Docker Registry Paths and Example Code for China (Ningxia) (cn-northwest-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1048)
- Chainer (DLC) (p. 1048)
- Clarify (algorithm) (p. 1049)
- Debugger (algorithm) (p. 1049)
- DeepAR Forecasting (algorithm) (p. 1049)
- Factorization Machines (algorithm) (p. 1050)
- Hugging Face (algorithm) (p. 1050)
- IP Insights (algorithm) (p. 1050)
- Image classification (algorithm) (p. 1050)
- Inferentia MXNet (DLC) (p. 1051)
- Inferentia PyTorch (DLC) (p. 1051)
- K-Means (algorithm) (p. 1052)
- KNN (algorithm) (p. 1052)
- Linear Learner (algorithm) (p. 1052)
- MXNet (DLC) (p. 1052)
- MXNet Coach (DLC) (p. 1055)
- Model Monitor (algorithm) (p. 1055)
- NTM (algorithm) (p. 1056)
- Neo Image Classification (algorithm) (p. 1056)
- Neo MXNet (DLC) (p. 1056)
- Neo PyTorch (DLC) (p. 1057)
Use built-in algorithms

- Neo Tensorflow (DLC) (p. 1057)
- Neo XGBoost (algorithm) (p. 1058)
- Object Detection (algorithm) (p. 1058)
- Object2Vec (algorithm) (p. 1058)
- PCA (algorithm) (p. 1059)
- PyTorch (DLC) (p. 1059)
- Random Cut Forest (algorithm) (p. 1061)
- Scikit-learn (algorithm) (p. 1061)
- Semantic Segmentation (algorithm) (p. 1062)
- Seq2Seq (algorithm) (p. 1062)
- Spark (algorithm) (p. 1062)
- SparkML Serving (algorithm) (p. 1063)
- Tensorflow (DLC) (p. 1063)
- Tensorflow Coach (DLC) (p. 1070)
- Tensorflow Inferentia (DLC) (p. 1071)
- Tensorflow Ray (DLC) (p. 1071)
- XGBoost (algorithm) (p. 1072)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='cn-northwest-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

</table>

#### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='cn-northwest-1')
```

#### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='cn-northwest-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

#### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='cn-northwest-1')
```
### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='cn-northwest-1')
```

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet', region='cn-northwest-1', version='1.5.1', instance_type='ml.inf1.6xlarge')
```

### Inferentia PyTorch (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch', region='cn-northwest-1', version='1.5.1', py_version='py3')
```
<table>
<thead>
<tr>

</tbody>
</table>
Docker Registry Paths and Example Code for Europe (Frankfurt) (eu-central-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- BlazingText (algorithm) (p. 1074)
- Chainer (DLC) (p. 1074)
- Clarify (algorithm) (p. 1075)
- Debugger (algorithm) (p. 1075)
- DeepAR Forecasting (algorithm) (p. 1075)
- Factorization Machines (algorithm) (p. 1075)
- Hugging Face (algorithm) (p. 1076)
- IP Insights (algorithm) (p. 1076)
- Image classification (algorithm) (p. 1076)
- Inferentia MXNet (DLC) (p. 1077)
- Inferentia PyTorch (DLC) (p. 1077)
- K-Means (algorithm) (p. 1077)
- KNN (algorithm) (p. 1078)
- LDA (algorithm) (p. 1078)
- Linear Learner (algorithm) (p. 1078)
- MXNet (DLC) (p. 1079)
- MXNet Coach (DLC) (p. 1081)
- Model Monitor (algorithm) (p. 1082)
- NTM (algorithm) (p. 1082)
- Neo Image Classification (algorithm) (p. 1082)
- Neo MXNet (DLC) (p. 1083)
- Neo PyTorch (DLC) (p. 1083)
- Neo Tensorflow (DLC) (p. 1083)
- Neo XGBoost (algorithm) (p. 1084)
- Object Detection (algorithm) (p. 1084)
- Object2Vec (algorithm) (p. 1084)
- PCA (algorithm) (p. 1085)
- PyTorch (DLC) (p. 1085)
- Random Cut Forest (algorithm) (p. 1087)
- Ray PyTorch (DLC) (p. 1087)
- Scikit-learn (algorithm) (p. 1088)

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>451049120500.dkr.ecr.cn-northwest-1.amazonaws.com/sagemaker-xgboost:&lt;tag&gt;</td>
<td>1.2-1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>
- Semantic Segmentation (algorithm) (p. 1088)
- Seq2Seq (algorithm) (p. 1088)
- Spark (algorithm) (p. 1089)
- SparkML Serving (algorithm) (p. 1089)
- Tensorflow (DLC) (p. 1089)
- Tensorflow Coach (DLC) (p. 1097)
- Tensorflow Inferentia (DLC) (p. 1097)
- Tensorflow Ray (DLC) (p. 1098)
- VW (algorithm) (p. 1099)
- XGBoost (algorithm) (p. 1099)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>813361260812.dkr.ecr.eu-central-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-central-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>520713654638.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>
Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='eu-central-1',version='1.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>017069133835.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-clarify-processing:&lt;tag&gt;</td>
<td>1.0</td>
<td>processing</td>
</tr>
</tbody>
</table>

Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>482524230118.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-debugger-rules:&lt;tag&gt;</td>
<td>latest</td>
<td>debugger</td>
</tr>
</tbody>
</table>

DeepAR Forecasting (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>

<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.
Use built-in algorithms

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>664544806723.dkr.ecr.eu-central-1.amazonaws.com/factorization-machines:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-central-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>763104351884.dkr.ecr.eu-central-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
<tr>
<td>763104351884.dkr.ecr.eu-central-1.amazonaws.com/huggingface-tensorflow-training:&lt;tag&gt;</td>
<td>4.4.2</td>
<td>training</td>
</tr>
</tbody>
</table>

IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>664544806723.dkr.ecr.eu-central-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='eu-central-1')

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>813361260812.dkr.ecr.eu-central-1.amazonaws.com/image-classification:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Inferentia MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-central-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-neo-mxnet:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

**Inferentia PyTorch (DLC)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-pytorch',region='eu-central-1',version='1.5.1',py_version='py3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>746233611703.dkr.ecr.eu-central-1.amazonaws.com/sagemaker-neo-pytorch:&lt;tag&gt;</td>
<td>1.5.1</td>
<td>inference</td>
<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>

**K-Means (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans',region='eu-central-1')
```
Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>664544806723.dkr.ecr.eu-central-1.amazonaws.com/kmeans:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='eu-central-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>

**Docker Registry Paths and Example Code for Europe (London) (eu-west-2)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**
- **BlazingText (algorithm) (p. 1127)**
- **Chainer (DLC) (p. 1128)**
- **Clarify (algorithm) (p. 1128)**
- **Debugger (algorithm) (p. 1128)**
Use built-in algorithms

- DeepAR Forecasting (algorithm) (p. 1129)
- Factorization Machines (algorithm) (p. 1129)
- Hugging Face (algorithm) (p. 1129)
- IP Insights (algorithm) (p. 1130)
- Image classification (algorithm) (p. 1130)
- Inferentia MXNet (DLC) (p. 1130)
- Inferentia PyTorch (DLC) (p. 1131)
- K-Means (algorithm) (p. 1131)
- KNN (algorithm) (p. 1131)
- LDA (algorithm) (p. 1132)
- Linear Learner (algorithm) (p. 1132)
- MXNet (DLC) (p. 1132)
- MXNet Coach (DLC) (p. 1135)
- Model Monitor (algorithm) (p. 1135)
- NTM (algorithm) (p. 1136)
- Neo Image Classification (algorithm) (p. 1136)
- Neo MXNet (DLC) (p. 1136)
- Neo PyTorch (DLC) (p. 1136)
- Neo Tensorflow (DLC) (p. 1137)
- Neo XGBoost (algorithm) (p. 1137)
- Object Detection (algorithm) (p. 1138)
- Object2Vec (algorithm) (p. 1138)
- PCA (algorithm) (p. 1138)
- PyTorch (DLC) (p. 1139)
- Random Cut Forest (algorithm) (p. 1141)
- Ray PyTorch (DLC) (p. 1141)
- Scikit-learn (algorithm) (p. 1141)
- Semantic Segmentation (algorithm) (p. 1142)
- Seq2Seq (algorithm) (p. 1142)
- Spark (algorithm) (p. 1142)
- SparkML Serving (algorithm) (p. 1143)
- Tensorflow (DLC) (p. 1143)
- Tensorflow Coach (DLC) (p. 1150)
- Tensorflow Inferentia (DLC) (p. 1151)
- Tensorflow Ray (DLC) (p. 1152)
- VW (algorithm) (p. 1152)
- XGBoost (algorithm) (p. 1153)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-2')
```
## Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>

### Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
e_image_uris.retrieve('framework'=chainer','region'=eu-west-2','version'=5.0.0',py_version=py3',image_scope='inference',instance_type=ml.c5.4xlarge')
```

### Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
e_image_uris.retrieve('framework'=clarify','region'=eu-west-2','version'=1.0',image_scope=processing')
```

### Debugger (algorithm)

SageMaker Python SDK example to retrieve registry path.
Use built-in algorithms

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger', region='eu-west-2')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

**XGBoost (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='xgboost', region='eu-west-2', version='1.2-1')
```

**Docker Registry Paths and Example Code for Europe (Paris) (eu-west-3)**

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- BlazingText (algorithm) (p. 1154)
- Chainer (DLC) (p. 1155)
- Clarify (algorithm) (p. 1155)
- Debugger (algorithm) (p. 1155)
- DeepAR Forecasting (algorithm) (p. 1156)
Use built-in algorithms

- Factorization Machines (algorithm) (p. 1156)
- Hugging Face (algorithm) (p. 1156)
- IP Insights (algorithm) (p. 1157)
- Image classification (algorithm) (p. 1157)
- Inferentia MXNet (DLC) (p. 1157)
- Inferentia PyTorch (DLC) (p. 1158)
- K-Means (algorithm) (p. 1158)
- KNN (algorithm) (p. 1158)
- Linear Learner (algorithm) (p. 1159)
- MXNet (DLC) (p. 1159)
- MXNet Coach (DLC) (p. 1161)
- Model Monitor (algorithm) (p. 1162)
- NTM (algorithm) (p. 1162)
- Neo Image Classification (algorithm) (p. 1162)
- Neo MXNet (DLC) (p. 1163)
- Neo PyTorch (DLC) (p. 1163)
- Neo Tensorflow (DLC) (p. 1164)
- Neo XGBoost (algorithm) (p. 1164)
- Object Detection (algorithm) (p. 1164)
- Object2Vec (algorithm) (p. 1165)
- PCA (algorithm) (p. 1165)
- PyTorch (DLC) (p. 1165)
- Random Cut Forest (algorithm) (p. 1167)
- Scikit-learn (algorithm) (p. 1168)
- Semantic Segmentation (algorithm) (p. 1168)
- Seq2Seq (algorithm) (p. 1168)
- Spark (algorithm) (p. 1169)
- SparkML Serving (algorithm) (p. 1169)
- Tensorflow (DLC) (p. 1169)
- Tensorflow Coach (DLC) (p. 1177)
- Tensorflow Inferentia (DLC) (p. 1177)
- Tensorflow Ray (DLC) (p. 1178)
- XGBoost (algorithm) (p. 1178)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-west-3')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>749696950732.dkr.ecr.eu-west-3.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>
Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-west-3', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>

Docker Registry Paths and Example Code for Europe (Stockholm) (eu-north-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- BlazingText (algorithm) (p. 1180)
- Chainer (DLC) (p. 1180)
- Clarify (algorithm) (p. 1181)
- Debugger (algorithm) (p. 1181)
- DeepAR Forecasting (algorithm) (p. 1181)
- Factorization Machines (algorithm) (p. 1182)
- Hugging Face (algorithm) (p. 1182)
- IP Insights (algorithm) (p. 1182)
- Image classification (algorithm) (p. 1183)
- Inferentia MXNet (DLC) (p. 1183)
- Inferentia PyTorch (DLC) (p. 1183)
- K-Means (algorithm) (p. 1184)
- KNN (algorithm) (p. 1184)
- Linear Learner (algorithm) (p. 1184)
- MXNet (DLC) (p. 1184)
- MXNet Coach (DLC) (p. 1187)
- Model Monitor (algorithm) (p. 1188)
- NTM (algorithm) (p. 1188)
- Neo Image Classification (algorithm) (p. 1188)
- Neo MXNet (DLC) (p. 1188)
- Neo PyTorch (DLC) (p. 1189)
- Neo Tensorflow (DLC) (p. 1189)
- Neo XGBoost (algorithm) (p. 1190)
- Object Detection (algorithm) (p. 1190)
- Object2Vec (algorithm) (p. 1190)
- PCA (algorithm) (p. 1191)
- PyTorch (DLC) (p. 1191)
- Random Cut Forest (algorithm) (p. 1193)
- Scikit-learn (algorithm) (p. 1193)
- Semantic Segmentation (algorithm) (p. 1194)
- Seq2Seq (algorithm) (p. 1194)
- Spark (algorithm) (p. 1194)
- SparkML Serving (algorithm) (p. 1195)
- Tensorflow (DLC) (p. 1195)
- Tensorflow Coach (DLC) (p. 1202)
- Tensorflow Inferentia (DLC) (p. 1203)
- Tensorflow Ray (DLC) (p. 1203)
- XGBoost (algorithm) (p. 1204)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Chainer (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-north-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr.eu-north-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>
Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>520713654638.dkr.ecr-north-1.amazonaws.com/sagemaker-chainer:tag</td>
<td></td>

</tr>
</tbody>
</table>

**Clarify (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
data = image_uris.retrieve(framework='clarify',region='eu-north-1',version='1.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>

<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
data = image_uris.retrieve(framework='debugger',region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>314864569078.dkr.ecr.eu-latestnorth-1.amazonaws.com/sagemaker-debugger-rules:tag</td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
data = image_uris.retrieve(framework='forecasting-deepar',region='eu-north-1')
```
### Factorization Machines (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='eu-north-1')
```

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-north-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-north-1')
```
### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='eu-north-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>669576153137.dkr.ecr.eu-north-1.amazonaws.com/ipinsights:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

### Inferentia MXNet (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='inferentia-mxnet',region='eu-north-1',version='1.5.1',instance_type='ml.inf1.6xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>

<td>inf</td>
<td>py3</td>
</tr>
</tbody>
</table>
**K-Means (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='kmeans', region='eu-north-1')
```

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn', region='eu-north-1')
```

**Linear Learner (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner', region='eu-north-1')
```

**MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet', region='eu-north-1', version='1.4.1', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')

Docker Registry Paths and Example Code for Europe (Milan) (eu-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics

- BlazingText (algorithm) (p. 1206)
- Chainer (DLC) (p. 1206)
- Clarify (algorithm) (p. 1206)
- Debugger (algorithm) (p. 1207)
- DeepAR Forecasting (algorithm) (p. 1207)
- Factorization Machines (algorithm) (p. 1207)
- Hugging Face (algorithm) (p. 1208)
- IP Insights (algorithm) (p. 1208)
- Image classification (algorithm) (p. 1208)
- Inferentia MXNet (DLC) (p. 1209)
- Inferentia PyTorch (DLC) (p. 1209)
- K-Means (algorithm) (p. 1209)
- KNN (algorithm) (p. 1210)
- Linear Learner (algorithm) (p. 1210)
- MXNet (DLC) (p. 1210)
- MXNet Coach (DLC) (p. 1213)
- Model Monitor (algorithm) (p. 1213)
- NTM (algorithm) (p. 1214)
- Neo Image Classification (algorithm) (p. 1214)
- Neo MXNet (DLC) (p. 1214)
- Neo PyTorch (DLC) (p. 1215)
- Neo Tensorflow (DLC) (p. 1215)
- Neo XGBoost (algorithm) (p. 1216)
- Object Detection (algorithm) (p. 1216)
- Object2Vec (algorithm) (p. 1216)
- PCA (algorithm) (p. 1216)
- PyTorch (DLC) (p. 1217)
- Random Cut Forest (algorithm) (p. 1219)
- Scikit-learn (algorithm) (p. 1219)
- Semantic Segmentation (algorithm) (p. 1220)
- Seq2Seq (algorithm) (p. 1220)
- Spark (algorithm) (p. 1220)
• SparkML Serving (algorithm) (p. 1221)
• Tensorflow (DLC) (p. 1221)
• Tensorflow Coach (DLC) (p. 1228)
• Tensorflow Inferentia (DLC) (p. 1229)
• Tensorflow Ray (DLC) (p. 1229)
• XGBoost (algorithm) (p. 1230)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/blazingtext:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

Chainer (DLC)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='chainer', region='eu-south-1', version='5.0.0', py_version='py3', image_scope='inference', instance_type='ml.c5.4xlarge')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
<th>Processor types</th>
<th>Python versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>

<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
<tr>
<td>048378556238.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-chainer:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
<td>CPU, GPU</td>
<td>py2, py3</td>
</tr>
</tbody>
</table>

Clarify (algorithm)

SageMaker Python SDK example to retrieve registry path.
Use built-in algorithms

```python
from sagemaker import image_uris
image_uris.retrieve(framework='clarify',region='eu-south-1',version='1.0',image_scope='processing')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>63885417683.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-clarify-processing:<em>tag</em></td>
<td></td>
<td>processing</td>
</tr>
</tbody>
</table>

**Debugger (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='debugger',region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>563282790590.dkr.ecr.eu-south-1.amazonaws.com/sagemaker-debugger-rules:<em>tag</em></td>
<td></td>
<td>debugger</td>
</tr>
</tbody>
</table>

**DeepAR Forecasting (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='forecasting-deepar',region='eu-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/forecasting-deepar:<em>tag</em></td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Factorization Machines (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines',region='eu-south-1')
```
### Use built-in algorithms

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>257386234256.dkr.ecr.eu-south-1.amazonaws.com/factorization-machines:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
<tr>
<td>692866216735.dkr.ecr.eu-south-1.amazonaws.com/huggingface-pytorch-training:&lt;tag&gt;</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface', region='eu-south-1', version='4.4.2', image_scope='training', base_framework_version='tensorflow2.4.1')
```

### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights', region='eu-south-1')
```

### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification', region='eu-south-1')
```
### Use built-in algorithms

#### Registry path

Docker Registry Paths and Example Code for Middle East (Bahrain) (me-south-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

**Topics**

- BlazingText (algorithm) (p. 1232)
- Chainer (DLC) (p. 1232)
- Clarify (algorithm) (p. 1232)
- Debugger (algorithm) (p. 1233)
- DeepAR Forecasting (algorithm) (p. 1233)
- Factorization Machines (algorithm) (p. 1233)
- Hugging Face (algorithm) (p. 1234)
- IP Insights (algorithm) (p. 1234)
- Image classification (algorithm) (p. 1234)
- Inferentia MXNet (DLC) (p. 1235)
- Inferentia PyTorch (DLC) (p. 1235)
- K-Means (algorithm) (p. 1235)
- KNN (algorithm) (p. 1236)
- Linear Learner (algorithm) (p. 1236)
- MXNet (DLC) (p. 1236)
- MXNet Coach (DLC) (p. 1239)
- Model Monitor (algorithm) (p. 1239)
- NTM (algorithm) (p. 1240)
- Neo Image Classification (algorithm) (p. 1240)
- Neo MXNet (DLC) (p. 1240)
- Neo PyTorch (DLC) (p. 1241)
- Neo Tensorflow (DLC) (p. 1241)
- Neo XGBoost (algorithm) (p. 1242)
- Object Detection (algorithm) (p. 1242)
- Object2Vec (algorithm) (p. 1242)
- PCA (algorithm) (p. 1242)
- PyTorch (DLC) (p. 1243)
- Random Cut Forest (algorithm) (p. 1245)
- Scikit-learn (algorithm) (p. 1245)
- Semantic Segmentation (algorithm) (p. 1246)
- Seq2Seq (algorithm) (p. 1246)
• Spark (algorithm) (p. 1246)
• SparkML Serving (algorithm) (p. 1247)
• Tensorflow (DLC) (p. 1247)
• Tensorflow Coach (DLC) (p. 1254)
• Tensorflow Inferentia (DLC) (p. 1255)
• Tensorflow Ray (DLC) (p. 1255)
• XGBoost (algorithm) (p. 1256)

BlazingText (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='me-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

<tbody>
<tr>
<td>249704162688.dkr.ecr.me-south-1.amazonaws.com/forecasting-deepar:tag</td>
<td>1</td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Factorization Machines (algorithm)**

SageMaker Python SDK example to retrieve registry path.

from sagemaker import image_uris
image_uris.retrieve(framework='factorization-machines', region='me-south-1')
### Use built-in algorithms

**Registry path** | **Version** | **Job types (image scope)**
---|---|---
249704162688.dkr.ecr.me-south-1.amazonaws.com/factorization-machines:<tag> | | inference, training

#### Hugging Face (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='huggingface',region='me-south-1',version='4.4.2',image_scope='training',base_framework_version='tensorflow2.4.1')
```

**Registry path** | **Version** | **Job types (image scope)**
---|---|---
217643126080.dkr.ecr.me-south-1.amazonaws.com/huggingface-pytorch-training:<tag> | 4.4.2 | training
217643126080.dkr.ecr.me-south-1.amazonaws.com/huggingface-tensorflow-training:<tag> | 4.4.2 | training

#### IP Insights (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='ipinsights',region='me-south-1')
```

**Registry path** | **Version** | **Job types (image scope)**
---|---|---
249704162688.dkr.ecr.me-south-1.amazonaws.com/ipinsights:<tag> | | inference, training

#### Image classification (algorithm)

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='image-classification',region='me-south-1')
```
Use built-in algorithms

### Registry path

<table>
<thead>
<tr>

<td>inference, training</td>
</tr>
</tbody>
</table>

**KNN (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='knn',region='me-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>249704162688.dkr.ecr.me-south-1.amazonaws.com/knn:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**Linear Learner (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='linear-learner',region='me-south-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>
<tr>
<td>249704162688.dkr.ecr.me-south-1.amazonaws.com/linear-learner:&lt;tag&gt;</td>
<td></td>
<td>inference, training</td>
</tr>
</tbody>
</table>

**MXNet (DLC)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='mxnet',region='me-south-1',version='1.4.1',py_version='py3',image_scope='inference',instance_type='ml.c5.4xlarge')
```

Docker Registry Paths and Example Code for South America (São Paulo) (sa-east-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1258)
- Chainer (DLC) (p. 1258)
- Clarify (algorithm) (p. 1258)
- Debugger (algorithm) (p. 1259)
- DeepAR Forecasting (algorithm) (p. 1259)
- Factorization Machines (algorithm) (p. 1259)
- Hugging Face (algorithm) (p. 1260)
- IP Insights (algorithm) (p. 1260)
- Image classification (algorithm) (p. 1260)
- Inferentia MXNet (DLC) (p. 1261)
- Inferentia PyTorch (DLC) (p. 1261)
- K-Means (algorithm) (p. 1261)
- KNN (algorithm) (p. 1261)
- Linear Learner (algorithm) (p. 1262)
- MXNet (DLC) (p. 1262)
- MXNet Coach (DLC) (p. 1265)
- Model Monitor (algorithm) (p. 1265)
- NTM (algorithm) (p. 1265)
- Neo Image Classification (algorithm) (p. 1266)
- Neo MXNet (DLC) (p. 1266)
- Neo PyTorch (DLC) (p. 1266)
- Neo Tensorflow (DLC) (p. 1267)
- Neo XGBoost (algorithm) (p. 1267)
- Object Detection (algorithm) (p. 1268)
- Object2Vec (algorithm) (p. 1268)
- PCA (algorithm) (p. 1268)
- PyTorch (DLC) (p. 1268)
- Random Cut Forest (algorithm) (p. 1271)
- Scikit-learn (algorithm) (p. 1271)
- Semantic Segmentation (algorithm) (p. 1271)
- Seq2Seq (algorithm) (p. 1272)
- Spark (algorithm) (p. 1272)
- SparkML Serving (algorithm) (p. 1272)
- Tensorflow (DLC) (p. 1273)
- Tensorflow Coach (DLC) (p. 1280)
- Tensorflow Inferentia (DLC) (p. 1281)
- Tensorflow Ray (DLC) (p. 1281)
- XGBoost (algorithm) (p. 1282)
BlazingText (algorithm)
SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='sa-east-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>

Docker Registry Paths and Example Code for AWS GovCloud (US-West) (us-gov-west-1)

The following topics list parameters for each of the algorithms and deep learning containers in this region provided by Amazon SageMaker.

Topics
- BlazingText (algorithm) (p. 1283)
- Chainer (DLC) (p. 1283)
- Debugger (algorithm) (p. 1284)
- DeepAR Forecasting (algorithm) (p. 1284)
- Factorization Machines (algorithm) (p. 1285)
- Hugging Face (algorithm) (p. 1285)
- IP Insights (algorithm) (p. 1285)
- Image classification (algorithm) (p. 1286)
Use built-in algorithms

- Inferentia MXNet (DLC) (p. 1286)
- Inferentia PyTorch (DLC) (p. 1286)
- K-Means (algorithm) (p. 1287)
- KNN (algorithm) (p. 1287)
- LDA (algorithm) (p. 1287)
- Linear Learner (algorithm) (p. 1288)
- MXNet (DLC) (p. 1288)
- MXNet Coach (DLC) (p. 1291)
- NTM (algorithm) (p. 1292)
- Neo Image Classification (algorithm) (p. 1292)
- Neo MXNet (DLC) (p. 1292)
- Neo PyTorch (DLC) (p. 1293)
- Neo Tensorflow (DLC) (p. 1293)
- Neo XGBoost (algorithm) (p. 1294)
- Object Detection (algorithm) (p. 1294)
- Object2Vec (algorithm) (p. 1294)
- PCA (algorithm) (p. 1295)
- PyTorch (DLC) (p. 1295)
- Random Cut Forest (algorithm) (p. 1298)
- Scikit-learn (algorithm) (p. 1298)
- Semantic Segmentation (algorithm) (p. 1298)
- Seq2Seq (algorithm) (p. 1299)
- Spark (algorithm) (p. 1299)
- SparkML Serving (algorithm) (p. 1299)
- Tensorflow (DLC) (p. 1300)
- Tensorflow Coach (DLC) (p. 1308)
- Tensorflow Inference (DLC) (p. 1309)
- Tensorflow Ray (DLC) (p. 1310)
- XGBoost (algorithm) (p. 1310)

**BlazingText (algorithm)**

SageMaker Python SDK example to retrieve registry path.

