
- Tensorflow (DLC) (p. 1575)
- Tensorflow Coach (DLC) (p. 1583)
- Tensorflow Inferentia (DLC) (p. 1584)
- Tensorflow Ray (DLC) (p. 1584)
- VW (algorithm) (p. 1585)
- XGBoost (algorithm) (p. 1586)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

Docker Registry Paths and Example Code for Europe (Paris) (eu-west-3)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1588)
- BlazingText (algorithm) (p. 1588)
- Chainer (DLC) (p. 1589)
- Clarify (algorithm) (p. 1589)
- Data Wrangler (algorithm) (p. 1589)
- Debugger (algorithm) (p. 1590)
- DeepAR Forecasting (algorithm) (p. 1590)
- Factorization Machines (algorithm) (p. 1590)
- Hugging Face (algorithm) (p. 1591)
- IP Insights (algorithm) (p. 1594)
- Image classification (algorithm) (p. 1594)
- Inferentia MXNet (DLC) (p. 1594)
- Inferentia PyTorch (DLC) (p. 1595)
- K-Means (algorithm) (p. 1595)
- KNN (algorithm) (p. 1596)
- Linear Learner (algorithm) (p. 1596)
- MXNet (DLC) (p. 1596)
- MXNet Coach (DLC) (p. 1599)
- Model Monitor (algorithm) (p. 1599)
- NTM (algorithm) (p. 1600)
- Neo Image Classification (algorithm) (p. 1600)
- Neo MXNet (DLC) (p. 1600)
- Neo PyTorch (DLC) (p. 1601)
- Neo Tensorflow (DLC) (p. 1601)
- Neo XGBoost (algorithm) (p. 1602)
- Object Detection (algorithm) (p. 1602)
- Object2Vec (algorithm) (p. 1602)
- PCA (algorithm) (p. 1603)
- PyTorch (DLC) (p. 1603)
- Random Cut Forest (algorithm) (p. 1606)
- Scikit-learn (algorithm) (p. 1606)
- Semantic Segmentation (algorithm) (p. 1606)
- Seq2Seq (algorithm) (p. 1607)
- Spark (algorithm) (p. 1607)
• SparkML Serving (algorithm) (p. 1607)
• Tensorflow (DLC) (p. 1608)
• Tensorflow Coach (DLC) (p. 1616)
• Tensorflow Inferentia (DLC) (p. 1617)
• Tensorflow Ray (DLC) (p. 1617)
• XGBoost (algorithm) (p. 1618)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
debug
image_uris.retrieve(framework='autogluon',region='eu-west-3',image_scope='inference',version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

**Docker Registry Paths and Example Code for Europe (Stockholm) (eu-north-1)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1620)
- BlazingText (algorithm) (p. 1621)
- Chainer (DLC) (p. 1621)
- Clarify (algorithm) (p. 1621)
- Data Wrangler (algorithm) (p. 1622)
- Debugger (algorithm) (p. 1622)
- DeepAR Forecasting (algorithm) (p. 1622)
- Factorization Machines (algorithm) (p. 1623)
- Hugging Face (algorithm) (p. 1623)
- IP Insights (algorithm) (p. 1626)
- Image classification (algorithm) (p. 1626)
- Inferentia MXNet (DLC) (p. 1627)
- Inferentia PyTorch (DLC) (p. 1627)
- K-Means (algorithm) (p. 1628)
- KNN (algorithm) (p. 1628)
- Linear Learner (algorithm) (p. 1628)
- MXNet (DLC) (p. 1628)
- MXNet Coach (DLC) (p. 1631)
- Model Monitor (algorithm) (p. 1632)
- NTM (algorithm) (p. 1632)
- Neo Image Classification (algorithm) (p. 1632)
- Neo MXNet (DLC) (p. 1632)
• Neo PyTorch (DLC) (p. 1633)
• Neo Tensorflow (DLC) (p. 1634)
• Neo XGBoost (algorithm) (p. 1634)
• Object Detection (algorithm) (p. 1634)
• Object2Vec (algorithm) (p. 1635)
• PCA (algorithm) (p. 1635)
• PyTorch (DLC) (p. 1635)
• Random Cut Forest (algorithm) (p. 1638)
• Scikit-learn (algorithm) (p. 1638)
• Semantic Segmentation (algorithm) (p. 1639)
• Seq2Seq (algorithm) (p. 1639)
• Spark (algorithm) (p. 1639)
• SparkML Serving (algorithm) (p. 1640)
• Tensorflow (DLC) (p. 1640)
• Tensorflow Coach (DLC) (p. 1648)
• Tensorflow Inferentia (DLC) (p. 1649)
• Tensorflow Ray (DLC) (p. 1650)
• XGBoost (algorithm) (p. 1650)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='eu-north-1', image_scope='inference', version='0.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.eu-north-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>
<td>0.4.0</td>
<td>training</td>

<td>inference</td>
</tr>
</tbody>
</table>

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='semantic-segmentation', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/semanticsegmentation:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Seq2Seq (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='seq2seq', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/seq2seq:&lt;tag&gt;</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Spark (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='spark', region='eu-north-1', version='3.0', image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>330188676905.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-spark-processing:&lt;tag&gt;</td>

<td>processing</td>
</tr>
<tr>
<td>330188676905.dkr.ecr.eu-north-1.amazonaws.com/</td>
<td>3.0</td>
<td>processing</td>
</tr>
</tbody>
</table>
**SparkML Serving (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='sparkml-serving', region='eu-north-1', version='2.4')
```

<table>
<thead>
<tr>
<th>Registry path</th>

<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**Tensorflow (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='tensorflow', region='eu-north-1', version='1.12.0', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>

Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- AutoGluon (algorithm) (p. 1652)
- BlazingText (algorithm) (p. 1653)
- Chainer (DLC) (p. 1653)
- Clarify (algorithm) (p. 1654)
- Data Wrangler (algorithm) (p. 1654)
- Debugger (algorithm) (p. 1654)
- DeepAR Forecasting (algorithm) (p. 1655)
- Factorization Machines (algorithm) (p. 1655)
- Hugging Face (algorithm) (p. 1655)
- IP Insights (algorithm) (p. 1659)
- Image classification (algorithm) (p. 1659)
- Inferentia MXNet (DLC) (p. 1659)
- Inferentia PyTorch (DLC) (p. 1659)
- K-Means (algorithm) (p. 1660)
- KNN (algorithm) (p. 1660)
Use built-in algorithms

- Linear Learner (algorithm) (p. 1661)
- MXNet (DLC) (p. 1661)
- MXNet Coach (DLC) (p. 1663)
- Model Monitor (algorithm) (p. 1664)
- NTM (algorithm) (p. 1664)
- Neo Image Classification (algorithm) (p. 1664)
- Neo MXNet (DLC) (p. 1665)
- Neo PyTorch (DLC) (p. 1665)
- Neo Tensorflow (DLC) (p. 1666)
- Neo XGBoost (algorithm) (p. 1666)
- Object Detection (algorithm) (p. 1667)
- Object2Vec (algorithm) (p. 1667)
- PCA (algorithm) (p. 1667)
- PyTorch (DLC) (p. 1667)
- Random Cut Forest (algorithm) (p. 1670)
- Scikit-learn (algorithm) (p. 1670)
- Semantic Segmentation (algorithm) (p. 1671)
- Seq2Seq (algorithm) (p. 1671)
- Spark (algorithm) (p. 1671)
- SparkML Serving (algorithm) (p. 1672)
- Tensorflow (DLC) (p. 1672)
- Tensorflow Coach (DLC) (p. 1681)
- Tensorflow Inferentia (DLC) (p. 1681)
- Tensorflow Ray (DLC) (p. 1682)
- XGBoost (algorithm) (p. 1682)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='eu-south-1', image_scope='inference', version='0.4')
```

Docker Registry Paths and Example Code for Middle East (Bahrain) (me-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- AutoGluon (algorithm) (p. 1684)
- BlazingText (algorithm) (p. 1685)
- Chainer (DLC) (p. 1685)
- Clarify (algorithm) (p. 1686)
Use built-in algorithms

- Data Wrangler (algorithm) (p. 1686)
- Debugger (algorithm) (p. 1686)
- DeepAR Forecasting (algorithm) (p. 1687)
- Factorization Machines (algorithm) (p. 1687)
- Hugging Face (algorithm) (p. 1687)
- IP Insights (algorithm) (p. 1691)
- Image classification (algorithm) (p. 1691)
- Inferentia MXNet (DLC) (p. 1691)
- Inferentia PyTorch (DLC) (p. 1691)
- K-Means (algorithm) (p. 1692)
- KNN (algorithm) (p. 1692)
- Linear Learner (algorithm) (p. 1693)
- MXNet (DLC) (p. 1693)
- MXNet Coach (DLC) (p. 1695)
- Model Monitor (algorithm) (p. 1696)
- NTM (algorithm) (p. 1696)
- Neo Image Classification (algorithm) (p. 1696)
- Neo MXNet (DLC) (p. 1697)
- Neo PyTorch (DLC) (p. 1697)
- Neo Tensorflow (DLC) (p. 1698)
- Neo XGBoost (algorithm) (p. 1698)
- Object Detection (algorithm) (p. 1699)
- Object2Vec (algorithm) (p. 1699)
- PCA (algorithm) (p. 1699)
- PyTorch (algorithm) (p. 1699)
- Random Cut Forest (algorithm) (p. 1702)
- Scikit-learn (algorithm) (p. 1702)
- Semantic Segmentation (algorithm) (p. 1703)
- Seq2Seq (algorithm) (p. 1703)
- Spark (algorithm) (p. 1703)
- SparkML Serving (algorithm) (p. 1704)
- Tensorflow (DLC) (p. 1704)
- Tensorflow Coach (DLC) (p. 1713)
- Tensorflow Inferentia (DLC) (p. 1713)
- Tensorflow Ray (DLC) (p. 1714)
- XGBoost (algorithm) (p. 1714)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='me-south-1', image_scope='inference', version='0.4')
```
## Use built-in algorithms

### Tensorflow Coach (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='me-south-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```

### Tensorflow Inferentia (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='coach-tensorflow', region='me-south-1', version='1.0.0', image_scope='training', instance_type='ml.c5.4xlarge')
```
Use built-in algorithms

```python
image_uris.retrieve(framework='inferentia-tensorflow',region='me-south-1',version='1.15.0',instance_type='ml.inf1.6xlarge')
```

<table>

Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1716)
- BlazingText (algorithm) (p. 1717)
- Chainer (DLC) (p. 1717)
- Clarify (algorithm) (p. 1718)
• Data Wrangler (algorithm) (p. 1718)
• Debugger (algorithm) (p. 1718)
• DeepAR Forecasting (algorithm) (p. 1719)
• Factorization Machines (algorithm) (p. 1719)
• Hugging Face (algorithm) (p. 1719)
• IP Insights (algorithm) (p. 1723)
• Image classification (algorithm) (p. 1723)
• Inferentia MXNet (DLC) (p. 1723)
• Inferentia PyTorch (DLC) (p. 1723)
• K-Means (algorithm) (p. 1724)
• KNN (algorithm) (p. 1724)
• Linear Learner (algorithm) (p. 1725)
• MXNet (DLC) (p. 1725)
• MXNet Coach (DLC) (p. 1727)
• Model Monitor (algorithm) (p. 1728)
• NTM (algorithm) (p. 1728)
• Neo Image Classification (algorithm) (p. 1728)
• Neo MXNet (DLC) (p. 1729)
• Neo PyTorch (DLC) (p. 1729)
• Neo Tensorflow (DLC) (p. 1730)
• Neo XGBoost (algorithm) (p. 1730)
• Object Detection (algorithm) (p. 1731)
• Object2Vec (algorithm) (p. 1731)
• PCA (algorithm) (p. 1731)
• PyTorch (DLC) (p. 1731)
• Random Cut Forest (algorithm) (p. 1734)
• Scikit-learn (algorithm) (p. 1734)
• Semantic Segmentation (algorithm) (p. 1735)
• Seq2Seq (algorithm) (p. 1735)
• Spark (algorithm) (p. 1735)
• SparkML Serving (algorithm) (p. 1736)
• Tensorflow (DLC) (p. 1736)
• Tensorflow Coach (DLC) (p. 1745)
• Tensorflow Inferentia (DLC) (p. 1745)
• Tensorflow Ray (DLC) (p. 1746)
• XGBoost (algorithm) (p. 1746)

**AutoGluon (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon',region='sa-east-1',image_scope='inference',version='0.4')
```
### BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.sa-east-1.amazonaws.com/autogluon-training:&lt;tag&gt;</td>

Docker Registry Paths and Example Code for AWS GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- AutoGluon (algorithm) (p. 1748)
- BlazingText (algorithm) (p. 1749)
- Chainer (DLC) (p. 1750)
- Clarify (algorithm) (p. 1750)
• Debugger (algorithm) (p. 1750)
• DeepAR Forecasting (algorithm) (p. 1751)
• Factorization Machines (algorithm) (p. 1751)
• Hugging Face (algorithm) (p. 1751)
• IP Insights (algorithm) (p. 1755)
• Image classification (algorithm) (p. 1755)
• Inferentia MXNet (DLC) (p. 1756)
• Inferentia PyTorch (DLC) (p. 1756)
• K-Means (algorithm) (p. 1757)
• KNN (algorithm) (p. 1757)
• LDA (algorithm) (p. 1757)
• Linear Learner (algorithm) (p. 1758)
• MXNet (DLC) (p. 1758)
• MXNet Coach (DLC) (p. 1761)
• NTM (algorithm) (p. 1762)
• Neo Image Classification (algorithm) (p. 1762)
• Neo MXNet (DLC) (p. 1762)
• Neo PyTorch (DLC) (p. 1763)
• Neo Tensorflow (DLC) (p. 1764)
• Neo XGBoost (algorithm) (p. 1764)
• Object Detection (algorithm) (p. 1764)
• Object2Vec (algorithm) (p. 1765)
• PCA (algorithm) (p. 1765)
• PyTorch (DLC) (p. 1765)
• Random Cut Forest (algorithm) (p. 1769)
• Scikit-learn (algorithm) (p. 1769)
• Semantic Segmentation (algorithm) (p. 1769)
• Seq2Seq (algorithm) (p. 1770)
• Spark (algorithm) (p. 1770)
• SparkML Serving (algorithm) (p. 1770)
• Tensorflow (DLC) (p. 1771)
• Tensorflow Coach (DLC) (p. 1781)
• Tensorflow Inferentia (DLC) (p. 1782)
• Tensorflow Ray (DLC) (p. 1782)
• XGBoost (algorithm) (p. 1783)

AutoGluon (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='autogluon', region='us-gov-west-1', image_scope='inference', version='0.4')
```
<table>
<thead>
<tr>
<th>Registry path</th>

<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
<td></td>
</tr>
</tbody>
</table>

Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='us-gov-west-1',version='1.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>598674086554.dkr.ecr.us-1.0.gov-west-1.amazonaws.com/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td>processing</td>
<td></td>
</tr>
</tbody>
</table>

Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='us-gov-west-1')
```
Use built-in algorithms

### DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar', region='us-gov-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

## Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

### Topics
- Common Data Formats for Training (p. 1784)
- Common Data Formats for Inference (p. 1788)

### Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

### Registry path | Version | Job types (image scope) |

<td>0.90-1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>
When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

Topics
- Content Types Supported by Built-In Algorithms (p. 1785)
- Using Pipe Mode (p. 1785)
- Using CSV Format (p. 1785)
- Using RecordIO Format (p. 1786)
- Trained Model Deserialization (p. 1788)

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported ContentType values and the algorithms that use them:

<table>
<thead>
<tr>

</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

Using Pipe Mode

In Pipe mode, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to File mode, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the AlgorithmSpecification for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify text/csv as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the
number of label columns in the content type. For example, in this case `content_type=text/csv;label_size=0`. For a notebook example that uses CSV format, see Breast Cancer Prediction. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However, if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**

For an example that shows how to convert the commonly used numpy array into the protobuf recordIO format, see An Introduction to Factorization Machines with MNIST.

```protobuf
syntax = "proto2";
package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 20) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as doubles (float64).
message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
  repeated double values = 1 [packed = true];

  // If this is not empty, the vector is treated as sparse, with
  // each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [ 10, 20 ], floor(keys[i] / 10) gives the row,
  // and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

// A sparse or dense rank-R tensor that stores data as 32-bit ints (int32).
message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a
  // dense vector.
}
```
repeated int32 values = 1 [packed = true];

// If this is not empty, the vector is treated as sparse with
// each key specifying the location of the value in the sparse vector.
repeated uint64 keys = 2 [packed = true];

// An optional shape that allows the vector to represent a matrix.
// For example, if shape = [10, 20], floor(keys[i] / 10) gives the row,
// and keys[i] % 20 gives the column.
// This also supports n-dimensional tensors.
// Note: If the tensor is sparse, you must specify this value.
repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
  repeated bytes value = 1;

  // If the content type of the data is known, stores it.
  // This allows for the possibility of using decoders for common formats
  // in the future.
  optional string content_type = 2;
}

message Value {
  oneof value {
    // The numbering assumes the possible use of:
    // - float16, float128
    // - int8, int16, int32
    Float32Tensor float32_tensor = 2;
    Float64Tensor float64_tensor = 3;
    Int32Tensor int32_tensor = 7;
    Bytes bytes = 9;
  }
}

message Record {
  // Map from the name of the feature to the value.
  // For vectors and libsvm-like datasets,
  // a single feature with the name `values`
  // should be specified.
  map<string, Value> features = 1;

  // An optional set of labels for this record.
  // Similar to the features field above, the key used for
  // generic scalar / vector labels should be `values`.
  map<string, Value> label = 2;

  // A unique identifier for this record in the dataset.
  // Whilst not necessary, this allows better
  // debugging where there are data issues.
  optional string uid = 3;

  // Textual metadata describing the record.
  // This may include JSON-serialized information
  // about the source of the record.
  optional string metadata = 4;
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of `InputDataConfig` in `create_training_job`.

**Note**
For all Amazon SageMaker algorithms, the `ChannelName` in `InputDataConfig` must be set to `train`. Some algorithms also support a validation or test input channel. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

**Trained Model Deserialization**

Amazon SageMaker models are stored as `model.tar.gz` in the S3 bucket specified in `OutputDataConfig` `S3OutputPath` parameter of the `create_training_job` call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When `model.tar.gz` is untarred, it contains `model_algo-1`, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

**Common Data Formats for Inference**

Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

**Topics**

- Convert Data for Inference Request Serialization (p. 1788)
- Convert Data for Inference Response Deserialization (p. 1790)
- Common Request Formats for All Algorithms (p. 1791)
- Use Batch Transform with Built-in Algorithms (p. 1792)

**Convert Data for Inference Request Serialization**

Content type options for Amazon SageMaker algorithm inference requests include: `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports `text/csv` from this list, but also supports `text/libsvm`. 

1788
For text/csv, the value for the Body argument to `invoke_endpoint` should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like `1.5, 16.0, 14, 23.0`. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

`application/json` is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
    // Instances might contain multiple rows that predictions are sought for.
    "instances": [
        {
            // Request and algorithm specific inference parameters.
            "configuration": {},
            // Data in the specific format required by the algorithm.
            "data": {
                "<field name>": dataElement
            }
        }
    ]
}
```

You have the following options for specifying the `dataElement`:

**Protocol buffers equivalent**

```javascript
// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
    "keys": [],
    "values": [],
    "shape": []
}
```

**Simple numeric vector**

```javascript
// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
    "features": {
        "values": dataElement
    }
}
```

**For multiple records**

```javascript
let request = {
    "instances": [
        // First instance.
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        },
        // Second instance.
        {
            "features": [-2.0, 100.2, 15.2, 9.2]
        }
    ]
}
```
Convert Data for Inference Response Deserialization

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

```javascript
let response = {
  "predictions": [{
    // Fields in the response object are defined on a per algorithm-basis.
  }]
}
```

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.

**Single-record inference**

```javascript
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

**Multi-record inference**

```javascript
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

**Multi-record inference with protobuf input**

```javascript
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": "{ "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:
While running batch transform, we recommended using the `jsonlines` response type by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

**Common Request Formats for All Algorithms**

Most algorithms use several of the following inference request formats.

**JSON Request Format**

**Content type:** `application/JSON`

**Dense format**

```json
let request = {
    "instances": [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}
```

```json
let request = {
    "instances": [
        {
            "data": {
                "features": {
                    "values": [1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

**Sparse format**

```json
{
    "instances": [
        {"data": {"features": {
            "keys": [26, 182, 232, 243, 431],
            "shape": [2000],
            "values": [1, 1, 1, 4, 1]
        }},
        {"data": {"features": {
            "keys": [0, 182, 232, 243, 431],
            "shape": [2000],
            "values": [13, 1, 1, 4, 1]
        }},
        ]
}
```

**JSONLINES Request Format**

**Content type:** `application/JSONLINES`
Dense format
A single record in dense format can be represented as either:

```
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } }
```

Sparse Format
A single record in sparse format is represented as:

```
{"data": { "features": { "keys": [26, 182, 232, 243, 431], "shape": [2000], "values": [1, 1, 1, 4, 1] } } }
```

Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{"data": { "features": { "keys": [0, 1, 3], "shape": [4], "values": [1, 4, 1] } } }
{"data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } } }
{"features": [1.5, 16.0, 14.0, 23.0] }
```

CSV Request Format
Content type: text/CSV; label_size=0

Note
CSV support is not available for factorization machines.

RECORDIO Request Format
Content type: application/x-recordio-protobuf

Use Batch Transform with Built-in Algorithms
While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

When you create a transform job, the SplitType must be set according to the ContentType of the input data. Similarly, depending on the Accept field in the CreateTransformJobRequest, AssembleWith must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Recommended SplitType</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
</tr>
<tr>
<td>text/csv</td>
<td>Line</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/x-image</td>
<td>None</td>
</tr>
<tr>
<td>image/*</td>
<td>None</td>
</tr>
</tbody>
</table>
### Use built-in algorithms

<table>
<thead>
<tr>
<th>Accept</th>
<th>Recommended AssembleWith</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>None</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
</tbody>
</table>

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats (p. 1816)
- Factorization Machines Response Formats (p. 1827)
- IP Insights Inference Data Formats (p. 1848)
- K-Means Response Formats (p. 1857)
- k-NN Request and Response Formats (p. 1864)
- Linear learner response formats (p. 1887)
- NTM Response Formats (p. 1894)
- Data Formats for Object2Vec Inference (p. 1908)
- Encoder Embeddings for Object2Vec (p. 1910)
- PCA Response Formats (p. 1925)
- RCF Response Formats (p. 1932)

### Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.10xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

### Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

**Note**

If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.
The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

**Common Errors**

If a training job fails, some details about the failure are provided by the `FailureReason` return value in the training job description, as follows:

```python
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']
```

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

From the CloudWatch Log

```
[10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]
Additional properties are not allowed (u'mini_batch_siz' was unexpected)
```

2. Specifying an invalid value for a hyperparameter.

FailureReason

```
AlgorithmError: u'abc' is not valid under any of the given schemas
```

FailureReason

```
[10/16/2017 23:57:17 ERROR 140373086025536 train.py:48] u'abc' is not valid under any of the given schemas
```

3. Inaccurate protobuf file format.

From the CloudWatch log

```
[10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot copy sequence with size 785 to array axis with dimension 784
```

**BlazingText algorithm**

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.
The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a word embedding. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A batch_skipgram mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The batch_skipgram mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>
<th>Word2Vec (Unsupervised Learning)</th>
<th>Text Classification (Supervised Learning)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single CPU instance</td>

</tr>
<tr>
<td>Single GPU instance (with 1 or more GPUs)</td>
<td>cbow</td>
<td>supervised with one GPU</td>
</tr>
<tr>
<td></td>
<td>Skip-gram</td>
<td></td>
</tr>
<tr>
<td>Multiple CPU instances</td>
<td>Batch Skip-gram</td>
<td>None</td>
</tr>
</tbody>
</table>

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

Topics
Input/Output Interface for the BlazingText Algorithm

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.

Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the `train` channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string `__label__`. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time, intel says, despite all the linux hype, the open-source movement has yet to make a huge splash in the desktop market. that may be about to change, thanks to chipmaking giant intel corp. 
__label__2  bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived. 
```

Note

The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the `source` tag and the label can be specified using the `label` tag. Both `source` and `label` tags should be provided under the `AttributeNames` parameter value as specified in the request.

```
{"source":"linux ready for prime time, intel says, despite all the linux hype", "label":1} 
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly", "label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.
Use built-in algorithms

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2380).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to True, an additional file, eval.json, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to True during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

Sample JSON Request

Mime-type: application/json

```json
{
  "instances": ["word1", "word2", "word3"]
}
```

Model Artifacts for the Text Classification Algorithm

Training with supervised outputs creates a model.bin file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

Sample JSON Request

Mime-type: application/json

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
  "configuration": {"k": 2}
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top k predictions, you can set k in the configuration, as follows:
For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines
{
"source": "source_0"
{
"source": "source_1"
}
if you need to pass the value of k for top-k, then you can do it in the following way:
{
"source": "source_0", "k": 2
{
"source": "source_1", "k": 3
}
```

The format for output follows:

```
accept: application/jsonlines
{
"prob": [prob_1], "label": ["__label__1"]
{
"prob": [prob_1], "label": ["__label__1"]
}
If you have passed the value of k to be more than 1, then response will be in this format:
{
"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]
{
"prob": [prob_1, prob_2], "label": ["__label__1", "__label__2"]
}
```

For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```bash
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz
#Unzip the model archive
tar -xzf model.tar.gz
#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks Text Classification with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the Word2Vec Algorithm.

**EC2 Instance Recommendation for the BlazingText Algorithm**

For `cbow` and `skipgram` modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an `ml.p3.2xlarge` instance.

For `batch_skipgram` mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the `S3DataDistributionType` field of the `S3DataSource` object
that you pass to `CreateTrainingJob` to `FullyReplicated`. BlazingText takes care of distributing
data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less
than 2 GB. For larger datasets, use an instance with a single GPU (ml.p2.xlarge or ml.p3.2xlarge).

**BlazingText Sample Notebooks**

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised
binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For
instructions for creating and accessing Jupyter notebook instances that you can use to run the example
in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After creating and opening a
notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The
topic modeling example notebooks that use the Blazing Text are located in the Introduction to Amazon
algorithms section. To open a notebook, choose its **Use** tab, then choose Create copy.

**BlazingText Hyperparameters**

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm.
You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters
for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text
Classification (supervised).

**Word2Vec Hyperparameters**

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided
by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>The Word2vec architecture used for training. Required</td>
</tr>
<tr>
<td></td>
<td>Valid values: batch_skipgram, skipgram, or cbow</td>
</tr>
<tr>
<td>batch_size</td>
<td>The size of each batch when mode is set to batch_skipgram. Set to a number between 10 and 20. Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Positive integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 11</td>
</tr>
<tr>
<td>buckets</td>
<td>The number of hash buckets to use for subwords. Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 2000000</td>
</tr>
<tr>
<td>epochs</td>
<td>The number of complete passes through the training data. Optional</td>

</tbody>
</table>
| evaluation           | Whether the trained model is evaluated using the WordSimilarity-353 Test.  
Optional  
Valid values: (Boolean) True or False  
Default value: True |
| learning_rate        | The step size used for parameter updates.  
Optional  
Valid values: Positive float  
Default value: 0.05 |
| min_char             | The minimum number of characters to use for subwords/character n-grams.  
Optional  
Valid values: positive integer  
Default value: 3 |
| min_count            | Words that appear less than min_count times are discarded.  
Optional  
Valid values: Non-negative integer  
Default value: 5 |
| max_char             | The maximum number of characters to use for subwords/character n-grams  
Optional  
Valid values: positive integer  
Default value: 6 |
| negative_samples     | The number of negative samples for the negative sample sharing strategy.  
Optional  
Valid values: Positive integer  
Default value: 5 |
### Text Classification Hyperparameters

The following table lists the hyperparameters for the Text Classification training algorithm provided by Amazon SageMaker.

**Note**

Although some of the parameters are common between the Text Classification and Word2Vec modes, they might have different meanings depending on the context.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>The training mode.</td>
</tr>
<tr>

**Tune a BlazingText Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Metrics Computed by the BlazingText Algorithm**

The BlazingText Word2Vec algorithm ([skipgram, cbow, and batch_skipgram modes](#)) reports on a single metric during training: `train:mean_rho`. This metric is computed on [WS-353 word similarity datasets](#). When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm ([supervised mode](#)), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

<table>
<thead>

DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly...
over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related
time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained
model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have
been generated by the same process or similar processes. Based on this input dataset, the algorithm
trains a model that learns an approximation of this process/processes and uses it to predict how the
target time series evolves. Each target time series can be optionally associated with a vector of static
(time-independent) categorical features provided by the cat field and a vector of dynamic (time-
dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by
randomly sampling training examples from each target time series in the training dataset. Each training
example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To
control how far in the past the network can see, use the context_length hyperparameter. To control
how far in the future predictions can be made, use the prediction_length hyperparameter. For more
information, see How the DeepAR Algorithm Works (p. 1808).

Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The
optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after
training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet
file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that
contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all
files in the directory as inputs for the corresponding channel, except those that start with a period (.) and
those named _SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as
input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz,
or .parquet) in the specified input path. If the path does not end in one of these extensions, you must
explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input
class.

The records in your input files should contain the following fields:
- start—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time
  zone information.
- target—An array of floating-point values or integers that represent the time series. You can encode
  missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- dynamic_feat (optional)—An array of arrays of floating-point values or integers that represents the
  vector of custom feature time series (dynamic features). If you set this field, all records must have the
  same number of inner arrays (the same number of feature time series). In addition, each inner array
  must be the same length as the associated target value plus length of the context. Missing values are
  not supported in the features. For example, if target time series represents the demand of different

1805
products, an associated `dynamicFeat` might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

```json
{"start": ..., "target": [1, 5, 10, 2], "dynamicFeat": [[0, 1, 1, 0]]}
```

- `cat` (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain \{R, G, B\} can be encoded as \{0, 1, 2\}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the `embedding_dimension` hyperparameter. For more information, see DeepAR Hyperparameters (p. 1811).

If you use a JSON file, it must be in JSON Lines format. For example:

```json
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
"dynamicFeat": [[1.1, 1.2, 0.5, ...]]
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamicFeat":
[[1.1, 2.05, ...]]
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamicFeat":
[[1.3, 0.4]]}
```

In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the `datetime` type. You can compress Parquet files using gzip (`gzip`) or the Snappy compression library (`snappy`).

If the algorithm is trained without `cat` and `dynamic_feat` fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the `cat` and `dynamic_feat` feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding `cat` features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional `cat` vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```json
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with `cat` values that are combinations of the `cat` values observed in the training data, for example:

```json
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the `start` field correctly. The algorithm uses the `start` timestamp to derive the internal features.
If you use categorical features (cat), all time series must have the same number of categorical features. If the dataset contains the `cat` field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, `cardinality` is "auto". If the dataset contains the `cat` field, but you don’t want to use it, you can disable it by setting `cardinality` to "". If a model was trained using a `cat` feature, you must include it for inference.

If your dataset contains the `dynamic_feat` field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the `dynamic_feat` field should have the same length as the target. If the dataset contains the `dynamic_feat` field, but you don’t want to use it, disable it by setting `num_dynamic_feat` to "". If the model was trained with the `dynamic_feat` field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the `prediction_length`. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

$$RMSE = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{i,t} - y_{i,t})^2}$$

$y_{i,t}$ is the true value of time series $i$ at the time $t$. $\hat{y}_{i,t}$ is the mean prediction. The sum is over all $n$ time series in the test set and over the last $T$ time points for each time series, where $T$ corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see DeepAR Hyperparameters (p. 1811).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range $[0, 1]$, the weighted quantile loss is defined as follows:

$$w\text{QuantileLoss}[\tau] = 2 \frac{\sum_{i,t} Q_{i,t}^{(\tau)}}{\sum_{i,t} |y_{i,t}|}, \quad \text{with} \quad Q_{i,t}^{(\tau)} = \begin{cases} (1-\tau)|\hat{q}_{i,t}^{(\tau)} - y_{i,t}| & \text{if } \hat{q}_{i,t}^{(\tau)} > y_{i,t} \\ \tau |\hat{q}_{i,t}^{(\tau)} - y_{i,t}| & \text{otherwise} \end{cases}$$

$q_{i,t}^{(\tau)}$ is the $\tau$-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 1811).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 1816).

**Best Practices for Using the DeepAR Algorithm**

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don’t break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.
- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but
on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholding the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 1815).

- Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use `5min` instead of `1min`.
- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.
- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.

**EC2 Instance Recommendations for the DeepAR Algorithm**

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, `ml.c4.2xlarge` or `ml.c4.4xlarge`), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for `context_length`, `prediction_length`, `num_cells`, `num_layers`, or `mini_batch_size` can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

**DeepAR Sample Notebooks**

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see Time series forecasting with DeepAR - Synthetic data as well as DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.

**How the DeepAR Algorithm Works**

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector
of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 1805).

For example, the following is an element of a training set indexed by \( i \) which consists of a target time series, \( Z_{i,t} \), and two associated feature time series, \( X_{i,1,t} \) and \( X_{i,2,t} \):

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run "what if?" scenarios. What happens, for example, if I change the price of a product in some way?

Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

How Feature Time Series Work in the DeepAR Algorithm

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. For example, DeepAR creates two feature time series (day of the month and day of the year) for a weekly time series frequency. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: \( u_{i,1,t} \) represents the hour of the day and \( u_{i,2,t} \) the day of the week.

The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.
DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The `context_length` hyperparameter controls how far in the past the network can see, and the `prediction_length` hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element $i$. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$.

To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, $t = T$, the model exposes the $z_{i,t}$ values, which occurred approximately one, two, and three days in the past.
For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next \texttt{prediction_length} values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

**DeepAR Hyperparameters**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context_length</td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the \texttt{prediction_length}. The model also receives lagged inputs from the target, so \texttt{context_length} can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the time series. For example, lag values for daily frequency are previous week, 2 weeks, 3 weeks, 4 weeks, and year. Required</td>
</tr>
<tr>
<td>epochs</td>
<td>The maximum number of passes over the training data. The optimal value depends on your data size and learning rate. See also early_stopping_patience. Typical values range from 10 to 1000. Required</td>
</tr>
<tr>
<td>prediction_length</td>
<td>The number of time-steps that the model is trained to predict, also called the forecast horizon. The trained model always generates forecasts with this length. It can't generate longer forecasts. The \texttt{prediction_length} is fixed when a model is trained and it cannot be changed later. Required</td>
</tr>
<tr>
<td>time_freq</td>
<td>The granularity of the time series in the dataset. Use \texttt{time_freq} to select appropriate date features and lags. The model supports the following basic frequencies. It also supports multiples of these basic frequencies. For example, \texttt{5min} specifies a frequency of 5 minutes.</td>
</tr>
</tbody>

</table>
## Tune a DeepAR Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

### Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see Best Practices for Using the DeepAR Algorithm (p. 1807).

<table>
<thead>
<tr>

</tbody>
</table>

**DeepAR Inference Formats**

**DeepAR JSON Request Formats**

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat` values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```json
{
    "instances": [,
    {
        "start": "2009-11-01 00:00:00",
        "target": [4.0, 10.0, "NaN", 100.0, 113.0],
        "cat": [0, 1],
        "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
    },,
    {
        "start": "2012-01-30",
        "target": [1.0],
        "cat": [2, 1],
        "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
    },,
    {
        "start": "1999-01-30",
```
Use built-in algorithms

The configuration field is optional. `configuration.num_samples` sets the number of sample paths that the model generates to estimate the mean and quantiles. `configuration.output_types` describes the information that will be returned in the request. Valid values are "mean", "quantiles", and "samples". If you specify "quantiles", each of the quantile values in `configuration.quantiles` is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

**DeepAR JSON Response Formats**

The following is the format of a response, where `[...]` are arrays of numbers:

```json
{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    }
  ]
}
```

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It's better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn't enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable.
Amazon SageMaker Developer Guide
Use built-in algorithms

MODEL_SERVER_WORKERS For example, by setting MODEL_SERVER_WORKERS=1) when calling the
SageMaker CreateModel API.

Batch Transform with the DeepAR Algorithm
DeepAR forecasting supports getting inferences by using batch transform from data using the JSON
Lines format. In this format, each record is represented on a single line as a JSON object, and lines
are separated by newline characters. The format is identical to the JSON Lines format used for model
training. For information, see Input/Output Interface for the DeepAR Algorithm (p. 1805). For example:
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
"dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":
[[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
[[1.3, 0.4]]}

Note

When creating the transformation job with CreateTransformJob, set the BatchStrategy
value to SingleRecord and set the SplitType value in the TransformInput conﬁguration
to Line, as the default values currently cause runtime failures.
Similar to the hosted endpoint inference request format, the cat and the dynamic_feat ﬁelds for each
instance are required if both of the following are true:
• The model is trained on a dataset that contained both the cat and the dynamic_feat ﬁelds.
• The corresponding cardinality and num_dynamic_feat values used in the training job are not set
to "".
Unlike hosted endpoint inference, the conﬁguration ﬁeld is set once for the entire batch
inference job using an environment variable named DEEPAR_INFERENCE_CONFIG. The
value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling
CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment,
the inference container uses the following default:
{

}

"num_samples": 100,
"output_types": ["mean", "quantiles"],
"quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance
order in the corresponding input ﬁle. Predictions are encoded as objects identical to the ones returned by
responses in online inference mode. For example:
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }

Note that in the TransformInput conﬁguration of the SageMaker CreateTransformJob request
clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all
JSON objects on the same line.
For example, here is a SageMaker CreateTransformJob request for a DeepAR job with a custom
DEEPAR_INFERENCE_CONFIG:
{

"BatchStrategy": "SingleRecord",
"Environment": {
"DEEPAR_INFERENCE_CONFIG" : "{ \"num_samples\": 200, \"output_types\": [\"mean\"] }",

1818


Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

**Note**
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

**Topics**
- Input/Output Interface for the Factorization Machines Algorithm (p. 1819)
- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1820)
- Factorization Machines Sample Notebooks (p. 1820)
- How Factorization Machines Work (p. 1820)
- Factorization Machines Hyperparameters (p. 1821)
- Tune a Factorization Machines Model (p. 1826)
- Factorization Machines Response Formats (p. 1827)

**Input/Output Interface for the Factorization Machines Algorithm**

The Factorization Machines algorithm can be run in either binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset. The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the **binary classification** problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the **regression** problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.
Please see Factorization Machines Sample Notebooks (p. 1820) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function $\hat{y}$ from a feature set $x_i$ to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset $(x_i,y_j)$ available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

$$\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j>i} <v_i, v_j> x_i x_j$$

The three terms in this equation correspond respectively to the three components of the model:

- The $w_0$ term represents the global bias.
- The $w_i$ linear terms model the strength of the $i^{th}$ variable.
- The $<v_i, v_j>$ factorization terms model the pairwise interaction between the $i^{th}$ and $j^{th}$ variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction $\hat{y}_n$ and the target value $y_n$. This is known as the square loss:

$$L = \frac{1}{N} \sum_{n} (y_n - \hat{y}_n)^2$$

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

$$L = \frac{1}{N} \sum_{n} [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]$$
where:

\[ \hat{p}_n = \frac{1}{1 + e^{-y_n}} \]

For more information about loss functions for classification, see Loss functions for classification.

**Factorization Machines Hyperparameters**

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

  Default value: None |
Tune a Factorization Machines Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

Metrics Computed by the Factorization Machines Algorithm

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a test:rmse regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

Tunable Factorization Machines Hyperparameters

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: uniform, normal, and constant. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is uniform, then only the scale parameters are tunable. Specifically, if bias_init_method=uniform, then bias_init_scale, linear_init_scale, and factors_init_scale are tunable. Similarly, if the initialization method is normal, then only sigma parameters are tunable. If the initialization method is constant, then only value parameters are tunable. These dependencies are listed in the following table.

**Factorization Machines Response Formats**

**JSON Response Format**

Binary classification

```javascript
let response = {
    "predictions": [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
};
```
Regression

```javascript
let response = {
    "predictions": [
        {
            "score": 0.4
        }
    ]
}
```

**JSONLINES Response Format**

Binary classification

```json
{"score": 0.4, "predicted_label": 0}
```

Regression

```json
{"score": 0.4}
```

**RECORDIO Response Format**

Binary classification

```json
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            },
            'predicted_label': {
                keys: [],
                values: [0.0]  # float32
            }
        }
    }
]
```

Regression

```json
[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4]  # float32
            }
        }
    }
]`
Image Classification Algorithm

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

For more information on convolutional networks, see:

- Deep residual learning for image recognition Kaiming He, et al., 2016 IEEE Conference on Computer Vision and Pattern Recognition

Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (.rec) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the S3DataDistributionType of the S3DataSource to FullyReplicated. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports image/png, image/jpeg, and application/x-image for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio.

Train with Image Format

If you use the Image format for training, specify train, validation, train_lst, and validation_lst channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify the individual image data (.jpg or .png files) for the train
and validation channels. Specify one .lst file in each of the train_lst and validation_lst channels. Set the content type for all four channels to application/x-image.

Note
SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

```
5      1   your_image_directory/train_img_dog1.jpg
1000   0   your_image_directory/train_img_cat1.jpg
22     1   your_image_directory/train_img_dog2.jpg
```

For example, if your training images are stored in s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on, specify the path for your train channel as s3://<your_bucket>/train, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named train_image_dog1.jpg in the class_dog class directory as class_dog/train_image_dog1.jpg. You can also store all your image files under one subdirectory inside the train directory. In that case, use that subdirectory for the relative path. For example, s3://<your_bucket>/train/your_image_directory.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ["source-ref", "class"]. The corresponding label value is "0" for the first image and "1" for the second image:

```
{"source-ref":"s3://image/filename1.jpg", "class":"0"}
{"source-ref":"s3://image/filename2.jpg", "class":"1", "class-metadata": {"class-name": "cat", "type" : "groundtruth/image-classification"}}
```

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class". When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:
Amazon SageMaker Developer Guide
Use built-in algorithms

{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data
point. The previous example would instead look like this:
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}

The multi-hot format is the default, but can be explicitly set in the content type with the label-format
parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which
is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; labelformat=class-id".
For more information on augmented manifest ﬁles, see Provide Dataset Metadata to Training Jobs with
an Augmented Manifest File (p. 2380).

Incremental Training
You can also seed the training of a new model with the artifacts from a model that you trained
previously with SageMaker. Incremental training saves training time when you want to train a new model
with the same or similar data. SageMaker image classiﬁcation models can be seeded only with another
To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in
the InputDataConfig parameter. Set the ContentType for the model channel to application/xsagemaker-model. The input hyperparameters of both the new model and the pretrained model that
you upload to the model channel must have the same settings for the num_layers, image_shape and
num_classes input parameters. These parameters deﬁne the network architecture. For the pretrained
model ﬁle, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use
either RecordIO or image formats for input data.
For a sample notebook that shows how to use incremental training with the SageMaker image
classiﬁcation algorithm, see the End-to-End Incremental Training Image Classiﬁcation Example. For more
information on incremental training and for instructions on how to use it, see Incremental Training in
Amazon SageMaker (p. 2369).

Inference with the Image Classiﬁcation Algorithm
The generated models can be hosted for inference and support encoded .jpg and .png image formats
as image/png, image/jpeg, and application/x-image content-type. The input image is resized
automatically. The output is the probability values for all classes encoded in JSON format, or in JSON
Lines text format for batch transform. The image classiﬁcation model processes a single image per
request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a
response in JSON Lines format:
accept: application/jsonlines
{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}

For more details on training and inference, see the image classiﬁcation sample notebook instances
referenced in the introduction.

EC2 Instance Recommendation for the Image Classiﬁcation Algorithm
For image classiﬁcation, we support the following GPU instances for training: ml.p2.xlarge,
ml.p2.8xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.8xlargeand ml.p3.16xlarge. We
recommend using GPU instances with more memory for training with large batch sizes. However, both

1831


CPU (such as C4) and GPU (such as P2 and P3) instances can be used for the inference. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training.

Both P2 and P3 instances are supported in the image classification algorithm.

### Image Classification Sample Notebooks

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the caltech-256 dataset and then to deploy it to perform inferences, see the End-to-End Multiclass Image Classification Example. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

### How Image Classification Works

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet[2] is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

### Image Classification Hyperparameters

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model (p. 1839) for information on image classification hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset.</td>
</tr>
<tr>
<td></td>
<td>Besides multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm (p. 1829) for details on how to work with multi-label classification with augmented manifest files.</td>
</tr>
<tr>
<td>num_training_samples</td>
<td>Number of training examples in the input dataset.</td>
</tr>
<tr>
<td>Required</td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter is undefined and distributed training accuracy might be affected.</td>
</tr>
<tr>
<td>Required</td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>augmentation_type</td>
<td>Data augmentation type. The input images can be augmented in multiple ways as specified below.</td>
</tr>
<tr>
<td></td>
<td>• crop: Randomly crop the image and flip the image horizontally</td>
</tr>
<tr>
<td></td>
<td>• crop_color: In addition to ‘crop’, three random values in the range [-36, 36], [-50, 50], and [-50, 50] are added to the corresponding Hue-Saturation-Lightness channels respectively</td>
</tr>
<tr>
<td></td>
<td>• crop_color_transform: In addition to crop_color, random transformations, including rotation, shear, and aspect ratio variations are applied to the image. The maximum angle of rotation is 10 degrees, the maximum shear ratio is 0.1, and the maximum aspect changing ratio is 0.25.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: crop, crop_color, or crop_color_transform.</td>
</tr>
<tr>
<td></td>
<td>Default value: no default value</td>
</tr>
<tr>
<td>beta_1</td>
<td>The beta1 for adam, that is the exponential decay rate for the first moment estimates.</td>
</tr>
<tr>
<td>Optional</td>
<td>Valid values: float. Range in [0, 1].</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.9</td>
</tr>
<tr>
<td>beta_2</td>
<td>The beta2 for adam, that is the exponential decay rate for the second moment estimates.</td>
</tr>

</tbody>
</table>
| epochs         | Number of training epochs.  
Optional  
Valid values: positive integer  
Default value: 30 |
| eps            | The epsilon for adam and rmsprop. It is usually set to a small value to avoid division by 0.  
Optional  
Valid values: float. Range in [0, 1].  
Default value: 1e-8 |
| gamma          | The gamma for rmsprop, the decay factor for the moving average of the squared gradient.  
Optional  
Valid values: float. Range in [0, 1].  
Default value: 0.9 |
| image_shape    | The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3, 224, 224'. This is similar to the ImageNet dataset.  
For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken.  
At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped.  
Optional  
Valid values: string  
Default value: '3, 224, 224' |
<table>

<tr>
<td></td>
<td>Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110]</td>
</tr>
<tr>
<td></td>
<td>Default value: 152</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
---|---
**optimizer** | The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.
  **Optional**
  Valid values: One of *sgd*, *adam*, *rmsprop*, or *nag*.
  - *sgd*: Stochastic gradient descent
  - *adam*: Adaptive momentum estimation
  - *rmsprop*: Root mean square propagation
  - *nag*: Nesterov accelerated gradient
  Default value: *sgd*

**precision_dtype** | The precision of the weights used for training. The algorithm can use either single precision (*float32*) or half precision (*float16*) for the weights. Using half-precision for weights results in reduced memory consumption.
  **Optional**
  Valid values: *float32* or *float16*
  Default value: *float32*

**resize** | The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of *image_shape* to prevent training failure.
  **Required** when using image content types
  **Optional** when using the RecordIO content type
  Valid values: positive integer
  Default value: no default value

**top_k** | Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.
  **Optional**
  Valid values: positive integer larger than 1.
  Default value: no default value
<table>

**Tune an Image Classification Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Metrics Computed by the Image Classification Algorithm**

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>

**IP Insights**

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as embeddings. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.
Input/Output Interface for the IP Insights Algorithm

Training and Validation

The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats (p. 1847).

Inference

For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference (p. 1788). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats (p. 1848).

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances.

GPU Instances for the IP Insights Algorithm

IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

CPU Instances for the IP Insights Algorithm

The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: vector_dim and num_entity_vectors. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for vector_dim in the first column range from 32 to 2048 and the values for num_entity_vectors in the first row range from 10,000 to 50,000,000.
The values for the `mini_batch_size`, `num_ip_encoder_layers`, `random_negative_sampling_rate`, and `shuffled_negative_sampling_rate` hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

**IP Insights Sample Notebooks**

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see [An Introduction to the SageMaker IP Insights Algorithm](#). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](#). After creating a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. To open a notebook, choose its Use tab and choose Create copy.

**How IP Insights Works**

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to ensure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see [Feature Hashing for Large Scale Multitask Learning](#). For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the log loss, defined as follows:
Use built-in algorithms

\[ L = \frac{1}{N} \sum_{n} [y_n \log p_n + (1 - y_n) \log (1 - p_n)] \]

\( y_n \) is the label that indicates whether the sample is from the real distribution governing observed data \((y_n=1)\) or from the distribution generating negative samples \((y_n=0)\). \( p_n \) is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the \texttt{random_negative_sampling_rate} and \texttt{shuffled_negative_sampling_rate} hyperparameters.

Given an \textit{nth} \((\text{entity, IP address pair})\), the IP Insights model outputs a \textit{score}, \( S_n \), that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given \((\text{entity, IP address})\) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

\[ S_n = \log \left( \frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)} \right) \]

The score is essentially a measure of the similarity between the vector representations of the \textit{nth} entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, \( p_n \), to use in the cross entropy minimization, where:

\[ p_n = \frac{1}{1 + e^{-S_n}} \]

### IP Insights Hyperparameters

In the \texttt{CreateTransformJob} request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_entity_vectors</td>
<td>The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers. Required Valid values: (1 \leq \text{positive integer} \leq 250,000,000)</td>
</tr>
<tr>
<td>Parameter Name</td>

**Tune an IP Insights Model**

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

**Metrics Computed by the IP Insights Algorithm**

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This `validation:discriminator_auc` metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a `validation:discriminator_auc` metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.

### IP Insights Data Formats

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

**Topics**
- IP Insights Training Data Formats (p. 1847)
- IP Insights Inference Data Formats (p. 1848)

**IP Insights Training Data Formats**

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for
Training (p. 1784). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

**IP Insights Training Data Input Formats**

**INPUT: CSV**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

```
content-type: text/csv

entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**IP Insights Inference Data Formats**

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1788). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

**IP Insights Input Request Formats**

**INPUT: CSV Format**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

```
content-type: text/csv

entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**INPUT: JSON Format**

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1788).

```
content-type: application/json

{
    "instances": [
        {
            "data": {
                "features": {
                    "values": ["entity_id_1", "192.168.1.2"]
                }
            },
            "features": {"entity_id_2", "10.10.1.2"}
        }
    ]
}
```

**INPUT: JSONLINES Format**

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1788). For more information on running batch transform jobs, see Use Batch Transform (p. 2565).
content-type: application/jsonlines

```json
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]},
{"features": ["entity_id_2", "10.10.1.2"]}}}
```

**IP Insights Output Response Formats**

**OUTPUT: JSON Response Format**

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMaker IP Insights Algorithm.

```json
{ "predictions": [
    {"dot_product": 0.0},
    {"dot_product": 2.0}
]}
```

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

```json
{ "predictions": [
    {
      "dot_product": 0.0,
      "entity_embedding": [1.0, 0.0, 0.0],
      "ip_embedding": [0.0, 1.0, 0.0]
    },
    {
      "dot_product": 2.0,
      "entity_embedding": [1.0, 0.0, 1.0],
      "ip_embedding": [1.0, 0.0, 1.0]
    }
]}
```

**OUTPUT: JSONLINES Response Format**

```json
{"dot_product": 0.0}
{"dot_product": 2.0}
```

```json
{"dot_product": 0.0, "entity_embedding": [1.0, 0.0, 0.0], "ip_embedding": [0.0, 1.0, 0.0]}
{"dot_product": 2.0, "entity_embedding": [1.0, 0.0, 1.0], "ip_embedding": [1.0, 0.0, 1.0]}
```
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The \( n \) attributes in each row represent a point in \( n \)-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works (p. 1851).

Topics

- Input/Output Interface for the K-Means Algorithm (p. 1850)
- EC2 Instance Recommendation for the K-Means Algorithm (p. 1850)
- K-Means Sample Notebooks (p. 1850)
- How K-Means Clustering Works (p. 1851)
- K-Means Hyperparameters (p. 1853)
- Tune a K-Means Model (p. 1856)
- K-Means Response Formats (p. 1857)

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the \texttt{train} channel (recommended \texttt{S3DataDistributionType=ShardedByS3Key}), with an optional \texttt{test} channel (recommended \texttt{S3DataDistributionType=FullyReplicated}) to score the data on. Both \texttt{recordIO-wrapped-protobuf} and \texttt{CSV} formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as \texttt{recordIO-wrapped-protobuf} or as \texttt{CSV}.

For inference, \texttt{text/csv}, \texttt{application/json}, and \texttt{application/x-recordio-protobuf} are supported. k-means returns a \texttt{closest_cluster} label and the \texttt{distance_to_cluster} for each observation.

For more information on input and output file formats, see K-Means Response Formats (p. 1857) for inference and the K-Means Sample Notebooks (p. 1850). The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to \texttt{p*.xlarge} instances because only one GPU per instance is used.

K-Means Sample Notebooks

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker.
SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

How K-Means Clustering Works

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the $n$-dimensional space (where $n$ is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points $(t, h)$ in 2-dimensional space.

**Note**

Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters ($k$) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space $(x, y)$. To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

**Note**

Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create $k$ clusters, you might choose to improve model accuracy by specifying extra cluster centers ($K = k \times x$). However, the algorithm ultimately reduces these to $k$ clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see CreateTrainingJob. In the request body, you add the HyperParameters string map to specify the $k$ and extra_center_factor strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial $K$ cluster centers.

   **Note**

   In the following topics, $K$ clusters refer to $k \times x$, where you specify $k$ and $x$ when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.

3. It reduces resulting clusters to $k$ (if the data scientist specified the creation of $k\times x$ clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

Topics

- Step 1: Determine the Initial Cluster Centers (p. 1852)
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 1852)
- Step 3: Reduce the Clusters from $K$ to $k$ (p. 1853)
Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose \( K \) observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.
- The k-means++ approach, which works as follows:

  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.

  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:

     - For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     - Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.

  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.

  4. Repeat the process until you have the \( K \) cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following `HyperParameters` string maps:

- To specify the number of clusters to create, add the `k` string.
- For greater accuracy, add the optional `extra_center_factor` string.
- To specify the strategy that you want to use to determine the initial cluster centers, add the `init_method` string and set its value to `random` or `k-means++`.

For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the \( K \) cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   **Note**
   When creating a model training job, you specify the batch size in the `mini_batch_size` string in the `HyperParameters` string map.
a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

For example, consider the following clusters:

Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

\[
\begin{align*}
    p_1 &= \text{proportion of points assigned to } c_1 = \frac{25}{(100+25)} \\
    p_2 &= \text{proportion of points assigned to } c_2 = \frac{40}{(150+40)} \\
    p_3 &= \text{proportion of points assigned to } c_3 = \frac{5}{(450+5)}
\end{align*}
\]

c. Compute the center of the new points added to each cluster:

\[
\begin{align*}
    d_1 &= \text{center of the new points added to cluster 1} \\
    d_2 &= \text{center of the new points added to cluster 2} \\
    d_3 &= \text{center of the new points added to cluster 3}
\end{align*}
\]

d. Compute the weighted average to find the updated cluster centers as follows:

\[
\begin{align*}
    \text{Center of cluster 1} &= ((1 - p_1) \times \text{center of cluster 1}) + (p_1 \times d_1) \\
    \text{Center of cluster 2} &= ((1 - p_2) \times \text{center of cluster 2}) + (p_2 \times d_2) \\
    \text{Center of cluster 3} &= ((1 - p_3) \times \text{center of cluster 3}) + (p_3 \times d_3)
\end{align*}
\]

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.

3. For more information about mini-batch k-means, see Web-Scale k-means Clustering.

**Step 3: Reduce the Clusters from K to k**

If the algorithm created K clusters—\(K = k \times x\) where \(x\) is greater than 1—then it reduces the K clusters to \(k\) clusters. (For more information, see extra_center_factor in the preceding discussion.) It does this by applying Lloyd’s method with kmeans++ initialization to the \(K\) cluster centers. For more information about Lloyd’s method, see k-means clustering.

**K-Means Hyperparameters**

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see How K-Means Clustering Works (p. 1851).

Valid values: Either a positive integer or auto.  
Default value: auto |
| local_lloyd_tol               | The tolerance for change in loss for early stopping of Lloyd's expectation-maximization (EM) procedure used to build the final model containing $k$ centers.  
Optional  
Valid values: Float. Range in [0, 1].  
Default value: 0.0001 |
**Tune a K-Means Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Metrics Computed by the K-Means Algorithm**

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>

**Tunable K-Means Hyperparameters**

Tune the Amazon SageMaker k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are: `mini_batch_size`, `extra_center_factor`, and `init_method`. Tuning the hyperparameter `epochs` generally results in minor improvements.

<table>
<thead>

**K-Means Response Formats**

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

**JSON Response Format**

```
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ...
  ]
}
```

**JSONLINES Response Format**

```
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

**RECORDIO Response Format**

```
[ Record = {
    features = {},
    label = {
      'closest_cluster': {
        keys: [],
        values: [1.0, 2.0] # float32
      },
      'distance_to_cluster': {
        keys: [],
        values: [3.0, 5.0] # float32
      }
    }
  }
]
```

**CSV Response Format**

The first value in each line corresponds to closest_cluster.
The second value in each line corresponds to distance_to_cluster.

| 1.0, 3.0 |
| 2.0, 5.0 |

**K-Nearest Neighbors (k-NN) Algorithm**

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the k points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the k closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d > 1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

- k-NN Hyperparameters (p. 1860)
- Tune a k-NN Model (p. 1862)
- Data Formats for k-NN Training Input (p. 1863)
- k-NN Request and Response Formats (p. 1864)

**Input/Output Interface for the k-NN Algorithm**

SageMaker k-NN supports train and test data channels.

- Use a *train channel* for data that you want to sample and construct into the k-NN index.
- Use a *test channel* to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports text/csv and application/x-recordio-protobuf data formats. For input type text/csv, the first label_size columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the application/json, application/x-recordio-protobuf, and text/csv data formats. The text/csv format accepts a label_size and encoding parameter. It assumes a label_size of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the application/json and application/x-recordio-protobuf data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.
For batch transform, k-NN supports the application/jsonlines data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 1863) for training, k-NN Request and Response Formats (p. 1864) for inference, and the k-NN Sample Notebooks (p. 1859).

**k-NN Sample Notebooks**

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How the k-NN Algorithm Works**

**Step 1: Sample**

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

**Step 2: Perform Dimension Reduction**

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The `fjlt` method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

**Step 3: Build an Index**

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.
Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- **model_algo-1**: Contains the serialized index for computing the nearest neighbors.
- **model_algo-1.labels**: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- **model_algo-1.json**: Contains the JSON-formatted model metadata which stores the k and predictor_type hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change k to 10 or change predictor_type to regressor.

```
{
  "k": 5,
  "predictor_type": "classifier",
  "dimension_reduction": {
    "type": "sign", 
    "seed": 3,
    "target_dim": 10,
    "input_dim": 20
  },
  "normalize": false,
  "version": "1.0"
}
```

EC2 Instance Recommendation for the k-NN Algorithm

**Instance Recommendation for Training with the k-NN Algorithm**

To start, try running training on a CPU, using, for example, an ml.m5.2xlarge instance, or on a GPU using, for example, an ml.p2.xlarge instance.

**Instance Recommendation for Inference with the k-NN Algorithm**

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

### Tune a k-NN Model

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

**Automatic model tuning**, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

### Metrics Computed by the k-NN Algorithm

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the `predictor_type` hyper-parameter.

- **classifier** specifies a classification task and computes `test:accuracy`
- **regressor** specifies a regression task and computes `test:mse`.

Choose the `predictor_type` value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:accuracy</td>
<td>When <code>predictor_type</code> is set to <strong>classifier</strong>, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The accuracy reported ranges from 0.0 (0%) to 1.0 (100%).</td>
<td>Maximize</td>
</tr>
</tbody>
</table>
Metric Name | Description | Optimization Direction
---|---|---
test:mse | When predictor_type is set to regressor, k-NN compares the predicted label, based on the average of the k-nearest neighbors' labels, to the ground truth label provided in the test channel data. The mean squared error is computed by comparing the two labels. | Minimize

Tunable k-NN Hyperparameters

Tune the Amazon SageMaker k-nearest neighbor model with the following hyperparameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Recommended Ranges</th>

k | IntegerParameterRanges | MinValue: 1, MaxValue: 1024 |
sample_size | IntegerParameterRanges | MinValue: 256, MaxValue: 2000000 |

Data Formats for k-NN Training Input

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in Common Data Formats - Training. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

**CSV Data Format**

content-type: text/csv; label_size=1

```
4,1.2,1.3,9.6,20.3
```

The first label_size columns are interpreted as the label vector for that row.

**RECORDIO Data Format**

content-type: application/x-recordio-protobuf

```
[  
  Record = {  
    features = {  
      'values': {  
        values: [1.2, 1.3, 9.6, 20.3]  # float32  
      }  
    },  
    label = {  
      'values': {  
        values: [4]  # float32  
      }  
    }  
  }  
]
```
### k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

**INPUT: CSV Request Format**

```
csv
1.2,1.3,9.6,20.3
```

This accepts a `label_size` or encoding parameter. It assumes a `label_size` of 0 and a utf-8 encoding.

**INPUT: JSON Request Format**

```
application/json
{
   "instances": [
      {
         "data": {
            "features": {
               "values": [-3, -1, -4, 2]
            }
         }
      },
      {
         "data": {
            "features": {
               "values": [3.0, 0.1, 0.04, 0.002]
            }
         }
      }
   ]
}
```

**INPUT: JSONLINES Request Format**

```
application/jsonlines
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

**INPUT: RECORDIO Request Format**

```
application/x-recordio-protobuf
[
   Record = {
      features = {
         'values': {
            values: [-3, -1, -4, 2] # float32
         }
      },
      label = {}
   },
   Record = {
      features = {
         'values': {
            values: [3.0, 0.1, 0.04, 0.002] # float32
         }
      },
      label = {}
   }
]
```

**OUTPUT: JSON Response Format**

```
application/json
{
   "predictions": [1864]
}
```
Use built-in algorithms

```json
[{
  "predicted_label": 0.0,
  "predicted_label": 2.0
}]
```

**OUTPUT: JSONLINES Response Format**

accept: application/jsonlines

```json
[{
  "predicted_label": 0.0
},
{
  "predicted_label": 2.0
}]
```

**OUTPUT: VERBOSE JSON Response Format**

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

```json
{
  "predictions": [
    {
      "predicted_label": 0.0,
      "distances": [3.11792408, 3.89746071, 6.32548437],
      "labels": [0.0, 1.0, 0.0]
    },
    {
      "predicted_label": 2.0,
      "distances": [1.08470316, 3.04917915, 5.25393973],
      "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

**OUTPUT: RECORDIO-PROTOBUF Response Format**

```json
[ Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [0.0]  # float32
      }
    }
  }, Record = {
    features = {},
    label = {
      'predicted_label': {
        values: [2.0]  # float32
      }
    }
  }]
```

**OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format**

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

```json
In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.
```
SAMPLE OUTPUT for the k-NN Algorithm

For regressor tasks:

```
[06/08/2018 20:15:33 INFO 140026520049408] #test_score (algo-1) : ('mse', 0.013333333333333334)
```

For classifier tasks:

```
[06/08/2018 20:15:46 INFO 140285487171328] #test_score (algo-1) : ('accuracy', 0.98666666666666669)
```

Latent Dirichlet Allocation (LDA) Algorithm

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use
them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: *eat, sleep, play, meow, and bark*, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>eat</th>
<th>sleep</th>
<th>play</th>
<th>meow</th>
<th>bark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to *meow* and *sleep*), and documents that fall into Topic 2 are about dogs (who prefer to *play* and *bark*). These topics can be found even though the words dog and cat never appear in any of the texts.

### Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM)

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.
Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, and optionally supports a test channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to \textit{number of records} \times \textit{vocabulary size}. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, \texttt{text/csv}, \texttt{application/json}, and \texttt{application/x-recordio-protobuf} content types are supported. Sparse data can also be passed for \texttt{application/json} and \texttt{application/x-recordio-protobuf}. LDA inference returns \texttt{application/json} or \texttt{application/x-recordio-protobuf} predictions, which include the \textit{topic_mixture} vector for each observation.

Please see the LDA Sample Notebooks (p. 1868) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

\textbf{Note}

Lemmatization significantly increases algorithm performance and accuracy. Consider preprocessing any input text data.

An LDA model is defined by two parameters:

- \(\alpha\) — A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- \(\beta\) — A collection of \(k\) topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a “topic-word distribution.”

LDA is a “bag-of-words” model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture \(\theta \sim \text{Dirichlet}(\alpha)\).
For each word in the document:

- Choose a topic \( z \sim \text{Multinomial}(\theta) \)
- Choose the corresponding topic-word distribution \( \beta_z \).
- Draw a word \( w \sim \text{Multinomial}(\beta_z) \).

When training the model, the goal is to find parameters \( \alpha \) and \( \beta \), which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a \( V \times V \times V \) tensor, which summarizes the moments of the documents in our corpus. \( V \) is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters \( \alpha \) and \( \beta \), which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this \( V \times V \times V \) tensor is prohibitively large to store in memory.
2. Instead, it uses a \( V \times V \) moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension \( V \times k \). This matrix can be used to convert the \( V \times V \) moment matrix into a \( k \times k \) identity matrix. \( k \) is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller \( k \times k \times k \) tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the \( V \times V \times V \) tensor.
4. **Alternating Least Squares** is used to decompose the smaller \( k \times k \times k \) tensor. This provides a substantial improvement in memory consumption and speed. The parameters \( \alpha \) and \( \beta \) can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:
LDA Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see How LDA Works (p. 1868).

<table>

### Parameter Name | Description
---|---
max_iterations | The maximum number of iterations to perform during the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted.  
**Optional**  
Valid values: Positive integer  
Default value: 1000

tol | Target error tolerance for the ALS phase of the algorithm. Can be used to find better quality minima at the expense of additional computation, but typically should not be adjusted.  
**Optional**  
Valid values: Positive float  
Default value: 1e-8

## Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood“ (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

### Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: test:pwll. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:pwll</td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

### Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, `alpha0` and `num_topics`, can affect the LDA objective metric (test:pwll). If you don’t already know the optimal
values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

**Linear Learner Algorithm**

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(num\_classes - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`. You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you’re using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

**Topics**

- Input/Output interface for the linear learner algorithm (p. 1873)
- EC2 instance recommendation for the linear learner algorithm (p. 1873)
- Linear learner sample notebooks (p. 1873)
- How linear learner works (p. 1874)
- Linear learner hyperparameters (p. 1875)
- Tune a linear learner model (p. 1883)
- Linear learner response formats (p. 1887)
Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

**For training**, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

**For inference**, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- **For binary classification**, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- **For multiclass classification**, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1887). For more information on inference formats, and the Linear learner sample notebooks (p. 1873).