```python
from sagemaker import image_uris
image_uris.retrieve(framework='blazingtext', region='us-gov-west-1')
```

<table>
<thead>
<tr>
<th>Registry path</th>
<th>Version</th>
<th>Job types (image scope)</th>
</tr>
</thead>
<tbody>

### Common Data Formats for Built-in Algorithms

The following topics explain the data formats for the algorithms provided by Amazon SageMaker.

**Topics**
- Common Data Formats for Training (p. 1311)
- Common Data Formats for Inference (p. 1315)

### Common Data Formats for Training

To prepare for training, you can preprocess your data using a variety of AWS services, including AWS Glue, Amazon EMR, Amazon Redshift, Amazon Relational Database Service, and Amazon Athena. After preprocessing, publish the data to an Amazon S3 bucket. For training, the data need to go through a series of conversions and transformations, including:

- Training data serialization (handled by you)
- Training data deserialization (handled by the algorithm)
- Training model serialization (handled by the algorithm)
- Trained model deserialization (optional, handled by you)

When using Amazon SageMaker in the training portion of the algorithm, make sure to upload all data at once. If more data is added to that location, a new training call would need to be made to construct a brand new model.

**Topics**
- Content Types Supported by Built-In Algorithms (p. 1312)
- Using Pipe Mode (p. 1312)
- Using CSV Format (p. 1312)
- Using RecordIO Format (p. 1312)
• Trained Model Deserialization (p. 1315)

Content Types Supported by Built-In Algorithms

The following table lists some of the commonly supported ContentType values and the algorithms that use them:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-image</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>application/x-recordio</td>
<td>Object Detection Algorithm</td>
</tr>
<tr>
<td>application/x-recordio-protobuf</td>
<td>Factorization Machines, K-Means, k-NN, Latent Dirichlet Allocation, Linear Learner, NTM, PCA, RCF, Sequence-to-Sequence</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>BlazingText, DeepAR</td>
</tr>
<tr>
<td>image/jpeg</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>image/png</td>
<td>Object Detection Algorithm, Semantic Segmentation</td>
</tr>
<tr>
<td>text/libsvm</td>
<td>XGBoost</td>
</tr>
</tbody>
</table>

For a summary of the parameters used by each algorithm, see the documentation for the individual algorithms or this table.

Using Pipe Mode

In Pipe mode, your training job streams data directly from Amazon Simple Storage Service (Amazon S3). Streaming can provide faster start times for training jobs and better throughput. This is in contrast to File mode, in which your data from Amazon S3 is stored on the training instance volumes. File mode uses disk space to store both your final model artifacts and your full training dataset. By streaming in your data directly from Amazon S3 in Pipe mode, you reduce the size of Amazon Elastic Block Store volumes of your training instances. Pipe mode needs only enough disk space to store your final model artifacts. See the AlgorithmSpecification for additional details on the training input mode.

Using CSV Format

Many Amazon SageMaker algorithms support training with data in CSV format. To use data in CSV format for training, in the input data channel specification, specify text/csv as the ContentType. Amazon SageMaker requires that a CSV file does not have a header record and that the target variable is in the first column. To run unsupervised learning algorithms that don't have a target, specify the number of label columns in the content type. For example, in this case 'content_type=text/csv;label_size=0'. For a notebook example that uses CSV format, see Breast Cancer Prediction. For more information, see Now use Pipe mode with CSV datasets for faster training on Amazon SageMaker built-in algorithms.

Using RecordIO Format

In the protobuf recordIO format, SageMaker converts each observation in the dataset into a binary representation as a set of 4-byte floats, then loads it in the protobuf values field. If you are using Python for your data preparation, we strongly recommend that you use these existing transformations. However,
if you are using another language, the protobuf definition file below provides the schema that you use to convert your data into SageMaker protobuf format.

**Note**
For an example that shows how to convert the commonly used numpy array into the protobuf recordIO format, see *An Introduction to Factorization Machines with MNIST*.

```protobuf
syntax = "proto2";

package aialgs.data;

option java_package = "com.amazonaws.aialgorithms.proto";
option java_outer_classname = "RecordProtos";

message Float32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated float values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 20) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

message Float64Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated double values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 10) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}

message Int32Tensor {
  // Each value in the vector. If keys is empty, this is treated as a dense vector.
  repeated int32 values = 1 [packed = true];

  // If key is not empty, the vector is treated as sparse, with each key specifying the location of the value in the sparse vector.
  repeated uint64 keys = 2 [packed = true];

  // An optional shape that allows the vector to represent a matrix.
  // For example, if shape = [10, 20], floor(keys[i] / 10) gives the row, and keys[i] % 20 gives the column.
  // This also supports n-dimensional tensors.
  // Note: If the tensor is sparse, you must specify this value.
  repeated uint64 shape = 3 [packed = true];
}
```
repeated uint64 shape = 3 [packed = true];
}

// Support for storing binary data for parsing in other ways (such as JPEG/etc).
// This is an example of another type of value and may not immediately be supported.
message Bytes {
  repeated bytes value = 1;
  // If the content type of the data is known, stores it.
  // This allows for the possibility of using decoders for common formats
  // in the future.
  optional string content_type = 2;
}

message Value {
  oneof value {
    // The numbering assumes the possible use of:
    // - float16, float128
    // - int8, int16, int32
    Float32Tensor float32_tensor = 2;
    Float64Tensor float64_tensor = 3;
    Int32Tensor int32_tensor = 7;
    Bytes bytes = 9;
  }
}

message Record {
  // Map from the name of the feature to the value.
  // For vectors and libsvm-like datasets,
  // a single feature with the name 'values'
  // should be specified.
  map<string, Value> features = 1;
  // An optional set of labels for this record.
  // Similar to the features field above, the key used for
  // generic scalar / vector labels should be 'values'.
  map<string, Value> label = 2;
  // A unique identifier for this record in the dataset.
  // Whilst not necessary, this allows better
  // debugging where there are data issues.
  // This is not used by the algorithm directly.
  optional string uid = 3;
  // Textual metadata describing the record.
  // This may include JSON-serialized information
  // about the source of the record.
  // This is not used by the algorithm directly.
  optional string metadata = 4;
  // An optional serialized JSON object that allows per-record
  // hyper-parameters/configuration/other information to be set.
  // The meaning/interpretation of this field is defined by
  // the algorithm author and may not be supported.
  // This is used to pass additional inference configuration
  // when batch inference is used (e.g. types of scores to return).
  optional string configuration = 5;
}
After creating the protocol buffer, store it in an Amazon S3 location that Amazon SageMaker can access and that can be passed as part of InputDataConfig in create_training_job.

**Note**
For all Amazon SageMaker algorithms, the ChannelName in InputDataConfig must be set to train. Some algorithms also support a validation or test input channels. These are typically used to evaluate the model's performance by using a hold-out dataset. Hold-out datasets are not used in the initial training but can be used to further tune the model.

**Trained Model Deserialization**
Amazon SageMaker models are stored as model.tar.gz in the S3 bucket specified in OutputDataConfig S3OutputPath parameter of the create_training_job call. You can specify most of these model artifacts when creating a hosting model. You can also open and review them in your notebook instance. When model.tar.gz is untarred, it contains model_algo-1, which is a serialized Apache MXNet object. For example, you use the following to load the k-means model into memory and view it:

```python
import mxnet as mx
print(mx.ndarray.load('model_algo-1'))
```

**Common Data Formats for Inference**
Amazon SageMaker algorithms accept and produce several different MIME types for the HTTP payloads used in retrieving online and mini-batch predictions. You can use various AWS services to transform or preprocess records prior to running inference. At a minimum, you need to convert the data for the following:

- Inference request serialization (handled by you)
- Inference request deserialization (handled by the algorithm)
- Inference response serialization (handled by the algorithm)
- Inference response deserialization (handled by you)

**Topics**
- Convert Data for Inference Request Serialization (p. 1315)
- Convert Data for Inference Response Deserialization (p. 1316)
- Common Request Formats for All Algorithms (p. 1317)
- Use Batch Transform with Built-in Algorithms (p. 1319)

**Convert Data for Inference Request Serialization**
Content type options for Amazon SageMaker algorithm inference requests include: text/csv, application/json, and application/x-recordio-protobuf. Algorithms that don't support all of these types can support other types. XGBoost, for example, only supports text/csv from this list, but also supports text/libsvm.

For text/csv, the value for the Body argument to invoke_endpoint should be a string with commas separating the values for each feature. For example, a record for a model with four features might look like 1.5,16.0,14,23.0. Any transformations performed on the training data should also be performed on the data before obtaining inference. The order of the features matters and must remain unchanged.

application/json is significantly more flexible and provides multiple possible formats for developers to use in their applications. At a high level, in JavaScript, the payload might look like the following:

```javascript
let request = {
  // Instances might contain multiple rows that predictions are sought for.
  "instances": [
    
```
// Request and algorithm specific inference parameters.
"configuration": {},
// Data in the specific format required by the algorithm.
"data": {
    "<field name>": dataElement
}
}
]

You have the following options for specifying the dataElement:

**Protocol buffers equivalent**

// Has the same format as the protocol buffers implementation described for training.
let dataElement = {
    "keys": [],
    "values": [],
    "shape": []
}

**Simple numeric vector**

// An array containing numeric values is treated as an instance containing a
// single dense vector.
let dataElement = [1.5, 16.0, 14.0, 23.0]

// It will be converted to the following representation by the SDK.
let converted = {
    "features": {
        "values": dataElement
    }
}

**For multiple records**

let request = {
    "instances": [
        // First instance.
        {
            "features": [ 1.5, 16.0, 14.0, 23.0 ]
        },
        // Second instance.
        {
            "features": [ -2.0, 100.2, 15.2, 9.2 ]
        }
    ]
}

**Convert Data for Inference Response Deserialization**

Amazon SageMaker algorithms return JSON in several layouts. At a high level, the structure is:

let response = {
    "predictions": [{
        // Fields in the response object are defined on a per algorithm-basis.
    }]
}

The fields that are included in predictions differ across algorithms. The following are examples of output for the k-means algorithm.
Single-record inference

```javascript
let response = {
  "predictions": [{
    "closest_cluster": 5,
    "distance_to_cluster": 36.5
  }]
}
```

Multi-record inference

```javascript
let response = {
  "predictions": [
    // First instance prediction.
    {
      "closest_cluster": 5,
      "distance_to_cluster": 36.5
    },
    // Second instance prediction.
    {
      "closest_cluster": 2,
      "distance_to_cluster": 90.3
    }
  ]
}
```

Multi-record inference with protobuf input

```javascript
{
  "features": [],
  "label": {
    "closest_cluster": {
      "values": [ 5.0 ] // e.g. the closest centroid/cluster was 1.0
    },
    "distance_to_cluster": {
      "values": [ 36.5 ]
    }
  },
  "uid": "abc123",
  "metadata": ": { "created_at": '2017-06-03' }"
}
```

SageMaker algorithms also support the JSONLINES format, where the per-record response content is same as that in JSON format. The multi-record structure is a concatenation of per-record response objects separated by newline characters. The response content for the built-in KMeans algorithm for 2 input data points is:

```
{"distance_to_cluster": 23.40593910217285, "closest_cluster": 0.0}
{"distance_to_cluster": 27.250282287597656, "closest_cluster": 0.0}
```

While running batch transform, we recommended using the jsonlines response type by setting the Accept field in the CreateTransformJobRequest to application/jsonlines.

Common Request Formats for All Algorithms

Most algorithms use several of the following inference request formats.

**JSON Request Format**

**Content type:** application/JSON
Dense format

```javascript
let request = {
    "instances": [
        {
            "features": [1.5, 16.0, 14.0, 23.0]
        }
    ]
}

let request = {
    "instances": [
        {
            "data": {
                "features": {
                    "values": [ 1.5, 16.0, 14.0, 23.0]
                }
            }
        }
    ]
}
```

Sparse format

```javascript
{
    "instances": [
        {"data": {"features": {
            "keys": [26, 182, 232, 243, 431],
            "shape": [2000],
            "values": [1, 1, 1, 4, 1]
        }}
    ],
    {"data": {"features": {
            "keys": [0, 182, 232, 243, 431],
            "shape": [2000],
            "values": [13, 1, 1, 4, 1]
        }}
    }
    ]
}
```

**JSONLINES Request Format**

**Content type:** application/JSONLINES

**Dense format**

A single record in dense format can be represented as either:

```javascript
{ "features": [1.5, 16.0, 14.0, 23.0] }
```

or:

```javascript
{ "data": { "features": { "values": [ 1.5, 16.0, 14.0, 23.0] } }
```

**Sparse Format**

A single record in sparse format is represented as:
Multiple records are represented as a concatenation of the above single-record representations, separated by newline characters:

```
{
  "data": {
    "features": {
      "keys": [0, 1, 3],
      "shape": [4],
      "values": [1, 4, 1]
    }
  }
}
{
  "data": {
    "features": {
      "values": [1.5, 16.0, 14.0, 23.0]
    }
  }
}
```

**CSV Request Format**

*Content type:* text/CSV; label_size=0

*Note*

CSV support is not available for factorization machines.

**RECORDIO Request Format**

*Content type:* application/x-recordio-protobuf

**Use Batch Transform with Built-in Algorithms**

While running batch transform, we recommended using the JSONLINES response type instead of JSON, if supported by the algorithm. This is accomplished by setting the `Accept` field in the `CreateTransformJobRequest` to `application/jsonlines`.

When you create a transform job, the `SplitType` must be set according to the `ContentType` of the input data. Similarly, depending on the `Accept` field in the `CreateTransformJobRequest`, `AssembleWith` must be set accordingly. Please use the following table to help appropriately set these fields:

<table>
<thead>
<tr>
<th>ContentType</th>
<th>Recommended SplitType</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>RecordIO</td>
</tr>
<tr>
<td>text/csv</td>
<td>Line</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/x-image</td>
<td>None</td>
</tr>
<tr>
<td>image/*</td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Accept</th>
<th>Recommended AssembleWith</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/x-recordio-protobuf</td>
<td>None</td>
</tr>
<tr>
<td>application/json</td>
<td>None</td>
</tr>
<tr>
<td>application/jsonlines</td>
<td>Line</td>
</tr>
</tbody>
</table>

For more information on response formats for specific algorithms, see the following:

- DeepAR Inference Formats (p. 1343)
- Factorization Machines Response Formats (p. 1354)
Use built-in algorithms

- IP Insights Inference Data Formats (p. 1375)
- K-Means Response Formats (p. 1384)
- k-NN Request and Response Formats (p. 1391)
- Linear learner response formats (p. 1413)
- NTM Response Formats (p. 1419)
- Data Formats for Object2Vec Inference (p. 1434)
- Encoder Embeddings for Object2Vec (p. 1435)
- PCA Response Formats (p. 1450)
- RCF Response Formats (p. 1457)

Instance Types for Built-in Algorithms

For training and hosting Amazon SageMaker algorithms, we recommend using the following Amazon EC2 instance types:

- ml.m5.xlarge, ml.m5.4xlarge, and ml.m5.10xlarge
- ml.c5.xlarge, ml.c5.2xlarge, and ml.c5.8xlarge
- ml.p3.xlarge, ml.p3.8xlarge, and ml.p3.16xlarge

Most Amazon SageMaker algorithms have been engineered to take advantage of GPU computing for training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. Exceptions are noted in this guide.

The size and type of data can have a great effect on which hardware configuration is most effective. When the same model is trained on a recurring basis, initial testing across a spectrum of instance types can discover configurations that are more cost-effective in the long run. Additionally, algorithms that train most efficiently on GPUs might not require GPUs for efficient inference. Experiment to determine the most cost effectiveness solution.

For more information on SageMaker hardware specifications, see Amazon SageMaker ML Instance Types.

Logs for Built-in Algorithms

Amazon SageMaker algorithms produce Amazon CloudWatch logs, which provide detailed information on the training process. To see the logs, in the AWS management console, choose CloudWatch, choose Logs, and then choose the /aws/sagemaker/TrainingJobs log group. Each training job has one log stream per node on which it was trained. The log stream's name begins with the value specified in the TrainingJobName parameter when the job was created.

Note
If a job fails and logs do not appear in CloudWatch, it's likely that an error occurred before the start of training. Reasons include specifying the wrong training image or S3 location.

The contents of logs vary by algorithms. However, you can typically find the following information:

- Confirmation of arguments provided at the beginning of the log
- Errors that occurred during training
- Measurement of an algorithm's accuracy or numerical performance
- Timings for the algorithm and any major stages within the algorithm

Common Errors

If a training job fails, some details about the failure are provided by the FailureReason return value in the training job description, as follows:
sage = boto3.client('sagemaker')
sage.describe_training_job(TrainingJobName=job_name)['FailureReason']

Others are reported only in the CloudWatch logs. Common errors include the following:

1. Misspecifying a hyperparameter or specifying a hyperparameter that is invalid for the algorithm.

   **From the CloudWatch Log**

   ```
   [10/16/2017 23:45:17 ERROR 139623806805824 train.py:48]  
   Additional properties are not allowed (u'mini_batch_siz' was unexpected)  
   ```

2. Specifying an invalid value for a hyperparameter.

   **FailureReason**

   ```
   AlgorithmError: u'abc' is not valid under any of the given schemas
   Failed validating u'oneOf' in  
   schema['properties'][u'feature_dim']:
   {u'oneOf':
   [{u'pattern': u'^([1-9][0-9]*$)', u'type': u'true'},
   {u'minimum': 1, u'type': u'integer'}}
   ```

3. Inaccurate protobuf file format.

   **From the CloudWatch log**

   ```
   [10/17/2017 18:01:04 ERROR 140234860816192 train.py:48] cannot copy sequence with size 785 to array axis with dimension 784
   ```

**BlazingText algorithm**

The Amazon SageMaker BlazingText algorithm provides highly optimized implementations of the Word2vec and text classification algorithms. The Word2vec algorithm is useful for many downstream natural language processing (NLP) tasks, such as sentiment analysis, named entity recognition, machine translation, etc. Text classification is an important task for applications that perform web searches, information retrieval, ranking, and document classification.

The Word2vec algorithm maps words to high-quality distributed vectors. The resulting vector representation of a word is called a *word embedding*. Words that are semantically similar correspond to vectors that are close together. That way, word embeddings capture the semantic relationships between words.

Many natural language processing (NLP) applications learn word embeddings by training on large collections of documents. These pretrained vector representations provide information about semantics and word distributions that typically improves the generalizability of other models that are later trained on a more limited amount of data. Most implementations of the Word2vec algorithm are not optimized for multi-core CPU architectures. This makes it difficult to scale to large datasets.

With the BlazingText algorithm, you can scale to large datasets easily. Similar to Word2vec, it provides the Skip-gram and continuous bag-of-words (CBOW) training architectures. BlazingText's
implementation of the supervised multi-class, multi-label text classification algorithm extends the fastText text classifier to use GPU acceleration with custom CUDA kernels. You can train a model on more than a billion words in a couple of minutes using a multi-core CPU or a GPU. And, you achieve performance on par with the state-of-the-art deep learning text classification algorithms.

The BlazingText algorithm is not parallelizable. For more information on parameters related to training, see Docker Registry Paths for SageMaker Built-in Algorithms.

The SageMaker BlazingText algorithms provides the following features:

- Accelerated training of the fastText text classifier on multi-core CPUs or a GPU and Word2Vec on GPUs using highly optimized CUDA kernels. For more information, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.
- Enriched Word Vectors with Subword Information by learning vector representations for character n-grams. This approach enables BlazingText to generate meaningful vectors for out-of-vocabulary (OOV) words by representing their vectors as the sum of the character n-gram (subword) vectors.
- A `batch_skipgram` mode for the Word2Vec algorithm that allows faster training and distributed computation across multiple CPU nodes. The `batch_skipgram` mode does mini-batching using the Negative Sample Sharing strategy to convert level-1 BLAS operations into level-3 BLAS operations. This efficiently leverages the multiply-add instructions of modern architectures. For more information, see Parallelizing Word2Vec in Shared and Distributed Memory.

To summarize, the following modes are supported by BlazingText on different types instances:

<table>
<thead>
<tr>
<th>Modes</th>
<th>Word2Vec (Unsupervised Learning)</th>
<th>Text Classification (Supervised Learning)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single CPU instance</td>
<td>cbow, Skip-gram, Batch Skip-gram</td>
<td>supervised</td>
</tr>
<tr>
<td>Single GPU instance (with 1 or more GPUs)</td>
<td>cbow, Skip-gram</td>
<td>supervised with one GPU</td>
</tr>
<tr>
<td>Multiple CPU instances</td>
<td>Batch Skip-gram</td>
<td>None</td>
</tr>
</tbody>
</table>

For more information about the mathematics behind BlazingText, see BlazingText: Scaling and Accelerating Word2Vec using Multiple GPUs.

**Topics**

- Input/Output Interface for the BlazingText Algorithm (p. 1322)
- EC2 Instance Recommendation for the BlazingText Algorithm (p. 1325)
- BlazingText Sample Notebooks (p. 1325)
- BlazingText Hyperparameters (p. 1326)
- Tune a BlazingText Model (p. 1329)

**Input/Output Interface for the BlazingText Algorithm**

The BlazingText algorithm expects a single preprocessed text file with space-separated tokens. Each line in the file should contain a single sentence. If you need to train on multiple text files, concatenate them into one file and upload the file in the respective channel.
Training and Validation Data Format

Training and Validation Data Format for the Word2Vec Algorithm

For Word2Vec training, upload the file under the train channel. No other channels are supported. The file should contain a training sentence per line.

Training and Validation Data Format for the Text Classification Algorithm

For supervised mode, you can train with file mode or with the augmented manifest text format.

Train with File Mode

For supervised mode, the training/validation file should contain a training sentence per line along with the labels. Labels are words that are prefixed by the string __label__. Here is an example of a training/validation file:

```
__label__4  linux ready for prime time, intel says, despite all the linux hype, the open-source movement has yet to make a huge splash in the desktop market. that may be about to change, thanks to shipmaking giant intel corp.

__label__2  bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly as the indian skippers return to international cricket was short lived.
```

Note
The order of labels within the sentence doesn't matter.

Upload the training file under the train channel, and optionally upload the validation file under the validation channel.

Train with Augmented Manifest Text Format

The supervised mode also supports the augmented manifest format, which enables you to do training in pipe mode without needing to create RecordIO files. While using the format, an S3 manifest file needs to be generated that contains the list of sentences and their corresponding labels. The manifest file format should be in JSON Lines format in which each line represents one sample. The sentences are specified using the source tag and the label can be specified using the label tag. Both source and label tags should be provided under the AttributeNames parameter value as specified in the request.

```
{"source":"linux ready for prime time, intel says, despite all the linux hype","label":1}
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly","label":2}
```

Multi-label training is also supported by specifying a JSON array of labels.

```
{"source":"linux ready for prime time, intel says, despite all the linux hype","label":[1, 3]}
{"source":"bowled by the slower one again, kolkata, november 14 the past caught up with sourav ganguly","label":[2, 4, 5]}
```

For more information on augmented manifest files, see Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1828).

Model Artifacts and Inference

Model Artifacts for the Word2Vec Algorithm

For Word2Vec training, the model artifacts consist of vectors.txt, which contains words-to-vectors mapping, and vectors.bin, a binary used by BlazingText for hosting, inference, or both. vectors.txt stores
the vectors in a format that is compatible with other tools like Gensim and Spacy. For example, a Gensim user can run the following commands to load the vectors.txt file:

```python
from gensim.models import KeyedVectors
word_vectors = KeyedVectors.load_word2vec_format('vectors.txt', binary=False)
word_vectors.most_similar(positive=['woman', 'king'], negative=['man'])
word_vectors.doesnt_match("breakfast cereal dinner lunch".split())
```

If the evaluation parameter is set to `True`, an additional file, `eval.json`, is created. This file contains the similarity evaluation results (using Spearman's rank correlation coefficients) on WS-353 dataset. The number of words from the WS-353 dataset that aren't there in the training corpus are reported.

For inference requests, the model accepts a JSON file containing a list of strings and returns a list of vectors. If the word is not found in vocabulary, inference returns a vector of zeros. If subwords is set to `True` during training, the model is able to generate vectors for out-of-vocabulary (OOV) words.

**Sample JSON Request**

Mime-type: `application/json`

```json
{
  "instances": ["word1", "word2", "word3"]
}
```

**Model Artifacts for the Text Classification Algorithm**

Training with supervised outputs creates a `model.bin` file that can be consumed by BlazingText hosting. For inference, the BlazingText model accepts a JSON file containing a list of sentences and returns a list of corresponding predicted labels and probability scores. Each sentence is expected to be a string with space-separated tokens, words, or both.

**Sample JSON Request**

Mime-type: `application/json`

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."]
}
```

By default, the server returns only one prediction, the one with the highest probability. For retrieving the top k predictions, you can set k in the configuration, as follows:

```json
{
  "instances": ["the movie was excellent", "i did not like the plot ."],
  "configuration": {"k": 2}
}
```

For BlazingText, the `content-type` and `accept` parameters must be equal. For batch transform, they both need to be `application/jsonlines`. If they differ, the `Accept` field is ignored. The format for input follows:

```
content-type: application/jsonlines

{"source": "source_0"}
{"source": "source_1"}
```

if you need to pass the value of k for top-k, then you can do it in the following way:
For both supervised (text classification) and unsupervised (Word2Vec) modes, the binaries (*.bin) produced by BlazingText can be cross-consumed by fastText and vice versa. You can use binaries produced by BlazingText by fastText. Likewise, you can host the model binaries created with fastText using BlazingText.

Here is an example of how to use a model generated with BlazingText with fastText:

```bash
#Download the model artifact from S3
aws s3 cp s3://<YOUR_S3_BUCKET>/<PREFIX>/model.tar.gz model.tar.gz

#Unzip the model archive
tar -xzf model.tar.gz

#Use the model archive with fastText
fasttext predict ./model.bin test.txt
```

However, the binaries are only supported when training on CPU and single GPU; training on multi-GPU will not produce binaries.

For more details on dataset formats and model hosting, see the example notebooks Text Classification with the BlazingText Algorithm, FastText Models, and Generating Subword Embeddings with the Word2Vec Algorithm.

**EC2 Instance Recommendation for the BlazingText Algorithm**

For cbow and skipgram modes, BlazingText supports single CPU and single GPU instances. Both of these modes support learning of subwords embeddings. To achieve the highest speed without compromising accuracy, we recommend that you use an ml.p3.2xlarge instance.

For batch_skipgram mode, BlazingText supports single or multiple CPU instances. When training on multiple instances, set the value of the S3DataDistributionType field of the S3DataSource object that you pass to CreateTrainingJob to FullyReplicated. BlazingText takes care of distributing data across machines.

For the supervised text classification mode, a C5 instance is recommended if the training dataset is less than 2 GB. For larger datasets, use an instance with a single GPU (ml.p2.xlarge or ml.p3.2xlarge).