EC2 instance recommendation for the linear learner algorithm

You can train the linear learner algorithm on single- or multi-machine CPU and GPU instances. During testing, we have not found substantial evidence that multi-GPU computers are faster than single-GPU computers. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

<table>
<thead>

<td>Using the MNIST dataset, we train a binary classifier to predict a single digit.</td>
</tr>
<tr>
<td>Predict Breast Cancer</td>
<td>Using UCI's Breast Cancer dataset, we train a model to predict Breast Cancer.</td>
</tr>
</tbody>
</table>
### How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate.

**Step 1: Preprocess**

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

**Note**

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

**Step 2: Train**

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

**Step 3: Validate and set the threshold**

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.
**Note**
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

**Linear learner hyperparameters**

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to `auto`, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

Tune a linear learner model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

**Linear learner response formats**

**JSON response formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

**Binary Classification**

```javascript
let response = {
    "predictions": [
        {
            "score": 0.4,
            "predicted_label": 0
        }
    ]
}
```

**Multiclass Classification**

```javascript
let response = {
    "predictions": [
        {
            "score": [0.1, 0.2, 0.4, 0.3],
            "predicted_label": 2
        }
    ]
}
```

**Regression**

```javascript
let response = {
    "predictions": [
        {
            "score": 0.4
        }
    ]
}
```

**JSONLINES response formats**

**Binary Classification**

`{"score": 0.4, "predicted_label": 0}`
Multiclass Classification

{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}

Regression

{"score": 0.4}

RECORDIO response formats

Binary Classification

[
    Record = {
        features = {},
        label = {
            'score': {
                keys: [],
                values: [0.4] # float32
            },
            'predicted_label': {
                keys: [],
                values: [0.0] # float32
            }
        }
    }
]

Multiclass Classification

[
    Record = {

            }
        }
    }
]
Neural Topic Model (NTM) Algorithm

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into topics that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a latent representation because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.

Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

- Tune an NTM Model (p. 1893)
- NTM Response Formats (p. 1894)

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to
the integer IDs provided in the data. The vocabulary file must be named `vocab.txt` and currently only UTF-8 encoding is supported.

For inference, `text/csv`, `application/json`, `application/jsonlines`, and `application/x-recordio-protobuf` content types are supported. Sparse data can also be passed for `application/json` and `application/x-recordio-protobuf`. NTM inference returns `application/json` or `application/x-recordio-protobuf` predictions, which include the `topic_weights` vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.

For more information on input and output file formats, see NTM Response Formats (p. 1894) for inference and the NTM Sample Notebooks (p. 1890).

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**Tune an NTM Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. *Training loss* measures how well the model fits the training data. *Validation loss* measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which is has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

**Metrics Computed by the NTM Algorithm**

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>validation:total_loss</code></td>
<td>Total Loss on validation set</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable NTM Hyperparameters**

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see [NTM Hyperparameters](p. 1890).

**NTM Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.

**JSON Response Format**

```json
{
  "predictions": [
    {"topic_weights": [0.02, 0.1, 0,...]},
    {"topic_weights": [0.25, 0.067, 0,...]}
  ]
}
```

**JSONLINES Response Format**

```json
{"topic_weights": [0.02, 0.1, 0,...]}
{"topic_weights": [0.25, 0.067, 0,...]}
```

**RECORDIO Response Format**

```json
[
  Record = {
    features = {},
    label = {
      'topic_weights': {
        keys: [],
        values: [0.25, 0.067, 0, ...]  # float32
      }
    }
  },
  Record = {
    features = {},
    label = {
      'topic_weights': {
        keys: [],
        values: [0.25, 0.067, 0, ...]  # float32
      }
    }
  }
]
```
Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 1794). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
<tr>
<td>Labels-sequence pairs</td>
<td>The genre tags of the movie &quot;Titanic&quot;, such as &quot;Romance&quot; and &quot;Drama&quot;, and its short description: &quot;James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the icy cold waters of the North Atlantic in the early hours of April 15, 1912.&quot;</td>
</tr>
<tr>
<td>Customer-customer pairs</td>
<td>The customer ID of Jane and customer ID of Jackie.</td>
</tr>
<tr>
<td>Product-product pairs</td>
<td>The product ID of football and product ID of basketball.</td>
</tr>
<tr>
<td>Item review user-item pairs</td>
<td>A user's ID and the items she has bought, such as apple, pear, and orange.</td>
</tr>
</tbody>
</table>

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

• A discrete token, which is represented as a list of a single integer-id. For example, [10].
A sequence of discrete tokens, which is represented as a list of integer-ids. For example, 

\[0, 12, 10, 13]\.

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

**EC2 Instance Recommendation for the Object2Vec Algorithm**

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inferences.

**Instance Recommendation for Training**

When training a model using the Object2Vec algorithm on a CPU, start with an ml.m5.2xlarge instance. For training on a GPU, start with an ml.p2.xlarge instance. If the training takes too long on this instance, you can use a larger instance, such as an ml.m5.4xlarge or an ml.m5.12xlarge instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs.

**Instance Recommendation for Inference**

For inference with a trained Object2Vec model that has a deep neural network, we recommend using ml.p3.2xlarge GPU instance. Due to GPU memory scarcity, the `INFECTION_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 1908) or the section called “GPU optimization: Encoder Embeddings” (p. 1910) inference network is loaded into GPU.

**Object2Vec Sample Notebooks**

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

**Note**

To run the notebooks on a notebook instance, see Example Notebooks (p. 250). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 131).

**How Object2Vec Works**

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.
Step 1: Process Data

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 1908). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

Step 2: Train a Model

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.

- **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.

- **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair. For example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to True when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.
Step 3: Produce Inferences

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

- To convert singleton input objects into fixed-length embeddings using the corresponding encoder
- To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enc0_max_seq_len</td>
<td>The maximum sequence length for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $1 \leq \text{integer} \leq 5000$</td>
</tr>
<tr>
<td>enc0_vocab_size</td>
<td>The vocabulary size of enc0 tokens.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $2 \leq \text{integer} \leq 3000000$</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bucket_width</td>
<td>The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0 \leq \text{integer} \leq 100$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (no bucketing)</td>
</tr>
<tr>
<td>comparator_list</td>
<td>A list used to customize the way in which two embeddings are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the <code>comparator_list</code> and the order in which they are passed determine how these subvectors are assembled. For example, if <code>comparator_list=\text{hadamard, concat}</code>, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, <code>comparator_list=\text{hadamard}</code>, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: A string that contains any combination of the names of the three binary operators: hadamard, concat, or abs_diff. The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</td>
</tr>
<tr>
<td></td>
<td>- hadamard: Constructs a vector as the Hadamard (element-wise) product of two encodings.</td>
</tr>
<tr>
<td></td>
<td>- concat: Constructs a vector as the concatenation of two encodings.</td>
</tr>
<tr>
<td></td>
<td>- abs_diff: Constructs a vector as the absolute difference between two encodings.</td>
</tr>
<tr>
<td></td>
<td>Default value: &quot;hadamard, concat, abs_diff&quot;</td>
</tr>
<tr>
<td>dropout</td>
<td>The dropout probability for network layers. Dropout is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0.0 \leq \text{float} \leq 1.0$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.0</td>
</tr>
<tr>
<td><strong>Parameter Name</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>early_stopping_patience</td>
<td>The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the early_stopping_tolerance hyperparameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $1 \leq \text{integer} \leq 5$</td>
</tr>
<tr>
<td></td>
<td>Default value: 3</td>
</tr>
<tr>
<td>early_stopping_tolerance</td>
<td>The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the early_stopping_patience hyperparameter concludes.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $0.000001 \leq \text{float} \leq 0.1$</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.01</td>
</tr>
<tr>
<td>enc_dim</td>
<td>The dimension of the output of the embedding layer.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: $4 \leq \text{integer} \leq 10000$</td>
</tr>
<tr>
<td></td>
<td>Default value: 4096</td>
</tr>
<tr>
<td>enc0_network</td>
<td>The network model for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: hcnn, bilstm, or pooled_embedding</td>
</tr>
<tr>
<td></td>
<td>• <strong>hcnn</strong>: A hierarchical convolutional neural network.</td>
</tr>
<tr>
<td></td>
<td>• <strong>bilstm</strong>: A bidirectional long short-term memory network (biLSTM), in which the signal propagates backward and forward in time. This is an appropriate recurrent neural network (RNN) architecture for sequential learning tasks.</td>
</tr>
<tr>
<td></td>
<td>• <strong>pooled_embedding</strong>: Averages the embeddings of all of the tokens in the input.</td>
</tr>
<tr>
<td></td>
<td>Default value: hcnn</td>
</tr>
<tr>
<td>enc0_cnn_filter_width</td>
<td>The filter width of the convolutional neural network (CNN) enc0 encoder.</td>

</tr>
<tr>
<td></td>
<td>• mean_squared_error: The MSE used for regression.</td>
</tr>
<tr>
<td></td>
<td>Default value: softmax</td>
</tr>
<tr>
<td>tied_token_embedding_weight</td>
<td>Whether to use a shared embedding layer for both encoders. If the inputs to both encoders use the same token-level units, use a shared token embedding layer. For example, for a collection of documents, if one encoder encodes sentences and another encodes whole documents, you can use a shared token embedding layer. That's because both sentences and documents are composed of word tokens from the same vocabulary.</td>

| token_embedding_storage_type          | The mode of gradient update used during training: when the dense mode is used, the optimizer calculates the full gradient matrix for the token embedding layer even if most rows of the gradient are zero-valued. When sparse mode is used, the optimizer only stores rows of the gradient that are actually being used in the mini-batch. If you want the algorithm to perform lazy gradient updates, which calculate the gradients only in the non-zero rows and which speed up training, specify row_sparse. Setting the value to row_sparse constrains the values available for other hyperparameters, as follows:  
  - The optimizer hyperparameter must be set to adam, adagrad, or sgd. Otherwise, the algorithm throws a CustomerValueError.  
  - The algorithm automatically disables bucketing, setting the bucket_width hyperparameter to 0.  
  
  **Optional**  
  Valid values: dense or row_sparse  
  Default value: dense |
| weight_decay                          | The weight decay parameter used for optimization.  
  
  **Optional**  
  Valid values: 0 \leq \text{float} \leq 10000  
  Default value: 0 (no decay) |

---

**Tune an Object2Vec Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

**Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm has both classification and regression metrics. The output_layer type determines which metric you can use for automatic model tuning.

**Regressor Metrics Computed by the Object2Vec Algorithm**

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.
Classification Metrics Computed by the Object2Vec Algorithm

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

**Data Formats for Object2Vec Training**

**Input: JSON Lines Request Format**

Content-type: application/jsonlines

```json
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}  
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}  
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The “in0” and “in1” are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field “label” can accept real valued inputs.

**Data Formats for Object2Vec Inference**

**GPU optimization: Classification or Regression**

Due to GPU memory scarcity, the INFERENCE_PREFERRED_MODE environment variable can be specified to optimize on whether the classification/regression or the section called “Output: Encoder Embeddings” (p. 1910) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify INFERENCE_PREFERRED_MODE=classification. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```python
transformer = o2v.transformer(instance_count=4,
```
Instance type="ml.p2.xlarge",
max_concurrent_transforms=2,
max_payload=1, # 1MB
strategy='MultiRecord',
env={'INFERENCE_PREFERRED_MODE': 'classification'}, # only useful with GPU
output_path=output_s3_path)

Input: Classification or Regression Request Format

Content-type: application/json

```json
{
    "instances": [
        {
            "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
            "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4],
        },
        {
            "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
            "in1": [22, 32, 13, 25, 1016, 573, 3252, 4],
        },
        {
            "in0": [774, 14, 21, 206],
            "in1": [21, 366, 125]
        }
    ]
}
```

Content-type: application/jsonlines

```json
("in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4],
"in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]),
("in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4],
"in1": [22, 32, 13, 25, 1016, 573, 3252, 4]),
("in0": [774, 14, 21, 206], "in1": [21, 366, 125])
```

For classification problems, the length of the scores vector corresponds to num_classes. For regression problems, the length is 1.

Output: Classification or Regression Response Format

Accept: application/json

```json
{
    "predictions": [
        {
            "scores": [
                0.653935070037842,
                0.07582679390907288,
                0.2707797586917877
            ]
        },
        {
            "scores": [
                0.026291321963071823,
                0.6577019095420837,
                0.31600672006607056
            ]
        }
    ]
}
```

Accept: application/jsonlines

```json
{"scores": [0.195667684078216, 0.395351558923721, 0.408980727195739]}
{"scores": [0.251988261938095, 0.258333487606048, 0.48977839862823]}
{"scores": [0.28008779833847, 0.368331134319305, 0.351581096649169]}
```
In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFORCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the the section called "Inference Formats: Scoring" (p. 1908) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFORCE_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```python
transformer = o2v.transformer(instance_count=4,
   instance_type="ml.p2.xlarge",
   max_concurrent_transforms=2,
   max_payload=1,  # 1MB
   strategy='MultiRecord',
   env={'INFORCE_PREFERRED_MODE': 'embedding'},  # only useful with GPU
   output_path=output_s3_path)
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```json
{
   "instances" : [
      {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]},
      {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]},
      {"in0": [774, 14, 21, 206]}
   ]
}
```

Content-type: application/jsonlines; infer_max_seqlens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```json
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: “in0” or “in1.” The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

**Output: Encoder Embeddings**

Content-type: application/json

```json
{
   "predictions": [
      {"embeddings": [0.057368703186511,0.030703511089086,0.099890425801277,0.063688032329082,0.026327300816774,0.003637571120634,0.021305780857801,0.004316598642617,0.0,0.003397724591195,0.0,0.000378780066967,0.0,0.0,0.0,0.007419463712722]}
      {"embeddings": [0.150190666317939,0.05145975202322,0.098204270005226,0.064249359071254,0.056249320507049,0.01513972133398]}
```

1910
The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

**Object Detection Algorithm**

The Amazon SageMaker Object Detection algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

**Topics**
- Input/Output Interface for the Object Detection Algorithm (p. 1911)
- EC2 Instance Recommendation for the Object Detection Algorithm (p. 1914)
- Object Detection Sample Notebooks (p. 1914)
- How Object Detection Works (p. 1914)
- Object Detection Hyperparameters (p. 1914)
- Tune an Object Detection Model (p. 1919)
- Object Detection Request and Response Formats (p. 1920)

**Input/Output Interface for the Object Detection Algorithm**

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

**Note**

To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 1914) for more details on data formats.

**Train with the RecordIO Format**

If you use the RecordIO format for training, specify both train and validation channels as values for the `InputDataConfig` parameter of the `CreateTrainingJob` request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels.
Use built-in algorithms to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```json
{
    "file": "your_image_directory/sample_image1.jpg",
    "image_size": [
        {
            "width": 500,
            "height": 400,
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
            "top": 134,
            "width": 61,
            "height": 128
        },
        {
            "class_id": 0,
            "left": 161,
            "top": 250,
            "width": 79,
            "height": 143
        },
        {
            "class_id": 1,
            "left": 101,
            "top": 185,
            "width": 42,
            "height": 130
        }
    ],
    "categories": [
        {
            "class_id": 0,
            "name": "dog"
        },
        {
            "class_id": 1,
            "name": "cat"
        }
    ]
}
```

Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/
train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

Train with Augmented Manifest Image Format

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames are contained in the list ["source-ref", "bounding-box"]:}

```
{"source-ref": "s3://your_bucket/image1.jpg", "bounding-box":{"image_size": [{ "width": 500, "height": 400, "depth":3}], "annotations": [{"class_id": 0, "left": 111, "top": 134, "width": 61, "height": 128}, {"class_id": 5, "left": 161, "top": 250, "width": 80, "height": 50}]}},
{"source-ref": "s3://your_bucket/image2.jpg", "bounding-box":{"image_size": [{ "width": 400, "height": 300, "depth":3}], "annotations": [{"class_id": 1, "left": 100, "top": 120, "width": 43, "height": 78}]}},
```

The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2380).

Incremental Training

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model" in the InputDataConfig parameter. Set the ContentType for the model channel to application/x-sagemaker-model. The input hyperparameters of both the new model and the pretrained model...
Use built-in algorithms

that you upload to the model channel must have the same settings for the base_network and num_classes input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 2369).

EC2 Instance Recommendation for the Object Detection Algorithm

For object detection, we support the following GPU instances for training:

- ml.p2.xlarge
- ml.p2.8xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.8xlarge
- ml.p3.16xlarge

We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. However, both CPU (such as C5 and M5) and GPU (such as P2 and P3) instances can be used for the inference. All the supported instance types for inference are itemized on Amazon SageMaker ML Instance Types.

Object Detection Sample Notebooks

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the

Caltech Birds (CUB 200 2011) dataset using the Single Shot multibox Detector algorithm, see Amazon SageMaker Object Detection for Bird Species. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the Introduction to Amazon Algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see How Object Detection Works (p. 1914).
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| num_classes             | The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. **Required**
|                         | Valid values: positive integer                                              |
| num_training_samples    | The number of training examples in the input dataset. **Note**
|                         | If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter will be undefined and distributed training accuracy may be affected. **Required**
|                         | Valid values: positive integer                                              |
| base_network            | The base network architecture to use. **Optional**
|                         | Valid values: 'vgg-16' or 'resnet-50' Default value: 'vgg-16'               |
| early_stopping          | True to use early stopping logic during training. False not to use it.      **Optional**
|                         | Valid values: True or False Default value: False                            |
| early_stopping_min_epochs| The minimum number of epochs that must be run before the early stopping logic can be invoked. It is used only when early_stopping = True. **Optional**
|                         | Valid values: positive integer Default value: 10                           |
| early_stopping_patience | The number of epochs to wait before ending training if no improvement, as defined by the early_stopping_tolerance hyperparameter, is made in the relevant metric. It is used only when early_stopping = True. **Optional**
<p>|                         | Valid values: positive integer Default value: 5                            |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>early_stopping_tolerance</td>
<td>The tolerance value that the relative improvement in validation:mAP, the mean average precision (mAP), is required to exceed to avoid early stopping. If the ratio of the change in the mAP divided by the previous best mAP is smaller than the early_stopping_tolerance value set, early stopping considers that there is no improvement. It is used only when early_stopping = True.</td>

</tbody>
</table>
| `kv_store`     | The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details.  
  **Note**  
  This parameter is not applicable to single machine training.  
  **Optional**  
  Valid values: 'dist_sync' or 'dist_async'  
  • 'dist_sync': The gradients are synchronized after every batch with all the workers. With 'dist_sync', batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b.  
  • 'dist_async': Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.  
  Default: - |
| `label_width`  | The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the `label_width` should be no smaller than (10*5 + header information length). The header information length is usually 2. We recommend using a slightly larger `label_width` for the training, such as 60 for this example.  
  **Optional**  
  Valid values: Positive integer large enough to accommodate the largest annotation information length in the data.  
  Default: 350 |
| `learning_rate` | The initial learning rate.  
  **Optional**  
  Valid values: float in (0, 1]  
  Default: 0.001 |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lr_scheduler_factor</td>
<td>The ratio to reduce learning rate. Used in conjunction with the lr_scheduler_step parameter defined as $lr_{new} = lr_{old} \times lr_{scheduler_factor}$.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: float in (0, 1)</td>
</tr>
<tr>
<td></td>
<td>Default: 0.1</td>
</tr>
<tr>
<td>lr_scheduler_step</td>
<td>The epochs at which to reduce the learning rate. The learning rate is reduced by lr_scheduler_factor at epochs listed in a comma-delimited string: &quot;epoch1, epoch2, ...&quot;. For example, if the value is set to &quot;10, 20&quot; and the lr_scheduler_factor is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: string</td>
</tr>
<tr>
<td></td>
<td>Default: empty string</td>
</tr>
<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-gpu setting, each GPU handles mini_batch_size/num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. A large mini_batch_size usually leads to faster training, but it may cause out of memory problem. The memory usage is related to mini_batch_size, image_shape, and base_network architecture. For example, on a single p3.2xlarge instance, the largest mini_batch_size without an out of memory error is 32 with the base_network set to &quot;resnet-50&quot; and an image_shape of 300. With the same instance, you can use 64 as the mini_batch_size with the base network vgg-16 and an image_shape of 300.</td>

**Tune an Object Detection Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see *Perform Automatic Model Tuning with SageMaker* (p. 2186).

**Metrics Computed by the Object Detection Algorithm**

The object detection algorithm reports on a single metric during training: *validation:mAP*. When tuning a model, choose this metric as the objective metric.

Object Detection Request and Response Formats

Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with image/jpeg and image/png content-types.

Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of response .json file:

```json
{"prediction": [
  [4.0, 0.86419455409049988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244],
  [0.0, 0.73376623392105103, 0.5714187026023865, 0.40427327156066895, 0.827075183391571, 0.971159633636475],
  [4.0, 0.32639385450267792, 0.3677481412887573, 0.0348332031573486, 0.6318609714508057, 0.9567587828636169],
  [8.0, 0.25552496790885925, 0.6152569651603699, 0.5722782611846924, 0.882301390171051, 0.8985623321261597],
  [3.0, 0.42260299175977707, 0.019305512309074402, 0.083861768245469702, 0.39093565940856934, 0.9574796557426453]
]}
```

Each row in this json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding
box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide examples of scripts that use a threshold to remove low confidence detections and to plot bounding boxes on the original images.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id, confidence_score, xmin, ymin, xmax, ymax]]}
```

For more details on training and inference, see the Object Detection Sample Notebooks (p. 1914).

**OUTPUT: JSON Response Format**

```
{  "image_size": [    {      "width": 500,      "height": 400,      "depth": 3    }  ],  "annotations": [    {      "class_id": 0,      "score": 0.943,      "left": 111,      "top": 134,      "width": 61,      "height": 128    },    {      "class_id": 0,      "score": 0.0013,      "left": 161,      "top": 250,      "width": 79,      "height": 143    },    {      "class_id": 1,      "score": 0.0133,      "left": 101,      "top": 185,      "width": 42,      "height": 130    }  ]}
```

**Principal Component Analysis (PCA) Algorithm**

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by
finding a new set of features called *components*, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

**Topics**

- Input/Output Interface for the PCA Algorithm (p. 1922)
- EC2 Instance Recommendation for the PCA Algorithm (p. 1922)
- PCA Sample Notebooks (p. 1922)
- How PCA Works (p. 1923)
- PCA Hyperparameters (p. 1924)
- PCA Response Formats (p. 1925)

**Input/Output Interface for the PCA Algorithm**

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, PCA supports text/csv, application/json, and application/x-recordio-protobuf. Results are returned in either application/json or application/x-recordio-protobuf format with a vector of "projections."

For more information on input and output file formats, see PCA Response Formats (p. 1925) for inference and the PCA Sample Notebooks (p. 1922).

**EC2 Instance Recommendation for the PCA Algorithm**

PCA supports both GPU and CPU computation. Which instance type is most performant depends heavily on the specifics of the input data.

**PCA Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to PCA with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.
How PCA Works

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called components, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

Given the input of a matrix with rows \( x_1, \ldots, x_n \) each of dimension 1 * d, the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.

Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm’s last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

**Mode 1: Regular**

The workers jointly compute both \( \sum x_i^T x_i \) and \( \sum x_i \).

**Note**

Because \( x_i \) are 1 * d row vectors, \( x_i^T x_i \) is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as \( \sum x_i^T x_i - (1/n)(\sum x_i)(\sum x_i)^T \), and its top \( \text{num\_components} \) singular vectors form the model.

**Note**

If `subtract\_mean` is `False`, we avoid computing and subtracting \( \sum x_i \).

Use this algorithm when the dimension \( d \) of the vectors is small enough so that \( d^2 \) can fit in memory.

**Mode 2: Randomized**

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch \( X_i \) of dimension \( b * d \), we randomly initialize a \( (\text{num\_components} + \text{extra\_components}) * b \) matrix that we multiply by each mini-batch, to create a \( (\text{num\_components} + \text{extra\_components}) * d \) matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final \( (\text{num\_components} + \text{extra\_components}) * d \) matrix. The top right \( \text{num\_components} \) singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let \( t = \text{num\_components} + \text{extra\_components} \). Given a mini-batch \( X_i \) of dimension \( b * d \), the worker draws a random matrix \( H_i \) of dimension \( t * b \). Depending on whether the environment uses a
GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is \(\pm 1\) or a FJLT (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes \(H_i X_i\) and maintains \(B = \sum H_i X_i\). The worker also maintains \(h^T\), the sum of columns of \(H_1, \ldots, H_t\) (\(t\) being the total number of mini-batches), and \(s\), the sum of all input rows. After processing the entire shard of data, the worker sends the server \(B, h, s, \text{ and } n\) (the number of input rows).

Denote the different inputs to the server as \(B^i, h^i, s^i, n^i\). The server computes \(B, h, s, n\), the sums of the respective inputs. It then computes \(C = B \cdot (1/n)h^T s\), and finds its singular value decomposition. The top-right singular vectors and singular values of \(C\) are used as the approximate solution to the problem.

### PCA Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see How PCA Works (p. 1923).

**PCA Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in *Common Data Formats - Inference*. This topic contains a list of the available output formats for the SageMaker PCA algorithm.

**JSON Response Format**

Accept—application/json

```
{
  "projections": [
    {
      "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
    },
    {
      "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
    },
    ....
  ]
}
```

**JSONLINES Response Format**

Accept—application/jsonlines

```
{ "projection": [1.0, 2.0, 3.0, 4.0, 5.0] }
{ "projection": [6.0, 7.0, 8.0, 9.0, 0.0] }
```

**RECORDIO Response Format**

Accept—application/x-recordio-protobuf

```
[ 
  Record = {
    features = {},
    label = {
      'projection': {
        keys: [],
        values: [1.0, 2.0, 3.0, 4.0, 5.0]
      }
    }
  },
  Record = {
    features = {},
    label = {
      'projection': {
        keys: [],
        values: [1.0, 2.0, 3.0, 4.0, 5.0]
      }
    }
  }
]```
Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

Input/Output Interface for the RCF Algorithm

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either application/x-recordio-protobuf or text/csv formats.

For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

Also note that the train channel only supports S3DataDistributionType=ShardedByS3Key and the test channel only supports S3DataDistributionType=FullyReplicated. The S3 distribution type can be specified using the Amazon SageMaker Python SDK as follows:

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
crf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.s3_input(...)
```
Use built-in algorithms

```python
s3_data=s3_training_data_location,
content_type='text/csv;label_size=0',
distribution='ShardedByS3Key')
# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, `AmazonSageMakerFullAccess` and `AmazonEC2ContainerRegistryFullAccess`. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger than the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account’s Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the `S3DataSource` for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports `application/x-recordio-protobuf`, `text/csv` and `application/json` input data content types. See the Common Data Formats for Built-in Algorithms (p. 1784) documentation for more information. RCF inference returns `application/x-recordio-protobuf` or `application/json` formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 1932) for inference and the RCF Sample Notebooks (p. 1927).

**Instance Recommendations for the RCF Algorithm**

For training, we recommend the `ml.m4`, `ml.c4`, and `ml.c5` instance families. For inference we recommend using a `ml.c5.xl` instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

**RCF Sample Notebooks**

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How RCF Works**

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first
determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

Sample Data Randomly

The first step in the RCF algorithm is to obtain a random sample of the training data. In particular, suppose we want a sample of size $K$ from $N$ total data points. If the training data is small enough, the entire dataset can be used, and we could randomly draw $K$ elements from this set. However, frequently the training data is too large to fit all at once, and this approach isn’t feasible. Instead, we use a technique called reservoir sampling.

Reservoir sampling is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1, \ldots, S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when $N$ is not known a priori. If only one sample is requested, such as when $K = 1$, the algorithm is like this:

Algorithm: Reservoir Sampling

- Input: dataset or data stream $S = \{S_1, \ldots, S_N\}$
- Initialize the random sample $X = S_1$
- For each observed sample $S_n, n = 2, \ldots, N$:
  - Pick a uniform random number $\xi \in [0, 1]$
  - If $\xi < 1/n$
    - Set $X = S_n$
  - Return $X$

This algorithm selects a random sample such that $P(X = S_n) = 1/N$ for all $n = 1, \ldots, N$. When $K > 1$ the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

Train a RCF Model and Produce Inferences

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:
A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher "variance"), and then randomly determining the position of a hyperplane "cut" through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.

A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point
is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

Choose Hyperparameters

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that \( \frac{1}{\text{num_samples_per_tree}} \) approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies \( \frac{1}{256} \) or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

RCF Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker RCF algorithm. For more information, including recommendations on how to choose hyperparameters, see *How RCF Works* (p. 1927).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_dim</td>
<td>The number of features in the data set. (If you use the Random Cut Forest estimator, this value is calculated for you and need not be specified.) Required</td>
</tr>
</tbody>
</table>
| eval_metrics   | A list of metrics used to score a labeled test data set. The following metrics can be selected for output:  
  * accuracy - returns fraction of correct predictions. |
| eval_samples   | The number of samples to use in the test data set. Required. Valid values: Positive integer (min: 1, max: 10000) |
### Parameter Name | Description
---|---
| **precision_recall_fscore** | returns the positive and negative precision, recall, and F1-scores. | Optional  
Valid values: a list with possible values taken from accuracy or precision_recall_fscore.  
Default value: Both accuracy, precision_recall_fscore are calculated. |
| num_samples_per_tree | Number of random samples given to each tree from the training data set. | Optional  
Valid values: Positive integer (min: 1, max: 2048)  
Default value: 256 |
| num_trees | Number of trees in the forest. | Optional  
Valid values: Positive integer (min: 50, max: 1000)  
Default value: 100 |

### Tune an RCF Model

**Automatic model tuning**, also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test datapoints and then labels the datapoints as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 2186).

**Metrics Computed by the RCF Algorithm**

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>

**RCF Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in [Common Data Formats - Inference](#). Note that SageMaker Random Cut Forest supports both dense and sparse JSON and RecordIO formats. This topic contains a list of the available output formats for the SageMaker RCF algorithm.

**JSON Response Format**

ACCEPT: application/json.

```json
{
    "scores": [
        {
            "score": 0.02,
        },
        {
            "score": 0.25
        }
    ]
}
```

**JSONLINES Response Format**

ACCEPT: application/jsonlines.

```json
{"score": 0.02},
```
RECORDIO Response Format

ACCEPT: application/x-recordio-protobuf.

[{
    "score": 0.25
}]

Record = {

    features = {},

    label = {

        'score': {

            keys: [],

            values: [0.25]  # float32

        }

    }

},

Record = {

    features = {},

    label = {

        'score': {

            keys: [],

        }

    }

},

Struct: RECORDIO
Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification Algorithm (p. 1829) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection Algorithm (p. 1911) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a segmentation mask. A segmentation mask is a grayscale image with the same shape as the input image.

The SageMaker semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit. It provides you with a choice of three built-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm, Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The **backbone (or encoder)**—A network that produces reliable activation maps of features.
- The **decoder**—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

Semantic Segmentation Sample Notebooks

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the SageMaker Examples tab. The example semantic segmentation notebooks are located under Introduction to Amazon algorithms. To open a notebook, choose its Use tab, and choose Create copy.

Input/Output Interface for the Semantic Segmentation Algorithm

SageMaker semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for train and one for validation using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (application/x-image) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an image/jpeg content type.

How Training Works

The training data is split into four directories: train, train_annotation, validation, and validation_annotation. There is a channel for each of these directories. The dataset also expected to have one label_map.json file per channel for train_annotation and validation_annotation respectively. If you don't provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```
s3://bucket_name
  |  
  |-- train
  |     |  
  |     |-- 0000.jpg
  |     |-- coffee.jpg
  |-- validation
  |     |  
  |     |-- 00a0.jpg
  |     |-- banana.jpg
  |-- train_annotation
  |     |  
  |     |-- 0000.png
  |     |-- coffee.png
  |-- validation_annotation
  |  
```

1935
Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the train_annotation and validation_annotation directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The train, train_annotation, validation, and validation_annotation channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the label map. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don't provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```
{
  "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn’t convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```
{
  "scale": "3"
}
```

The following example shows how this "scale" value is used to rescale the encoded_label values of the input annotation image when they are mapped to the mapped_label values to be used in training. The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

Training with the Augmented Manifest Format

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the CreateTrainingJob request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a source-ref key. The source-ref key should contain the value of the Amazon S3 URI to the image. The labels are provided under the AttributeNames parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the example below, the AttributeNames are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO" and value of the ContentType parameter must be application/x-recordio.

{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets",}}

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 2380).

Incremental Training

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.

To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 2369).

Produce Inferences

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.
EC2 Instance Recommendation for the Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2/P3 EC2 Amazon Elastic Compute Cloud (Amazon EC2) instances in single machine configurations. It supports the following GPU instances for training:

- ml.p2.xlarge
- ml.p2.8xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.8xlarge
- ml.p3.16xlarge

For inference, you can use either CPU instances (such as c5 and m5) and GPU instances (such as p2 and p3) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

Semantic Segmentation Hyperparameters

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.

|                        | Default value: 0.0001                                                                                                                                                                                        |
Tuning a Semantic Segmentation Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

Metrics Computed by the Semantic Segmentation Algorithm

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:mIOU</td>
<td>The area of the intersection of the predicted segmentation and the ground truth divided by the area of union between them for images in the validation set. Also known as the Jaccard Index.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:pixel_acc</td>
<td>The percentage of pixels that are correctly classified in images from the validation set.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

Tunable Semantic Segmentation Hyperparameters

You can tune the following hyperparameters for the semantic segmentation algorithm.

<table>

Sequence-to-Sequence Algorithm

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

Topics
Input/Output Interface for the Sequence-to-Sequence Algorithm

Training

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
- **validation**: It should contain the validation data (for example, the val.rec file generated by the preprocessing script).
- **vocab**: It should contain two vocabulary files (vocab.src.json and vocab.trg.json)

If the algorithm doesn't find data in any of these three channels, training results in an error.

Inference

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the application/json format. Otherwise, use the recordio-protobuf format to work with the integer encoded data. Both modes support batching of input data. application/json format also allows you to visualize the attention matrix.

- **application/json**: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be application/json. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:
  
  **configuration**: {**attention_matrix**: true}: Returns the attention matrix for the particular input sequence.

- **application/x-recordio-protobuf**: Expects the input in recordio-protobuf format and returns the output in recordio-protobuf format. Both content and accept types should be application/x-recordio-protobuf. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be application/jsonlines. The format for input is as follows:

```
content-type: application/jsonlines
```
EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm

Currently Amazon SageMaker seq2seq is only supported on GPU instance types and is only set up to train on a single machine. But it does also offer support for multiple GPUs.

Sequence-to-Sequence Sample Notebooks

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English-German translation model, see Machine Translation English-German Example Using SageMaker Seq2Seq. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- **An embedding layer.** In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

- **An encoder layer.** After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah’s blog explains LSTM in a great detail.)

- **A decoder layer.** The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.
For more in details, see the whitepaper *Effective Approaches to Attention-based Neural Machine Translation* by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper *Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation* by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

| checkpoint_frequency_num_batches | Checkpoint and evaluate every x batches. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped.  
**Optional**  
Valid values: positive integer  
Default value: 1000 |
| checkpoint_threshold | Maximum number of checkpoints model is allowed to not improve in optimized_metric on validation dataset before training is stopped. This checkpointing hyperparameter is passed to the SageMaker's seq2seq algorithm for early stopping and retrieving the best model. The algorithm's checkpointing runs locally in the algorithm's training container and is not compatible with SageMaker checkpointing. The algorithm temporarily saves checkpoints to a local path and stores the best model artifact to the model output path in S3 after the training job has stopped.  
**Optional**

**Tune a Sequence-to-Sequence Model**

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Metrics Computed by the Sequence-to-Sequence Algorithm**

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.

<table>

### XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 0.90, 1.0, 1.2, and 1.3.

#### Supported versions

- Framework (open source) mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1
- Algorithm mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2, 1.3-1, 1.5-1

**Warning**

The XGBoost 0.90 version will be deprecated on December 31, 2021. Supports for security updates or bug fixes for XGBoost 0.90 will be discontinued after this date. It is highly recommended to upgrade the XGBoost version to one of the newer versions (1.0-1 or later) before the deprecation.

**Warning**

SageMaker Python SDK v1 supports up to version 1.0-1 of XGBoost. For later versions of XGBoost, use SageMaker Python SDK v2. For more information see changes from [SDK v1 to SDK v2](#).

**Note**

XGBoost 1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost 1.2. Consider using SageMaker XGBoost 1.2-2 or later.

### How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts.
• **Use XGBoost as a framework**

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

### SageMaker Python SDK v1

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:linear",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.0-1',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     train_instance_count=1,
                     train_instance_type='ml.m5.2xlarge',
                     output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}/{}/train".format(bucket, prefix, 'train'),
                        content_type=content_type)
validation_input = s3_input("s3://{}/{}/validation".format(bucket, prefix, 'validation'),
                           content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

### SageMaker Python SDK v2

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.0-1',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     train_instance_count=1,
                     train_instance_type='ml.m5.2xlarge',
                     output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/train".format(bucket, prefix, 'train'),
                            content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/validation".format(bucket, prefix, 'validation'),
                                content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```
Use built-in algorithms

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

```python
import sagemaker
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}{}'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                   framework_version='1.2-2',
                   hyperparameters=hyperparameters,
                   role=sagemaker.get_execution_role(),
                   instance_count=1,
                   instance_type='ml.m5.2xlarge',
                   output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}/{}".format(bucket, prefix,
                                           'validation'), content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost

Use XGBoost as a built-in algorithm

Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.

```python
import sagemaker
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "objective": "reg:squarederror",
    "num_round": "50"}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}{}'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                   framework_version='1.2-2',
                   hyperparameters=hyperparameters,
                   role=sagemaker.get_execution_role(),
                   instance_count=1,
                   instance_type='ml.m5.2xlarge',
                   output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}/{}".format(bucket, prefix,
                                           'validation'), content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = get_image_uri(boto3.Session().region_name, 'xgboost', repo_version='1.0-1')

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_name=xgboost_container,
                                       hyperparameters=hyperparameters,
                                       role=sagemaker.get_execution_role(),
                                       train_instance_count=1,
                                       train_instance_type='ml.m5.2xlarge',
                                       train_volume_size=5, # 5 GB
                                       output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}/{}/{}").format(bucket, prefix, 'train'),
validation_input = s3_input("s3://{}/{}/{}").format(bucket, prefix, 'validation'),

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})

SageMaker Python SDK v2

import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
"max_depth": "5",
"eta": "0.2",
"gamma": "4",
"min_child_weight": "6",
"subsample": "0.7",
"objective": "reg:squarederror",
"num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
output_path = 's3://{}/{}/{}output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-2")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                        hyperparameters=hyperparameters,
                                        role=sagemaker.get_execution_role(),
                                        train_instance_count=1,
                                        train_instance_type='ml.m5.2xlarge',
                                        train_volume_size=5, # 5 GB
                                        output_path=output_path)
For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.
- For Inference ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: `<label> <index0>:<value0> <index1>:<value1> ...` Inference requests for libsvm might not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
```
To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1,...`. For text/csv input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

EC2 Instance Recommendation for the XGBoost Algorithm

SageMaker XGBoost 1.0-1 or earlier currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker currently does not support multi-GPU training.

XGBoost Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.

<table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

## How XGBoost Works

**XGBoost** is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It's called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.
For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

### XGBoost Hyperparameters

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see [XGBoost Parameters](#).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>refresh_leaf</td>
<td>This is a parameter of the 'refresh' updater plug-in. When set to true (1), tree leaves and tree node stats are updated. When set to false (0), only tree node stats are updated.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 0/1</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>sample_type</td>
<td>Type of sampling algorithm.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Either uniform or weighted.</td>
</tr>
<tr>
<td></td>
<td>Default value: uniform</td>
</tr>
<tr>
<td>scale_pos_weight</td>
<td>Controls the balance of positive and negative weights. It's useful for unbalanced classes. A typical value to consider: sum(negative cases) / sum(positive cases).</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: float</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>seed</td>
<td>Random number seed.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>single_precision_histogram</td>
<td>When this flag is enabled, XGBoost uses single precision to build histograms instead of double precision. Used only if tree_method is set to hist or gpu_hist.</td>
</tr>
<tr>
<td></td>
<td>For a full list of valid inputs, please refer to XGBoost Parameters.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String. Range: true or false</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
<tr>
<td>sketch_eps</td>
<td>Used only for approximate greedy algorithm. This translates into O(1 / sketch_eps) number of bins. Compared to directly select number of bins, this comes with theoretical guarantee with sketch accuracy.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float, Range: [0, 1].</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.03</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>skip_drop</td>
<td>Probability of skipping the dropout procedure during a boosting iteration.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float. Range: [0.0, 1.0].</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.0</td>
</tr>
<tr>
<td>subsample</td>
<td>Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float. Range: [0,1].</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>tree_method</td>
<td>The tree construction algorithm used in XGBoost.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: One of auto, exact, approx, hist, or gpu_hist.</td>
</tr>
<tr>
<td></td>
<td>Default value: auto</td>
</tr>
<tr>
<td>tweedie_variance_power</td>
<td>Parameter that controls the variance of the Tweedie distribution.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float. Range: (1, 2).</td>
</tr>
<tr>
<td></td>
<td>Default value: 1.5</td>
</tr>
<tr>
<td>updater</td>
<td>A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees.</td>
</tr>
<tr>
<td></td>
<td>For a full list of valid inputs, please refer to XGBoost Parameters.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: comma-separated string.</td>
</tr>
<tr>
<td></td>
<td>Default value: grow_colmaker, prune</td>
</tr>
<tr>
<td>verbosity</td>
<td>Verbosity of printing messages.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug).</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>

Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

**Note**

Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Evaluation Metrics Computed by the XGBoost Algorithm**

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Classification rate, calculated as #(right)/#(all cases).</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:auc</td>
<td>Area under the curve.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:error</td>
<td>Binary classification error rate, calculated as #(wrong cases)/#(all cases).</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:f1</td>
<td>Indicator of classification accuracy, calculated as the harmonic mean of precision and recall.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:logloss</td>
<td>Negative log-likelihood.</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mae</td>
<td>Mean absolute error.</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:map</td>
<td>Mean average precision.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:merror</td>
<td>Multiclass classification error rate, calculated as #(wrong cases)/#(all cases).</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mlogloss</td>
<td>Negative log-likelihood for multiclass classification.</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mse</td>
<td>Mean squared error.</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:ndcg</td>
<td>Normalized Discounted Cumulative Gain.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:rmse</td>
<td>Root mean square error.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>
Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: alpha, min_child_weight, subsample, eta, and num_round.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>

<td>MinValue: 0.5, MaxValue: 1</td>
</tr>
</tbody>
</table>

Deprecated Versions of XGBoost and their Upgrades

This topic contains documentation for previous versions of Amazon SageMaker XGBoost that are still available but deprecated. It also provides instructions on how to upgrade deprecated versions of XGBoost, when possible, to more current versions.

Topics
- Upgrade XGBoost Version 0.90 to Version 1.2 (p. 1972)
- XGBoost Version 0.72 (p. 1974)

Upgrade XGBoost Version 0.90 to Version 1.2

If you are using the SageMaker Python SDK, to upgrade existing XGBoost 0.90 jobs to version 1.2, you must have version 2.x of the SDK installed and change the XGBoost version and framework_version parameters to 1.2-2. If you are using Boto3, you need to update the Docker image, and a few hyperparameters and learning objectives.
Topics

- Upgrade SageMaker Python SDK Version 1.x to Version 2.x (p. 1973)
- Change the image tag to 1.2-2 (p. 1973)
- Change Docker Image for Boto3 (p. 1973)
- Update Hyperparameters and Learning Objectives (p. 1974)

Upgrade SageMaker Python SDK Version 1.x to Version 2.x

If you are still using Version 1.x of the SageMaker Python SDK, you must upgrade to Version 2.x of the SageMaker Python SDK. For information on the latest version of the SageMaker Python SDK, see Use Version 2.x of the SageMaker Python SDK. To install the latest version, run:

```
python -m pip install --upgrade sagemaker
```

Change the image tag to 1.2-2

If you are using the SageMaker Python SDK and using the XGBoost build-in algorithm, change the version parameter in `image_uris.retrieve`.

```
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")

estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           train_volume_size=5, # 5 GB
                                           output_path=output_path)
```

If you are using the SageMaker Python SDK and using XGBoost as a framework to run your customized training scripts, change the `framework_version` parameter in the XGBoost API.

```
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
                     framework_version='1.2-2',
                     hyperparameters=hyperparameters,
                     role=sagemaker.get_execution_role(),
                     instance_count=1,
                     instance_type='ml.m5.2xlarge',
                     output_path=output_path)
```

`sagemaker.session.s3_input` in SageMaker Python SDK version 1.x has been renamed to `sagemaker.inputs.TrainingInput`. You must use `sagemaker.inputs.TrainingInput` as in the following example.

```
content_type = "libsvm"

Use built-in algorithms

```json
{
  "AlgorithmSpecification": {
    "TrainingImage": "746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-xgboost:1.2-2"
  }
}
```

If you are using the SageMaker Python SDK to retrieve registry path, change the `version` parameter in `image_uris.retrieve`.

```python
from sagemaker import image_uris
image_uris.retrieve(framework="xgboost", region="us-west-2", version="1.2-2")
```

### Update Hyperparameters and Learning Objectives

The silent parameter has been deprecated and is no longer available in XGBoost 1.2 and later versions. Use `verbosity` instead. If you were using the `reg:linear` learning objective, it has been deprecated as well in favor of `reg:squarederror`. Use `reg:squarederror` instead.

```python
hyperparameters = {
  "verbosity": "2",
  "objective": "reg:squarederror",
  "num_round": "50",
  ...
}
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                          hyperparameters=hyperparameters,
                                          ...
)
```

### XGBoost Version 0.72

**Important**

The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

**SageMaker Python SDK v1**

```python
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
repo_version="1")
```

**SageMaker Python SDK v2**

```python
import boto3
from sagemaker import image_uris
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see [Supported versions](#)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. **XGBoost** (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of
the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1956). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72
Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm or (the default) text/csv.

Note
For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.
For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format:
<label> <index0>:<value0> <index1>:<value1> ... Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

To use a model trained with SageMaker XGBoost in open source XGBoost

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
```
To differentiate the importance of labelled data points use Instance Weight Supports

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, label:weight idx_0:val_0 idx_1:val_1... For text/csv input, customers need to turn on the csv_weights flag in the parameters and attach weight values in the column after labels. For example: label,weight,val_0,val_1,...).

EC2 Instance Recommendation for the XGBoost Release 0.72

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

XGBoost Release 0.72 Sample Notebooks

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 237). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

XGBoost Release 0.72 Hyperparameters

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

</tbody>
</table>
| **eta**        | Step size shrinkage used in updates to prevent overfitting. After each boosting step, you can directly get the weights of new features. The eta parameter actually shrinks the feature weights to make the boosting process more conservative.  
  **Optional**  
  Valid values: Float. Range: [0,1].  
  Default value: 0.3 |
| **eval_metric** | Evaluation metrics for validation data. A default metric is assigned according to the objective:  
  • rmse: for regression  
  • error: for classification  
  • map: for ranking  
  For a list of valid inputs, see XGBoost Parameters.  
  **Optional**  
  Valid values: string  
  Default value: Default according to objective. |
| **gamma**      | Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger, the more conservative the algorithm is.  
  **Optional**  
  Valid values: Float. Range: [0,∞).  
  Default value: 0 |
| **grow_policy** | Controls the way that new nodes are added to the tree. Currently supported only if tree_method is set to hist.  
  **Optional**  
  Valid values: String. Either depthwise or lossguide.  
  Default value: depthwise |
| **lambda**     | L2 regularization term on weights. Increasing this value makes models more conservative.  
  **Optional**  
  Valid values: float  
  Default value: 1 |
<table>

**Tune an XGBoost Release 0.72 Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning **objective** function to optimize during model training
- an **eval_metric** to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically
You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 2186).

**Metrics Computed by the XGBoost Release 0.72 Algorithm**

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid `eval_metric` values, refer to XGBoost Learning Task Parameters.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:auc</td>
<td>Area under the curve.</td>
<td>Maximize</td>
</tr>

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent's current state. Furthermore, the learning agent's goals should correlate strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

What are the differences between reinforcement, supervised, and unsupervised learning paradigms?

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

Why is Reinforcement Learning Important?

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

Markov Decision Process (MDP)

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

Environment

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

State

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

Action

What the agent does. For example, the robot takes a step forward.

Reward

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a policy.

Observation

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many episodes. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.
Key Features of Amazon SageMaker RL

To train RL models in SageMaker RL, use the following components:

- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see RL Environments in Amazon SageMaker (p. 1989).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker reinforcement learning.

<table>

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

For complete code examples, see the sample notebooks at https://github.com/awslabs/amazon-sagemaker-examples/tree/master/reinforcement-learning.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   a. **Objective**—Scale instance capacity so that it matches the desired load profile.
   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   c. **State**—The current load, number of failed jobs, and number of active machines.
   d. **Action**—Remove, add, or keep the same number of instances.
   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the main() function.

5. **Train the RL Model**—Use the SageMaker RLEstimator in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance.
When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The `RLEstimator` requires the following information as parameters.

a. The source directory where the environment, presets, and training code are uploaded.

b. The path to the training script.

c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.

d. The training parameters, such as the instance count, job name, and S3 path for output.

e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**
   If you train in local mode, you can't visualize metrics in CloudWatch.

7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](https://docs.aws.amazon.com/sagemaker/latest/dg/rl confronting-revelt.html).

### RL Environments in Amazon SageMaker

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.
The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form \( \text{state}_t, \text{action}, \text{state}_{t+1}, \text{reward}_{t+1} \). Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**

- Use OpenAI Gym Interface for Environments in SageMaker RL (p. 1990)
- Use Open-Source Environments (p. 1991)
- Use Commercial Environments (p. 1991)

**Use OpenAI Gym Interface for Environments in SageMaker RL**

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see [https://gym.openai.com/docs/](https://gym.openai.com/docs/).

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()` returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.
- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an `info` dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.
Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you organize, track, compare, and evaluate your machine learning experiments.

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithm and parameters, all the while observing the impact of incremental changes on model accuracy. Over time this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It’s also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements.

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as trials. You can assign, group, and organize these trials into experiments. SageMaker
Experiments is integrated with Amazon SageMaker Studio providing a visual interface to browse your active and past experiments, compare trials on key performance metrics, and identify the best performing models.

SageMaker Experiments comes with its own Experiments Python SDK which makes the analytics capabilities easily accessible in Amazon SageMaker Notebooks. Because SageMaker Experiments enables tracking of all the steps and artifacts that went into creating a model, you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

SageMaker Experiments Features

The following sections provide a brief overview of the features provided by SageMaker Experiments.

Topics
- Organize Experiments (p. 1992)
- Track Experiments (p. 1992)
- Compare and Evaluate Experiments (p. 1993)
- Amazon SageMaker Autopilot (p. 1993)

Organize Experiments

Amazon SageMaker Experiments offers a structured organization scheme to help users group and organize their machine learning iterations. The top level entity, an experiment, is a collection of trials that are observed, compared, and evaluated as a group. A trial is a set of steps called trial components. Each trial component can include a combination of inputs such as datasets, algorithms, and parameters, and produce specific outputs such as models, metrics, datasets, and checkpoints. Examples of trial components are data pre-processing jobs, training jobs, and batch transform jobs.

The goal of an experiment is to determine the trial that produces the best model. Multiple trials are performed, each one isolating and measuring the impact of a change to one or more inputs, while keeping the remaining inputs constant. By analyzing the trials, you can determine which features have the most effect on the model.

Track Experiments

Amazon SageMaker Experiments enables tracking of experiments.

Automated Tracking

SageMaker Experiments automatically tracks Amazon SageMaker Autopilot jobs as experiments with their underlying training jobs tracked as trials. SageMaker Experiments also automatically tracks
SageMaker independently executed training, batch transform, and processing jobs as trial components, whether assigned to a trial or left unassigned. Unassigned trial components can be associated with a trial at a later time. All experiment artifacts including datasets, algorithms, hyperparameters, and model metrics are tracked and recorded. This data allows customers to trace the complete lineage of a model which helps with model governance, auditing, and compliance verifications.

**Manual Tracking**

SageMaker Experiments provides tracking APIs for recording and tracking machine learning workflows running locally on SageMaker Studio notebooks, including classic SageMaker notebooks. These experiments must be part of a SageMaker training, batch transform, or processing job.

**Compare and Evaluate Experiments**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Studio. When you use SageMaker Studio, SageMaker Experiments automatically tracks your experiments and trials, and presents visualizations of the tracked data and an interface to search the data.

SageMaker Experiments automatically organizes, ranks, and sorts trials based on a chosen metric using the concept of a trial leaderboard. SageMaker Studio produces real-time data visualizations, such as metric charts and graphs, to quickly compare and identify the best performing models. These are updated in real-time as the experiment progresses.

**Amazon SageMaker Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for the job, and trials for each of the different combinations of the available trial components, parameters, and artifacts. You can visually drill into all trials and components using SageMaker Studio.

**Create an Amazon SageMaker Experiment**

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

For a tutorial that shows this functionality in an existing SageMaker Studio notebook, see [Track and Compare Tutorial (p. 2000)](p. 2000).

1. Import the `sys` module to install the SDKs.

   ```python
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.
import time
from time import strftime
import sagemaker

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker

5. Get the execution role and create the SageMaker session.

```python
role = sagemaker.get_execution_role()
sm_sess = sagemaker.session.Session()
```

6. Create a SageMaker experiment. The experiment name must be unique in your account.

    **Note**
    The `tags` parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components. For information on how to search tags using Studio, see Search by Tag (p. 2010).

```python
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-{}.format(create_date),
                                      description = "Demo experiment",
                                      tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the **Components and registries** icon (☞). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:
8. Create a trial for the experiment. The trial name must be unique in your account.

```python
demo_trial = Trial.create(trial_name = "DEMO-{}").format(create_date),
              experiment_name = demo_experiment.experiment_name,
              tags = [{'Key': 'demo-trials', 'Value': 'demo1'}]
```

9. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment (this example has one trial). Your list should look similar to the following:
10. Create a trial component as part of the trial. The trial component is the SageMaker job.

   Add the `ExperimentConfig` parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td><code>Estimator.fit</code></td>
<td><code>CreateTrainingJob</code></td>
</tr>
<tr>
<td>Processing</td>
<td><code>Processor.run</code></td>
<td><code>CreateProcessingJob</code></td>
</tr>
<tr>
<td>Transform</td>
<td><code>Transformer.transform</code></td>
<td><code>CreateTransformJob</code></td>
</tr>
</tbody>
</table>

   The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

**Using the SageMaker Python SDK**

```python
sagemaker.estimator.Estimator(
    
    sagemaker_session = sm_sess,
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])

estimator.fit(
    
    experiment_config = {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

**Using Boto3**

```python

```
create_training_job(
    ...
    "ExperimentConfig": {
        # "ExperimentName"
        "TrialName": demo_trial.trial_name,
        "TrialComponentDisplayName": "TrainingJob",
    },
    "Tags": [{"Key": 'demo-jobs', 'Value': 'demo2'}])

11. (Studio) In the trial list, double-click the trial to display a list of the components in the trial (this example has one trial). Your list should look similar to the following:

12. (Studio) To view information about the experiment, trial, and job (trial component), see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 1997).

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 2011).

View and Compare Amazon SageMaker Experiments, Trials, and Trial Components

An Amazon SageMaker experiment consists of multiple trials with a related objective. A trial consists of one or more trial components, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. The entities are presented in a hierarchical view (that is, experiments > trials > trial components). Double-click an entity to see other entities that are at a lower level in the hierarchy. Use the breadcrumbs above the list to move to a higher level in the hierarchy.

For a tutorial using a SageMaker example notebook, see Track and Compare Tutorial (p. 2000). For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 122).

Topics
- View Experiments, Trials, and Trial Components (p. 1998)
- Compare Experiments, Trials, and Trial Components (p. 1999)
View Experiments, Trials, and Trial Components

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments, trials, and trial components. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments, trials, and trial components

1. In the left sidebar of Studio, choose the Components and registries icon (左手箭头). In the drop-down menu, select Experiments and trials to display the experiments browser.

   A list of experiments and their properties is displayed. The list includes all the SageMaker experiments in your account, including experiments created outside of SageMaker Studio.

   **Note**
   To view all the properties, you might have to expand the width of the experiments browser by dragging the right border.

2. In the experiments list, double-click an experiment to display a list of the trials in the experiment.

3. Double-click a trial to display a list of the components in the trial.
4. Double-click one of the components to open the **Describe Trial Component** tab.

5. On the **Describe Trial Component** tab, choose any of the following column headings to see available information about each trial component:

   - **Charts** – Build your own charts.
   - **Metrics** – Metrics that are logged by a Tracker during a trial run.
   - **Parameters** – Hyperparameter values and instance information.
   - **Artifacts** – Amazon S3 bucket storage locations for the input dataset and the output model.
   - **AWS Settings** – Job name, ARN, status, creation time, training time, billable time, instance information, and others.
   - **Debugger** – A list of debugger rules and any issues found.
   - **Trial Mappings**

For information about comparing Experiments entities, see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 1997).

## Compare Experiments, Trials, and Trial Components

You can compare experiments, trials, and trial components by selecting the entities and opening them in the trial components list. The trial components list is referred to as the Studio Leaderboard. In the Leaderboard you can do the following:

- View detailed information about the entities
- Compare entities
Stop a training job

Deploy a model

To compare experiments, trials, and trial components

1. In the left sidebar of SageMaker Studio, choose the SageMaker Experiment List icon.

2. In the Experiments browser, choose either the experiment or trial list. For more information, see View Experiments, Trials, and Trial Components (p. 1998).

3. Choose the experiments or trials that you want to compare, right-click the selection, and then choose Open in trial component list. The Leaderboard opens and lists the associated Experiments entities as shown in the following screenshot.

The Leaderboard has a TABLE PROPERTIES pane on the right side. Use the Settings icon to open and close the pane. You can hide or display properties by category or by individual columns. When you display a chart, the pane changes to display chart properties.

For information on searching the Experiments entities, see Search Experiments Using Amazon SageMaker Studio (p. 2006).

Track and Compare Tutorial

This tutorial demonstrates how to visually track and compare trials in a model training experiment using Amazon SageMaker Studio. The basis of the tutorial is the MNIST Handwritten Digits Classification Experiment notebook.

It is intended that this topic be viewed alongside Studio with the MNIST notebook open. As you run through the cells, the sections in this document highlight the relevant code and show you how to observe the results in Studio. Some of the code snippets have been edited for brevity.

To clean up the resources created by the notebook, see Clean Up Amazon SageMaker Experiment Resources (p. 2011).

For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Tour (p. 130).

Prerequisites

2000
- A local copy of the MNIST example notebook and the companion mnist.py file. Both files are available from the sagemaker_experiments/mnist-handwritten-digits-classification-experiment folder in the aws/amazon-sagemaker-examples repository. To download the files, choose each link, right-click on the Raw button, and then choose Save as.
- An AWS SSO or IAM account to sign-on to SageMaker Studio. For more information, see Onboard to Amazon SageMaker Domain (p. 36).

Topics
- Open the Notebook in Studio (p. 2001)
- Install the Experiments SDK and Import Modules (p. 2001)
- Transform and Track the Input Data (p. 2002)
- Create and Track an Experiment (p. 2002)
- Compare and Analyze Trials (p. 2004)

Open the Notebook in Studio

To open the notebook
1. Sign-on to Studio.
2. In the left sidebar, choose the File Browser icon.
3. At the top of the file browser pane, choose the Up arrow icon and then a File Upload dialog opens. Browse to and choose your local versions of the mnist-handwritten-digits-classification-experiment.ipynb and mnist.py files, and then choose Open.
4. The two files are listed in the file browser. Double-click the uploaded notebook file to open the notebook in a new tab.
5. At the top right of the notebook, make sure the kernel is Python 3 (Data Science). If not, choose the current kernel name to open the Select Kernel dropdown. Choose Python 3 (Data Science) and then choose Select.

Install the Experiments SDK and Import Modules

The Amazon SageMaker Experiments Python SDK is separate from the Amazon SageMaker Python SDK, which comes preinstalled in SageMaker Studio. Run the first few cells in the notebook to install the Experiments SDK and import the Experiments modules. The relevant sections of the notebook cells are displayed below.

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.analytics import ExperimentAnalytics
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```
Transform and Track the Input Data

The next few cells create an Amazon S3 bucket and a folder in the bucket named `mnist`. In Studio, the file browser displays the `mnist` folder. The input data is downloaded to the `mnist/MNIST/raw` folder, normalized, and then the transformed data is uploaded to the `mnist/MNIST/processed` folder. You can drill down into the `mnist` folder to display, but not open, the data files.

Your screen should look similar to the following:

![Image of Amazon SageMaker Studio with the "mnist" folder displayed]

The last cell in the Dataset section creates a Tracker for the transform job. The tracker logs the normalization parameters and the URI of the Amazon S3 bucket where the transformed dataset is stored. In a later section, we show how to find this information in Studio. In the next section, the tracker is used to track the experiment and trial runs.

```python
with Tracker.create(display_name="Preprocessing", sagemaker_boto_client=sm) as tracker:
    tracker.log_parameters(
        "normalization_mean": 0.1307,
        "normalization_std": 0.3081,
    )
    tracker.log_input(name="mnist-dataset", media_type="s3/uri", value=inputs)
```

Create and Track an Experiment

The following procedure creates and tracks an experiment to determine the effect of the model's `num_hidden_channel` hyperparameter. As part of the experiment, five trials are created inside a loop, one for each value of the `num_hidden_channel` hyperparameter. Later in the notebook, you'll compare the results of these five trials.

1. In the left sidebar of Studio, choose the SageMaker Components and registries icon (🔍). In the dropdown menu, choose Experiments and trials to display the list of experiments in your account.
2. Run the following cell.

```python
mnist_experiment = Experiment.create(
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}",
    description="Classification of mnist hand-written digits",
    sagemaker_boto_client=sm)
print(mnist_experiment)
```

Output:

```python
Experiment(sagemaker_boto_client=<botocore.client.SageMaker object at 0x7f7152b326d8>,
    experiment_name='mnist-hand-written-digits-classification-1575947870',
    description='Classification of mnist hand-written digits',
    experiment_arn='arn:aws:sagemaker:us-east-2:acct-id:experiment/mnist-hand-
written-digits-classification-1575947870')
```

After the code runs, the experiments list contains an entry for the experiment. It might take a moment to display and you might have to refresh the experiments list. Your screen should look similar to the following:
3. Run the following cell.

```python
test_sage = tracker.trial_component
```

After the code runs, the experiments list contains an entry labeled **Unassigned trial components**. The trial component entry is the data preprocessing step previously created. Double-click the trial component for verification. The trial component isn’t associated with an experiment at this time. Your screen should look similar to the following:

4. Choose the **Home** icon in the navigation breadcrumb at the top on the experiments browser. From there, double-click on your experiment to display a list of the trials in the experiment.

5. The following code creates trials for the experiment. Each trial trains a model using a different number for the `num_hidden_channel` hyperparameter. The preprocessing trial component is added to each trial for complete tracking (for example, for auditing purposes). The code also specifies definitions for the following metrics:
   - Train loss
   - Test loss
   - Test accuracy

   ```python
   for i, num_hidden_channel in enumerate([2, 5, 10, 20, 32]):
       trial_name = f"cnn-training-job-{num_hidden_channel}-hidden-channels-\{int(time.time())}\"
       cnn_trial = Trial.create(
           trial_name=trial_name,
           experiment_name=mnist_experiment.experiment_name,
           sagemaker_boto_client=sm,
       )
       hidden_channel_trial_name_map[num_hidden_channel] = trial_name
   cnn_trial.add_trial_component(preprocessing_trial_component)
   ```
estimator = PyTorch(
    py_version='py3',
    framework_version='1.1.0',
    ...,
    hyperparameters={
        'hidden_channels': num_hidden_channel,
        ...,
    },
    metric_definitions=[
        {'Name':'train:loss', 'Regex':'Train Loss: (.*?);'},
        {'Name':'test:loss', 'Regex':'Test Average loss: (.*?),'},
        {'Name':'test:accuracy', 'Regex':'Test Accuracy: (.*%)'},
    ],
    enable_sagemaker_metrics=True,
)

cnn_training_job_name = "cnn-training-job-{}.format(int(time.time()))
estimator.fit(
    inputs={'training': inputs},
    job_name=cnn_training_job_name,
    experiment_config={
        "TrialName": cnn_trial.trial_name,
        "TrialComponentDisplayName": "Training",
    },
)

The trial list automatically updates as each training job runs. It takes a few minutes for each trial to be displayed. Your screen should look similar to the following:

**Compare and Analyze Trials**

This section deviates from the notebook and shows you how to compare and analyze the trained models using the SageMaker Studio UI.

**To view the details of a trial**

1. Double-click one of the trials to display a list of the trial components associated with the trial. There's a preprocessing job and training job for each trial. Double-click one of the components to open a new tab that displays information about each component.
2. Under **Trial stages**, choose **Preprocessing**. On the **Describe Trial Component** menu, choose **Parameters** to display the normalization parameters that were previously logged. Next, choose **Artifacts** to display the URI of the Amazon S3 bucket where the transformed dataset was stored.
3. Under **Trial stages**, choose **Training**. On the **Describe Trial Component** menu, choose the following items to display information about the training job trial component.
• **Metrics** – test:loss, test:accuracy, and train:loss
• **Parameters** – hyperparameter values and instance information
• **Artifacts** – Amazon S3 storage for the input dataset and the output model
• **AWS Settings** – job name, ARN, status, creation time, training time, billable time, instance information, and others

**To view a list of trials ordered by test:accuracy**

1. Choose the experiment name on the navigation breadcrumb above **TRIAL COMPONENTS** to display the trial list.
2. Choose all five trials. Hold down the CTRL/CMD key and select each trial. Right-click the selection and then choose **Open in trial component list**. A new tab opens that displays each trial and trial component.
3. If the **TABLE PROPERTIES** pane isn't open, choose the **Settings** icon (⚙️) in the upper right corner to open it. Deselect everything except **Trial**, **Metrics**, and **Training job**. Choose the **Settings** icon to close the pane.
4. Choose the **test:accuracy** column header to sort the list by decreasing maximum test accuracy. Your screen should look similar to the following:

![Screen shot of trial component list](image)

**To view a chart of test:loss versus num_hidden_channel**

1. In the **TRIAL COMPONENTS** pane, choose all five trials and then choose **Add chart**. Select inside the chart area to open the preferences pane for **CHART PROPERTIES**.
2. In **CHART PROPERTIES**, choose the following:
   - **Data type** - Summary statistics
   - **Chart type** - Line
   - **X-axis** - hidden-channels
   - **Y-axis** - test:loss_last
Search Experiments Using Amazon SageMaker Studio

You can search your experiments, trials, and trial components using the experiments browser. After choosing the entities, you can search on properties of these entities on the Amazon SageMaker Leaderboard.

Topics
- Search Experiments, Trials, and Trial Components (p. 2006)
- Search the SageMaker Studio Leaderboard (p. 2007)
- Search by Tag (p. 2010)

Search Experiments, Trials, and Trial Components

You can search and create multiple filters to display a subset of experiments, trials, and trial components in the experiments browser. After you search and filter your list, you can open the entities in the Leaderboard and search on additional properties.

To search for experiments, trials, and trial components, and apply filters

For more information about the following steps, along with screenshots, see Search the SageMaker Studio Leaderboard (p. 2007).

1. In the experiments browser, navigate to the entity type you want to search for: experiment, trial, or trial component.
2. Place your cursor in the search box to display the list of column that are searchable.
3. Choose the column that you want to search on and one of the following dialog boxes opens that's specific to the column you chose:
Search Experiments Using Studio

- **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

- **Discrete values** – Choose one or more property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values.

- **Date** – Enter a date in *From Date* and *To Date*, or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

- **Tag** – In *Search tag key*, start entering the tag's key. A list of tag keys is filtered to only those keys with a name that starts with the text string that you enter. Choose the tag key that you want to search on from the list. In *Search tag value*, enter the complete tag value, and then choose **Apply**.

4. To create the filter, choose **Apply**.

5. To apply additional filters, repeat the preceding steps. You can have a maximum of 20 filters. An entity must match all filters to be displayed.

### Search the SageMaker Studio Leaderboard

The Amazon SageMaker Studio trial components list is referred to as the Leaderboard. You can use the Leaderboard to compare your trials and experiments. The Leaderboard lists properties of the trials, such as the trial status, debugger status, tags, metrics, hyperparameters, and input and output artifacts.

You can search the Leaderboard to find specific trial components. You apply the results of a search to create a filter that displays only those components that satisfy the filter. You can apply up to 20 filters. A component is displayed only if it matches all filters. To remove a filter, choose the X that displays to the right of the filter.

#### To search the Leaderboard and apply filters

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.

2. In the **Settings** pane, select the check boxes for the columns that you want to view, and then choose the **Settings** icon to close the pane.

3. Place your cursor in the **Search column name** box to display the following list of **TABLE PROPERTIES** column names that are searchable:

   **Summary section**
   - Trial component name
   - Trial component type
   - Created
   - Last modified
   - Created by
   - Tags

   **Detail sections** (all columns)
   - Metrics
   - Parameters
   - Input artifacts
   - Output artifacts
4. To limit the column names when you search the detail sections, start typing the column name. The list displays only those columns with a name that starts with the text string that you enter.

5. Choose the column that you want to search on. This opens a dialog that's specific to the type of data in that column.

6. Enter your search criteria in the dialog for the appropriate data type:

   - **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

   - **Discrete values** – Choose one or more of the property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values. For the **Trial component type** column, **Others** matches components with no value in the column.
• **Date** – Enter a date in **From Date** and **To Date** or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

• **Created by** – Select **Me** or **Everyone else**. This filter limits the list to those components that were created by the currently signed-in user or everyone but the currently signed-in user.

• **Tag** – Choose the tag to search. For more information, see [Search by Tag](#) (p. 2010).

• **Detail columns** – Specify the conditions that the component's property value must satisfy.
To create the filter, choose **Apply**.

To apply additional filters, repeat the preceding steps. A component must match all filters to be displayed. You can have a maximum of 20 filters.

**Search by Tag**

You can add searchable tags to experiments, trials, and trial components when the entities are created or afterwards using the **AddTags** API. A tag consists of a unique case-sensitive key and an optional value. Multiple tags can be added to an entity. You can add the same tag to multiple entities.

**To search by tag and apply filters**

1. If the **TABLE PROPERTIES** pane isn't open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.
2. In the **Settings** pane, select **Tags** if it isn't selected, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box and then choose **Tags**.
4. In **Search tag key**, start entering the tag's key. A list of tag keys displays only those keys with a name that starts with the text string that you enter.
5. Choose the tag key that you want to search on from the list.
6. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

7. The trial component list displays only those components that have tags that match the key-value pair you chose.

8. To add more tag filters, repeat the previous steps. A tag must match all filters for the component to be displayed.

**Clean Up Amazon SageMaker Experiment Resources**

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using Boto3 and the Experiments SDK. For more information about the Experiments SDK, see [sagemaker-experiments](#).

To delete the experiment, you must delete all trials in the experiment. To delete a trial, you must remove all trial components from the trial. To delete a trial component, you must remove the component from all trials.

**Note**

Trial components can exist independent of trials and experiments. You do not have to delete them. If you want to reuse them, comment out `tc.delete()` in the code.
Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import time

from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent

Define cleanup_sme_sdk

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
                # to prevent throttling
                time.sleep(.5)
            trial.delete()
    experiment_name = experiment.experiment_name
    experiment.delete()
    print(f"\nExperiment {experiment_name} deleted")

Call cleanup_sme_sdk

experiment_to_cleanup = Experiment.load(
    # Use experiment name not display name
    experiment_name="experiment-name")
cleanup_sme_sdk(experiment_to_cleanup)
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto3