**BlazingText Sample Notebooks**

For a sample notebook that uses the SageMaker BlazingText algorithm to train and deploy supervised binary and multiclass classification models, see Blazing Text classification on the DBPedia dataset. For instructions for creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After creating and opening a
notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the Blazing Text are located in the **Introduction to Amazon algorithms** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

### BlazingText Hyperparameters

When you start a training job with a `CreateTrainingJob` request, you specify a training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The hyperparameters for the BlazingText algorithm depend on which mode you use: Word2Vec (unsupervised) and Text Classification (supervised).

#### Word2Vec Hyperparameters

The following table lists the hyperparameters for the BlazingText Word2Vec training algorithm provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mode</strong></td>
<td>The Word2vec architecture used for training. <a href="#">Required</a></td>
</tr>
<tr>
<td></td>
<td><strong>Valid values</strong>: batch_skipgram, skipgram, or cbow</td>
</tr>
<tr>
<td><strong>batch_size</strong></td>
<td>The size of each batch when <code>mode</code> is set to <code>batch_skipgram</code>. Set to a number between 10 and 20. <a href="#">Optional</a></td>
</tr>
<tr>
<td></td>
<td><strong>Valid values</strong>: Positive integer</td>
</tr>
<tr>
<td></td>
<td><strong>Default value</strong>: 11</td>

</table>

**Tune a BlazingText Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric.
from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the BlazingText Algorithm**

The BlazingText Word2Vec algorithm (skipgram, cbow, and batch_skipgram modes) reports on a single metric during training: `train:mean_rho`. This metric is computed on WS-353 word similarity datasets. When tuning the hyperparameter values for the Word2Vec algorithm, use this metric as the objective.

The BlazingText Text Classification algorithm (supervised mode), also reports on a single metric during training: the `validation:accuracy`. When tuning the hyperparameter values for the text classification algorithm, use these metrics as the objective.

<table>

DeepAR Forecasting Algorithm

The Amazon SageMaker DeepAR forecasting algorithm is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). Classical forecasting methods, such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS), fit a single model to each individual time series. They then use that model to extrapolate the time series into the future.

In many applications, however, you have many similar time series across a set of cross-sectional units. For example, you might have time series groupings for demand for different products, server loads, and requests for webpages. For this type of application, you can benefit from training a single model jointly over all of the time series. DeepAR takes this approach. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the ones it has been trained on.

The training input for the DeepAR algorithm is one or, preferably, more target time series that have been generated by the same process or similar processes. Based on this input dataset, the algorithm trains a model that learns an approximation of this process/processes and uses it to predict how the target time series evolves. Each target time series can be optionally associated with a vector of static (time-independent) categorical features provided by the cat field and a vector of dynamic (time-dependent) time series provided by the dynamic_feat field. SageMaker trains the DeepAR model by randomly sampling training examples from each target time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. To control how far in the past the network can see, use the context_length hyperparameter. To control how far in the future predictions can be made, use the prediction_length hyperparameter. For more information, see How the DeepAR Algorithm Works (p. 1335).

Topics
- Input/Output Interface for the DeepAR Algorithm (p. 1332)
- Best Practices for Using the DeepAR Algorithm (p. 1334)
- EC2 Instance Recommendations for the DeepAR Algorithm (p. 1335)
- DeepAR Sample Notebooks (p. 1335)
- How the DeepAR Algorithm Works (p. 1335)
Input/Output Interface for the DeepAR Algorithm

DeepAR supports two data channels. The required train channel describes the training dataset. The optional test channel describes a dataset that the algorithm uses to evaluate model accuracy after training. You can provide training and test datasets in JSON Lines format. Files can be in gzip or Parquet file format.

When specifying the paths for the training and test data, you can specify a single file or a directory that contains multiple files, which can be stored in subdirectories. If you specify a directory, DeepAR uses all files in the directory as inputs for the corresponding channel, except those that start with a period (.) and those named _SUCCESS. This ensures that you can directly use output folders produced by Spark jobs as input channels for your DeepAR training jobs.

By default, the DeepAR model determines the input format from the file extension (.json, .json.gz, or .parquet) in the specified input path. If the path does not end in one of these extensions, you must explicitly specify the format in the SDK for Python. Use the content_type parameter of the s3_input class.

The records in your input files should contain the following fields:

- **start**—A string with the format YYYY-MM-DD HH:MM:SS. The start timestamp can't contain time zone information.
- **target**—An array of floating-point values or integers that represent the time series. You can encode missing values as null literals, or as "NaN" strings in JSON, or as nan floating-point values in Parquet.
- **dynamic_feat** (optional)—An array of arrays of floating-point values or integers that represents the vector of custom feature time series (dynamic features). If you set this field, all records must have the same number of inner arrays (the same number of feature time series). In addition, each inner array must be the same length as the associated target value plus length of the context. Missing values are not supported in the features. For example, if target time series represents the demand of different products, an associated dynamic_feat might be a boolean time-series which indicates whether a promotion was applied (1) to the particular product or not (0):

  ```json
  {"start": ..., "target": [1, 5, 10, 2], "dynamic_feat": [[0, 1, 1, 0]]}
  ```

- **cat** (optional)—An array of categorical features that can be used to encode the groups that the record belongs to. Categorical features must be encoded as a 0-based sequence of positive integers. For example, the categorical domain {R, G, B} can be encoded as {0, 1, 2}. All values from each categorical domain must be represented in the training dataset. That's because the DeepAR algorithm can forecast only for categories that have been observed during training. And, each categorical feature is embedded in a low-dimensional space whose dimensionality is controlled by the embedding_dimension hyperparameter. For more information, see DeepAR Hyperparameters (p. 1337).

If you use a JSON file, it must be in JSON Lines format. For example:

```json
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1], "dynamic_feat": [[1.1, 1.2, 0.5, ...]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat": [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat": [[1.3, 0.4]]}
```
In this example, each time series has two associated categorical features and one time series features.

For Parquet, you use the same three fields as columns. In addition, "start" can be the datetime type. You can compress Parquet files using gzip (gzip) or the Snappy compression library (snappy).

If the algorithm is trained without cat and dynamic_feat fields, it learns a "global" model, that is a model that is agnostic to the specific identity of the target time series at inference time and is conditioned only on its shape.

If the model is conditioned on the cat and dynamic_feat feature data provided for each time series, the prediction will probably be influenced by the character of time series with the corresponding cat features. For example, if the target time series represents the demand of clothing items, you can associate a two-dimensional cat vector that encodes the type of item (e.g. 0 = shoes, 1 = dress) in the first component and the color of an item (e.g. 0 = red, 1 = blue) in the second component. A sample input would look as follows:

```
{ "start": ..., "target": ..., "cat": [0, 0], ... } # red shoes
{ "start": ..., "target": ..., "cat": [1, 1], ... } # blue dress
```

At inference time, you can request predictions for targets with cat values that are combinations of the cat values observed in the training data, for example:

```
{ "start": ..., "target": ..., "cat": [0, 1], ... } # blue shoes
{ "start": ..., "target": ..., "cat": [1, 0], ... } # red dress
```

The following guidelines apply to training data:

- The start time and length of the time series can differ. For example, in marketing, products often enter a retail catalog at different dates, so their start dates naturally differ. But all series must have the same frequency, number of categorical features, and number of dynamic features.
- Shuffle the training file with respect to the position of the time series in the file. In other words, the time series should occur in random order in the file.
- Make sure to set the start field correctly. The algorithm uses the start timestamp to derive the internal features.
- If you use categorical features (cat), all time series must have the same number of categorical features. If the dataset contains the cat field, the algorithm uses it and extracts the cardinality of the groups from the dataset. By default, cardinality is "auto". If the dataset contains the cat field, but you don't want to use it, you can disable it by setting cardinality to "". If a model was trained using a cat feature, you must include it for inference.
- If your dataset contains the dynamic_feat field, the algorithm uses it automatically. All time series have to have the same number of feature time series. The time points in each of the feature time series correspond one-to-one to the time points in the target. In addition, the entry in the dynamic_feat field should have the same length as the target. If the dataset contains the dynamic_feat field, but you don't want to use it, disable it by setting(num_dynamic_feat to ""). If the model was trained with the dynamic_feat field, you must provide this field for inference. In addition, each of the features has to have the length of the provided target plus the prediction_length. In other words, you must provide the feature value in the future.

If you specify optional test channel data, the DeepAR algorithm evaluates the trained model with different accuracy metrics. The algorithm calculates the root mean square error (RMSE) over the test data as follows:

\[ \text{RMSE} = \sqrt{\frac{1}{nT} \sum_{i,t} (\hat{y}_{it} - y_{it})^2} \]
Use built-in algorithms

\( y_{i,t} \) is the true value of time series \( i \) at the time \( t \). \( \hat{y}_{i,t} \) is the mean prediction. The sum is over all \( n \) time series in the test set and over the last \( T \) time points for each time series, where \( T \) corresponds to the forecast horizon. You specify the length of the forecast horizon by setting the `prediction_length` hyperparameter. For more information, see DeepAR Hyperparameters (p. 1337).

In addition, the algorithm evaluates the accuracy of the forecast distribution using weighted quantile loss. For a quantile in the range \([0, 1]\), the weighted quantile loss is defined as follows:

\[
q_{i,t}^{(\tau)} = \begin{cases} 
\frac{1 - \tau}{\tau} |y_{i,t} - \hat{y}_{i,t}| & \text{if } \hat{y}_{i,t} > y_{i,t} \\
\tau |y_{i,t} - \hat{y}_{i,t}| & \text{otherwise}
\end{cases}
\]

\( q_{i,t}^{(\tau)} \) is the \( \tau \)-quantile of the distribution that the model predicts. To specify which quantiles to calculate loss for, set the `test_quantiles` hyperparameter. In addition to these, the average of the prescribed quantile losses is reported as part of the training logs. For information, see DeepAR Hyperparameters (p. 1337).

For inference, DeepAR accepts JSON format and the following fields:

- "instances", which includes one or more time series in JSON Lines format
- A name of "configuration", which includes parameters for generating the forecast

For more information, see DeepAR Inference Formats (p. 1343).

**Best Practices for Using the DeepAR Algorithm**

When preparing your time series data, follow these best practices to achieve the best results:

- Except for when splitting your dataset for training and testing, always provide the entire time series for training, testing, and when calling the model for inference. Regardless of how you set `context_length`, don't break up the time series or provide only a part of it. The model uses data points further back than the value set in `context_length` for the lagged values feature.

- When tuning a DeepAR model, you can split the dataset to create a training dataset and a test dataset. In a typical evaluation, you would test the model on the same time series used for training, but on the future `prediction_length` time points that follow immediately after the last time point visible during training. You can create training and test datasets that satisfy this criteria by using the entire dataset (the full length of all time series that are available) as a test set and removing the last `prediction_length` points from each time series for training. During training, the model doesn't see the target values for time points on which it is evaluated during testing. During testing, the algorithm withholds the last `prediction_length` points of each time series in the test set and generates a prediction. Then it compares the forecast with the withheld values. You can create more complex evaluations by repeating time series multiple times in the test set, but cutting them at different endpoints. With this approach, accuracy metrics are averaged over multiple forecasts from different time points. For more information, see Tune a DeepAR Model (p. 1342).

- Avoid using very large values (>400) for the `prediction_length` because it makes the model slow and less accurate. If you want to forecast further into the future, consider aggregating your data at a lower frequency. For example, use 5min instead of 1min.

- Because lags are used, a model can look further back in the time series than the value specified for `context_length`. Therefore, you don't need to set this parameter to a large value. We recommend starting with the value that you used for `prediction_length`.

- We recommend training a DeepAR model on as many time series as are available. Although a DeepAR model trained on a single time series might work well, standard forecasting algorithms, such as ARIMA or ETS, might provide more accurate results. The DeepAR algorithm starts to outperform the standard methods when your dataset contains hundreds of related time series. Currently, DeepAR requires that the total number of observations available across all training time series is at least 300.
EC2 Instance Recommendations for the DeepAR Algorithm

You can train DeepAR on both GPU and CPU instances and in both single and multi-machine settings. We recommend starting with a single CPU instance (for example, ml.c4.2xlarge or ml.c4.4xlarge), and switching to GPU instances and multiple machines only when necessary. Using GPUs and multiple machines improves throughput only for larger models (with many cells per layer and many layers) and for large mini-batch sizes (for example, greater than 512).

For inference, DeepAR supports only CPU instances.

Specifying large values for context_length, prediction_length, num_cells, num_layers, or mini_batch_size can create models that are too large for small instances. In this case, use a larger instance type or reduce the values for these parameters. This problem also frequently occurs when running hyperparameter tuning jobs. In that case, use an instance type large enough for the model tuning job and consider limiting the upper values of the critical parameters to avoid job failures.

DeepAR Sample Notebooks

For a sample notebook that shows how to prepare a time series dataset for training the SageMaker DeepAR algorithm and how to deploy the trained model for performing inferences, see Time series forecasting with DeepAR - Synthetic data as well as DeepAR demo on electricity dataset, which illustrates the advanced features of DeepAR on a real world dataset. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all of the SageMaker examples. To open a notebook, choose its Use tab, and choose Create copy.

How the DeepAR Algorithm Works

During training, DeepAR accepts a training dataset and an optional test dataset. It uses the test dataset to evaluate the trained model. In general, the datasets don't have to contain the same set of time series. You can use a model trained on a given training set to generate forecasts for the future of the time series in the training set, and for other time series. Both the training and the test datasets consist of one or, preferably, more target time series. Each target time series can optionally be associated with a vector of feature time series and a vector of categorical features. For more information, see Input/Output Interface for the DeepAR Algorithm (p. 1332).

For example, the following is an element of a training set indexed by $i$ which consists of a target time series, $Z_{i,t}$, and two associated feature time series, $X_{i,1,t}$ and $X_{i,2,t}$:

The target time series might contain missing values, which are represented by line breaks in the time series. DeepAR supports only feature time series that are known in the future. This allows you to run “what if?” scenarios. What happens, for example, if I change the price of a product in some way?
Each target time series can also be associated with a number of categorical features. You can use these features to encode which groupings a time series belongs to. Categorical features allow the model to learn typical behavior for groups, which it can use to increase model accuracy. DeepAR implements this by learning an embedding vector for each group that captures the common properties of all time series in the group.

**How Feature Time Series Work in the DeepAR Algorithm**

To facilitate learning time-dependent patterns, such as spikes during weekends, DeepAR automatically creates feature time series based on the frequency of the target time series. For example, DeepAR creates two feature time series (day of the month and day of the year) for a weekly time series frequency. It uses these derived feature time series with the custom feature time series that you provide during training and inference. The following figure shows two of these derived time series features: $u_{i,1,t}$ represents the hour of the day and $u_{i,2,t}$ the day of the week.

The DeepAR algorithm automatically generates these feature time series. The following table lists the derived features for the supported basic time frequencies.

<table>
<thead>
<tr>
<th>Frequency of the Time Series</th>
<th>Derived Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minute</td>
<td>minute-of-hour, hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Hour</td>
<td>hour-of-day, day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Day</td>
<td>day-of-week, day-of-month, day-of-year</td>
</tr>
<tr>
<td>Week</td>
<td>day-of-month, week-of-year</td>
</tr>
<tr>
<td>Month</td>
<td>month-of-year</td>
</tr>
</tbody>
</table>

DeepAR trains a model by randomly sampling several training examples from each of the time series in the training dataset. Each training example consists of a pair of adjacent context and prediction windows with fixed predefined lengths. The context_length hyperparameter controls how far in the past the network can see, and the prediction_length hyperparameter controls how far in the future predictions can be made. During training, the algorithm ignores training set elements containing time series that are shorter than a specified prediction length. The following figure represents five samples with context lengths of 12 hours and prediction lengths of 6 hours drawn from element $i$. For brevity, we've omitted the feature time series $x_{i,1,t}$ and $u_{i,2,t}$. 

1336
To capture seasonality patterns, DeepAR also automatically feeds lagged values from the target time series. In the example with hourly frequency, for each time index, \( t = T \), the model exposes the \( z_{i,t} \) values, which occurred approximately one, two, and three days in the past.

For inference, the trained model takes as input target time series, which might or might not have been used during training, and forecasts a probability distribution for the next \( \text{prediction\_length} \) values. Because DeepAR is trained on the entire dataset, the forecast takes into account patterns learned from similar time series.

For information on the mathematics behind DeepAR, see DeepAR: Probabilistic Forecasting with Autoregressive Recurrent Networks.

### DeepAR Hyperparameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context_length</td>
<td>The number of time-points that the model gets to see before making the prediction. The value for this parameter should be about the same as the ( \text{prediction_length} ). The model also receives lagged inputs from the target, so context_length can be much smaller than typical seasonalities. For example, a daily time series can have yearly seasonality. The model automatically includes a lag of one year, so the context length can be shorter than a year. The lag values that the model picks depend on the frequency of the</td>

### Tune a DeepAR Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker (p. 1715)](https://docs.aws.amazon.com/sagemaker/latest/dg/automatic-model-tuning.html).

### Metrics Computed by the DeepAR Algorithm

The DeepAR algorithm reports three metrics, which are computed during training. When tuning a model, choose one of these as the objective. For the objective, use either the forecast accuracy on a provided test channel (recommended) or the training loss. For recommendations for the training/test split for the DeepAR algorithm, see [Best Practices for Using the DeepAR Algorithm (p. 1334)](https://docs.aws.amazon.com/sagemaker/latest/dg/deepar-best-practices.html).

### DeepAR Inference Formats

#### DeepAR JSON Request Formats

Query a trained model by using the model's endpoint. The endpoint takes the following JSON request format.

In the request, the `instances` field corresponds to the time series that should be forecast by the model.

If the model was trained with categories, you must provide a `cat` for each instance. If the model was trained without the `cat` field, it should be omitted.

If the model was trained with a custom feature time series (`dynamic_feat`), you have to provide the same number of `dynamic_feat` values for each instance. Each of them should have a length given by `length(target) + prediction_length`, where the last `prediction_length` values correspond to the time points in the future that will be predicted. If the model was trained without custom feature time series, the field should not be included in the request.

```json
{
    "instances": [
        {
            "start": "2009-11-01 00:00:00",
            "target": [4.0, 10.0, "NaN", 100.0, 113.0],
            "cat": [0, 1],
            "dynamic_feat": [[1.0, 1.1, 2.1, 0.5, 3.1, 4.1, 1.2, 5.0, ...]]
        },
        {
            "start": "2012-01-30",
            "target": [1.0],
            "cat": [2, 1],
            "dynamic_feat": [[2.0, 3.1, 4.5, 1.5, 1.8, 3.2, 0.1, 3.0, ...]]
        },
        {
            "start": "1999-01-30",
            "target": [10.0],
            "cat": [0],
            "dynamic_feat": [[10.0, 11.0, 10.0, 9.0, ...]]
        }
    ]
}
```
"target": [2.0, 1.0],
"cat": [1, 3],
"dynamic_feat": [[1.0, 0.1, -2.5, 0.3, 2.0, -1.2, -0.1, -3.0, ...]]
}
},
"configuration": {
  "num_samples": 50,
  "output_types": ["mean", "quantiles", "samples"],
  "quantiles": ["0.5", "0.9"]
}
}

The configuration field is optional. configuration.num_samples sets the number of sample paths that the model generates to estimate the mean and quantiles. configuration.output_types describes the information that will be returned in the request. Valid values are "mean" "quantiles" and "samples". If you specify "quantiles", each of the quantile values in configuration.quantiles is returned as a time series. If you specify "samples", the model also returns the raw samples used to calculate the other outputs.

DeepAR JSON Response Formats

The following is the format of a response, where [...] are arrays of numbers:

{
  "predictions": [
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    },
    {
      "quantiles": {
        "0.9": [...],
        "0.5": [...]
      },
      "samples": [...],
      "mean": [...]
    }
  ]
}

DeepAR has a response timeout of 60 seconds. When passing multiple time series in a single request, the forecasts are generated sequentially. Because the forecast for each time series typically takes about 300 to 1000 milliseconds or longer, depending on the model size, passing too many time series in a single request can cause time outs. It’s better to send fewer time series per request and send more requests. Because the DeepAR algorithm uses multiple workers per instance, you can achieve much higher throughput by sending multiple requests in parallel.

By default, DeepAR uses one worker per CPU for inference, if there is sufficient memory per CPU. If the model is large and there isn’t enough memory to run a model on each CPU, the number of workers is reduced. The number of workers used for inference can be overwritten using the environment variable
MODEL_SERVER_WORKERS For example, by setting MODEL_SERVER_WORKERS=1) when calling the SageMaker CreateModel API.

Batch Transform with the DeepAR Algorithm

DeepAR forecasting supports getting inferences by using batch transform from data using the JSON Lines format. In this format, each record is represented on a single line as a JSON object, and lines are separated by newline characters. The format is identical to the JSON Lines format used for model training. For information, see Input/Output Interface for the DeepAR Algorithm (p. 1332). For example:

```json
{"start": "2009-11-01 00:00:00", "target": [4.3, "NaN", 5.1, ...], "cat": [0, 1],
 "dynamic_feat": [[1.1, 1.2, 0.5, ..]]}
{"start": "2012-01-30 00:00:00", "target": [1.0, -5.0, ...], "cat": [2, 3], "dynamic_feat":
 [[1.1, 2.05, ...]]}
{"start": "1999-01-30 00:00:00", "target": [2.0, 1.0], "cat": [1, 4], "dynamic_feat":
 [[1.3, 0.4]]}
```

**Note**

When creating the transformation job with CreateTransformJob, set the BatchStrategy value to SingleRecord and set the SplitType value in the TransformInput configuration to Line, as the default values currently cause runtime failures.

Similar to the hosted endpoint inference request format, the cat and the dynamic_feat fields for each instance are required if both of the following are true:

- The model is trained on a dataset that contained both the cat and the dynamic_feat fields.
- The corresponding cardinality and num_dynamic_feat values used in the training job are not set to ""

Unlike hosted endpoint inference, the configuration field is set once for the entire batch inference job using a configuration object named DEEPAR_INFERENCE_CONFIG. The value of DEEPAR_INFERENCE_CONFIG can be passed when the model is created by calling CreateTransformJob API. If DEEPAR_INFERENCE_CONFIG is missing in the container environment, the inference container uses the following default:

```json
{
 "num_samples": 100,
 "output_types": ["mean", "quantiles"],
 "quantiles": ["0.1", "0.2", "0.3", "0.4", "0.5", "0.6", "0.7", "0.8", "0.9"]
}
```

The output is also in JSON Lines format, with one line per prediction, in an order identical to the instance order in the corresponding input file. Predictions are encoded as objects identical to the ones returned by responses in online inference mode. For example:

```json
{ "quantiles": { "0.1": [...], "0.2": [...] }, "samples": [...], "mean": [...] }
```

**Note that in the TransformInput configuration of the SageMaker CreateTransformJob request clients must explicitly set the AssembleWith value to Line, as the default value None concatenates all JSON objects on the same line.**

For example, here is a SageMaker CreateTransformJob request for a DeepAR job with a custom DEEPAR_INFERENCE_CONFIG:

```json
{
 "BatchStrategy": "SingleRecord",
 "Environment": {
 "DEEPAR_INFERENCE_CONFIG": "{ \"num_samples\": 200, \"output_types\": [\"mean\"] }
}
```

Factorization Machines Algorithm

The Factorization Machines algorithm is a general-purpose supervised learning algorithm that you can use for both classification and regression tasks. It is an extension of a linear model that is designed to capture interactions between features within high dimensional sparse datasets economically. For example, in a click prediction system, the Factorization Machines model can capture click rate patterns observed when ads from a certain ad-category are placed on pages from a certain page-category. Factorization machines are a good choice for tasks dealing with high dimensional sparse datasets, such as click prediction and item recommendation.

Note
The Amazon SageMaker implementation of the Factorization Machines algorithm considers only pair-wise (2nd order) interactions between features.

Topics

- EC2 Instance Recommendation for the Factorization Machines Algorithm (p. 1347)
- Factorization Machines Sample Notebooks (p. 1347)
- How Factorization Machines Work (p. 1347)
- Factorization Machines Hyperparameters (p. 1348)
- Tune a Factorization Machines Model (p. 1353)
- Factorization Machines Response Formats (p. 1354)

Input/Output Interface for the Factorization Machines Algorithm

The Factorization Machines algorithm can be run in either in binary classification mode or regression mode. In each mode, a dataset can be provided to the test channel along with the train channel dataset.

The scoring depends on the mode used. In regression mode, the testing dataset is scored using Root Mean Square Error (RMSE). In binary classification mode, the test dataset is scored using Binary Cross Entropy (Log Loss), Accuracy (at threshold=0.5) and F1 Score (at threshold =0.5).

For training, the Factorization Machines algorithm currently supports only the recordIO-protobuf format with float32 tensors. Because their use case is predominantly on sparse data, CSV is not a good candidate. Both File and Pipe mode training are supported for recordIO-wrapped protobuf.

For inference, the Factorization Machines algorithm supports the application/json and x-recordio-protobuf formats.

- For the binary classification problem, the algorithm predicts a score and a label. The label is a number and can be either 0 or 1. The score is a number that indicates how strongly the algorithm believes that the label should be 1. The algorithm computes score first and then derives the label from the score value. If the score is greater than or equal to 0.5, the label is 1.
- For the regression problem, just a score is returned and it is the predicted value. For example, if Factorization Machines is used to predict a movie rating, score is the predicted rating value.
Please see Factorization Machines Sample Notebooks (p. 1347) for more details on training and inference file formats.

EC2 Instance Recommendation for the Factorization Machines Algorithm

The Amazon SageMaker Factorization Machines algorithm is highly scalable and can train across distributed instances. We recommend training and inference with CPU instances for both sparse and dense datasets. In some circumstances, training with one or more GPUs on dense data might provide some benefit. Training with GPUs is available only on dense data. Use CPU instances for sparse data.

Factorization Machines Sample Notebooks

For a sample notebook that uses the SageMaker Factorization Machines algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see An Introduction to Factorization Machines with MNIST. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. Example notebooks that use Factorization Machines algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How Factorization Machines Work

The prediction task for a Factorization Machines model is to estimate a function \( \hat{y} \) from a feature set \( x_i \) to a target domain. This domain is real-valued for regression and binary for classification. The Factorization Machines model is supervised and so has a training dataset \((x_i, y_j)\) available. The advantages this model presents lie in the way it uses a factorized parametrization to capture the pairwise feature interactions. It can be represented mathematically as follows:

\[
\hat{y} = w_0 + \sum_i w_i x_i + \sum_i \sum_{j>i} v_i v_j \cdot x_i x_j
\]

The three terms in this equation correspond respectively to the three components of the model:

- The \( w_0 \) term represents the global bias.
- The \( w_i \) linear terms model the strength of the \( i \)th variable.
- The \( <v_i, v_j> \) factorization terms model the pairwise interaction between the \( i \)th and \( j \)th variable.