```python
import boto3
sm = boto3.Session().client('sagemaker')

Define cleanup_boto3
```
Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API. For information on searching in Amazon SageMaker Studio, see Search Experiments Using Studio (p. 2006).

Topics

- Sample Notebooks for Managing ML Experiments (p. 2014)
- Organize, Find, and Evaluate Training Jobs (Console) (p. 2014)
- Find and Evaluate Training Jobs (API) (p. 2016)
- Verify the Datasets Used by Your Training Jobs (p. 2017)
Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see Managing ML Experimentation using Amazon SageMaker Model Tracking Capability.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances. After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the Advanced Functionality section. To open a notebook, choose its Use tab, and choose Create copy. If you have questions, post them on the Amazon Machine Learning Developer Forum.

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics
- Use Tags to Track Training Jobs (Console) (p. 2014)
- Find Training Jobs (Console) (p. 2015)
- Evaluate Models (Console) (p. 2015)

Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

Add tags to training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.

4. To add another tag, choose Add tag, and add another key-value pair.
Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, Tags appears only if you have added a tag for a training job.

To find training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search.
3. Add Parameters.
   a. In the search box, enter a parameter and choose a parameter type, for example TrainingJobName.
   b. Choose a conditional operation. For numeric values, use operators such as is equals to, lesser than, or or greater than. For text-based values, use operators such as equals to or contains.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose Add row and enter the parameter values.
5. Choose Search.

Evaluate Models (Console)

To evaluate a model’s performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

To evaluate a model (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Search and search for training jobs by specifying relevant parameters. The results are displayed in a table.

3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric**.

5. Make necessary changes, then choose **Update view**.

6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

**Find and Evaluate Training Jobs (API)**

To find training jobs or to get suggestions for items used in experiments that are searchable, you can use the **Search API**.

**Topics**

- Find Training Jobs (API) (p. 2016)
- Evaluate Models (API) (p. 2016)
- Get Suggestions for a Search (API) (p. 2017)

**Find Training Jobs (API)**

To find training jobs, create a search parameter using the `search_params` parameter. Then use the search function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the **Search API** to find training jobs.

```python
import boto3

search_params={
    "MaxResults": 10,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [{
            "Name": "Tags.Project",
            "Operator": "Equals",
            "Value": "Project_Binary_Classifier"
        }],
        "SortBy": "Metrics.train:binary_classification_accuracy",
        "SortOrder": "Descending"
    }
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

**Evaluate Models (API)**

To evaluate models, run a search as described in Find Training Jobs (API) (p. 2016), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers=["Training Job Name", "Training Job Status", "Batch Size", "Binary Classification Accuracy"]
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
    rows.append([trainingJob['TrainingJobName'],
```

2016
Get Suggestions for a Search (API)

To get suggestions for a search, use the `GetSearchSuggestions` API.

The following example for AWS SDK for Python (Boto3) is a `get_search_suggestions` request for items containing `linear`.

```python
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a `get_search_suggestions` request.

```json
{
    'PropertyNameSuggestions': [
        {'PropertyName': 'hyperparameters.linear_init_method'},
        {'PropertyName': 'hyperparameters.linear_init_value'},
        {'PropertyName': 'hyperparameters.linear_init_sigma'},
        {'PropertyName': 'hyperparameters.linear_lr'},
        {'PropertyName': 'hyperparameters.linear_wd'}
    ]
}
```

After getting search suggestions, you can use one of the property names in a search.

Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.
- Trace Model Lineage (Console) (p. 2018)
- Trace Model Lineage (API) (p. 2018)

Trace Model Lineage (Console)

To trace a model's lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Endpoints, and choose the relevant endpoint.
3. Scroll to the Endpoint configuration settings section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

Trace Model Lineage (API)

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```python
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={'
  "MaxResults": 1,
  "Resource": "TrainingJob",
  "SearchExpression": {
    "Filters": [
    {
      "Name": "ModelArtifacts.S3ModelArtifacts",
      "Operator": "Equals",
      "Value": model['PrimaryContainer']['ModelDataUrl']
    }],
  }
},
results = smclient.search(**search_params)
```

After finding the training job, you can review the resources used to train the model.

Amazon SageMaker Debugger

Debug, monitor, and profile training jobs in real time, detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.

SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model's compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.
SageMaker Debugger supports Apache MXNet, TensorFlow, PyTorch, and XGBoost. For more information about available frameworks and versions, see Supported Frameworks and Algorithms (p. 2020).

The high-level Debugger workflow is as follows:

1. Configure a SageMaker training job with Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker CreateTrainingJob request (for Boto3 or CLI).
   - Configure custom training containers (p. 2111) with Debugger.
2. Start a training job and monitor training issues in real time.
   - SageMaker Studio Debugger dashboards in Studio Experiments and trials (p. 2124).
   - List of Debugger Built-in Rules (p. 2065).
3. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 2115).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 2119).
4. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
   - Studio Debugger Insights dashboard for deep learning frameworks
   - Deep learning framework profiling report
   - SageMaker XGBoost training report
5. Explore deep analysis of the training issues and bottlenecks.
   - For profiling training jobs, see Analyze Data Using the SMDebug Client Library (p. 2164).
   - For debugging model parameters, see Visualize Debugger Output Tensors in TensorBoard (p. ).
6. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics
- Supported Frameworks and Algorithms (p. 2020)
- Amazon SageMaker Debugger Architecture (p. 2021)
- Get Started with Debugger Tutorials (p. 2023)
- Configure Debugger Using Amazon SageMaker Python SDK (p. 2032)
- Configure Debugger Using Amazon SageMaker API (p. 2054)
- List of Debugger Built-in Rules (p. 2065)
- Create Debugger Custom Rules for Training Job Analysis (p. 2109)
Supported Frameworks and Algorithms

The following table shows SageMaker machine learning frameworks and algorithms supported by Debugger.

<table>
<thead>
<tr>

- **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.
- **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.
- **Debugging output tensors** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.
Important
For the TensorFlow framework with Keras, SageMaker Debugger deprecates the zero code change support for debugging models built using the \texttt{tf.keras} modules of TensorFlow 2.6 and later. This is due to breaking changes announced in the TensorFlow 2.6.0 release note. SageMaker Debugger continues to support the zero code change experience for the native TensorFlow (which excludes the \texttt{tf.keras} modules).

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

Use Debugger with Custom Training Containers
Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the SMDebug client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 2111).

Debugger Open-Source GitHub Repositories
Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker CreateTrainingJob and DescribeTrainingJob API operations. The SMDebug client library provides tools to register hooks and access the training data through its trial feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and SMDebug API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Debugger APIs
- The SMDebug open source client library
- The SMDebug PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations (p. 2178)
- Configure Debugger Using Amazon SageMaker API (p. 2054)

Amazon SageMaker Debugger Architecture
This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for performance optimization to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger’s debugging functionality for model optimization is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.

- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.

- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

**Note**
By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics.
every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

See the following topics for best practices to improve the performance of your model using SageMaker Debugger.

**Get Started with Debugger Tutorials**

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

**Topics**

- Debugger Tutorial Videos (p. 2023)
- Debugger Example Notebooks (p. 2024)
- Debugger Advanced Demos and Visualization (p. 2026)

**Debugger Tutorial Videos**

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker Studio and SageMaker notebook instances.

**Topics**

- Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger (p. 2023)
- Debug Models with Amazon SageMaker Debugger in Studio (p. 2023)

**Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger**

*Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds*

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes the training process transparent by automatically capturing metrics, analyzing training runs, and detecting problems.

**Debug Models with Amazon SageMaker Debugger in Studio**

*Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds*
This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

**Debug Models with Amazon SageMaker Debugger (part 1)**

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the debugger.ipynb notebook file and the mnist_keras_tf.py training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path keras_script_path to the mnist_keras_tf.py file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as keras_script_path = "mnist_keras_tf.py".

**Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor**

*Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds*

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

**Debug Models with Debugger (part 2)**

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

**Debugger Example Notebooks**

*SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.*

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

**Important**

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger Example Notebooks for Profiling Training Jobs**

The following list shows Debugger example notebooks introducing Debugger's adaptability to monitor and profile training jobs for various machine learning models, datasets, and frameworks.

---

2024
This notebook provides an introduction to interactive analysis of profiled data captured by SageMaker Debugger. Explore the full functionality of the SMDebug interactive analysis tools.

Profile TensorFlow 1-D CNN for sentiment analysis of IMDB data that consists of movie reviews labeled as having positive or negative sentiment. Explore the Studio Debugger insights and Debugger profiling report.

Run TensorFlow training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.

Run PyTorch training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 2026).

**Debugger Advanced Demos and Visualization**

The following demos walk you through advanced use cases and visualization scripts using Debugger.

**Topics**

- Train and Tune Your Models with Amazon SageMaker Experiments and Debugger (p. 2026)
- Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training (p. 2029)
- Using SageMaker Debugger to Monitor Attentions in BERT Model Training (p. 2029)
- Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs) (p. 2032)

**Train and Tune Your Models with Amazon SageMaker Experiments and Debugger**

*Dr. Nathalie Rauschmayr, AWS Applied Scientist* | *Length: 49 minutes 26 seconds*

**Train and Prune Models with SageMaker Experiments and Debugger**

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as *trials* through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.
SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

Total params: 50,883,321
Trainable params: 50,883,321
Non-trainable params: 0

Input size (MB): 0.57
Forward/backward pass size (MB): 7.27
Params size (MB): 194.10
Estimated Total Size (MB): 201.95
You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**
To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the *train* function in the *train.py* script.

```python
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ["SM_MODEL_DIR"] + '/model.pt')
```

2028
Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size \((1, 20)\) from an original input image of size \((28, 28)\) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.
The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called attention.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting attention scores and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the attention-head view in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters while constructing SageMaker estimators. There are three parameters you need to configure: profiler_config, debugger_hook_config, and rules.

**Note**

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.
Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

**Note**
The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

**TensorFlow**

To access the deep profiling feature for TensorFlow, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```
PyTorch

To access the deep profiling feature for PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
     Rule.sagemaker(rule_configs.built_in_rule()),
     ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]

estimator=PyTorch(
   entry_point="directory/to/your_training_script.py",
   role=sagemaker.get_execution_role(),
   base_job_name="debugger-demo",
   instance_count=1,
   instance_type="ml.p3.2xlarge",
   image_uri="763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04",
   # Debugger-specific parameters
   profiler_config=profiler_config,
   debugger_hook_config=debugger_hook_config,
   rules=rules
)

estimator.fit(wait=False)
```

MXNet

```python
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
     Rule.sagemaker(rule_configs.built_in_rule()),
     ProfilerRule.sagemaker(rule_configs.BuiltinRule())
]

estimator=MXNet(
   entry_point="directory/to/your_training_script.py",
   role=sagemaker.get_execution_role(),
   base_job_name="debugger-demo",
   instance_count=1,
   instance_type="ml.p3.2xlarge",
   framework_version="1.7.0",
   py_version="py37",
)
```

...
# Debugger-specific parameters
profiler_config=profiler_config,
debugger_hook_config=debugger_hook_config,
rules=rules
)
estimator.fit(wait=False)

**Note**
For MXNet, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for MXNet.

### XGBoost

# An example of constructing a SageMaker XGBoost estimator
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs
profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
estimator=XGBoost(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",
    
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
estimator.fit(wait=False)

**Note**
For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

### Generic estimator

# An example of constructing a SageMaker generic estimator using the XGBoost algorithm
base image
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs
profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)

Where you configure the following parameters:

- **profiler_config** parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the profiler_config parameter, see Configure Debugger Monitoring Hardware System Resource Utilization (p. 2037) and Configure Debugger Framework Profiling (p. 2037).

- **debugger_hook_config** parameter – Configure Debugger to collect output tensors from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the debugger_hook_config parameter, see Configure Debugger Hook to Save Tensors (p. 2041).

- **rules** parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket URI. To learn how to configure the rules parameter, see Configure Debugger Built-in Rules (p. 2047).

**Note**
Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/). There are three subfolders created by Debugger: debug-output, profiler-output, and rule-output. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 2053).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure Debugger Monitoring Hardware System Resource Utilization (p. 2037)

- Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 2041)
- Configure Debugger Hook to Save Tensors (p. 2041)
- Configure Debugger Built-in Rules (p. 2047)
- Turn Off Debugger (p. 2053)
- Useful SageMaker Estimator Classmethods for Debugger (p. 2053)
Configure Debugger Monitoring Hardware System Resource Utilization

To adjust Debugger system monitoring time intervals, use the `ProfilerConfig` API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**
By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following example code shows how to set up the `profiler_config` parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

• `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open the Amazon SageMaker Debugger Insights Dashboard (p. 2125).

Configure Debugger Framework Profiling

To enable Debugger framework profiling, configure the `framework_profile_params` parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the `FrameworkProfile` class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms (p. 2020).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

Start a Training Job with the Default System Monitoring and Framework Profiling

The following example code is the simplest `profiler_config` parameter setting to start the default system monitoring and the default framework profiling. The `FrameworkProfile` class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```
With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 2039) and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

**Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range**

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**
  
  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      system_monitor_interval_millis=1000,
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

- **For a target time range**
With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

### Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options

You can use the following profiling configuration classes to manage the framework profiling options:

- **DetailedProfilingConfig** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- **DataloaderProfilingConfig** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

  **Note**
  Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps.
  Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
• **cProfile** – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

• **Pyinstrument** – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**
Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig,
                                 PythonProfiler, cProfileTimer)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
        python_profiling_config=PythonProfilingConfig(
            start_step=9,
            num_steps=1,
            python_profiler=PythonProfiler.CPROFILE,
            cprofile_timer=cProfileTimer.TOTAL_TIME
        )
    )
)
```

For more information about available profiling options, see `DetailedProfilingConfig`, `DataloaderProfilingConfig`, and `PythonProfilingConfig` in the Amazon SageMaker Python SDK.
Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:

  ```python
  estimator.enable_default_profiling()
  ```

  When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

  For more information, see `estimator.enable_default_profiling` in the Amazon SageMaker Python SDK.

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:

  ```python
  estimator.update_profiler(
    rules=[ProfilerRule.sagemaker(rule_configs.BuiltInRule()),
          system_monitor_interval_millis=500,
          framework_profile_params=FrameworkProfile()
    )
  ```

  For more information, see `estimator.update_profiler` in the Amazon SageMaker Python SDK.

Configure Debugger Hook to Save Tensors

*Tensors* are data collections of updated parameters from the backward and forward pass of each training iteration, and Debugger collects output tensors to analyze the state of a training job. The Amazon SageMaker Debugger `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into *collections* and saving them to a target S3 bucket.

**Note**

By default, for all SageMaker training jobs, Debugger collects loss and accuracy output scalars from the training jobs every 500 steps, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the output data in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, enable Debugger by specifying the hook configuration parameter, `debugger_hook_config`. The following steps include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them. If you use Debugger-supported AWS containers for zero script change, you can simply run the training job without changing your training script. You can also use Debugger for training jobs running in any other Debugger-supported AWS containers with script mode, making minimal changes to your training script.

**Configure Debugger Tensor Collections Using the CollectionConfig API Operation**

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-
supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]
```

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

For a full list of available Debugger built-in collections, see Debugger Built-in Collections.

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following `CollectionConfig` template to adjust parameters.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters={
            "key_1": "value_1",
            "key_2": "value_2",
            ...
            "key_n": "value_n"
        }
    )
]
```

For more information about available parameter keys, see `CollectionConfig` in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

```python
from sagemaker.debugger import CollectionConfig
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "100",
            "eval.save_interval": "10"
        }
    )
]
```

**Tip**
This tensor collection configuration object can be used for both `DebuggerHookConfig` and `Rule` API operations.

**Configure Debugger Hook to Save Tensors**

Use the `DebuggerHookConfig` class to create a `debugger_hook_config` object using the `collection_configs` object you created in the previous step.

```python
from sagemaker.debugger import DebuggerHookConfig
```
Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig
d debugger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri",
    collection_configs=collection_configs
)
```

For more information, see `DebuggerHookConfig` in the Amazon SageMaker Python SDK.

**Example Notebooks and Code Samples to Configure Debugger Hook**

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

**Topics**
- Tensor Visualization Example Notebooks (p. 2043)
- Save Tensors Using Debugger Built-in Collections (p. 2045)
- Save Tensors Using Debugger Modified Built-in Collections (p. 2046)
- Save Tensors Using Debugger Custom Collections (p. 2046)

**Tensor Visualization Example Notebooks**

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.
This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- **Visualizing and Debugging Tensors from MXNet Model Training**

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the `TensorPlot` class imported from `tensor_plot.py` is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The `tensor_plot.py` script provided with the notebook retrieves tensors using Debugger and visualizes
the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

**Save Tensors Using Debugger Built-in Collections**

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=
  [
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
  ]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
  s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                 LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
  collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
  entry_point='directory/to/your_training_script.py',
  role=sm.get_execution_role(),
  base_job_name='debugger-demo-job',
  instance_count=1,
  instance_type="ml.m4.xlarge",
  framework_version="2.3.0",
  py_version="py37",
  version=2045)
```
# debugger-specific hook argument below
d lines for debugger_hook_config=hook_config
sagemaker_estimator.fit()

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the CollectionConfig API operation. The following example shows how to tweak the built-in losses collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs = [
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.
    format(BUCKET_NAME=BUCKET_NAME,
           LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
    # debugger-specific hook argument below
    debugger_hook_config=hook_config)

sagemaker_estimator.fit()
```

For a full list of CollectionConfig parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection

collection_configs = [
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session = sagemaker.Session()
BUCKET_NAME = sagemaker_session.default_bucket()
LOCATION_IN_BUCKET = 'debugger-custom-collections-hook'

hook_config = DebuggerHookConfig(
    s3_output_path="s3://{}/*{}*".format(BUCKET_NAME, LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

Configure Debugger Built-in Rules

Amazon SageMaker Debugger rules analyze tensors emitted during the training of a model. Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 2065).

Note
The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the ProfilerReport (p. 2067) rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The ProfilerReport rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

• BatchSize (p. 2068)
• CPUBottleneck (p. 2070)
• GPUMemoryIncrease (p. 2071)
• IOBottleneck (p. 2072)
• LoadBalancing (p. 2073)
• LowGPUUtilization (p. 2074)
• OverallSystemUsage (p. 2075)

Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/. For more information about how to download the profiling report, see SageMaker Debugger Profiling Report (p. 2141). SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

In the following topics, learn how to use the Debugger built-in rules.