The global bias and linear terms are the same as in a linear model. The pairwise feature interactions are modeled in the third term as the inner product of the corresponding factors learned for each feature. Learned factors can also be considered as embedding vectors for each feature. For example, in a classification task, if a pair of features tends to co-occur more often in positive labeled samples, then the inner product of their factors would be large. In other words, their embedding vectors would be close to each other in cosine similarity. For more information about the Factorization Machines model, see Factorization Machines.

For regression tasks, the model is trained by minimizing the squared error between the model prediction \( \hat{y}_n \) and the target value \( y_n \). This is known as the square loss:

\[
L = \frac{1}{N} \sum_n (y_n - \hat{y}_n)^2
\]

For a classification task, the model is trained by minimizing the cross entropy loss, also known as the log loss:

\[
L = \frac{1}{N} \sum_n [y_n \log \hat{p}_n + (1 - y_n) \log (1 - \hat{p}_n)]
\]
where:
\[
\hat{p}_n = \frac{1}{1 + e^{-\theta_n}}
\]

For more information about loss functions for classification, see Loss functions for classification.

**Factorization Machines Hyperparameters**

The following table contains the hyperparameters for the Factorization Machines algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order.

<table>
<thead>
<tr>

Tune a Factorization Machines Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the Factorization Machines Algorithm**

The Factorization Machines algorithm has both binary classification and regression predictor types. The predictor type determines which metric you can use for automatic model tuning. The algorithm reports a `test:rmse` regressor metric, which is computed during training. When tuning the model for regression tasks, choose this metric as the objective.

<table>

**Tunable Factorization Machines Hyperparameters**

You can tune the following hyperparameters for the Factorization Machines algorithm. The initialization parameters that contain the terms bias, linear, and factorization depend on their initialization method. There are three initialization methods: `uniform`, `normal`, and `constant`. These initialization methods are not themselves tunable. The parameters that are tunable are dependent on this choice of the initialization method. For example, if the initialization method is `uniform`, then only the `scale` parameters are tunable. Specifically, if `bias_init_method==uniform`, then `bias_init_scale`, `linear_init_scale`, and `factors_init_scale` are tunable. Similarly, if the initialization method is `normal`, then only `sigma` parameters are tunable. If the initialization method is `constant`, then only `value` parameters are tunable. These dependencies are listed in the following table.

<table>
<thead>

### Factorization Machines Response Formats

#### JSON Response Format

**Binary classification**

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
```

1354
Regression

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

**JSONLINES Response Format**

Binary classification

```
{"score": 0.4, "predicted_label": 0}
```

Regression

```
{"score": 0.4}
```

**RECORDIO Response Format**

Binary classification

```
[ Record = {
  features = {},
  label = {
    'score': {
      keys: [],
      values: [0.4]  # float32
    },
    'predicted_label': {
      keys: [],
      values: [0.0]  # float32
    }
  }
}
```

Regression

```
[ Record = {
  features = {},
  label = {
    'score': {
      keys: [],
      values: [0.4]  # float32
    }
  }
}
```
Image Classification Algorithm

The Amazon SageMaker image classification algorithm is a supervised learning algorithm that supports multi-label classification. It takes an image as input and outputs one or more labels assigned to that image. It uses a convolutional neural network (ResNet) that can be trained from scratch or trained using transfer learning when a large number of training images are not available.

The recommended input format for the Amazon SageMaker image classification algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. Refer to this discussion for a broad overview of efficient data preparation and loading for machine learning systems.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

- Tune an Image Classification Model (p. 1366)

Input/Output Interface for the Image Classification Algorithm

The SageMaker Image Classification algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode, and supports the RecordIO (application/x-recordio) content type for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format.

Distributed training is supported for file mode and pipe mode. When using the RecordIO content type in pipe mode, you must set the S3DataDistributionType of the S3DataSource to FullyReplicated. The algorithm supports a fully replicated model where your data is copied onto each machine.

The algorithm supports image/png, image/jpeg, and application/x-image for inference.

Train with RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio.

Train with Image Format

If you use the Image format for training, specify train, validation, train_lst, and validation_lst channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify the individual image data (.jpg or .png files) for the train
and validation channels. Specify one .lst file in each of the train_lst and validation_lst channels. Set the content type for all four channels to application/x-image.

**Note**
SageMaker reads the training and validation data separately from different channels, so you must store the training and validation data in different folders.

A .lst file is a tab-separated file with three columns that contains a list of image files. The first column specifies the image index, the second column specifies the class label index for the image, and the third column specifies the relative path of the image file. The image index in the first column must be unique across all of the images. The set of class label indices are numbered successively and the numbering should start with 0. For example, 0 for the cat class, 1 for the dog class, and so on for additional classes.

The following is an example of a .lst file:

<table>
<thead>
<tr>
<th>Image Index</th>
<th>Class Index</th>
<th>Relative Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>1</td>
<td>your_image_directory/train_img_dog1.jpg</td>
</tr>
<tr>
<td>1000</td>
<td>0</td>
<td>your_image_directory/train_img_cat1.jpg</td>
</tr>
<tr>
<td>22</td>
<td>1</td>
<td>your_image_directory/train_img_dog2.jpg</td>
</tr>
</tbody>
</table>

For example, if your training images are stored in s3://<your_bucket>/train/class_dog, s3://<your_bucket>/train/class_cat, and so on, specify the path for your train channel as s3://<your_bucket>/train, which is the top-level directory for your data. In the .lst file, specify the relative path for an individual file named train_image_dog1.jpg in the class_dog class directory as class_dog/train_image_dog1.jpg. You can also store all your image files under one subdirectory inside the train directory. In that case, use that subdirectory for the relative path. For example, s3://<your_bucket>/train/your_image_directory.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames" are contained in the list of image and annotation references ["source-ref", "class"].

The order of "AttributeNames" in the input files matters when training the ImageClassification algorithm. It accepts piped data in a specific order, with image first, followed by label. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "class".

When using the ImageClassification algorithm with Augmented Manifest, the value of the RecordWrapperType parameter must be "RecordIO".

Multi-label training is also supported by specifying a JSON array of values. The num_classes hyperparameter must be set to match the total number of classes. There are two valid label formats: multi-hot and class-id.

In the multi-hot format, each label is a multi-hot encoded vector of all classes, where each class takes the value of 0 or 1. In the following example, there are three classes. The first image is labeled with classes 0 and 2, while the second image is labeled with class 2 only:
Amazon SageMaker Developer Guide
Use built-in algorithms

{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[1, 0, 1]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[0, 0, 1]"}

In the class-id format, each label is a list of the class ids, from [0, num_classes), which apply to the data
point. The previous example would instead look like this:
{"image-ref": "s3://mybucket/sample01/image1.jpg", "class": "[0, 2]"}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "class": "[2]"}

The multi-hot format is the default, but can be explicitly set in the content type with the label-format
parameter: "application/x-recordio; label-format=multi-hot". The class-id format, which
is the format outputted by GroundTruth, must be set explicitly: "application/x-recordio; labelformat=class-id".
For more information on augmented manifest ﬁles, see Provide Dataset Metadata to Training Jobs with
an Augmented Manifest File (p. 1828).

Incremental Training
You can also seed the training of a new model with the artifacts from a model that you trained
previously with SageMaker. Incremental training saves training time when you want to train a new model
with the same or similar data. SageMaker image classiﬁcation models can be seeded only with another
To use a pretrained model, in the CreateTrainingJob request, specify the ChannelName as "model"
in the InputDataConfig parameter. Set the ContentType for the model channel to application/xsagemaker-model. The input hyperparameters of both the new model and the pretrained model that
you upload to the model channel must have the same settings for the num_layers, image_shape and
num_classes input parameters. These parameters deﬁne the network architecture. For the pretrained
model ﬁle, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use
either RecordIO or image formats for input data.
For a sample notebook that shows how to use incremental training with the SageMaker image
classiﬁcation algorithm, see the End-to-End Incremental Training Image Classiﬁcation Example. For more
information on incremental training and for instructions on how to use it, see Incremental Training in
Amazon SageMaker (p. 1819).

Inference with the Image Classiﬁcation Algorithm
The generated models can be hosted for inference and support encoded .jpg and .png image formats
as image/png, image/jpeg, and application/x-image content-type. The input image is resized
automatically. The output is the probability values for all classes encoded in JSON format, or in JSON
Lines text format for batch transform. The image classiﬁcation model processes a single image per
request and so outputs only one line in the JSON or JSON Lines format. The following is an example of a
response in JSON Lines format:
accept: application/jsonlines
{"prediction": [prob_0, prob_1, prob_2, prob_3, ...]}

For more details on training and inference, see the image classiﬁcation sample notebook instances
referenced in the introduction.

EC2 Instance Recommendation for the Image Classiﬁcation Algorithm
For image classiﬁcation, we support the following GPU instances for training: ml.p2.xlarge,
ml.p2.8xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.8xlargeand ml.p3.16xlarge. We
recommend using GPU instances with more memory for training with large batch sizes. However, both

1358


CPU (such as C4) and GPU (such as P2 and P3) instances can be used for the inference. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training.

Both P2 and P3 instances are supported in the image classification algorithm.

**Image Classification Sample Notebooks**

For a sample notebook that uses the SageMaker image classification algorithm to train a model on the caltech-256 dataset and then to deploy it to perform inferences, see the End-to-End Multiclass Image Classification Example. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The example image classification notebooks are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How Image Classification Works**

The image classification algorithm takes an image as input and classifies it into one of the output categories. Deep learning has revolutionized the image classification domain and has achieved great performance. Various deep learning networks such as ResNet [1], DenseNet, inception, and so on, have been developed to be highly accurate for image classification. At the same time, there have been efforts to collect labeled image data that are essential for training these networks. ImageNet[2] is one such large dataset that has more than 11 million images with about 11,000 categories. Once a network is trained with ImageNet data, it can then be used to generalize with other datasets as well, by simple re-adjustment or fine-tuning. In this transfer learning approach, a network is initialized with weights (in this example, trained on ImageNet), which can be later fine-tuned for an image classification task in a different dataset.

Image classification in Amazon SageMaker can be run in two modes: full training and transfer learning. In full training mode, the network is initialized with random weights and trained on user data from scratch. In transfer learning mode, the network is initialized with pre-trained weights and just the top fully connected layer is initialized with random weights. Then, the whole network is fine-tuned with new data. In this mode, training can be achieved even with a smaller dataset. This is because the network is already trained and therefore can be used in cases without sufficient training data.

**Image Classification Hyperparameters**

Hyperparameters are parameters that are set before a machine learning model begins learning. The following hyperparameters are supported by the Amazon SageMaker built-in Image Classification algorithm. See Tune an Image Classification Model (p. 1366) for information on image classification hyperparameter tuning.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>Number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset. Beside multi-class classification, multi-label classification is supported too. Please refer to Input/Output Interface for the Image Classification Algorithm (p. 1356) for details on how to work with multi-label classification with augmented manifest files. Required Valid values: positive integer</td>

</tbody>
</table>
| epochs         | Number of training epochs.  
  **Optional**  
  Valid values: positive integer  
  Default value: 30 |
| eps            | The epsilon for adam and rmsprop. It is usually set to a small value to avoid division by 0.  
  **Optional**  
  Valid values: float. Range in [0, 1].  
  Default value: 1e-8 |
| gamma          | The gamma for rmsprop, the decay factor for the moving average of the squared gradient.  
  **Optional**  
  Valid values: float. Range in [0, 1].  
  Default value: 0.9 |
| image_shape    | The input image dimensions, which is the same size as the input layer of the network. The format is defined as 'num_channels, height, width'. The image dimension can take on any value as the network can handle varied dimensions of the input. However, there may be memory constraints if a larger image dimension is used. Pretrained models can use only a fixed 224 x 224 image size. Typical image dimensions for image classification are '3, 224, 224'. This is similar to the ImageNet dataset.  
  For training, if any input image is smaller than this parameter in any dimension, training fails. If an image is larger, a portion of the image is cropped, with the cropped area specified by this parameter. If hyperparameter augmentation_type is set, random crop is taken; otherwise, central crop is taken.  
  At inference, input images are resized to the image_shape that was used during training. Aspect ratio is not preserved, and images are not cropped.  
  **Optional**  
  Valid values: string  
  Default value: ‘3, 224, 224’ |

<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-GPU setting, each GPU handles mini_batch_size/num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. See MXNet docs for more details. Optional Valid values: positive integer Default value: 32</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for sgd and nag, ignored for other optimizers. Optional Valid values: float. Range in [0, 1]. Default value: 0.9</td>
</tr>
<tr>
<td>multi_label</td>
<td>Flag to use for multi-label classification where each sample can be assigned multiple labels. Average accuracy across all classes is logged. Optional Valid values: 0 or 1 Default value: 0</td>
</tr>
<tr>
<td>num_layers</td>
<td>Number of layers for the network. For data with large image size (for example, 224x224 - like ImageNet), we suggest selecting the number of layers from the set [18, 34, 50, 101, 152, 200]. For data with small image size (for example, 28x28 - like CIFAR), we suggest selecting the number of layers from the set [20, 32, 44, 56, 110]. The number of layers in each set is based on the ResNet paper. For transfer learning, the number of layers defines the architecture of base network and hence can only be selected from the set [18, 34, 50, 101, 152, 200]. Optional Valid values: positive integer in [18, 34, 50, 101, 152, 200] or [20, 32, 44, 56, 110] Default value: 152</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| optimizer      | The optimizer type. For more details of the parameters for the optimizers, please refer to MXNet's API.  
  
  **Optional**  
  
  Valid values: One of sgd, adam, rmsprop, or nag.  
  
  - sgd: Stochastic gradient descent  
  - adam: Adaptive momentum estimation  
  - rmsprop: Root mean square propagation  
  - nag: Nesterov accelerated gradient  
  
  Default value: sgd |
| precision_dtype | The precision of the weights used for training. The algorithm can use either single precision (float32) or half precision (float16) for the weights. Using half-precision for weights results in reduced memory consumption.  
  
  **Optional**  
  
  Valid values: float32 or float16  
  
  Default value: float32 |
| resize         | The number of pixels in the shortest side of an image after resizing it for training. If the parameter is not set, then the training data is used without resizing. The parameter should be larger than both the width and height components of image_shape to prevent training failure.  
  
  **Required** when using image content types  
  
  **Optional** when using the RecordIO content type  
  
  Valid values: positive integer  
  
  Default value: no default value |
| top_k          | Reports the top-k accuracy during training. This parameter has to be greater than 1, since the top-1 training accuracy is the same as the regular training accuracy that has already been reported.  
  
  **Optional**  
  
  Valid values: positive integer larger than 1.  
  
  Default value: no default value |

### Tune an Image Classification Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see [Perform Automatic Model Tuning with SageMaker](p. 1715).

### Metrics Computed by the Image Classification Algorithm

The image classification algorithm is a supervised algorithm. It reports an accuracy metric that is computed during training. When tuning the model, choose this metric as the objective metric.

**IP Insights**

Amazon SageMaker IP Insights is an unsupervised learning algorithm that learns the usage patterns for IPv4 addresses. It is designed to capture associations between IPv4 addresses and various entities, such as user IDs or account numbers. You can use it to identify a user attempting to log into a web service from an anomalous IP address, for example. Or you can use it to identify an account that is attempting to create computing resources from an unusual IP address. Trained IP Insight models can be hosted at an endpoint for making real-time predictions or used for processing batch transforms.

SageMaker IP insights ingests historical data as (entity, IPv4 Address) pairs and learns the IP usage patterns of each entity. When queried with an (entity, IPv4 Address) event, a SageMaker IP Insights model returns a score that infers how anomalous the pattern of the event is. For example, when a user attempts to log in from an IP address, if the IP Insights score is high enough, a web login server might decide to trigger a multi-factor authentication system. In more advanced solutions, you can feed the IP Insights score into another machine learning model. For example, you can combine the IP Insight score with other features to rank the findings of another security system, such as those from Amazon GuardDuty.

The SageMaker IP Insights algorithm can also learn vector representations of IP addresses, known as embeddings. You can use vector-encoded embeddings as features in downstream machine learning tasks that use the information observed in the IP addresses. For example, you can use them in tasks such as measuring similarities between IP addresses in clustering and visualization tasks.

Input/Output Interface for the IP Insights Algorithm

Training and Validation
The SageMaker IP Insights algorithm supports training and validation data channels. It uses the optional validation channel to compute an area-under-curve (AUC) score on a predefined negative sampling strategy. The AUC metric validates how well the model discriminates between positive and negative samples. Training and validation data content types need to be in text/csv format. The first column of the CSV data is an opaque string that provides a unique identifier for the entity. The second column is an IPv4 address in decimal-dot notation. IP Insights currently supports only File mode. For more information and some examples, see IP Insights Training Data Formats (p. 1374).

Inference
For inference, IP Insights supports text/csv, application/json, and application/jsonlines data content types. For more information about the common data formats for inference provided by SageMaker, see Common Data Formats for Inference (p. 1315). IP Insights inference returns output formatted as either application/json or application/jsonlines. Each record in the output data contains the corresponding dot_product (or compatibility score) for each input data point. For more information and some examples, see IP Insights Inference Data Formats (p. 1375).

EC2 Instance Recommendation for the IP Insights Algorithm

The SageMaker IP Insights algorithm can run on both GPU and CPU instances. For training jobs, we recommend using GPU instances. However, for certain workloads with large training datasets, distributed CPU instances might reduce training costs. For inference, we recommend using CPU instances.

GPU Instances for the IP Insights Algorithm
IP Insights supports all available GPUs. If you need to speed up training, we recommend starting with a single GPU instance, such as ml.p3.2xlarge, and then moving to a multi-GPU environment, such as ml.p3.8xlarge and ml.p3.16xlarge. Multi-GPUs automatically divide the mini batches of training data across themselves. If you switch from a single GPU to multiple GPUs, the mini_batch_size is divided equally into the number of GPUs used. You may want to increase the value of the mini_batch_size to compensate for this.

CPU Instances for the IP Insights Algorithm
The type of CPU instance that we recommend depends largely on the instance's available memory and the model size. The model size is determined by two hyperparameters: vector_dim and num_entity_vectors. The maximum supported model size is 8 GB. The following table lists typical EC2 instance types that you would deploy based on these input parameters for various model sizes. In Table 1, the value for vector_dim in the first column range from 32 to 2048 and the values for num_entity_vectors in the first row range from 10,000 to 50,000,000.
vector_dim
\num_entity_vectors

<table>
<thead>
<tr>
<th>vector_dim</th>
<th>num_entity_vectors</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>64</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>128</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>256</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>512</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>1024</td>
<td>ml.m5.large</td>
</tr>
<tr>
<td>2048</td>
<td>ml.m5.large</td>
</tr>
</tbody>
</table>

The values for the mini_batch_size, num_ip_encoder_layers, random_negative_sampling_rate, and shuffled_negative_sampling_rate hyperparameters also affect the amount of memory required. If these values are large, you might need to use a larger instance type than normal.

**IP Insights Sample Notebooks**

For a sample notebook that shows how to train the SageMaker IP Insights algorithm and perform inferences with it, see An Introduction to the SageMakerIP Insights Algorithm. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After creating a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. To open a notebook, choose its Use tab and choose Create copy.

**How IP Insights Works**

Amazon SageMaker IP Insights is an unsupervised algorithm that consumes observed data in the form of (entity, IPv4 address) pairs that associates entities with IP addresses. IP Insights determines how likely it is that an entity would use a particular IP address by learning latent vector representations for both entities and IP addresses. The distance between these two representations can then serve as the proxy for how likely this association is.

The IP Insights algorithm uses a neural network to learn the latent vector representations for entities and IP addresses. Entities are first hashed to a large but fixed hash space and then encoded by a simple embedding layer. Character strings such as user names or account IDs can be fed directly into IP Insights as they appear in log files. You don't need to preprocess the data for entity identifiers. You can provide entities as an arbitrary string value during both training and inference. The hash size should be configured with a value that is high enough to insure that the number of collisions, which occur when distinct entities are mapped to the same latent vector, remain insignificant. For more information about how to select appropriate hash sizes, see Feature Hashing for Large Scale Multitask Learning. For representing IP addresses, on the other hand, IP Insights uses a specially designed encoder network to uniquely represent each possible IPv4 address by exploiting the prefix structure of IP addresses.

During training, IP Insights automatically generates negative samples by randomly pairing entities and IP addresses. These negative samples represent data that is less likely to occur in reality. The model is trained to discriminate between positive samples that are observed in the training data and these generated negative samples. More specifically, the model is trained to minimize the cross entropy, also known as the log loss, defined as follows:
\[ L = \frac{1}{N} \sum_{n} [y_n \log p_n + (1 - y_n) \log (1 - p_n)] \]

\( y_n \) is the label that indicates whether the sample is from the real distribution governing observed data \((y_n = 1)\) or from the distribution generating negative samples \((y_n = 0)\). \( p_n \) is the probability that the sample is from the real distribution, as predicted by the model.

Generating negative samples is an important process that is used to achieve an accurate model of the observed data. If negative samples are extremely unlikely, for example, if all of the IP addresses in negative samples are 10.0.0.0, then the model trivially learns to distinguish negative samples and fails to accurately characterize the actual observed dataset. To keep negative samples more realistic, IP Insights generates negative samples both by randomly generating IP addresses and randomly picking IP addresses from training data. You can configure the type of negative sampling and the rates at which negative samples are generated with the \texttt{random_negative_sampling_rate} and \texttt{shuffled_negative_sampling_rate} hyperparameters.

Given an \( n \)th (entity, IP address pair), the IP Insights model outputs a score, \( S_n \), that indicates how compatible the entity is with the IP address. This score corresponds to the log odds ratio for a given (entity, IP address) of the pair coming from a real distribution as compared to coming from a negative distribution. It is defined as follows:

\[ S_n = \log \left( \frac{P_{\text{real}}(n)}{P_{\text{neg}}(n)} \right) \]

The score is essentially a measure of the similarity between the vector representations of the \( n \)th entity and IP address. It can be interpreted as how much more likely it would be to observe this event in reality than in a randomly generated dataset. During training, the algorithm uses this score to calculate an estimate of the probability of a sample coming from the real distribution, \( p_n \), to use in the cross entropy minimization, where:

\[ p_n = \frac{1}{1 + e^{-S_n}} \]

**IP Insights Hyperparameters**

In the \texttt{CreateTransformJob} request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Amazon SageMaker IP Insights algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_entity_vectors</td>
<td>The number of entity vector representations (entity embedding vectors) to train. Each entity in the training set is randomly assigned to one of these vectors using a hash function. Because of hash collisions, it might be possible to have multiple entities assigned to the same vector. This would cause the same vector to represent multiple entities. This generally has a negligible effect on model performance, as long as the collision rate is not too severe. To keep the collision rate low, set this value as high as possible. However, the model size, and, therefore, the memory requirement, for both training and inference, scales linearly with this hyperparameter. We recommend that you set this value to twice the number of unique entity identifiers.</td>
</tr>
<tr>
<td>Required</td>
<td>Valid values: ( 1 \leq \text{positive integer} \leq 250,000,000 )</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| vector_dim                | The size of embedding vectors to represent entities and IP addresses. The larger the value, the more information that can be encoded using these representations. In practice, model size scales linearly with this parameter and limits how large the dimension can be. In addition, using vector representations that are too large can cause the model to overfit, especially for small training datasets. Overfitting occurs when a model doesn't learn any pattern in the data but effectively memorizes the training data and, therefore, cannot generalize well and performs poorly during inference. The recommended value is 128. **Required**  
Valid values: $4 \leq \text{positive integer} \leq 4096$   |
| batch_metrics_publish_interval | The interval (every X batches) at which the Apache MXNet Speedometer function prints the training speed of the network (samples/second). **Optional**  
Valid values: positive integer $\geq 1$  
Default value: 1,000 |
| epochs                    | The number of passes over the training data. The optimal value depends on your data size and learning rate. Typical values range from 5 to 100. **Optional**  
Valid values: positive integer $\geq 1$  
Default value: 10 |
| learning_rate             | The learning rate for the optimizer. IP Insights use a gradient-descent-based Adam optimizer. The learning rate effectively controls the step size to update model parameters at each iteration. Too large a learning rate can cause the model to diverge because the training is likely to overshoot a minima. On the other hand, too small a learning rate slows down convergence. Typical values range from $1e^{-4}$ to $1e^{-1}$. **Optional**  
Valid values: $1e^{-6} \leq \text{float} \leq 10.0$  
Default value: 0.001 |
### Parameter Name | Description
--- | ---
**mini_batch_size** | The number of examples in each mini batch. The training procedure processes data in mini batches. The optimal value depends on the number of unique account identifiers in the dataset. In general, the larger the mini_batch_size, the faster the training and the greater the number of possible shuffled-negative-sample combinations. However, with a large mini_batch_size, the training is more likely to converge to a poor local minimum and perform relatively worse for inference.

**Optional**

Valid values: $1 \leq$ positive integer $\leq 500000$

Default value: 10,000

**num_ip_encoder_layers** | The number of fully connected layers used to encode the IP address embedding. The larger the number of layers, the greater the model's capacity to capture patterns among IP addresses. However, using a large number of layers increases the chance of overfitting.

**Optional**

Valid values: $0 \leq$ positive integer $\leq 100$

Default value: 1

**random_negative_sampling_rate** | The number of random negative samples, $R$, to generate per input example. The training procedure relies on negative samples to prevent the vector representations of the model collapsing to a single point. Random negative sampling generates $R$ random IP addresses for each input account in the mini batch. The sum of the random_negative_sampling_rate ($R$) and shuffled_negative_sampling_rate ($S$) must be in the interval: $1 \leq R + S \leq 500$.

**Optional**

Valid values: $0 \leq$ positive integer $\leq 500$

Default value: 1
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>shuffled_negative_sampling_rate</td>
<td>The number of shuffled negative samples, S, to generate per input example. In some cases, it helps to use more realistic negative samples that are randomly picked from the training data itself. This kind of negative sampling is achieved by shuffling the data within a mini batch. Shuffled negative sampling generates S negative IP addresses by shuffling the IP address and account pairings within a mini batch. The sum of the random_negative_sampling_rate (R) and shuffled_negative_sampling_rate (S) must be in the interval: 1 ≤ R + S ≤ 500.</td>
<td></td>
</tr>
<tr>

**Tune an IP Insights Model**

*Automatic model tuning*, also called hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the IP Insights Algorithm**

The Amazon SageMaker IP Insights algorithm is an unsupervised learning algorithm that learns associations between IP addresses and entities. The algorithm trains a discriminator model, which learns to separate observed data points (*positive samples*) from randomly generated data points (*negative samples*). Automatic model tuning on IP Insights helps you find the model that can most accurately distinguish between unlabeled validation data and automatically generated negative samples. The model accuracy on the validation dataset is measured by the area under the receiver operating characteristic curve. This *validation:discriminator_auc* metric can take values between 0.0 and 1.0, where 1.0 indicates perfect accuracy.

The IP Insights algorithm computes a *validation:discriminator_auc* metric during validation, the value of which is used as the objective function to optimize for hyperparameter tuning.
<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

**IP Insights Data Formats**

This section provides examples of the available input and output data formats used by the IP Insights algorithm during training and inference.

**Topics**
- IP Insights Training Data Formats (p. 1374)
- IP Insights Inference Data Formats (p. 1375)

**IP Insights Training Data Formats**

The following are the available data input formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input training format described in Common Data Formats for
Training (p. 1311). However, the SageMaker IP Insights algorithm currently supports only the CSV data input format.

**IP Insights Training Data Input Formats**

**INPUT: CSV**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**IP Insights Inference Data Formats**

The following are the available input and output formats for the IP Insights algorithm. Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats for Inference (p. 1315). However, the SageMaker IP Insights algorithm does not currently support RecordIO format.

**IP Insights Input Request Formats**

**INPUT: CSV Format**

The CSV file must have two columns. The first column is an opaque string that corresponds to an entity's unique identifier. The second column is the IPv4 address of the entity's access event in decimal-dot notation.

content-type: text/csv

```
entity_id_1, 192.168.1.2
entity_id_2, 10.10.1.2
```

**INPUT: JSON Format**

JSON data can be provided in different formats. IP Insights follows the common SageMaker formats. For more information about inference formats, see Common Data Formats for Inference (p. 1315).

content-type: application/json

```
{
  "instances": [
    {"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]}},
     {"features": ["entity_id_2", "10.10.1.2"]}
  ]
}
```

**INPUT: JSONLINES Format**

The JSON Lines content type is useful for running batch transform jobs. For more information on SageMaker inference formats, see Common Data Formats for Inference (p. 1315). For more information on running batch transform jobs, see Get Inferences for an Entire Dataset with Batch Transform (p. 13).
Use built-in algorithms

IP Insights Output Response Formats

OUTPUT: JSON Response Format

The default output of the SageMaker IP Insights algorithm is the dot_product between the input entity and IP address. The dot_product signifies how compatible the model considers the entity and IP address. The dot_product is unbounded. To make predictions about whether an event is anomalous, you need to set a threshold based on your defined distribution. For information about how to use the dot_product for anomaly detection, see the An Introduction to the SageMakerIP Insights Algorithm.

Advanced users can access the model's learned entity and IP embeddings by providing the additional content-type parameter verbose=True to the Accept heading. You can use the entity_embedding and ip_embedding for debugging, visualizing, and understanding the model. Additionally, you can use these embeddings in other machine learning techniques, such as classification or clustering.

OUTPUT: JSONLINES Response Format

accept: application/json

```
{"data": {"features": {"values": ["entity_id_1", "192.168.1.2"]},
"features": ["entity_id_2", "10.10.1.2"]}
}

{"dot_product": 2.0, "entity_embedding": [1.0, 0.0, 1.0], "ip_embedding": [1.0, 0.0, 1.0]}
```
K-Means Algorithm

K-means is an unsupervised learning algorithm. It attempts to find discrete groupings within data, where members of a group are as similar as possible to one another and as different as possible from members of other groups. You define the attributes that you want the algorithm to use to determine similarity.

Amazon SageMaker uses a modified version of the web-scale k-means clustering algorithm. Compared with the original version of the algorithm, the version used by Amazon SageMaker is more accurate. Like the original algorithm, it scales to massive datasets and delivers improvements in training time. To do this, the version used by Amazon SageMaker streams mini-batches (small, random subsets) of the training data. For more information about mini-batch k-means, see Web-scale k-means Clustering.

The k-means algorithm expects tabular data, where rows represent the observations that you want to cluster, and the columns represent attributes of the observations. The $n$ attributes in each row represent a point in $n$-dimensional space. The Euclidean distance between these points represents the similarity of the corresponding observations. The algorithm groups observations with similar attribute values (the points corresponding to these observations are closer together). For more information about how k-means works in Amazon SageMaker, see How K-Means Clustering Works (p. 1378).

Topics
- Input/Output Interface for the K-Means Algorithm (p. 1377)
- EC2 Instance Recommendation for the K-Means Algorithm (p. 1377)
- K-Means Sample Notebooks (p. 1377)
- How K-Means Clustering Works (p. 1378)
- K-Means Hyperparameters (p. 1380)
- Tune a K-Means Model (p. 1383)
- K-Means Response Formats (p. 1384)

Input/Output Interface for the K-Means Algorithm

For training, the k-means algorithm expects data to be provided in the train channel (recommended S3DataDistributionType=ShardedByS3Key), with an optional test channel (recommended S3DataDistributionType=FullyReplicated) to score the data on. Both recordIO-wrapped-protobuf and CSV formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, text/csv, application/json, and application/x-recordio-protobuf are supported. k-means returns a closest_cluster label and the distance_to_cluster for each observation.

For more information on input and output file formats, see K-Means Response Formats (p. 1384) for inference and the K-Means Sample Notebooks (p. 1377). The k-means algorithm does not support multiple instance learning, in which the training set consists of labeled “bags”, each of which is a collection of unlabeled instances.

EC2 Instance Recommendation for the K-Means Algorithm

We recommend training k-means on CPU instances. You can train on GPU instances, but should limit GPU training to p*.xlarge instances because only one GPU per instance is used.

K-Means Sample Notebooks

For a sample notebook that uses the SageMaker K-means algorithm to segment the population of counties in the United States by attributes identified using principle component analysis, see Analyze US census data for population segmentation using Amazon SageMaker. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon
SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

How K-Means Clustering Works

K-means is an algorithm that trains a model that groups similar objects together. The k-means algorithm accomplishes this by mapping each observation in the input dataset to a point in the n-dimensional space (where n is the number of attributes of the observation). For example, your dataset might contain observations of temperature and humidity in a particular location, which are mapped to points (t, h) in 2-dimensional space.

Note
Clustering algorithms are unsupervised. In unsupervised learning, labels that might be associated with the objects in the training dataset aren’t used.

In k-means clustering, each cluster has a center. During model training, the k-means algorithm uses the distance of the point that corresponds to each observation in the dataset to the cluster centers as the basis for clustering. You choose the number of clusters (k) to create.

For example, suppose that you want to create a model to recognize handwritten digits and you choose the MNIST dataset for training. The dataset provides thousands of images of handwritten digits (0 through 9). In this example, you might choose to create 10 clusters, one for each digit (0, 1, ..., 9). As part of model training, the k-means algorithm groups the input images into 10 clusters.

Each image in the MNIST dataset is a 28x28-pixel image, with a total of 784 pixels. Each image corresponds to a point in a 784-dimensional space, similar to a point in a 2-dimensional space (x,y). To find a cluster to which a point belongs, the k-means algorithm finds the distance of that point from all of the cluster centers. It then chooses the cluster with the closest center as the cluster to which the image belongs.

Note
Amazon SageMaker uses a customized version of the algorithm where, instead of specifying that the algorithm create k clusters, you might choose to improve model accuracy by specifying extra cluster centers (K = k*x). However, the algorithm ultimately reduces these to k clusters.

In SageMaker, you specify the number of clusters when creating a training job. For more information, see CreateTrainingJob. In the request body, you add the HyperParameters string map to specify the k and extra_center_factor strings.

The following is a summary of how k-means works for model training in SageMaker:

1. It determines the initial K cluster centers.
   
   Note
   In the following topics, K clusters refer to k * x, where you specify k and x when creating a model training job.

2. It iterates over input training data and recalculates cluster centers.

3. It reduces resulting clusters to k (if the data scientist specified the creation of k*x clusters in the request).

The following sections also explain some of the parameters that a data scientist might specify to configure a model training job as part of the HyperParameters string map.

Topics
- Step 1: Determine the Initial Cluster Centers (p. 1379)
- Step 2: Iterate over the Training Dataset and Calculate Cluster Centers (p. 1379)
- Step 3: Reduce the Clusters from K to k (p. 1380)
Step 1: Determine the Initial Cluster Centers

When using k-means in SageMaker, the initial cluster centers are chosen from the observations in a small, randomly sampled batch. Choose one of the following strategies to determine how these initial cluster centers are selected:

- The random approach—Randomly choose $K$ observations in your input dataset as cluster centers. For example, you might choose a cluster center that points to the 784-dimensional space that corresponds to any 10 images in the MNIST training dataset.
- The k-means++ approach, which works as follows:
  1. Start with one cluster and determine its center. You randomly select an observation from your training dataset and use the point corresponding to the observation as the cluster center. For example, in the MNIST dataset, randomly choose a handwritten digit image. Then choose the point in the 784-dimensional space that corresponds to the image as your cluster center. This is cluster center 1.
  2. Determine the center for cluster 2. From the remaining observations in the training dataset, pick an observation at random. Choose one that is different than the one you previously selected. This observation corresponds to a point that is far away from cluster center 1. Using the MNIST dataset as an example, you do the following:
     * For each of the remaining images, find the distance of the corresponding point from cluster center 1. Square the distance and assign a probability that is proportional to the square of the distance. That way, an image that is different from the one that you previously selected has a higher probability of getting selected as cluster center 2.
     * Choose one of the images randomly, based on probabilities assigned in the previous step. The point that corresponds to the image is cluster center 2.
  3. Repeat Step 2 to find cluster center 3. This time, find the distances of the remaining images from cluster center 2.
  4. Repeat the process until you have the $K$ cluster centers.

To train a model in SageMaker, you create a training job. In the request, you provide configuration information by specifying the following HyperParameters string maps:

- To specify the number of clusters to create, add the $k$ string.
- For greater accuracy, add the optional extra_center_factor string.
- To specify the strategy that you want to use to determine the initial cluster centers, add the init_method string and set its value to random or k-means++.

For more information about the SageMaker k-means estimator, see K-means in the Amazon SageMaker Python SDK documentation.

You now have an initial set of cluster centers.

Step 2: Iterate over the Training Dataset and Calculate Cluster Centers

The cluster centers that you created in the preceding step are mostly random, with some consideration for the training dataset. In this step, you use the training dataset to move these centers toward the true cluster centers. The algorithm iterates over the training dataset, and recalculates the $K$ cluster centers.

1. Read a mini-batch of observations (a small, randomly chosen subset of all records) from the training dataset and do the following.

   **Note**
   When creating a model training job, you specify the batch size in the mini_batch_size string in the HyperParameters string map.
a. Assign all of the observations in the mini-batch to one of the clusters with the closest cluster center.

b. Calculate the number of observations assigned to each cluster. Then, calculate the proportion of new points assigned per cluster.

For example, consider the following clusters:

Cluster c1 = 100 previously assigned points. You added 25 points from the mini-batch in this step.

Cluster c2 = 150 previously assigned points. You added 40 points from the mini-batch in this step.

Cluster c3 = 450 previously assigned points. You added 5 points from the mini-batch in this step.

Calculate the proportion of new points assigned to each of clusters as follows:

\[
\begin{align*}
p_1 &= \text{proportion of points assigned to c1} = \frac{25}{100+25} \\
p_2 &= \text{proportion of points assigned to c2} = \frac{40}{150+40} \\
p_3 &= \text{proportion of points assigned to c3} = \frac{5}{450+5}
\end{align*}
\]

c. Compute the center of the new points added to each cluster:

\[
\begin{align*}
d_1 &= \text{center of the new points added to cluster 1} \\
d_2 &= \text{center of the new points added to cluster 2} \\
d_3 &= \text{center of the new points added to cluster 3}
\end{align*}
\]

d. Compute the weighted average to find the updated cluster centers as follows:

\[
\begin{align*}
\text{Center of cluster 1} &= ((1 - p1) \times \text{center of cluster 1}) + (p1 \times d1) \\
\text{Center of cluster 2} &= ((1 - p2) \times \text{center of cluster 2}) + (p2 \times d2) \\
\text{Center of cluster 3} &= ((1 - p3) \times \text{center of cluster 3}) + (p3 \times d3)
\end{align*}
\]

2. Read the next mini-batch, and repeat Step 1 to recalculate the cluster centers.

3. For more information about mini-batch k-means, see Web-Scale k-means Clustering.

Step 3: Reduce the Clusters from K to k

If the algorithm created K clusters—\((K = k \times x)\) where \(x\) is greater than 1—it reduces the K clusters to \(k\) clusters. (For more information, see extra_center_factor in the preceding discussion.) It does this by applying Lloyd’s method with kmeans++ initialization to the K cluster centers. For more information about Lloyd’s method, see k-means clustering.

K-Means Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the k-means training algorithm provided by Amazon SageMaker. For more information about how k-means clustering works, see How K-Means Clustering Works (p. 1378).

<table>

**Tune a K-Means Model**

Autoamtic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker k-means algorithm is an unsupervised algorithm that groups data into clusters whose members are as similar as possible. Because it is unsupervised, it doesn't use a validation dataset that hyperparameters can optimize against. But it does take a test dataset and emits metrics that depend on the squared distance between the data points and the final cluster centroids at the end of each training run. To find the model that reports the tightest clusters on the test dataset, you can use a hyperparameter tuning job. The clusters optimize the similarity of their members.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the K-Means Algorithm**

The k-means algorithm computes the following metrics during training. When tuning a model, choose one of these metrics as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:msd</td>
<td>Mean squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:ssd</td>
<td>Sum of the squared distances between each record in the test set and the closest center of the model.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable K-Means Hyperparameters**

Tune the Amazon SageMaker k-means model with the following hyperparameters. The hyperparameters that have the greatest impact on k-means objective metrics are: mini_batch_size, extra_center_factor, and init_method. Tuning the hyperparameter epochs generally results in minor improvements.

<table>

K-Means Response Formats

All SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-means algorithm.

JSON Response Format

```json
{
  "predictions": [
    {
      "closest_cluster": 1.0,
      "distance_to_cluster": 3.0,
    },
    {
      "closest_cluster": 2.0,
      "distance_to_cluster": 5.0,
    },
    ....
  ]
}
```

JSONLINES Response Format

```json
{"closest_cluster": 1.0, "distance_to_cluster": 3.0}
{"closest_cluster": 2.0, "distance_to_cluster": 5.0}
```

RECORDIO Response Format

```json
[
  Record = {
    features = {},
    label = {
      'closest_cluster': {
        keys: [],
        values: [1.0, 2.0]  # float32
      },
      'distance_to_cluster': {
        keys: [],
        values: [3.0, 5.0]  # float32
      }
    }
  }
]
```

CSV Response Format

The first value in each line corresponds to closest_cluster.
The second value in each line corresponds to `distance_to_cluster`.

```
1.0,3.0
2.0,5.0
```

**K-Nearest Neighbors (k-NN) Algorithm**

Amazon SageMaker k-nearest neighbors (k-NN) algorithm is an index-based algorithm. It uses a non-parametric method for classification or regression. For classification problems, the algorithm queries the k points that are closest to the sample point and returns the most frequently used label of their class as the predicted label. For regression problems, the algorithm queries the k closest points to the sample point and returns the average of their feature values as the predicted value.

Training with the k-NN algorithm has three steps: sampling, dimension reduction, and index building. Sampling reduces the size of the initial dataset so that it fits into memory. For dimension reduction, the algorithm decreases the feature dimension of the data to reduce the footprint of the k-NN model in memory and inference latency. We provide two methods of dimension reduction methods: random projection and the fast Johnson-Lindenstrauss transform. Typically, you use dimension reduction for high-dimensional (d > 1000) datasets to avoid the “curse of dimensionality” that troubles the statistical analysis of data that becomes sparse as dimensionality increases. The main objective of k-NN's training is to construct the index. The index enables efficient lookups of distances between points whose values or class labels have not yet been determined and the k nearest points to use for inference.

**Topics**

- Input/Output Interface for the k-NN Algorithm (p. 1385)
- k-NN Sample Notebooks (p. 1386)
- How the k-NN Algorithm Works (p. 1386)
- EC2 Instance Recommendation for the k-NN Algorithm (p. 1387)
- k-NN Hyperparameters (p. 1387)
- Tune a k-NN Model (p. 1389)
- Data Formats for k-NN Training Input (p. 1390)
- k-NN Request and Response Formats (p. 1391)

**Input/Output Interface for the k-NN Algorithm**

SageMaker k-NN supports train and test data channels.

- Use a **train channel** for data that you want to sample and construct into the k-NN index.
- Use a **test channel** to emit scores in log files. Scores are listed as one line per mini-batch: accuracy for classifier, mean-squared error (mse) for regressor for score.

For training inputs, k-NN supports **text/csv** and **application/x-recordio-protobuf** data formats. For input type **text/csv**, the first `label_size` columns are interpreted as the label vector for that row. You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference inputs, k-NN supports the **application/json**, **application/x-recordio-protobuf**, and **text/csv** data formats. The **text/csv** format accepts a `label_size` and encoding parameter. It assumes a `label_size` of 0 and a UTF-8 encoding.

For inference outputs, k-NN supports the **application/json** and **application/x-recordio-protobuf** data formats. These two data formats also support a verbose output mode. In verbose output mode, the API provides the search results with the distances vector sorted from smallest to largest, and corresponding elements in the labels vector.
For batch transform, k-NN supports the `application/jsonlines` data format for both input and output. An example input is as follows:

```
content-type: application/jsonlines

{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

An example output is as follows:

```
accept: application/jsonlines

{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

For more information on input and output file formats, see Data Formats for k-NN Training Input (p. 1390) for training, k-NN Request and Response Formats (p. 1391) for inference, and the k-NN Sample Notebooks (p. 1386).

**k-NN Sample Notebooks**

For a sample notebook that uses the SageMaker k-nearest neighbor algorithm to predict wilderness cover types from geological and forest service data, see the K-Nearest Neighbor Covertype.

Use a Jupyter notebook instance to run the example in SageMaker. To learn how to create and open a Jupyter notebook instance in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker example notebooks. Find K-Nearest Neighbor notebooks in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**How the k-NN Algorithm Works**

**Step 1: Sample**

To specify the total number of data points to be sampled from the training dataset, use the `sample_size` parameter. For example, if the initial dataset has 1,000 data points and the `sample_size` is set to 100, where the total number of instances is 2, each worker would sample 50 points. A total set of 100 data points would be collected. Sampling runs in linear time with respect to the number of data points.

**Step 2: Perform Dimension Reduction**

The current implementation of the k-NN algorithm has two methods of dimension reduction. You specify the method in the `dimension_reduction_type` hyperparameter. The `sign` method specifies a random projection, which uses a linear projection using a matrix of random signs, and the `fjlt` method specifies a fast Johnson-Lindenstrauss transform, a method based on the Fourier transform. Both methods preserve the L2 and inner product distances. The `fjlt` method should be used when the target dimension is large and has better performance with CPU inference. The methods differ in their computational complexity. The `sign` method requires O(ndk) time to reduce the dimension of a batch of n points of dimension d into a target dimension k. The `fjlt` method requires O(nd log(d)) time, but the constants involved are larger. Using dimension reduction introduces noise into the data and this noise can reduce prediction accuracy.

**Step 3: Build an Index**

During inference, the algorithm queries the index for the k-nearest-neighbors of a sample point. Based on the references to the points, the algorithm makes the classification or regression prediction. It makes the prediction based on the class labels or values provided. k-NN provides three different types of indexes: a flat index, an inverted index, and an inverted index with product quantization. You specify the type with the `index_type` parameter.
Serialize the Model

When the k-NN algorithm finishes training, it serializes three files to prepare for inference.

- `model_algo-1`: Contains the serialized index for computing the nearest neighbors.
- `model_algo-1.labels`: Contains serialized labels (np.float32 binary format) for computing the predicted label based on the query result from the index.
- `model_algo-1.json`: Contains the JSON-formatted model metadata which stores the \( k \) and \( \text{predictor} \text{\_} \text{type} \) hyper-parameters from training for inference along with other relevant state.

With the current implementation of k-NN, you can modify the metadata file to change the way predictions are computed. For example, you can change \( k \) to 10 or change \( \text{predictor} \text{\_} \text{type} \) to `regressor`.

```json
{
    "k": 5,
    "predictor_type": "classifier",
    "dimension_reduction": {"type": "sign", "seed": 3, "target_dim": 10, "input_dim": 20},
    "normalize": false,
    "version": "1.0"
}
```

EC2 Instance Recommendation for the k-NN Algorithm

Instance Recommendation for Training with the k-NN Algorithm

To start, try running training on a CPU, using, for example, an ml.m5.2xlarge instance, or on a GPU using, for example, an ml.p2.xlarge instance.

Instance Recommendation for Inference with the k-NN Algorithm

Inference requests from CPUs generally have a lower average latency than requests from GPUs because there is a tax on CPU-to-GPU communication when you use GPU hardware. However, GPUs generally have higher throughput for larger batches.

**Tune a k-NN Model**

The Amazon SageMaker k-nearest neighbors algorithm is a supervised algorithm. The algorithm consumes a test data set and emits a metric about the accuracy for a classification task or about the mean squared error for a regression task. These accuracy metrics compare the model predictions for their respective task to the ground truth provided by the empirical test data. To find the best model that reports the highest accuracy or lowest error on the test dataset, run a hyperparameter tuning job for k-NN.

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric appropriate for the prediction task of the algorithm. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric. The hyperparameters are used only to help estimate model parameters and are not used by the trained model to make predictions.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the k-NN Algorithm**

The k-nearest neighbors algorithm computes one of two metrics in the following table during training depending on the type of task specified by the predictor_type hyper-parameter.

- *classifier* specifies a classification task and computes test:accuracy
- *regressor* specifies a regression task and computes test:mse.

Choose the predictor_type value appropriate for the type of task undertaken to calculate the relevant objective metric when tuning a model.

**Data Formats for k-NN Training Input**

All Amazon SageMaker built-in algorithms adhere to the common input training formats described in *Common Data Formats - Training*. This topic contains a list of the available input formats for the SageMaker k-nearest-neighbor algorithm.

**CSV Data Format**

```plaintext
content-type: text/csv; label_size=1

4,1.2,1.3,9.6,20.3
```

The first label_size columns are interpreted as the label vector for that row.

**RECORDIO Data Format**

```plaintext
content-type: application/x-recordio-protobuf

```
k-NN Request and Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker k-nearest-neighbor algorithm.

INPUT: CSV Request Format

cell-type: text/csv

1.2,1.3,9.6,20.3

This accepts a label_size or encoding parameter. It assumes a label_size of 0 and a utf-8 encoding.

INPUT: JSON Request Format

cell-type: application/json

```json
{
   "instances": [
      {
         "data": {
            "features": {
               "values": [-3, -1, -4, 2]
            }
         },
         "features": [3.0, 0.1, 0.04, 0.002]
      }
   ]
}
```

INPUT: JSONLINES Request Format

cell-type: application/jsonlines

```json
{"features": [1.5, 16.0, 14.0, 23.0]}
{"data": {"features": {"values": [1.5, 16.0, 14.0, 23.0]}}}
```

INPUT: RECORDIO Request Format

cell-type: application/x-recordio-protobuf

```json
[
   Record = {
      features = {
         'values': {
            values: [-3, -1, -4, 2] # float32
         }
      },
      label = {}
   },
   Record = {
      features = {
         'values': {
            values: [3.0, 0.1, 0.04, 0.002] # float32
         }
      },
      label = {}
   }
]
```

OUTPUT: JSON Response Format

accept: application/json

```json
{
   "predictions": [
```

1391
Use built-in algorithms

```
{"predicted_label": 0.0},
{"predicted_label": 2.0}
```

**OUTPUT: JSONLINES Response Format**

accept: application/jsonlines

```
{"predicted_label": 0.0}
{"predicted_label": 2.0}
```

**OUTPUT: VERBOSE JSON Response Format**

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.

accept: application/json; verbose=true

```
{
  "predictions": [
    {

      "distances": [3.11792408, 3.89746071, 6.32548437],
      "labels": [0.0, 1.0, 0.0]
    },
    {
      "predicted_label": 2.0,
      "distances": [1.08470316, 3.04917915, 5.25393973],
      "labels": [2.0, 2.0, 0.0]
    }
  ]
}
```

**OUTPUT: RECORDIO-PROTOBUF Response Format**

content-type: application/x-recordio-protobuf

```
[Record = {
  features = {},
  label = {
    'predicted_label': {
      values: [0.0] # float32
    }
  }
}, Record = {
  features = {},
  label = {
    'predicted_label': {
      values: [2.0] # float32
    }
  }
}]
```

**OUTPUT: VERBOSE RECORDIO-PROTOBUF Response Format**

In verbose mode, the API provides the search results with the distances vector sorted from smallest to largest, with corresponding elements in the labels vector. In this example, k is set to 3.
Use built-in algorithms

accept: application/x-recordio-protobuf; verbose=true

```

**Latent Dirichlet Allocation (LDA) Algorithm**

The Amazon SageMaker Latent Dirichlet Allocation (LDA) algorithm is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of distinct categories. LDA is most commonly used to discover a user-specified number of topics shared by documents within a text corpus. Here each observation is a document, the features are the presence (or occurrence count) of each word, and the categories are the topics. Since the method is unsupervised, the topics are not specified up front, and are not guaranteed to align with how a human may naturally categorize documents. The topics are learned as a probability distribution over the words that occur in each document. Each document, in turn, is described as a mixture of topics.

The exact content of two documents with similar topic mixtures will not be the same. But overall, you would expect these documents to more frequently use a shared subset of words, than when compared with a document from a different topic mixture. This allows LDA to discover these word groups and use
them to form topics. As an extremely simple example, given a set of documents where the only words that occur within them are: eat, sleep, play, meow, and bark, LDA might produce topics like the following:

<table>
<thead>
<tr>
<th>Topic</th>
<th>eat</th>
<th>sleep</th>
<th>play</th>
<th>meow</th>
<th>bark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic 1</td>
<td>0.1</td>
<td>0.3</td>
<td>0.2</td>
<td>0.4</td>
<td>0.0</td>
</tr>
<tr>
<td>Topic 2</td>
<td>0.2</td>
<td>0.1</td>
<td>0.4</td>
<td>0.0</td>
<td>0.3</td>
</tr>
</tbody>
</table>

You can infer that documents that are more likely to fall into Topic 1 are about cats (who are more likely to meow and sleep), and documents that fall into Topic 2 are about dogs (who prefer to play and bark). These topics can be found even though the words dog and cat never appear in any of the texts.

**Choosing between Latent Dirichlet Allocation (LDA) and Neural Topic Model (NTM) (p. 1394)**

Topic models are commonly used to produce topics from corpuses that (1) coherently encapsulate semantic meaning and (2) describe documents well. As such, topic models aim to minimize perplexity and maximize topic coherence.