Topics
• Use Debugger Built-in Rules with the Default Parameter Settings (p. 2048)
• Use Debugger Built-in Rules with Custom Parameter Values (p. 2049)
• Example Notebooks and Code Samples to Configure Debugger Rules (p. 2050)

Use Debugger Built-in Rules with the Default Parameter Settings

To specify Debugger built-in rules in an estimator, you need to configure a rules list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs
rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_n()),
    Rule.sagemaker(rule_configsbuiltin_rule_name_1()),
    Rule.sagemaker(rule_configsbuiltin_rule_name_2()),
    ...
    Rule.sagemaker(rule_configsbuiltin_rule_name_n())
]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 2065).

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration:

```python
from sagemaker.debugger import Rule, rule_configs
rules=[
```
When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The loss_not_decreasing, overfit, overtraining, and stalled_training_rule monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to IssueFound. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 2114).

Use Debugger Built-in Rules with Custom Parameter Values

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the base_config and rule_parameters parameters for the ProfilerRule.sagemaker and Rule.sagemaker classmethods. In case of the Rule.sagemaker class methods, you can also customize tensor collections through the collections_to_save parameter. The instruction of how to use the CollectionConfig class is provided at Configure Debugger Tensor Collections Using the CollectionConfig API Operation (p. 2041).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The base_config argument is where you call the built-in rule methods.
- The rule_parameters argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules (p. 2065).
- The collections_to_save argument takes in a tensor configuration through the CollectionConfig API, which requires name and parameters arguments.
- To find available tensor collections for name, see Debugger Built-in Tensor Collections.
- For a full list of adjustable parameters, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs, CollectionConfig
rules=[
    ProfilerRule.sagemaker(
        base_config=rule_configs.BuiltInProfilerRuleName(),
        rule_parameters={
            "key": "value"
        }
    ),
    Rule.sagemaker(
        base_config=rule_configs.builtin_in_rule_name(),
        rule_parameters={
            "key": "value"
        }
    ),
    collections_to_save=[
        CollectionConfig(
            name="tensor_collection_name",
            parameters={
```
The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 2065).

Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics

- Debugger Built-in Rules Example Notebooks (p. 2050)
- Debugger Built-in Rules Example Code (p. 2051)
- Use Debugger Built-in Rules with Parameter Modifications (p. 2052)

Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
- Using a SageMaker Debugger built-in rule with XGBoost
- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the Studio Experiment List tab. For example, as shown in the following screenshot, you can find and open a Describe Trial Component window of your current training job. On the Debugger tab, you can check if the Debugger rules, vanishing_gradient() and loss_not_decreasing(), are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.
There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_configs` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger Built-in Rules (p. 2065).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules = [
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(
        base_config=rule_configs.loss_not_decreasing(),
        collections_to_save=['
            CollectionConfig(
                name='some',
                parameters={
                    'save_interval': '50',
                    'train_save_interval': '10',
                    'eval_save_interval': '100'})
    )]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator = TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    rules=built_in_rules)
```

2051
instance_count=1,
instance_type="ml.m4.xlarge",
framework_version="2.1.0",
py_version="py3",

    # debugger-specific arguments below
    rules=built_in_rules
)
sagemaker_estimator.fit()

Note
The Debugger built-in rules run in parallel with your training job. The maximum number of
built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker
Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger
Built-in Rules with Parameter Modifications (p. 2052) section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example,
the stalled_training_rule collects the losses tensor collection from a training job at every 50
steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting
tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))
built_in_rules_modified=[
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire': 'True'
        }
    )
    collections_to_save=[
        CollectionConfig(
            name="losses",
            parameters={
                "train.save_interval": "50",
                "eval.save_interval": "10"
            }
        )
    ]
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    py_version="py3",
# debugger-specific arguments below

```python
rules=built_in_rules_modified
```

sagemaker_estimator.fit()

For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see Configure Debugger Using Amazon SageMaker API (p. 2054).

## Turn Off Debugger

If you want to completely turn off Debugger, do one of the following:

- **Before starting a training job**, do the following:
  
  To disable both monitoring and profiling, include the `disable_profiler` parameter to your estimator and set it to `True`.

  **Warning**
  
  If you disable it, you won't be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  To disable debugging, set the `debugger_hook_config` parameter to `False`.

  **Warning**
  
  If you disable it, you won't be able to collect output tensors and cannot debug your model parameters.

  ```python
  estimator=Estimator(
      ...
      disable_profiler=True
      debugger_hook_config=False
  )
  ```

  For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

- **While a training job is running**, do the following:

  To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

  ```python
  estimator.disable_profiling()
  ```

  To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

  ```python
  estimator.update_profiler(disable_framework_metrics=true)
  ```

  For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.

## Useful SageMaker Estimator Classmethods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.
To check the base S3 bucket URI of a SageMaker training job:
```python
estimator.output_path
```

To check the base job name of a SageMaker training job:
```python
estimator.latest_training_job.job_name
```

To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:
```python
estimator.latest_training_job.describe()
```

To check a full list of the Debugger rules while a SageMaker training job is running:
```python
estimator.latest_training_job.rule_job_summary()
```

To check the S3 bucket URI where the model parameter data (output tensors) are saved:
```python
estimator.latest_job_debugger_artifacts_path()
```

To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:
```python
estimator.latest_job_profiler_artifacts_path()
```

To check the Debugger rule configuration for debugging output tensors:
```python
estimator.debugger_rule_configs
```

To check the list of the Debugger rules for debugging while a SageMaker training job is running:
```python
estimator.debugger_rules
```

To check the Debugger rule configuration for monitoring and profiling system and framework metrics:
```python
estimator.profiler_rule_configs
```

To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:
```python
estimator.profiler_rules
```

For more information about the SageMaker estimator class and its methods, see `Estimator API` in the Amazon SageMaker Python SDK.

**Configure Debugger Using Amazon SageMaker API**

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure `CreateTrainingJob`, `UpdateTrainingJob`, Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.
Configure Debugger Using SageMaker API

- JSON (AWS CLI) (p. 2055)
- AWS Boto3 (p. 2059)

### JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `DebugHookConfig`, `DebugRuleConfigurations`, `ProfilerConfig`, and `ProfilerRuleConfiguration` objects through the SageMaker `CreateTrainingJob` API operation. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the JSON strings to request `CreateTrainingJob`.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as `debugger-training-job-cli.json`.

**Note**

Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179).

```json
{
    "TrainingJobName": "debugger-aws-cli-test",
    "RoleArn": "arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-YYYYMMDDT123456",
    "AlgorithmSpecification": {
        // Specify a training Docker container image URI (Deep Learning Container or your own
        // training container) to TrainingImage.
        "TrainingImage": "763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-
        training:2.4.1-gpu-py37-cu110-ubuntu18.04",
        "TrainingInputMode": "File",
        "EnableSageMakerMetricsTimeSeries": false
    },
    "HyperParameters": {
        "sagemaker_program": "entry_point/tf-hvd-train.py",
        "sagemaker_submit_directory": "s3://sagemaker-us-west-2-111122223333/debugger-boto3-
        profiling-test/source.tar.gz"
    },
    "OutputDataConfig": {
        "S3OutputPath": "s3://
        sagemaker-us-west-2-111122223333/debugger-aws-cli-test/output"
    },
    "DebugHookConfig": {
        "S3OutputPath": "s3://
        sagemaker-us-west-2-111122223333/debugger-aws-cli-test/debug-
        output",
        "CollectionConfigurations": [
            {
                "CollectionName": "losses",
                "CollectionParameters": {
                    "train.save_interval": "50"
                }
            }
        ],
        "DebugRuleConfigurations": [
            {
                "RuleConfigurationName": "LossNotDecreasing",
                "RuleEvaluatorImage": "895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
                debugger-rules:latest",
                "RuleParameters": {"rule_to_invoke": "LossNotDecreasing"}
            }
        ],
        "ProfilerConfig": {
```
"S3OutputPath": "s3://sagemaker-us-west-2-111122223333/debugger-aws-cli-test/profiler-output",
"ProfilingIntervalInMilliseconds": 500,
"ProfilingParameters": {
  "DataloaderProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3, \"MetricsRegex\": \"\'.\'\", \"\"},
  "DetailedProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3, \"}\",
  "PythonProfilingConfig": "{\"StartStep\": 5, \"NumSteps\": 3, \"ProfilerName\": \"cprofile\", \"cProfileTimer\": \"total_time\"},
  "LocalPath": "/opt/ml/output/profiler/"
},
"ProfilerRuleConfigurations": [
  {"RuleConfigurationName": "ProfilerReport",
   "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
  }
],
"ResourceConfig": {
  "InstanceType": "ml.p3.8xlarge",
  "InstanceCount": 1,
  "VolumeSizeInGB": 30
},
"StoppingCondition": {
  "MaxRuntimeInSeconds": 86400
}
}

After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```bash
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```json
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "gradients",
      "CollectionParameters": {
        "save_interval": "500"
      }
    }
  ]
}
```

This will make the training job save the tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.
To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
"DebugRuleConfigurations": [
  {
    "RuleConfigurationName": "VanishingGradient",
    "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
    "RuleParameters": {
      "rule_to_invoke": "VanishingGradient",
      "threshold": "20.0"
    }
  }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2065).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  "ProfilingIntervalInMilliseconds": 500,
  "ProfilingParameters": {
    "DataloaderProfilingConfig": "{"StartStep": 5, "NumSteps": 3, "MetricsRegex": ".*" }",
    "DetailedProfilingConfig": "{"StartStep": 5, "NumSteps": 3 }",
    // For PythonProfilingConfig,
    // available ProfilerName options: cProfile, Pyinstrument
    // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
    "PythonProfilingConfig": "{"StartStep": 5, "NumSteps": 3, "ProfilerName": "cProfile", "cProfileTimer": "total_time" }",
    // Optional. Local path for profiling outputs
    "LocalPath": "/opt/ml/output/profiler/"
  }
}
```

Target Time Duration

```
"ProfilerConfig": {
  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
```
"ProfilingIntervalInMilliseconds": 500,
"ProfilingParameters": {
  "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10, "MetricsRegex": ".*" }",
  "DetailedProfilingConfig": "{ ( "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10 ) }",
  // For PythonProfilingConfig,
  // available ProfilerName options: cProfile, Pyinstrument
  // available cProfileTimer options only when using cProfile: cpu, off_cpu,
  total_time
  "PythonProfilingConfig": "{ ( "StartTimeInSecSinceEpoch": 12345567789,
  "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer":
  "total_time" ) }",
  // Optional. Local path for profiling outputs
  "LocalPath": "/opt/ml/output/profiler/"
}
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

"ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "ProfilerReport",
    "RuleParameters": {
      "rule_to_invoke": "ProfilerReport",
      "CPUBottleneck_cpu_threshold": "90",
      "IOBottleneck_threshold": "90"
    }
  }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2065).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

{  
  "ProfilerConfig": {
    "DisableProfiler": boolean,
    "ProfilingIntervalInMilliseconds": number,
    "ProfilingParameters": {
      "string" : "string"
    }
  },
  "ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "string",
    "RuleEvaluatorImage": "string",
    "RuleParameters": {
      "string" : "string"
    }
  }
]
Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects in the `CreateTrainingJob` API operation. The following code sample shows how to configure a custom `ImproperActivation` rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2180). You specify the URL registry address for the pre-built Docker image in the `RuleEvaluatorImage` parameter.

```json
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "relu_activations",
      "CollectionParameters": {
        "include_regex": "relu",
        "save_interval": "500",
        "end_step": "5000"
      }
    }
  ],
  "DebugRulesConfigurations": [
    {
      "RuleConfigurationName": "improper_activation_job",
      "InstanceType": "ml.c4.xlarge",
      "VolumeSizeInGB": 400,
      "RuleParameters": {
        "source_s3_uri": "s3://bucket/custom_rules.py",
        "rule_to_invoke": "ImproperActivation",
        "collection_names": "relu_activations"
      }
    }
  ]
}
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for `RuleParameters`, see List of Debugger Built-in Rules (p. 2065).

**AWS Boto3**

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in us-west-2, assuming that a
training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

**Note**

Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179).

```python
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'
tar = tarfile.open(source, 'w:gz')
tar.add('entry_point/train.py') # Specify the directory and name of your training script
tar.close()

s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-19oct2020',
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training script file location and name under the sagemaker_submit_directory
    },
    AlgorithmSpecification={
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/output',
    },
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {'CollectionName': 'losses',
```
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {'CollectionName': 'gradients',
         'CollectionParameters': { 'train.save_interval': '500',
                                    'eval.save_interval': '50'}
    ]
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps.
To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client.
library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
        'RuleParameters': {
            'rule_to_invoke': 'VanishingGradient',
            'threshold': '20.0'
        }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2065).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
    'S3OutputPath': '$s3://<default-bucket>/<training-job-name>/profiler-output', #
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        }',
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time" # Include only when using cprofile.
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
    }
}
```
Target Time Duration

ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        }',
        'DetailedProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10
        }',
        'PythonProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 1234567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "ProfilerTimer": "total_time" # Include only when using cprofile.
        }',
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
    }
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

ProfilerRuleConfigurations=[
    { # Optional. Rule parameters for Debugger rules
        'RuleConfigurationName': 'ProfilerReport',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2065).

Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation

Debugger profiling configuration can be updated while your training job is running by using the update_training_job() function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string': 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string': 'string'
        }
    }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects using the AWS Boto3 SageMaker client's create_training_job() function. The following code sample shows how to configure a custom ImproperActivation rule written with the smdebug library using this SageMaker API operation. This example assumes that you've written the custom rule in custom_rules.py file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 2180). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.

DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
                'include_regex': 'relu',
                'save_interval': '500',
                'end_step': '5000'
            }
        }
    ],
},
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'ImproperActivation_job',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
            'source_s3_uri': 's3://bucket/custom_rules.py',
            'rule_to_invoke': 'ImproperActivation',
            'collection_names': 'relu_activations'
        }
    }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 2179). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 2065).
List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

**Note**
The maximum numbers of built-in rules for a training job are 20 for ProfilerRule and 20 for Rule. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the **Amazon SageMaker Studio is available at no additional charge** section of the Amazon SageMaker Pricing page.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger ProfilerRule**

The following rules are the Debugger built-in rules that are callable using the ProfilerRule.sagemaker classmethod.

**Debugger Built-in Rules for Generating Profiling Reports**

<table>
<thead>
<tr>
<th>Scope of Validity</th>
<th>Built-in Rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profiling Report for any SageMaker training job</td>
<td>• ProfilerReport (p. 2067)</td>
</tr>
</tbody>
</table>

**Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics)**

<table>
<thead>
<tr>
<th>Scope of Validity</th>
<th>Built-in Rules</th>
</tr>
</thead>
</table>
| Generic system monitoring rules for any SageMaker training job | • BatchSize (p. 2068)  
• CPUBottleneck (p. 2070)  
• GPUMemoryIncrease (p. 2071)  
• IOBottleneck (p. 2072)  
• LoadBalancing (p. 2073)  
• LowGPUtilization (p. 2074)  
• OverallSystemUsage (p. 2075) |

**Debugger Built-in Rules for Profiling Framework Metrics**

<table>
<thead>
<tr>
<th>Scope of Validity</th>

• StepOutlier (p. 2076)

Debugger Rule

The following rules are the Debugger built-in rules that are callable using the `Rule.sagemaker` classmethod.

**Debugger Built-in Rules for Generating Training Reports**

Scope of Validity | Built-in Rules
--- | ---
Training Report for SageMaker XGboost training job | • create_xgboost_report (p. 2077)

**Debugger Built-in Rules for Debugging Model Training Data (Output Tensors)**

Scope of Validity | Built-in Rules
--- | ---
Deep learning frameworks (TensorFlow, MXNet, and PyTorch) | • dead_relu (p. 2078)
• exploding_tensor (p. 2079)
• poor_weight_initialization (p. 2080)
• saturated_activation (p. 2082)
• vanishing_gradient (p. 2085)
• weight_update_ratio (p. 2086)

Deep learning frameworks (TensorFlow, MXNet, and PyTorch) and the XGBoost algorithm | • all_zero (p. 2087)
• class_imbalance (p. 2089)
• loss_not_decreasing (p. 2091)
• overfit (p. 2093)
• overtraining (p. 2094)
• similar_across_runs (p. 2096)
• stalled_training_rule (p. 2097)
• tensor_variance (p. 2098)
• unchanged_tensor (p. 2100)

Deep learning applications | • check_input_images (p. 2102)
• nlp_sequence_ratio (p. 2103)

XGBoost algorithm | • confusion (p. 2105)
• feature_importance_overweight (p. 2107)
• tree_depth (p. 2108)

To use the built-in rules with default parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),
    ...
]```

2066
To use the built-in rules with customizing the parameter values – use the following configuration format:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [
    ProfilerRule.sagemaker(
        base_config=rule_configs.ProfilerReport(),
        rule_parameters={
            "key": "value"
        }
    ),
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule_name(),
        rule_parameters={
            "key": "value"
        },
        collections_to_save=[
            CollectionConfig(
                name="tensor_collection_name",
                parameters={
                    "key": "value"
                }
            )
        ]
    ),
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.

- For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 2051).
- For a full instruction of using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 2054).

**ProfilerReport**

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```python
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>._<parameter_name> = value
        )
    )
]"
If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's cpu_threshold parameter and the IOBottleneck rule's threshold parameter.

```
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

### Parameter Descriptions for the OverallSystemUsage Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required</td>
</tr>
<tr>
<td>&lt;BuiltInRuleName&gt;_&lt;parameter_name&gt;</td>
<td>Customizable parameter to adjust thresholds of other built-in monitoring and profiling rules. Optional</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

### BatchSize

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

### Parameter Descriptions for the BatchSize Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

<td><strong>patience</strong></td>
<td>Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</td>
</tr>
</tbody>
</table>

**Parameter Descriptions**

- **base_trial**: The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.
  - **Required**
  - **Valid values**: String

- **threshold**: Defines the threshold when Rule to return True.
  - **Optional**
  - **Valid values**: Integer
  - Default value: 50 (in percentage)

- **gpu_threshold**: A threshold that defines when GPU is considered underutilized.
  - **Optional**
  - **Valid values**: Integer
  - Default value: 70 (in percentage)

- **io_threshold**: A threshold that defines high IO wait time.
  - **Optional**
  - **Valid values**: Integer
  - Default values: 50 (in percentage)

- **patience**: Defines the number of data points to skip until the rule starts evaluation. The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.
  - **Optional**
  - **Valid values**: Integer
  - Default values: 1000
### LoadBalancing

The LoadBalancing rule helps detect issues in workload balancing among multiple GPUs.

LowGPUUtilization

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

#### CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- hyperparameters – Saves at the first step
- metrics – Saves loss and accuracy every 5 steps
- feature_importance – Saves every 5 steps
- predictions – Saves every 5 steps
- labels – Saves every 5 steps

#### Parameter Descriptions for the CreateXgboostReport Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tr>
</tbody>
</table>

```python
def rules()
    return [Rule.sagemaker(
        rule_configs.create_xgboost_report()
    )]
```

### DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns True.

#### Parameter Descriptions for the DeadRelu Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger. Required Valid values: String</td>
</tr>
<tr>
<td>tensor_regex</td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched. Optional Valid values: List of strings or a comma-separated string Default value: &quot;.*relu_output&quot;</td>
</tr>
<tr>
<td>threshold_inactivity</td>
<td>Defines a level of activity below which a ReLU is considered to be dead. A ReLU might be active in the beginning of a trial and then slowly die during the training process. If the ReLU is active less than the <code>threshold_inactivity</code>, it is considered to be dead. Optional Valid values: Float Default values: 1.0 (in percentage)</td>
</tr>
</tbody>
</table>
**List of Built-in Rules**

### threshold_layer

Parameter Name: `threshold_layer`  
Description: Returns `True` if the percentage of inactive ReLUs in a layer is greater than `threshold_layer`. Returns `False` if the percentage of inactive ReLUs in a layer is less than `threshold_layer`.

**Optional**  
Valid values: Float  
Default values: 50.0 (in percentage)

```python
built_in_rules = [
    Rule.sagemaker(  
        base_config=rule_configs.dead_relu(),  
        rule_parameters={  
            "tensor_regex": ".*relu_output|.*ReLU_output"  
        }  
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Note**  
This rule is not available for the XGBoost algorithm.

### ExplodingTensor

This rule detects whether the tensors emitted during training have non-finite values, either infinite or NaN (not a number). If a non-finite value is detected, the rule returns `True`.

#### Parameter Descriptions for the ExplodingTensor Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base_trial</code></td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tensor_regex</strong></td>
<td>A list of regex patterns used to restrict this comparison to specific scalar-valued tensors. The rule inspects only the tensors that match the regex patterns specified in the list. If no patterns are passed, the rule compares all tensors gathered in the trials by default. Only scalar-valued tensors can be matched.</td>
</tr>
<tr>
<td><strong>only_nan</strong></td>
<td>True to monitor the base_trial tensors only for NaN values and not for infinity. False to treat both NaN and infinity as exploding values and to monitor for both.</td>
</tr>
</tbody>
</table>

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*gradient",
            "only_nan": "False"
        }
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Note**
This rule is not available for the XGBoost algorithm.

**PoorWeightInitialization**

This rule detects if your model parameters have been poorly initialized.
Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

### Parameter Descriptions for the PoorWeightInitialization Rule

</table>

### SaturatedActivation

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective `min_threshold` and `max_thresholds` values. If the activity of a node drops below the `threshold_inactivity` percentage, it is considered saturated. If more than a `threshold_layer` percent of the nodes are saturated, the rule returns True.

Note

This rule is not available for the XGBoost algorithm.

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(name="gradients",
```
parameters={
    "save_interval": "500"
}
}
]
}
]

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Note
This rule is not available for the XGBoost algorithm.

WeightUpdateRatio

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the large_threshold value or if this ratio is smaller than small_threshold, the rule returns True.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and train.save_interval needs to be set equal to num_steps.

Parameter Descriptions for the WeightUpdateRatio Rule

                parameters={  
                    "train.save_interval": "100"  
                }  
            )  
        ]  
    )  
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

**Note**
This rule is not available for the XGBoost algorithm.

### AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

            CollectionConfig(
                name="all",
                parameters={
```
ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 2047).

Parameter Descriptions for the ClassImbalance Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>threshold_imbalance</td>
<td>The acceptable imbalance between the number of samples in the smallest class and in the largest class. Exceeding this threshold value throws an error.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float</td>
</tr>
<tr>
<td></td>
<td>Default value: 10</td>
</tr>
<tr>
<td>threshold_misprediction</td>
<td>A limit on the fraction of mispredictions allowed for each class. Exceeding this threshold throws an error. The underrepresented classes are most at risk of crossing this threshold.</td>