Perplexity is an intrinsic language modeling evaluation metric that measures the inverse of the geometric mean per-word likelihood in your test data. A lower perplexity score indicates better generalization performance. Research has shown that the likelihood computed per word often does not align to human judgement, and can be entirely non-correlated, thus topic coherence has been introduced. Each inferred topic from your model consists of words, and topic coherence is computed to the top N words for that particular topic from your model. It is often defined as the average or median of the pairwise word-similarity scores of the words in that topic e.g., Pointwise Mutual Information (PMI). A promising model generates coherent topics or topics with high topic coherence scores.

While the objective is to train a topic model that minimizes perplexity and maximizes topic coherence, there is often a tradeoff with both LDA and NTM. Recent research by Amazon, Dinget et al., 2018 has shown that NTM is promising for achieving high topic coherence but LDA trained with collapsed Gibbs sampling achieves better perplexity. There is a tradeoff between perplexity and topic coherence. From a practicality standpoint regarding hardware and compute power, SageMaker NTM hardware is more flexible than LDA and can scale better because NTM can run on CPU and GPU and can be parallelized across multiple GPU instances, whereas LDA only supports single-instance CPU training.
Input/Output Interface for the LDA Algorithm

LDA expects data to be provided on the train channel, which is scored by the final model. LDA supports both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV, the data must be dense and have dimension equal to number of records \* vocabulary size. LDA can be trained in File or Pipe mode when using recordIO-wrapped protobuf, but only in File mode for the CSV format.

For inference, text/csv, application/json, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. LDA inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_mixture vector for each observation.

Please see the LDA Sample Notebooks (p. 1395) for more detail on training and inference formats.

EC2 Instance Recommendation for the LDA Algorithm

LDA currently only supports single-instance CPU training. CPU instances are recommended for hosting/inference.

LDA Sample Notebooks

For a sample notebook that shows how to train the SageMaker Latent Dirichlet Allocation algorithm on a dataset and then how to deploy the trained model to perform inferences about the topic mixtures in input documents, see the An Introduction to SageMaker LDA. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

How LDA Works

Amazon SageMaker LDA is an unsupervised learning algorithm that attempts to describe a set of observations as a mixture of different categories. These categories are themselves a probability distribution over the features. LDA is a generative probability model, which means it attempts to provide a model for the distribution of outputs and inputs based on latent variables. This is opposed to discriminative models, which attempt to learn how inputs map to outputs.

You can use LDA for a variety of tasks, from clustering customers based on product purchases to automatic harmonic analysis in music. However, it is most commonly associated with topic modeling in text corpuses. Observations are referred to as documents. The feature set is referred to as vocabulary. A feature is referred to as a word. And the resulting categories are referred to as topics.

Note

Lemmatization significantly increases algorithm performance and accuracy. Consider pre-processing any input text data.

An LDA model is defined by two parameters:

- \(\alpha\)—A prior estimate on topic probability (in other words, the average frequency that each topic within a given document occurs).
- \(\beta\)—a collection of \(k\) topics where each topic is given a probability distribution over the vocabulary used in a document corpus, also called a "topic-word distribution."

LDA is a "bag-of-words" model, which means that the order of words does not matter. LDA is a generative model where each document is generated word-by-word by choosing a topic mixture \(\theta \sim \text{Dirichlet}(\alpha)\).
For each word in the document:
- Choose a topic $z \sim \text{Multinomial}(\theta)$
- Choose the corresponding topic-word distribution $\beta_z$.
- Draw a word $w \sim \text{Multinomial}(\beta_z)$.

When training the model, the goal is to find parameters $\alpha$ and $\beta$, which maximize the probability that the text corpus is generated by the model.

The most popular methods for estimating the LDA model use Gibbs sampling or Expectation Maximization (EM) techniques. The Amazon SageMaker LDA uses tensor spectral decomposition. This provides several advantages:

- **Theoretical guarantees on results.** The standard EM-method is guaranteed to converge only to local optima, which are often of poor quality.
- **Embarrassingly parallelizable.** The work can be trivially divided over input documents in both training and inference. The EM-method and Gibbs Sampling approaches can be parallelized, but not as easily.
- **Fast.** Although the EM-method has low iteration cost it is prone to slow convergence rates. Gibbs Sampling is also subject to slow convergence rates and also requires a large number of samples.

At a high-level, the tensor decomposition algorithm follows this process:

1. The goal is to calculate the spectral decomposition of a $V \times V \times V$ tensor, which summarizes the moments of the documents in our corpus. $V$ is vocabulary size (in other words, the number of distinct words in all of the documents). The spectral components of this tensor are the LDA parameters $\alpha$ and $\beta$, which maximize the overall likelihood of the document corpus. However, because vocabulary size tends to be large, this $V \times V \times V$ tensor is prohibitively large to store in memory.
2. Instead, it uses a $V \times V$ moment matrix, which is the two-dimensional analog of the tensor from step 1, to find a whitening matrix of dimension $V \times k$. This matrix can be used to convert the $V \times V$ moment matrix into a $k \times k$ identity matrix. $k$ is the number of topics in the model.
3. This same whitening matrix can then be used to find a smaller $k \times k \times k$ tensor. When spectrally decomposed, this tensor has components that have a simple relationship with the components of the $V \times V \times V$ tensor.
4. **Alternating Least Squares** is used to decompose the smaller $k \times k \times k$ tensor. This provides a substantial improvement in memory consumption and speed. The parameters $\alpha$ and $\beta$ can be found by "unwhitening" these outputs in the spectral decomposition.

After the LDA model's parameters have been found, you can find the topic mixtures for each document. You use stochastic gradient descent to maximize the likelihood function of observing a given topic mixture corresponding to these data.

Topic quality can be improved by increasing the number of topics to look for in training and then filtering out poor quality ones. This is in fact done automatically in SageMaker LDA: 25% more topics are computed and only the ones with largest associated Dirichlet priors are returned. To perform further topic filtering and analysis, you can increase the topic count and modify the resulting LDA model as follows:

```python
> import mxnet as mx
> alpha, beta = mx.ndarray.load('model.tar.gz')
> # modify alpha and beta
> mx.nd.save('new_model.tar.gz', [new_alpha, new_beta])
> # upload to S3 and create new SageMaker model using the console
```

For more information about algorithms for LDA and the SageMaker implementation, see the following:
Amazon SageMaker Developer Guide
Use built-in algorithms

**LDA Hyperparameters**

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the LDA training algorithm provided by Amazon SageMaker. For more information, see How LDA Works (p. 1395).

<table>

### Tune an LDA Model

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

LDA is an unsupervised topic modeling algorithm that attempts to describe a set of observations (documents) as a mixture of different categories (topics). The “per-word log-likelihood” (PWLL) metric measures the likelihood that a learned set of topics (an LDA model) accurately describes a test document dataset. Larger values of PWLL indicate that the test data is more likely to be described by the LDA model.

For more information about model tuning, see *Perform Automatic Model Tuning with SageMaker* (p. 1715).

### Metrics Computed by the LDA Algorithm

The LDA algorithm reports on a single metric during training: test:pwll. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:pwll</td>
<td>Per-word log-likelihood on the test dataset. The likelihood that the test dataset is accurately described by the learned LDA model.</td>
<td>Maximize</td>
</tr>
</tbody>
</table>

### Tunable LDA Hyperparameters

You can tune the following hyperparameters for the LDA algorithm. Both hyperparameters, alpha0 and num_topics, can affect the LDA objective metric (test:pwll). If you don’t already know the optimal
values for these hyperparameters, which maximize per-word log-likelihood and produce an accurate LDA model, automatic model tuning can help find them.

Linear Learner Algorithm

*Linear models* are supervised learning algorithms used for solving either classification or regression problems. For input, you give the model labeled examples \((x, y)\). \(x\) is a high-dimensional vector and \(y\) is a numeric label. For binary classification problems, the label must be either 0 or 1. For multiclass classification problems, the labels must be from 0 to \(\text{num\_classes} - 1\). For regression problems, \(y\) is a real number. The algorithm learns a linear function, or, for classification problems, a linear threshold function, and maps a vector \(x\) to an approximation of the label \(y\).

The Amazon SageMaker linear learner algorithm provides a solution for both classification and regression problems. With the SageMaker algorithm, you can simultaneously explore different training objectives and choose the best solution from a validation set. You can also explore a large number of models and choose the best. The best model optimizes either of the following:

- Continuous objectives, such as mean square error, cross entropy loss, absolute error.
- Discrete objectives suited for classification, such as F1 measure, precision, recall, or accuracy.

Compared with methods that provide a solution for only continuous objectives, the SageMaker linear learner algorithm provides a significant increase in speed over naive hyperparameter optimization techniques. It is also more convenient.

The linear learner algorithm requires a data matrix, with rows representing the observations, and columns representing the dimensions of the features. It also requires an additional column that contains the labels that match the data points. At a minimum, Amazon SageMaker linear learner requires you to specify input and output data locations, and objective type (classification or regression) as arguments. The feature dimension is also required. For more information, see `CreateTrainingJob`.

You can specify additional parameters in the `HyperParameters` string map of the request body. These parameters control the optimization procedure, or specifics of the objective function that you train on. For example, the number of epochs, regularization, and loss type.

If you’re using Managed Spot Training, the linear learner algorithm supports using checkpoints to take a snapshot of the state of the model.

Topics

Input/Output interface for the linear learner algorithm

The Amazon SageMaker linear learner algorithm supports three data channels: train, validation (optional), and test (optional). If you provide validation data, the S3DataDistributionType should be FullyReplicated. The algorithm logs validation loss at every epoch, and uses a sample of the validation data to calibrate and select the best model. If you don't provide validation data, the algorithm uses a sample of the training data to calibrate and select the model. If you provide test data, the algorithm logs include the test score for the final model.

For training, the linear learner algorithm supports both recordIO-wrapped protobuf and CSV formats. For the application/x-recordio-protobuf input type, only Float32 tensors are supported. For the text/csv input type, the first column is assumed to be the label, which is the target variable for prediction. You can use either File mode or Pipe mode to train linear learner models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

For inference, the linear learner algorithm supports the application/json, application/x-recordio-protobuf, and text/csv formats. When you make predictions on new data, the format of the response depends on the type of model. For regression (predictor_type='regressor'), the score is the prediction produced by the model. For classification (predictor_type='binary_classifier' or predictor_type='multiclass_classifier'), the model returns a score and also a predicted_label. The predicted_label is the class predicted by the model and the score measures the strength of that prediction.

- For binary classification, predicted_label is 0 or 1, and score is a single floating point number that indicates how strongly the algorithm believes that the label should be 1.
- For multiclass classification, the predicted_class will be an integer from 0 to num_classes-1, and score will be a list of one floating point number per class.

To interpret the score in classification problems, you have to consider the loss function used. If the loss hyperparameter value is logistic for binary classification or softmax_loss for multiclass classification, then the score can be interpreted as the probability of the corresponding class. These are the loss values used by the linear learner when the loss value is auto default value. But if the loss is set to hinge_loss, then the score cannot be interpreted as a probability. This is because hinge loss corresponds to a Support Vector Classifier, which does not produce probability estimates.

For more information on input and output file formats, see Linear learner response formats (p. 1413). For more information on inference formats, and the Linear learner sample notebooks (p. 1400).

EC2 instance recommendation for the linear learner algorithm

You can train the linear learner algorithm on single- or multi-machine CPU and GPU instances. During testing, we have not found substantial evidence that multi-GPU computers are faster than single-GPU computers. Results can vary, depending on your specific use case.

Linear learner sample notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker linear learner algorithm.

How to Build a Machine Learning (ML) Pipeline for Inference? | Using a Scikit-learn container, we demonstrate how to build an end-to-end ML pipeline.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

How linear learner works

There are three steps involved in the implementation of the linear learner algorithm: preprocess, train, and validate. Step 4 provides example code that shows how to deploy a trained model.

Step 1: Preprocess

Normalization, or feature scaling, is an important preprocessing step for certain loss functions that ensures the model being trained on a dataset does not become dominated by the weight of a single feature. The Amazon SageMaker Linear Learner algorithm has a normalization option to assist with this preprocessing step. If normalization is turned on, the algorithm first goes over a small sample of the data to learn the mean value and standard deviation for each feature and for the label. Each of the features in the full dataset is then shifted to have mean of zero and scaled to have a unit standard deviation.

**Note**

For best results, ensure your data is shuffled before training. Training with unshuffled data may cause training to fail.

You can configure whether the linear learner algorithm normalizes the feature data and the labels using the `normalize_data` and `normalize_label` hyperparameters, respectively. Normalization is enabled by default for both features and labels for regression. Only the features can be normalized for binary classification and this is the default behavior.

Step 2: Train

With the linear learner algorithm, you train with a distributed implementation of stochastic gradient descent (SGD). You can control the optimization process by choosing the optimization algorithm. For example, you can choose to use Adam, AdaGrad, stochastic gradient descent, or other optimization algorithms. You also specify their hyperparameters, such as momentum, learning rate, and the learning rate schedule. If you aren't sure which algorithm or hyperparameter value to use, choose a default that works for the majority of datasets.

During training, you simultaneously optimize multiple models, each with slightly different objectives. For example, you vary L1 or L2 regularization and try out different optimizer settings.

Step 3: Validate and set the threshold

When training multiple models in parallel, the models are evaluated against a validation set to select the most optimal model once training is complete. For regression, the most optimal model is the one that achieves the best loss on the validation set. For classification, a sample of the validation set is used to calibrate the classification threshold. The most optimal model selected is the one that achieves the best binary classification selection criteria on the validation set. Examples of such criteria include the F1 measure, accuracy, and cross-entropy loss.
Note
If the algorithm is not provided a validation set, then evaluating and selecting the most optimal model is not possible. To take advantage of parallel training and model selection ensure you provide a validation set to the algorithm.

Step 4: Deploy a trained linear model

Here is an example of Python code that you can use to deploy a model in MXNet that has been trained with SageMaker linear learner

```python
import mxnet as mx
import tarfile
t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

# Load the mxnet module from the model files
mod = mx.module.Module.load('mx-mod', 0)
# model's weights
mod._arg_params['fc0_weight'].asnumpy().flatten()

# model bias
mod._arg_params['fc0_bias'].asnumpy().flatten()

mod.bind(data_shapes=data_iter.provide_data)  # data_iter is an iterator configured with your test data
#perform inference
result = mod.predict(data_iter)
```

Linear learner hyperparameters

The following table contains the hyperparameters for the linear learner algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. When a hyperparameter is set to auto, Amazon SageMaker will automatically calculate and set the value of that hyperparameter.

<table>
<thead>
<tr>

| binary_classifier_model_selection_criteria  | When predictor_type is set to binary_classifier, the model evaluation criteria for the validation dataset (or for the training dataset if you don't provide a validation dataset). Criteria include:  
  - accuracy—The model with the highest accuracy.  
  - f_beta—The model with the highest F1 score. The default is F1.  
  - precision_at_target_recall—The model with the highest precision at a given recall target.  
  - recall_at_target_precision—The model with the highest recall at a given precision target.  
  - loss_function—The model with the lowest value of the loss function used in training.  
  
Optional  
Valid values: accuracy, f_beta, precision_at_target_recall, recall_at_target_precision, or loss_function  
Default value: accuracy |
| early_stopping_patience                    | If no improvement is made in the relevant metric, the number of epochs to wait before ending training. If you have provided a value for binary_classifier_model_selection_criteria, the metric is that value. Otherwise, the metric is the same as the value specified for the loss hyperparameter.  
  
The metric is evaluated on the validation data. If you haven't provided validation data, the metric is always the same as the value specified for the loss hyperparameter and is evaluated on the training data. To disable early stopping, set early_stopping_patience to a value greater than the value specified for epochs.  
  
Optional  
Valid values: Positive integer  
Default value: 3 |
| early_stopping_tolerance                   | The relative tolerance to measure an improvement in loss. If the ratio of the improvement in loss divided by the previous best loss is smaller than this value, early stopping considers the improvement to be zero.  
  
Optional  
Valid values: Positive floating-point integer  
Default value: 0.001 |
| epochs                                      | The maximum number of passes over the training data.  
  
Optional  
Valid values: Positive integer  
Default value: 15 |
<table>

</thead>
</table>
| f_beta         | The value of beta to use when calculating F score metrics for binary or multiclass classification. Also used if the value specified for binary_classifier_model_selection_criteria is f_beta.  
  **Optional**  
  Valid values: Positive floating-point integers  
  Default value: 1.0 |
| feature_dim    | The number of features in the input data.  
  **Optional**  
  Valid values: auto or positive integer  
  Default values: auto |
| huber_delta    | The parameter for Huber loss. During training and metric evaluation, compute L2 loss for errors smaller than delta and L1 loss for errors larger than delta.  
  **Optional**  
  Valid values: Positive floating-point integer  
  Default value: 1.0 |
| init_bias      | Initial weight for the bias term.  
  **Optional**  
  Valid values: Floating-point integer  
  Default value: 0 |
| init_method    | Sets the initial distribution function used for model weights. Functions include:  
  • uniform—Uniformly distributed between (-scale, +scale)  
  • normal—Normal distribution, with mean 0 and sigma  
  **Optional**  
  Valid values: uniform or normal  
  Default value: uniform |
| init_scale     | Scales an initial uniform distribution for model weights. Applies only when the init_method hyperparameter is set to uniform.  
  **Optional**  
  Valid values: Positive floating-point integer  
  Default value: 0.07 |
<table>
<thead>
<tr>

### Parameter Name | Description
--- | ---
**target_recall** | The target recall. If `binary_classifier_model_selection_criteria` is `precision_at_target_recall`, then recall is held at this value while precision is maximized.
- **Optional**
- Valid values: Floating-point integer between 0 and 1.0
- Default value: 0.8

**unbias_data** | Unbiases the features before training so that the mean is 0. By default data is unbiased as the `use_bias` hyperparameter is set to `true`.
- **Optional**
- Valid values: `auto`, `true`, or `false`
- Default value: `auto`

**unbias_label** | Unbiases labels before training so that the mean is 0. Applies to regression only if the `use_bias` hyperparameter is set to `true`.
- **Optional**
- Valid values: `auto`, `true`, or `false`
- Default value: `auto`

**use_bias** | Specifies whether the model should include a bias term, which is the intercept term in the linear equation.
- **Optional**
- Valid values: `true` or `false`
- Default value: `true`

**use_lr_scheduler** | Whether to use a scheduler for the learning rate. If you want to use a scheduler, specify `true`.
- **Optional**
- Valid values: `true` or `false`
- Default value: `true`

**wd** | The weight decay parameter, also known as the L2 regularization parameter. If you don't want to use L2 regularization, set the value to 0.
- **Optional**
- Valid values: `auto` or non-negative floating-point integer
- Default value: `auto`
Tune a linear learner model

*Automatic model tuning,* also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The linear learner algorithm also has an internal mechanism for tuning hyperparameters separate from the automatic model tuning feature described here. By default, the linear learner algorithm tunes hyperparameters by training multiple models in parallel. When you use automatic model tuning, the linear learner internal tuning mechanism is turned off automatically. This sets the number of parallel models, `num_models`, to 1. The algorithm ignores any value that you set for `num_models`.

For more information about model tuning, see *Perform Automatic Model Tuning with SageMaker* (p. 1715).

Metrics computed by the linear learner algorithm

The linear learner algorithm reports the metrics in the following table, which are computed during training. Choose one of them as the objective metric. To avoid overfitting, we recommend tuning the model against a validation metric instead of a training metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>test:objective_loss</td>
<td>The mean value of the objective loss function on the test dataset after the model is trained. By default, the loss is logistic loss for binary classification and squared loss for regression. To set the loss to other types, use the loss hyperparameter.</td>
<td>Minimize</td>
</tr>
<tr>
<td>test:binary_classifiers_accuracy</td>
<td>The accuracy of the final model on the test dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:binary_f_beta</td>
<td>The F_beta score of the final model on the test dataset. By default, it is the F1 score, which is the harmonic mean of precision and recall.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:precision</td>
<td>The precision of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target recall by setting the binary_classifier_model_selection hyperparameter to precision_at_target_recall and setting the value for the target_recall hyperparameter.</td>
<td>Maximize</td>
</tr>
<tr>
<td>test:recall</td>
<td>The recall of the final model on the test dataset. If you choose this metric as the objective, we recommend setting a target precision by setting the binary_classifier_model_selection hyperparameter to recall_at_target_precision and setting the value for the target_precision hyperparameter.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:objective_loss</td>
<td>The mean value of the objective loss function on the validation dataset every epoch. By default,</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

Linear learner response formats

JSON response formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. The following are the available output formats for the SageMaker linear learner algorithm.

Binary Classification

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4,
      "predicted_label": 0
    }
  ]
}
```

Multiclass Classification

```javascript
let response = {
  "predictions": [
    {
      "score": [0.1, 0.2, 0.4, 0.3],
      "predicted_label": 2
    }
  ]
}
```

Regression

```javascript
let response = {
  "predictions": [
    {
      "score": 0.4
    }
  ]
}
```

JSONLINES response formats

Binary Classification

```
{"score": 0.4, "predicted_label": 0}
```

Multiclass Classification

```
{"score": [0.1, 0.2, 0.4, 0.3], "predicted_label": 2}
```

Regression

```
{"score": 0.4}
```

RECORDIO response formats

Binary Classification

}
]

**Neural Topic Model (NTM) Algorithm**

Amazon SageMaker NTM is an unsupervised learning algorithm that is used to organize a corpus of documents into *topics* that contain word groupings based on their statistical distribution. Documents that contain frequent occurrences of words such as "bike", "car", "train", "mileage", and "speed" are likely to share a topic on "transportation" for example. Topic modeling can be used to classify or summarize documents based on the topics detected or to retrieve information or recommend content based on topic similarities. The topics from documents that NTM learns are characterized as a *latent representation* because the topics are inferred from the observed word distributions in the corpus. The semantics of topics are usually inferred by examining the top ranking words they contain. Because the method is unsupervised, only the number of topics, not the topics themselves, are prespecified. In addition, the topics are not guaranteed to align with how a human might naturally categorize documents.
Topic modeling provides a way to visualize the contents of a large document corpus in terms of the learned topics. Documents relevant to each topic might be indexed or searched for based on their soft topic labels. The latent representations of documents might also be used to find similar documents in the topic space. You can also use the latent representations of documents that the topic model learns for input to another supervised algorithm such as a document classifier. Because the latent representations of documents are expected to capture the semantics of the underlying documents, algorithms based in part on these representations are expected to perform better than those based on lexical features alone.

Although you can use both the Amazon SageMaker NTM and LDA algorithms for topic modeling, they are distinct algorithms and can be expected to produce different results on the same input data.

For more information on the mathematics behind NTM, see Neural Variational Inference for Text Processing.

Input/Output Interface for the NTM Algorithm

Amazon SageMaker Neural Topic Model supports four data channels: train, validation, test, and auxiliary. The validation, test, and auxiliary data channels are optional. If you specify any of these optional channels, set the value of the S3DataDistributionType parameter for them to FullyReplicated. If you provide validation data, the loss on this data is logged at every epoch, and the model stops training as soon as it detects that the validation loss is not improving. If you don't provide validation data, the algorithm stops early based on the training data, but this can be less efficient. If you provide test data, the algorithm reports the test loss from the final model.

The train, validation, and test data channels for NTM support both recordIO-wrapped-protobuf (dense and sparse) and CSV file formats. For CSV format, each row must be represented densely with zero counts for words not present in the corresponding document, and have dimension equal to: (number of records) * (vocabulary size). You can use either File mode or Pipe mode to train models on data that is formatted as recordIO-wrapped-protobuf or as CSV. The auxiliary channel is used to supply a text file that contains vocabulary. By supplying the vocabulary file, users are able to see the top words for each of the topics printed in the log instead of their integer IDs. Having the vocabulary file also allows NTM to compute the Word Embedding Topic Coherence (WETC) scores, a new metric displayed in the log that captures similarity among the top words in each topic effectively. The ContentType for the auxiliary channel is text/plain, with each line containing a single word, in the order corresponding to the integer IDs provided in the data. The vocabulary file must be named vocab.txt and currently only UTF-8 encoding is supported.

For inference, text/csv, application/json, application/jsonlines, and application/x-recordio-protobuf content types are supported. Sparse data can also be passed for application/json and application/x-recordio-protobuf. NTM inference returns application/json or application/x-recordio-protobuf predictions, which include the topic_weights vector for each observation.

See the blog post and the companion notebook for more details on using the auxiliary channel and the WETC scores. For more information on how to compute the WETC score, see Coherence-Aware Neural Topic Modeling. We used the pairwise WETC described in this paper for the Amazon SageMaker Neural Topic Model.
For more information on input and output file formats, see NTM Response Formats (p. 1419) for inference and the NTM Sample Notebooks (p. 1416).

EC2 Instance Recommendation for the NTM Algorithm

NTM training supports both GPU and CPU instance types. We recommend GPU instances, but for certain workloads, CPU instances may result in lower training costs. CPU instances should be sufficient for inference.

NTM Sample Notebooks

For a sample notebook that uses the SageMaker NTM algorithm to uncover topics in documents from a synthetic data source where the topic distributions are known, see the Introduction to Basic Functionality of NTM. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**Tune an NTM Model**

*Automatic model tuning,* also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.
Amazon SageMaker NTM is an unsupervised learning algorithm that learns latent representations of large collections of discrete data, such as a corpus of documents. Latent representations use inferred variables that are not directly measured to model the observations in a dataset. Automatic model tuning on NTM helps you find the model that minimizes loss over the training or validation data. Training loss measures how well the model fits the training data. Validation loss measures how well the model can generalize to data that it is not trained on. Low training loss indicates that a model is a good fit to the training data. Low validation loss indicates that a model has not overfit the training data and so should be able to model documents successfully on which it has not been trained. Usually, it's preferable to have both losses be small. However, minimizing training loss too much might result in overfitting and increase validation loss, which would reduce the generality of the model.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the NTM Algorithm**

The NTM algorithm reports a single metric that is computed during training: `validation:total_loss`. The total loss is the sum of the reconstruction loss and Kullback-Leibler divergence. When tuning hyperparameter values, choose this metric as the objective.

<table>

<td><code>validation:total_loss</code></td>
<td>Total Loss on validation set</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable NTM Hyperparameters**

You can tune the following hyperparameters for the NTM algorithm. Usually setting low `mini_batch_size` and small `learning_rate` values results in lower validation losses, although it might take longer to train. Low validation losses don't necessarily produce more coherent topics as interpreted by humans. The effect of other hyperparameters on training and validation loss can vary from dataset to dataset. To see which values are compatible, see NTM Hyperparameters (p. 1416).

**NTM Response Formats**

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker NTM algorithm.
Object2Vec Algorithm

The Amazon SageMaker Object2Vec algorithm is a general-purpose neural embedding algorithm that is highly customizable. It can learn low-dimensional dense embeddings of high-dimensional objects. The embeddings are learned in a way that preserves the semantics of the relationship between pairs of objects in the original space in the embedding space. You can use the learned embeddings to efficiently compute nearest neighbors of objects and to visualize natural clusters of related objects in low-dimensional space, for example. You can also use the embeddings as features of the corresponding objects in downstream supervised tasks, such as classification or regression.

Object2Vec generalizes the well-known Word2Vec embedding technique for words that is optimized in the SageMaker BlazingText algorithm (p. 1321). For a blog post that discusses how to apply Object2Vec to some practical use cases, see Introduction to Amazon SageMaker Object2Vec.

I/O Interface for the Object2Vec Algorithm

You can use Object2Vec on many input data types, including the following examples.

<table>
<thead>
<tr>
<th>Input Data Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sentence-sentence pairs</td>
<td>&quot;A soccer game with multiple males playing.&quot; and &quot;Some men are playing a sport.&quot;</td>
</tr>
</tbody>
</table>
| Labels-sequence pairs            | The genre tags of the movie "Titanic", such as "Romance" and "Drama", and its short description: "James Cameron's Titanic is an epic, action-packed romance set against the ill-fated maiden voyage of the R.M.S. Titanic. She was the most luxurious liner of her era, a ship of dreams, which ultimately carried over 1,500 people to their death in the ice cold waters of the North Atlantic in the early hours of April 15, 1912."
| Customer-customer pairs          | The customer ID of Jane and customer ID of Jackie.                      |
| Product-product pairs            | The product ID of football and product ID of basketball.                |
| Item review user-item pairs      | A user's ID and the items she has bought, such as apple, pear, and orange. |

To transform the input data into the supported formats, you must preprocess it. Currently, Object2Vec natively supports two types of input:

- A discrete token, which is represented as a list of a single integer-id. For example, [10].
- A sequences of discrete tokens, which is represented as a list of integer-ids. For example, [0,12,10,13].

The object in each pair can be asymmetric. For example, the pairs can be (token, sequence) or (token, token) or (sequence, sequence). For token inputs, the algorithm supports simple embeddings as compatible encoders. For sequences of token vectors, the algorithm supports the following as encoders:

- Average-pooled embeddings
- Hierarchical convolutional neural networks (CNNs),
- Multi-layered bidirectional long short-term memory (BiLSTMs)

The input label for each pair can be one of the following:

- A categorical label that expresses the relationship between the objects in the pair
- A score that expresses the strength of the similarity between the two objects

For categorical labels used in classification, the algorithm supports the cross-entropy loss function. For ratings/score-based labels used in regression, the algorithm supports the mean squared error (MSE) loss.
function. Specify these loss functions with the `output_layer` hyperparameter when you create the model training job.

**EC2 Instance Recommendation for the Object2Vec Algorithm**

The type of Amazon Elastic Compute Cloud (Amazon EC2) instance that you use depends on whether you are training or running inferences.

**Instance Recommendation for Training**

When training a model using the Object2Vec algorithm on a CPU, start with an `ml.m5.2xlarge` instance. For training on a GPU, start with an `ml.p2.xlarge` instance. If the training takes too long on this instance, you can use a larger instance, such as an `ml.m5.4xlarge` or an `ml.m5.12xlarge` instance. Currently, the Object2Vec algorithm can train only on a single machine. However, it does offer support for multiple GPUs.

**Instance Recommendation for Inference**

For inference with a trained Object2Vec model that has a deep neural network, we recommend using `ml.p3.2xlarge` GPU instance. Due to GPU memory scarcity, the `INFECTION_PREFERRED_MODE` environment variable can be specified to optimize on whether the section called “GPU optimization: Classification or Regression” (p. 1434) or the section called “GPU optimization: Encoder Embeddings” (p. 1435) inference network is loaded into GPU.

**Object2Vec Sample Notebooks**

- Using Object2Vec to Encode Sentences into Fixed Length Embeddings
- Using Object2Vec to learn document embeddings

**Note**

To run the notebooks on a notebook instance, see Example Notebooks (p. 130). To run the notebooks on Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81).

**How Object2Vec Works**

When using the Amazon SageMaker Object2Vec algorithm, you follow the standard workflow: process the data, train the model, and produce inferences.

**Topics**

- Step 1: Process Data (p. 1422)
- Step 2: Train a Model (p. 1422)
- Step 3: Produce Inferences (p. 1423)

**Step 1: Process Data**

During preprocessing, convert the data to the JSON Lines text file format specified in Data Formats for Object2Vec Training (p. 1434). To get the highest accuracy during training, also randomly shuffle the data before feeding it into the model. How you generate random permutations depends on the language. For python, you could use `np.random.shuffle`; for Unix, `shuf`.

**Step 2: Train a Model**

The SageMaker Object2Vec algorithm has the following main components:

- **Two input channels** – The input channels take a pair of objects of the same or different types as inputs, and pass them to independent and customizable encoders.
• **Two encoders** – The two encoders, enc0 and enc1, convert each object into a fixed-length embedding vector. The encoded embeddings of the objects in the pair are then passed into a comparator.

• **A comparator** – The comparator compares the embeddings in different ways and outputs scores that indicate the strength of the relationship between the paired objects. In the output score for a sentence pair, for example, 1 indicates a strong relationship between a sentence pair, and 0 represents a weak relationship.

During training, the algorithm accepts pairs of objects and their relationship labels or scores as inputs. The objects in each pair can be of different types, as described earlier. If the inputs to both encoders are composed of the same token-level units, you can use a shared token embedding layer by setting the `tied_token_embedding_weight` hyperparameter to True when you create the training job. This is possible, for example, when comparing sentences that both have word token-level units. To generate negative samples at a specified rate, set the `negative_sampling_rate` hyperparameter to the desired ratio of negative to positive samples. This hyperparameter expedites learning how to discriminate between the positive samples observed in the training data and the negative samples that are not likely to be observed.

Pairs of objects are passed through independent, customizable encoders that are compatible with the input types of corresponding objects. The encoders convert each object in a pair into a fixed-length embedding vector of equal length. The pair of vectors are passed to a comparator operator, which assembles the vectors into a single vector using the value specified in the `comparator_list` hyperparameter. The assembled vector then passes through a multilayer perceptron (MLP) layer, which produces an output that the loss function compares with the labels that you provided. This comparison evaluates the strength of the relationship between the objects in the pair as predicted by the model. The following figure shows this workflow.

![Architecture of the Object2Vec Algorithm from Data Inputs to Scores](image)

**Step 3: Produce Inferences**

After the model is trained, you can use the trained encoder to preprocess input objects or to perform two types of inference:

• To convert singleton input objects into fixed-length embeddings using the corresponding encoder
• To predict the relationship label or score between a pair of input objects

The inference server automatically figures out which of the types is requested based on the input data. To get the embeddings as output, provide only one input. To predict the relationship label or score, provide both inputs in the pair.

Object2Vec Hyperparameters

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific hyperparameters as string-to-string maps. The following table lists the hyperparameters for the Object2Vec training algorithm.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enc0_max_seq_len</td>
<td>The maximum sequence length for the enc0 encoder.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 1 ≤ integer ≤ 5000</td>
</tr>
<tr>
<td>enc0_vocab_size</td>
<td>The vocabulary size of enc0 tokens.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 2 ≤ integer ≤ 3000000</td>
</tr>
<tr>
<td>bucket_width</td>
<td>The allowed difference between data sequence length when bucketing is enabled. To enable bucketing, specify a non-zero value for this parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 0 ≤ integer ≤ 100</td>
</tr>
<tr>
<td></td>
<td>Default value: 0 (no bucketing)</td>
</tr>
<tr>
<td>comparator_list</td>
<td>A list used to customize the way in which two embeddings are compared. The Object2Vec comparator operator layer takes the encodings from both encoders as inputs and outputs a single vector. This vector is a concatenation of subvectors. The string values passed to the comparator_list and the order in which they are passed determine how these subvectors are assembled. For example, if comparator_list=&quot;hadamard, concat&quot;, then the comparator operator constructs the vector by concatenating the Hadamard product of two encodings and the concatenation of two encodings. If, on the other hand, comparator_list=&quot;hadamard&quot;, then the comparator operator constructs the vector as the hadamard product of only two encodings.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: A string that contains any combination of the names of the three binary operators: hadamard, concat, or abs_diff.</td>
</tr>
<tr>
<td></td>
<td>The Object2Vec algorithm currently requires that the two vector encodings have the same dimension. These operators produce the subvectors as follows:</td>
</tr>
<tr>
<td></td>
<td>• hadamard: Constructs a vector as the Hadamard (element-wise) product of two encodings.</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
|                           | • **concat**: Constructs a vector as the concatenation of two encodings.  
<p>|                           | • <strong>abs_diff</strong>: Constructs a vector as the absolute difference between two encodings.                                                                                                                      |
|                           | Default value: &quot;hadamard, concat, abs_diff&quot;                                                                                                                                                                |
| dropout                   | The dropout probability for network layers. <em>Dropout</em> is a form of regularization used in neural networks that reduces overfitting by trimming codependent neurons.                                           |
|                           | <strong>Optional</strong>                                                                                                                                                                                                |
|                           | Valid values: $0.0 \leq \text{float} \leq 1.0$                                                                                                                                                             |
|                           | Default value: 0.0                                                                                                                                                                                            |
| early_stopping_patience   | The number of consecutive epochs without improvement allowed before early stopping is applied. Improvement is defined by with the early_stopping_tolerance hyperparameter.                                    |
|                           | <strong>Optional</strong>                                                                                                                                                                                                |
|                           | Valid values: $1 \leq \text{integer} \leq 5$                                                                                                                                                                |
|                           | Default value: 3                                                                                                                                                                                             |
| early_stopping_tolerance  | The reduction in the loss function that an algorithm must achieve between consecutive epochs to avoid early stopping after the number of consecutive epochs specified in the early_stopping_patience hyperparameter concludes. |
|                           | <strong>Optional</strong>                                                                                                                                                                                                |
|                           | Valid values: $0.000001 \leq \text{float} \leq 0.1$                                                                                                                                                         |
|                           | Default value: 0.01                                                                                                                                                                                           |
| enc_dim                   | The dimension of the output of the embedding layer.                                                                                                                                                           |
|                           | <strong>Optional</strong>                                                                                                                                                                                                |
|                           | Valid values: $4 \leq \text{integer} \leq 10000$                                                                                                                                                            |
|                           | Default value: 4096                                                                                                                                                                                           |</p>

<tr>
<td>negative_sampling_rate</td>
<td>The ratio of negative samples, generated to assist in training the algorithm, to positive samples that are provided by users. Negative samples represent data that is unlikely to occur in reality and are labelled negatively for training. They facilitate training a model to discriminate between the positive samples observed and the negative samples that are not. To specify the ratio of negative samples to positive samples used for training, set the value to a positive integer. For example, if you train the algorithm on input data in which all of the samples are positive and set <code>negative_sampling_rate</code> to 2, the Object2Vec algorithm internally generates two negative samples per positive sample. If you don't want to generate or use negative samples during training, set the value to 0. <strong>Optional</strong>&lt;br&gt;Valid values: $0 \leq \text{integer}$&lt;br&gt;Default value: 0 (off)</td>

**Tune an Object2Vec Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. For the objective metric, you use one of the metrics that the algorithm computes. Automatic model tuning searches the chosen hyperparameters to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm has both classification and regression metrics. The `output_layer` type determines which metric you can use for automatic model tuning.

**Regressor Metrics Computed by the Object2Vec Algorithm**

The algorithm reports a mean squared error regressor metric, which is computed during testing and validation. When tuning the model for regression tasks, choose this metric as the objective.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

<td>test:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
<tr>
<td>validation:mean_squared_error</td>
<td>The Mean Square Error</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Classification Metrics Computed by the Object2Vec Algorithm**

The Object2Vec algorithm reports accuracy and cross-entropy classification metrics, which are computed during test and validation. When tuning the model for classification tasks, choose one of these as the objective.

<table>

Data Formats for Object2Vec Training

Input: JSON Lines Request Format

Content-type: application/jsonlines

```json
{"label": 0, "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"label": 1, "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"label": 1, "in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```

The "in0" and "in1" are the inputs for encoder0 and encoder1, respectively. The same format is valid for both classification and regression problems. For regression, the field "label" can accept real valued inputs.

Data Formats for Object2Vec Inference

GPU optimization: Classification or Regression

Due to GPU memory scarcity, the `INFERENCES_PREFERRED_MODE` environment variable can be specified to optimize on whether the classification/regression or the section called “Output: Encoder Embeddings” (p. 1436) inference network is loaded into GPU. If the majority of your inference is for classification or regression, specify `INFERENCES_PREFERRED_MODE=classification`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for classification/regression inference:

```python
transformer = o2v.transformer(instance_count=4,
instance_type="ml.p2.xlarge",
max_concurrent_transforms=2,
max_payload=1, # 1MB
strategy='MultiRecord',
env={'INFERENCES_PREFERRED_MODE': 'classification'}, # only useful with GPU
output_path=output_s3_path)
```

Input: Classification or Regression Request Format

Content-type: application/json

```json
{
 "instances" : [
   {"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]},
   {"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]},
   {"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
]
}
```

Content-type: application/jsonlines

```json
{"in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4], "in1": [16, 21, 13, 45, 14, 9, 80, 59, 164, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4], "in1": [22, 32, 13, 25, 1016, 573, 3252, 4]}
{"in0": [774, 14, 21, 206], "in1": [21, 366, 125]}
```
For classification problems, the length of the scores vector corresponds to `num_classes`. For regression problems, the length is 1.

**Output: Classification or Regression Response Format**

```
Accept: application/json

```{ "predictions": [  
  {  "scores": [  
    0.6533935070037842,  
    0.07582679390907288,  
    0.2707797586917877  
  ],  
  },  
  {  "scores": [  
    0.026291321963071823,  
    0.6577019095420837,  
    0.31600672006607056  
  ]  
  }  
]}

Accept: application/jsonlines

```{  
"scores":[0.195667684078216,0.395351558923721,0.408980727195739],  
"scores":[0.251988261938095,0.258233487606048,0.489778339862823],  
"scores":[0.280087798833847,0.368331134319305,0.351581096649169]  
}  

In both the classification and regression formats, the scores apply to individual labels.

**Encoder Embeddings for Object2Vec**

**GPU optimization: Encoder Embeddings**

An embedding is a mapping from discrete objects, such as words, to vectors of real numbers.

Due to GPU memory scarcity, the `INFEERENCE_PREFERRED_MODE` environment variable can be specified to optimize on whether the the section called "Inference Formats: Scoring" (p. 1434) or the encoder embedding inference network is loaded into GPU. If the majority of your inference is for encoder embeddings, specify `INFEERENCE_PREFERRED_MODE=embedding`. The following is a Batch Transform example of using 4 instances of p3.2xlarge that optimizes for encoder embedding inference:

```
transformer = o2v.transformer(instance_count=4,  
instance_type="ml.p2.xlarge",  
max_concurrent_transforms=2,  
max_payload=1,  
strategy='MultiRecord',  
env={'INFEERENCE_PREFERRED_MODE': 'embedding'},  
output_path=output_s3_path)  
```

**Input: Encoder Embeddings**

Content-type: application/json; infer_max_seqlen=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.
Use built-in algorithms

```json
{
  "instances": [
    {
      "in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]
    },
    {
      "in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]
    },
    {
      "in0": [774, 14, 21, 206]
    }
  ]
}
```

Content-type: application/jsonlines; infer_max_seqLens=<FWD-LENGTH>,<BCK-LENGTH>

Where `<FWD-LENGTH>` and `<BCK-LENGTH>` are integers in the range [1,5000] and define the maximum sequence lengths for the forward and backward encoder.

```json
["in0": [6, 17, 606, 19, 53, 67, 52, 12, 5, 10, 15, 10178, 7, 33, 652, 80, 15, 69, 821, 4]}
{"in0": [22, 1016, 32, 13, 25, 11, 5, 64, 573, 45, 5, 80, 15, 67, 21, 7, 9, 107, 4]}
{"in0": [774, 14, 21, 206]}
```

In both of these formats, you specify only one input type: "in0" or "in1." The inference service then invokes the corresponding encoder and outputs the embeddings for each of the instances.

**Output: Encoder Embeddings**

Content-type: application/json

```json
{
  "predictions": [
    {
      "embeddings": [0.057368703186511, 0.030703511089086, 0.099890425801277, 0.063688032329082, 0.026327300816774, 0.003637571120634, 0.021305780857801, 0.004316598642617, 0.0, 0.003397724591195, 0.0, 0.000378780066967, 0.0, 0.0, 0.0, 0.007419463712722]
    },
    {
      "embeddings": [0.150190666317939, 0.05145975202322, 0.098204270005226, 0.064249359071254, 0.056249320507049, 0.01513972133398, 0.047553978860378, 0.0, 0.0, 0.011533712036907, 0.011472506448626, 0.010696629062294, 0.0, 0.0, 0.0, 0.008508535102009]
    }
  ]
}
```

The vector length of the embeddings output by the inference service is equal to the value of one of the following hyperparameters that you specify at training time: `enc0_token_embedding_dim`, `enc1_token_embedding_dim`, or `enc_dim`.

**Object Detection Algorithm**

The Amazon SageMaker Object Detection algorithm detects and classifies objects in images using a single deep neural network. It is a supervised learning algorithm that takes images as input and identifies all instances of objects within the image scene. The object is categorized into one of the classes in a specified collection with a confidence score that it belongs to the class. Its location and scale in the image are indicated by a rectangular bounding box. It uses the Single Shot multibox Detector (SSD) framework and supports two base networks: VGG and ResNet. The network can be trained from scratch, or trained with models that have been pre-trained on the ImageNet dataset.

**Topics**

- [Input/Output Interface for the Object Detection Algorithm (p. 1437)](#)
- [EC2 Instance Recommendation for the Object Detection Algorithm (p. 1439)](#)
Input/Output Interface for the Object Detection Algorithm

The SageMaker Object Detection algorithm supports both RecordIO (application/x-recordio) and image (image/png, image/jpeg, and application/x-image) content types for training in file mode and supports RecordIO (application/x-recordio) for training in pipe mode. However, you can also train in pipe mode using the image files (image/png, image/jpeg, and application/x-image), without creating RecordIO files, by using the augmented manifest format. The recommended input format for the Amazon SageMaker object detection algorithms is Apache MXNet RecordIO. However, you can also use raw images in .jpg or .png format. The algorithm supports only application/x-image for inference.

Note
To maintain better interoperability with existing deep learning frameworks, this differs from the protobuf data formats commonly used by other Amazon SageMaker algorithms.

See the Object Detection Sample Notebooks (p. 1439) for more details on data formats.

Train with the RecordIO Format

If you use the RecordIO format for training, specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Specify one RecordIO (.rec) file in the train channel and one RecordIO file in the validation channel. Set the content type for both channels to application/x-recordio. An example of how to generate RecordIO file can be found in the object detection sample notebook. You can also use tools from the MXNet's GluonCV to generate RecordIO files for popular datasets like the PASCAL Visual Object Classes and Common Objects in Context (COCO).

Train with the Image Format

If you use the image format for training, specify train, validation, train_annotation, and validation_annotation channels as values for the InputDataConfig parameter of CreateTrainingJob request. Specify the individual image data (.jpg or .png) files for the train and validation channels. For annotation data, you can use the JSON format. Specify the corresponding .json files in the train_annotation and validation_annotation channels. Set the content type for all four channels to image/png or image/jpeg based on the image type. You can also use the content type application/x-image when your dataset contains both .jpg and .png images. The following is an example of a .json file.

```json
{
    "file": "your_image_directory/sample_image1.jpg",
    "image_size": [
        {
            "width": 500,
            "height": 400,
            "depth": 3
        }
    ],
    "annotations": [
        {
            "class_id": 0,
            "left": 111,
            "top": 134,
            "width": 61,
            "height": 128
        }
    ]
}
```
Each image needs a .json file for annotation, and the .json file should have the same name as the corresponding image. The name of above .json file should be "sample_image1.json". There are four properties in the annotation .json file. The property "file" specifies the relative path of the image file. For example, if your training images and corresponding .json files are stored in s3://your_bucket/train/sample_image and s3://your_bucket/train_annotation, specify the path for your train and train_annotation channels as s3://your_bucket/train and s3://your_bucket/train_annotation, respectively.

In the .json file, the relative path for an image named sample_image1.jpg should be sample_image/sample_image1.jpg. The "image_size" property specifies the overall image dimensions. The SageMaker object detection algorithm currently only supports 3-channel images. The "annotations" property specifies the categories and bounding boxes for objects within the image. Each object is annotated by a "class_id" index and by four bounding box coordinates ("left", "top", "width", "height"). The "left" (x-coordinate) and "top" (y-coordinate) values represent the upper-left corner of the bounding box. The "width" (x-coordinate) and "height" (y-coordinate) values represent the dimensions of the bounding box. The origin (0, 0) is the upper-left corner of the entire image. If you have multiple objects within one image, all the annotations should be included in a single .json file. The "categories" property stores the mapping between the class index and class name. The class indices should be numbered successively and the numbering should start with 0. The "categories" property is optional for the annotation .json file.

**Train with Augmented Manifest Image Format**

The augmented manifest format enables you to do training in pipe mode using image files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. While using the format, an S3 manifest file needs to be generated that contains the list of images and their corresponding annotations. The manifest file format should be in JSON Lines format in which each line represents one sample. The images are specified using the 'source-ref' tag that points to the S3 location of the image. The annotations are provided under the "AttributeNames" parameter value as specified in the CreateTrainingJob request. It can also contain additional metadata under the metadata tag, but these are ignored by the algorithm. In the following example, the "AttributeNames are contained in the list ['source-ref', 'bounding-box']:
The order of "AttributeNames" in the input files matters when training the Object Detection algorithm. It accepts piped data in a specific order, with image first, followed by annotations. So the "AttributeNames" in this example are provided with "source-ref" first, followed by "bounding-box". When using Object Detection with Augmented Manifest, the value of parameter RecordWrapperType must be set as "RecordIO".

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File](p. 1828).

**Incremental Training**

You can also seed the training of a new model with the artifacts from a model that you trained previously with SageMaker. Incremental training saves training time when you want to train a new model with the same or similar data. SageMaker object detection models can be seeded only with another built-in object detection model trained in SageMaker.

To use a pretrained model, in the `CreateTrainingJob` request, specify the ChannelName as "model" in the `InputDataConfig` parameter. Set the `ContentType` for the model channel to `application/x-sagemaker-model`. The input hyperparameters of both the new model and the pretrained model that you upload to the model channel must have the same settings for the `base_network` and `num_classes` input parameters. These parameters define the network architecture. For the pretrained model file, use the compressed model artifacts (in .tar.gz format) output by SageMaker. You can use either RecordIO or image formats for input data.

For a sample notebook that shows how to use incremental training with the SageMaker object detection algorithm, see [SageMaker Object Detection Incremental Training sample notebook](p. 1819). For more information on incremental training and for instructions on how to use it, see [Incremental Training in Amazon SageMaker](p. 1819).

**EC2 Instance Recommendation for the Object Detection Algorithm**

For object detection, we support the following GPU instances for training: ml.p2.xlarge, ml.p2.8xlarge, ml.p2.16xlarge, ml.p3.2xlarge, ml.p3.8xlarge, and ml.p3.16xlarge. We recommend using GPU instances with more memory for training with large batch sizes. You can also run the algorithm on multi-GPU and multi-machine settings for distributed training. However, both CPU (such as C5 and M5) and GPU (such as P2 and P3) instances can be used for the inference. All the supported instance types for inference are itemized on Amazon SageMaker ML Instance Types.

**Object Detection Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Object Detection algorithm to train and host a model on the COCO dataset using the Single Shot multibox Detector algorithm, see [Object Detection using the Image and JSON format](p. 119). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](p. 119). Once you have created a notebook instance and opened it, select the [SageMaker Examples](p. 119) tab to see a list of all the SageMaker samples. The object detection example notebook using the Object Detection algorithm is located in the [Introduction to Amazon Algorithms](p. 119) section. To open a notebook, click on its [Use](p. 119) tab and select [Create copy](p. 119).
How Object Detection Works

The object detection algorithm identifies and locates all instances of objects in an image from a known collection of object categories. The algorithm takes an image as input and outputs the category that the object belongs to, along with a confidence score that it belongs to the category. The algorithm also predicts the object's location and scale with a rectangular bounding box. Amazon SageMaker Object Detection uses the Single Shot multibox Detector (SSD) algorithm that takes a convolutional neural network (CNN) pretrained for classification task as the base network. SSD uses the output of intermediate layers as features for detection.

Various CNNs such as VGG and ResNet have achieved great performance on the image classification task. Object detection in Amazon SageMaker supports both VGG-16 and ResNet-50 as a base network for SSD. The algorithm can be trained in full training mode or in transfer learning mode. In full training mode, the base network is initialized with random weights and then trained on user data. In transfer learning mode, the base network weights are loaded from pretrained models.

The object detection algorithm uses standard data augmentation operations, such as flip, rescale, and jitter, on the fly internally to help avoid overfitting.

Object Detection Hyperparameters

In the `CreateTrainingJob` request, you specify the training algorithm that you want to use. You can also specify algorithm-specific hyperparameters that are used to help estimate the parameters of the model from a training dataset. The following table lists the hyperparameters provided by Amazon SageMaker for training the object detection algorithm. For more information about how object training works, see How Object Detection Works (p. 1440).

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_classes</td>
<td>The number of output classes. This parameter defines the dimensions of the network output and is typically set to the number of classes in the dataset.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: positive integer</td>
</tr>
<tr>
<td>num_training_samples</td>
<td>The number of training examples in the input dataset.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>If there is a mismatch between this value and the number of samples in the training set, then the behavior of the lr_scheduler_step parameter will be undefined and distributed training accuracy may be affected.</td>

</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>freeze_layer_pattern</code></td>
<td>The regular expression (regex) for freezing layers in the base network. For example, if we set `freeze_layer_pattern = &quot;^(conv1_</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: string</td>
</tr>
<tr>
<td></td>
<td>Default: No layers frozen.</td>
</tr>
<tr>
<td><code>kv_store</code></td>
<td>The weight update synchronization mode used for distributed training. The weights can be updated either synchronously or asynchronously across machines. Synchronous updates typically provide better accuracy than asynchronous updates but can be slower. See the Distributed Training MXNet tutorial for details.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td></td>
<td>This parameter is not applicable to single machine training.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: 'dist_sync' or 'dist_async'</td>
</tr>
<tr>
<td></td>
<td>• 'dist_sync': The gradients are synchronized after every batch with all the workers. With 'dist_sync', batch-size now means the batch size used on each machine. So if there are n machines and we use batch size b, then dist_sync behaves like a single machine with batch size n*b.</td>
</tr>
<tr>
<td></td>
<td>• 'dist_async': Performs asynchronous updates. The weights are updated whenever gradients are received from any machine and the weight updates are atomic. However, the order is not guaranteed.</td>
</tr>
<tr>
<td></td>
<td>Default: -</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| label_width         | The force padding label width used to sync across training and validation data. For example, if one image in the data contains at most 10 objects, and each object's annotation is specified with 5 numbers, [class_id, left, top, width, height], then the label_width should be no smaller than (10*5 + header information length). The header information length is usually 2. We recommend using a slightly larger label_width for the training, such as 60 for this example.  
Optional  
Valid values: Positive integer large enough to accommodate the largest annotation information length in the data.  
Default: 350                                                                                           |
| learning_rate       | The initial learning rate.                                                                                                                  |
|                     | Optional  
Valid values: float in (0, 1)                                                                                                             |
|                     | Default: 0.001                                                                                                                             |
| lr_scheduler_factor | The ratio to reduce learning rate. Used in conjunction with the lr_scheduler_step parameter defined as \( lr_{new} = lr_{old} \times lr\_scheduler\_factor \).  
Optional  
Valid values: float in (0, 1)                                                                 |
|                     | Default: 0.1                                                                                                                              |
| lr_scheduler_step   | The epochs at which to reduce the learning rate. The learning rate is reduced by lr_scheduler_factor at epochs listed in a comma-delimited string: "epoch1, epoch2, ...". For example, if the value is set to "10, 20" and the lr_scheduler_factor is set to 1/2, then the learning rate is halved after 10th epoch and then halved again after 20th epoch.  
Optional  
Valid values: string  |
<p>|                     | Default: empty string                                                                                                                     |</p>
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mini_batch_size</td>
<td>The batch size for training. In a single-machine multi-gpu setting, each GPU handles mini_batch_size/num_gpu training samples. For the multi-machine training in dist_sync mode, the actual batch size is mini_batch_size*number of machines. A large mini_batch_size usually leads to faster training, but it may cause out of memory problem. The memory usage is related to mini_batch_size, image_shape, and base_network architecture. For example, on a single p3.2xlarge instance, the largest mini_batch_size without an out of memory error is 32 with the base_network set to &quot;resnet-50&quot; and an image_shape of 300. With the same instance, you can use 64 as the mini_batch_size with the base network vgg-16 and an image_shape of 300. Optional Valid values: positive integer Default: 32</td>
</tr>
<tr>
<td>momentum</td>
<td>The momentum for sgd. Ignored for other optimizers. Optional Valid values: float in (0, 1] Default: 0.9</td>
</tr>
<tr>
<td>nms_threshold</td>
<td>The non-maximum suppression threshold. Optional Valid values: float in (0, 1] Default: 0.45</td>
</tr>
<tr>
<td>optimizer</td>
<td>The optimizer types. For details on optimizer values, see MXNet's API. Optional Valid values: ['sgd', 'adam', 'rmsprop', 'adadelta'] Default: 'sgd'</td>
</tr>
<tr>
<td>overlap_threshold</td>
<td>The evaluation overlap threshold. Optional Valid values: float in (0, 1] Default: 0.5</td>
</tr>
</tbody>

Tune an Object Detection Model

Automated model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automated model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

Metrics Computed by the Object Detection Algorithm

The object detection algorithm reports on a single metric during training: validation:mAP. When tuning a model, choose this metric as the objective metric.

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>

Object Detection Request and Response Formats

Request Format

Query a trained model by using the model's endpoint. The endpoint takes .jpg and .png image formats with image/jpeg and image/png content-types.

Response Formats

The response is the class index with a confidence score and bounding box coordinates for all objects within the image encoded in JSON format. The following is an example of a response .json file:

```json
{"prediction": [
  [4.0, 0.86419455409409988, 0.3088374733924866, 0.07030484080314636, 0.7110607028007507, 0.9345266819000244],
  [0.0, 0.73376623392105103, 0.57114187026023865, 0.40427327156066895, 0.827075183391571, 0.9712159633636475],
  [4.0, 0.32643985450267792, 0.3677481412887573, 0.034883320331573486, 0.6318609714508057, 0.5967587828636169],
  [8.0, 0.22552496790859295, 0.6152569651603699, 0.5722782611846924, 0.882301390171051, 0.8985623121261597],
  [3.0, 0.42260299175977707, 0.019305512309074402, 0.08386176824569702, 0.39093565940856934, 0.9574796557426453]
]}
```

Each row in this .json file contains an array that represents a detected object. Each of these object arrays consists of a list of six numbers. The first number is the predicted class label. The second number is the associated confidence score for the detection. The last four numbers represent the bounding box coordinates [xmin, ymin, xmax, ymax]. These output bounding box corner indices are normalized by the overall image size. Note that this encoding is different than that use by the input .json format. For example, in the first entry of the detection result, 0.3088374733924866 is the left coordinate (x-coordinate of upper-left corner) of the bounding box as a ratio of the overall image width, 0.07030484080314636 is the top coordinate (y-coordinate of upper-left corner) of the bounding box as a ratio of the overall image height, 0.7110607028007507 is the right coordinate (x-coordinate of lower-right corner) of the bounding box as a ratio of the overall image width, and 0.9345266819000244 is the bottom coordinate (y-coordinate of lower-right corner) of the bounding box as a ratio of the overall image height.

To avoid unreliable detection results, you might want to filter out the detection results with low confidence scores. In the object detection sample notebook, we provide scripts to remove the low confidence detections. Scripts are also provided to plot the bounding boxes on the original image.

For batch transform, the response is in JSON format, where the format is identical to the JSON format described above. The detection results of each image is represented as a JSON file. For example:

```json
{"prediction": [[label_id, confidence_score, xmin, ymin, xmax, ymax], [label_id, confidence_score, xmin, ymin, xmax, ymax]]}
```
Principal Component Analysis (PCA) Algorithm

PCA is an unsupervised machine learning algorithm that attempts to reduce the dimensionality (number of features) within a dataset while still retaining as much information as possible. This is done by finding a new set of features called components, which are composites of the original features that are uncorrelated with one another. They are also constrained so that the first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

In Amazon SageMaker, PCA operates in two modes, depending on the scenario:

- **regular**: For datasets with sparse data and a moderate number of observations and features.
- **randomized**: For datasets with both a large number of observations and features. This mode uses an approximation algorithm.

PCA uses tabular data.

The rows represent observations you want to embed in a lower dimensional space. The columns represent features that you want to find a reduced approximation for. The algorithm calculates the...
covariance matrix (or an approximation thereof in a distributed manner), and then performs the singular value decomposition on this summary to produce the principal components.

- **PCA Hyperparameters (p. 1449)**
- **PCA Response Formats (p. 1450)**

**Input/Output Interface for the PCA Algorithm**

For training, PCA expects data provided in the train channel, and optionally supports a dataset passed to the test dataset, which is scored by the final algorithm. Both `recordIO-wrapped-protobuf` and `CSV` formats are supported for training. You can use either File mode or Pipe mode to train models on data that is formatted as `recordIO-wrapped-protobuf` or as `CSV`.

For inference, PCA supports `text/csv`, `application/json`, and `application/x-recordio-protobuf`. Results are returned in either `application/json` or `application/x-recordio-protobuf` format with a vector of "projections."

For more information on input and output file formats, see **PCA Response Formats (p. 1450)** for inference and the **PCA Sample Notebooks (p. 1448)**.

**EC2 Instance Recommendation for the PCA Algorithm**

PCA supports both GPU and CPU computation. Which instance type is most performant depends heavily on the specifics of the input data.

**PCA Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Principal Component Analysis algorithm to analyze the images of handwritten digits from zero to nine in the MNIST dataset, see **An Introduction to PCA with MNIST**. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see **Use Amazon SageMaker Notebook Instances (p. 119)**. Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the NTM algorithms are located in the **Introduction to Amazon algorithms** section. To open a notebook, click on its **Use** tab and select **Create copy**.

**How PCA Works**

Principal Component Analysis (PCA) is a learning algorithm that reduces the dimensionality (number of features) within a dataset while still retaining as much information as possible.

PCA reduces dimensionality by finding a new set of features called *components*, which are composites of the original features, but are uncorrelated with one another. The first component accounts for the largest possible variability in the data, the second component the second most variability, and so on.

It is an unsupervised dimensionality reduction algorithm. In unsupervised learning, labels that might be associated with the objects in the training dataset aren't used.

Given the input of a matrix with rows \( x_1, \ldots, x_n \) each of dimension \( 1 \times d \), the data is partitioned into mini-batches of rows and distributed among the training nodes (workers). Each worker then computes a summary of its data. The summaries of the different workers are then unified into a single solution at the end of the computation.
Modes

The Amazon SageMaker PCA algorithm uses either of two modes to calculate these summaries, depending on the situation:

- **regular**: for datasets with sparse data and a moderate number of observations and features.
- **randomized**: for datasets with both a large number of observations and features. This mode uses an approximation algorithm.

As the algorithm’s last step, it performs the singular value decomposition on the unified solution, from which the principal components are then derived.

**Mode 1: Regular**

The workers jointly compute both $\sum x_i^T x_i$ and $\sum x_i$.

**Note**

Because $x_i$ are $1 \times d$ row vectors, $x_i^T x_i$ is a matrix (not a scalar). Using row vectors within the code allows us to obtain efficient caching.

The covariance matrix is computed as $\sum x_i^T x_i - (1/n)(\sum x_i)^T \sum x_i$, and its top $\text{num\_components}$ singular vectors form the model.

**Note**

If $\text{subtract\_mean}$ is False, we avoid computing and subtracting $\sum x_i$.

Use this algorithm when the dimension $d$ of the vectors is small enough so that $d^3$ can fit in memory.

**Mode 2: Randomized**

When the number of features in the input dataset is large, we use a method to approximate the covariance metric. For every mini-batch $X_i$ of dimension $b \times d$, we randomly initialize a $(\text{num\_components} + \text{extra\_components}) \times b$ matrix that we multiply by each mini-batch, to create a $(\text{num\_components} + \text{extra\_components}) \times d$ matrix. The sum of these matrices is computed by the workers, and the servers perform SVD on the final $(\text{num\_components} + \text{extra\_components}) \times d$ matrix. The top right $\text{num\_components}$ singular vectors of it are the approximation of the top singular vectors of the input matrix.

Let $t = \text{num\_components} + \text{extra\_components}$. Given a mini-batch $X_i$ of dimension $b \times d$, the worker draws a random matrix $H_i$ of dimension $t \times b$. Depending on whether the environment uses a GPU or CPU and the dimension size, the matrix is either a random sign matrix where each entry is $\pm 1$ or a FJLT (fast Johnson Lindenstrauss transform; for information, see FJLT Transforms and the follow-up papers). The worker then computes $H_i X_i$ and maintains $B = \sum H_i X_i$. The worker also maintains $h^r$, the sum of columns of $H_1, \ldots, H_t$ ($t$ being the total number of mini-batches), and $s$, the sum of all input rows. After processing the entire shard of data, the worker sends the server $B$, $h$, $s$, and $n$ (the number of input rows).

Denote the different inputs to the server as $B^i, h^i, s^i, n^i$. The server computes $B = (1/n) h^T s$, and finds its singular value decomposition. The top-right singular vectors and singular values of $C$ are used as the approximate solution to the problem.

**PCA Hyperparameters**

In the CreateTrainingJob request, you specify the training algorithm. You can also specify algorithm-specific HyperParameters as string-to-string maps. The following table lists the hyperparameters for the PCA training algorithm provided by Amazon SageMaker. For more information about how PCA works, see How PCA Works (p. 1448).
### Parameter Name | Description
---|---
**feature_dim** | Input dimension. 
**Required** 
Valid values: positive integer

**mini_batch_size** | Number of rows in a mini-batch. 
**Required** 
Valid values: positive integer

**num_components** | The number of principal components to compute. 
**Required** 
Valid values: positive integer

**algorithm_mode** | Mode for computing the principal components. 
**Optional** 
Valid values: *regular* or *randomized*
Default value: *regular*

**extra_components** | As the value increases, the solution becomes more accurate but the runtime and memory consumption increase linearly. The default, -1, means the maximum of 10 and num_components. Valid for *randomized* mode only. 
**Optional** 
Valid values: Non-negative integer or -1 
Default value: -1

**subtract_mean** | Indicates whether the data should be unbiased both during training and at inference. 
**Optional** 
Valid values: One of *true* or *false* 
Default value: *true*

### PCA Response Formats

All Amazon SageMaker built-in algorithms adhere to the common input inference format described in Common Data Formats - Inference. This topic contains a list of the available output formats for the SageMaker PCA algorithm.

**JSON Response Format**

Accept—application/json

```json
{
```
"projections": [
  {
    "projection": [1.0, 2.0, 3.0, 4.0, 5.0]
  },
  {
    "projection": [6.0, 7.0, 8.0, 9.0, 0.0]
  },
  ...
]

JSONLINES Response Format

Accept—application/jsonlines

{ "projection": [1.0, 2.0, 3.0, 4.0, 5.0] }
{ "projection": [6.0, 7.0, 8.0, 9.0, 0.0] }

RECORDIO Response Format

Accept—application/x-recordio-protobuf

[ Record = {
  features = {},
  label = {
    'projection': {
      keys: [],
      values: [1.0, 2.0, 3.0, 4.0, 5.0]
    }
  }
},
 Record = {
  features = {},
  label = {
    'projection': {
      keys: [],
      values: [1.0, 2.0, 3.0, 4.0, 5.0]
    }
  }
} ]

Random Cut Forest (RCF) Algorithm

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a data set. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a data set can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

With each data point, RCF associates an anomaly score. Low score values indicate that the data point is considered "normal." High values indicate the presence of an anomaly in the data. The definitions of "low" and "high" depend on the application but common practice suggests that scores beyond three standard deviations from the mean score are considered anomalous.

While there are many applications of anomaly detection algorithms to one-dimensional time series data such as traffic volume analysis or sound volume spike detection, RCF is designed to work with arbitrary-

1451
dimensional input. Amazon SageMaker RCF scales well with respect to number of features, data set size, and number of instances.

**Topics**
- Input/Output Interface for the RCF Algorithm (p. 1452)
- Instance Recommendations for the RCF Algorithm (p. 1453)
- RCF Sample Notebooks (p. 1453)
- How RCF Works (p. 1453)
- RCF Hyperparameters (p. 1456)
- Tune an RCF Model (p. 1456)
- RCF Response Formats (p. 1457)

**Input/Output Interface for the RCF Algorithm**

Amazon SageMaker Random Cut Forest supports the train and test data channels. The optional test channel is used to compute accuracy, precision, recall, and F1-score metrics on labeled data. Train and test data content types can be either application/x-recordio-protobuf or text/csv formats. For the test data, when using text/csv format, the content must be specified as text/csv;label_size=1 where the first column of each row represents the anomaly label: "1" for an anomalous data point and "0" for a normal data point. You can use either File mode or Pipe mode to train RCF models on data that is formatted as recordIO-wrapped-protobuf or as CSV.

Also note that the train channel only supports S3DataDistributionType=ShardedByS3Key and the test channel only supports S3DataDistributionType=FullyReplicated. The S3 distribution type can be specified using the Amazon SageMaker Python SDK as follows:

```python
import sagemaker

# specify Random Cut Forest training job information and hyperparameters
rcf = sagemaker.estimator.Estimator(...)

# explicitly specify "ShardedByS3Key" distribution type
train_data = sagemaker.inputs.s3_input(
    s3_data=s3_training_data_location,
    content_type='text/csv;label_size=0',
    distribution='ShardedByS3Key')

# run the training job on input data stored in S3
rcf.fit({'train': train_data})
```

To avoid common errors around execution roles, ensure that you have the execution roles required, AmazonSageMakerFullAccess and AmazonEC2ContainerRegistryFullAccess. To avoid common errors around your image not existing or its permissions being incorrect, ensure that your ECR image is not larger than the allocated disk space on the training instance. To avoid this, run your training job on an instance that has sufficient disk space. In addition, if your ECR image is from a different AWS account's Elastic Container Service (ECS) repository, and you do not set repository permissions to grant access, this will result in an error. See the ECR repository permissions for more information on setting a repository policy statement.

See the S3DataSource for more information on customizing the S3 data source attributes. Finally, in order to take advantage of multi-instance training the training data must be partitioned into at least as many files as instances.

For inference, RCF supports application/x-recordio-protobuf, text/csv and application/json input data content types. See the Common Data Formats for Built-in Algorithms (p. 1311)
documentation for more information. RCF inference returns application/x-recordio-protobuf or application/json formatted output. Each record in these output data contains the corresponding anomaly scores for each input data point. See Common Data Formats--Inference for more information.

For more information on input and output file formats, see RCF Response Formats (p. 1457) for inference and the RCF Sample Notebooks (p. 1453).

**Instance Recommendations for the RCF Algorithm**

For training, we recommend the ml.m4, ml.c4, and ml.c5 instance families. For inference we recommend using a ml.c5.xl instance type in particular, for maximum performance as well as minimized cost per hour of usage. Although the algorithm could technically run on GPU instance types it does not take advantage of GPU hardware.

**RCF Sample Notebooks**

For an example of how to train an RCF model and perform inferences with it, see the An Introduction to SageMaker Random Cut Forests notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, click on its Use tab and select Create copy.

**How RCF Works**

Amazon SageMaker Random Cut Forest (RCF) is an unsupervised algorithm for detecting anomalous data points within a dataset. These are observations which diverge from otherwise well-structured or patterned data. Anomalies can manifest as unexpected spikes in time series data, breaks in periodicity, or unclassifiable data points. They are easy to describe in that, when viewed in a plot, they are often easily distinguishable from the "regular" data. Including these anomalies in a dataset can drastically increase the complexity of a machine learning task since the "regular" data can often be described with a simple model.

The main idea behind the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

**Sample Data Randomly**

The first step in the RCF algorithm is to create a forest of trees where each tree is obtained using a partition of a sample of the training data. For example, a random sample of the input data is first determined. The random sample is then partitioned according to the number of trees in the forest. Each tree is given such a partition and organizes that subset of points into a k-d tree. The anomaly score assigned to a data point by the tree is defined as the expected change in complexity of the tree as a result adding that point to the tree; which, in approximation, is inversely proportional to the resulting depth of the point in the tree. The random cut forest assigns an anomaly score by computing the average score from each constituent tree and scaling the result with respect to the sample size. The RCF algorithm is based on the one described in reference [1].

**Reservoir sampling** is an algorithm for efficiently drawing random samples from a dataset $S = \{S_1, \ldots, S_N\}$ where the elements in the dataset can only be observed one at a time or in batches. In fact, reservoir sampling works even when $N$ is not known a priori. If only one sample is requested, such as when $K = 1$, the algorithm is like this:

**Algorithm: Reservoir Sampling**
• Input: dataset or data stream $S = \{S_1, \ldots, S_N\}$
• Initialize the random sample $X = S_1$
• For each observed sample $S_n, n = 2, \ldots, N$:
  • Pick a uniform random number $\xi \in [0, 1]$
  • If $\xi < 1/n$
    • Set $X = S_n$
• Return $X$

This algorithm selects a random sample such that $P(X = S_n) = 1/N$ for all $n = 1, \ldots, N$. When $K > 1$ the algorithm is more complicated. Additionally, a distinction must be made between random sampling that is with and without replacement. RCF performs an augmented reservoir sampling without replacement on the training data based on the algorithms described in [2].

**Train a RCF Model and Produce Inferences**

The next step in RCF is to construct a random cut forest using the random sample of data. First, the sample is partitioned into a number of equal-sized partitions equal to the number of trees in the forest. Then, each partition is sent to an individual tree. The tree recursively organizes its partition into a binary tree by partitioning the data domain into bounding boxes.

This procedure is best illustrated with an example. Suppose a tree is given the following two-dimensional dataset. The corresponding tree is initialized to the root node:

A two-dimensional dataset where the majority of data lies in a cluster (blue) except for one anomalous data point (orange). The tree is initialized with a root node.

The RCF algorithm organizes these data in a tree by first computing a bounding box of the data, selecting a random dimension (giving more weight to dimensions with higher “variance”), and then randomly determining the position of a hyperplane “cut” through that dimension. The two resulting subspaces define their own sub tree. In this example, the cut happens to separate a lone point from the remainder of the sample. The first level of the resulting binary tree consists of two nodes, one which will consist of the subtree of points to the left of the initial cut and the other representing the single point on the right.
A random cut partitioning the two-dimensional dataset. An anomalous data point is more likely to lie isolated in a bounding box at a smaller tree depth than other points.

Bounding boxes are then computed for the left and right halves of the data and the process is repeated until every leaf of the tree represents a single data point from the sample. Note that if the lone point is sufficiently far away then it is more likely that a random cut would result in point isolation. This observation provides the intuition that tree depth is, loosely speaking, inversely proportional to the anomaly score.

When performing inference using a trained RCF model the final anomaly score is reported as the average across scores reported by each tree. Note that it is often the case that the new data point does not already reside in the tree. To determine the score associated with the new point the data point is inserted into the given tree and the tree is efficiently (and temporarily) reassembled in a manner equivalent to the training process described above. That is, the resulting tree is as if the input data point were a member of the sample used to construct the tree in the first place. The reported score is inversely proportional to the depth of the input point within the tree.

**Choose Hyperparameters**

The primary hyperparameters used to tune the RCF model are `num_trees` and `num_samples_per_tree`. Increasing `num_trees` has the effect of reducing the noise observed in anomaly scores since the final score is the average of the scores reported by each tree. While the optimal value is application-dependent we recommend using 100 trees to begin with as a balance between score noise and model complexity. Note that inference time is proportional to the number of trees. Although training time is also affected it is dominated by the reservoir sampling algorithm describe above.

The parameter `num_samples_per_tree` is related to the expected density of anomalies in the dataset. In particular, `num_samples_per_tree` should be chosen such that $1/num_samples_per_tree$ approximates the ratio of anomalous data to normal data. For example, if 256 samples are used in each tree then we expect our data to contain anomalies $1/256$ or approximately 0.4% of the time. Again, an optimal value for this hyperparameter is dependent on the application.

**Tune an RCF Model**

*Automatic model tuning,* also known as hyperparameter tuning or hyperparameter optimization, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset.
You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

The Amazon SageMaker RCF algorithm is an unsupervised anomaly-detection algorithm that requires a labeled test dataset for hyperparameter optimization. RCF calculates anomaly scores for test datapoints and then labels the datapoints as anomalous if their scores are beyond three standard deviations from the mean score. This is known as the three-sigma limit heuristic. The F1-score is based on the difference between calculated labels and actual labels. The hyperparameter tuning job finds the model that maximizes that score. The success of hyperparameter optimization depends on the applicability of the three-sigma limit heuristic to the test dataset.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

**Metrics Computed by the RCF Algorithm**

The RCF algorithm computes the following metric during training. When tuning the model, choose this metric as the objective metric.

1458
Semantic Segmentation Algorithm

The SageMaker semantic segmentation algorithm provides a fine-grained, pixel-level approach to developing computer vision applications. It tags every pixel in an image with a class label from a predefined set of classes. Tagging is fundamental for understanding scenes, which is critical to an increasing number of computer vision applications, such as self-driving vehicles, medical imaging diagnostics, and robot sensing.

For comparison, the SageMaker Image Classification Algorithm (p. 1356) is a supervised learning algorithm that analyzes only whole images, classifying them into one of multiple output categories. The Object Detection Algorithm (p. 1436) is a supervised learning algorithm that detects and classifies all instances of an object in an image. It indicates the location and scale of each object in the image with a rectangular bounding box.

Because the semantic segmentation algorithm classifies every pixel in an image, it also provides information about the shapes of the objects contained in the image. The segmentation output is represented as a grayscale image, called a segmentation mask. A segmentation mask is a grayscale image with the same shape as the input image.
The SageMaker semantic segmentation algorithm is built using the MXNet Gluon framework and the Gluon CV toolkit, and provides you with a choice of three build-in algorithms to train a deep neural network. You can use the Fully-Convolutional Network (FCN) algorithm, Pyramid Scene Parsing (PSP) algorithm, or DeepLabV3.

Each of the three algorithms has two distinct components:

- The **backbone** (or encoder)—A network that produces reliable activation maps of features.
- The **decoder**—A network that constructs the segmentation mask from the encoded activation maps.

You also have a choice of backbones for the FCN, PSP, and DeepLabV3 algorithms: ResNet50 or ResNet101. These backbones include pretrained artifacts that were originally trained on the ImageNet classification task. You can fine-tune these backbones for segmentation using your own data. Or, you can initialize and train these networks from scratch using only your own data. The decoders are never pretrained.

To deploy the trained model for inference, use the SageMaker hosting service. During inference, you can request the segmentation mask either as a PNG image or as a set of probabilities for each class for each pixel. You can use these masks as part of a larger pipeline that includes additional downstream image processing or other applications.

For a sample Jupyter notebook that uses the SageMaker semantic segmentation algorithm to train a model and deploy it to perform inferences, see the Semantic Segmentation Example. For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119).

To see a list of all of the SageMaker samples, create and open a notebook instance, and choose the **SageMaker Examples** tab. The example semantic segmentation notebooks are located under Introduction to Amazon algorithms. To open a notebook, choose its **Use** tab, and choose **Create copy**.

### Input/Output Interface for the Semantic Segmentation Algorithm

SageMaker semantic segmentation expects the customer's training dataset to be on Amazon Simple Storage Service (Amazon S3). Once trained, it produces the resulting model artifacts on Amazon S3. The input interface format for the SageMaker semantic segmentation is similar to that of most standardized semantic segmentation benchmarking datasets. The dataset in Amazon S3 is expected to be presented in two channels, one for train and one for validation using four directories, two for images and two for annotations. Annotations are expected to be uncompressed PNG images. The dataset might also have a label map that describes how the annotation mappings are established. If not, the algorithm uses a default. It also supports the augmented manifest image format (application/x-image) for training in Pipe input mode straight from Amazon S3. For inference, an endpoint accepts images with an image/jpeg content type.

### How Training Works

The training data is split into four directories: train, train_annotation, validation, and validation_annotation. There is a channel for each of these directories. The dataset also expected
to have one `label_map.json` file per channel for `train_annotation` and `validation_annotation` respectively. If you don’t provide these JSON files, SageMaker provides the default set label map.

The dataset specifying these files should look similar to the following example:

```plaintext
s3://bucket_name
 |- train

```

Every JPG image in the train and validation directories has a corresponding PNG label image with the same name in the `train_annotation` and `validation_annotation` directories. This naming convention helps the algorithm to associate a label with its corresponding image during training. The `train`, `train_annotation`, `validation`, and `validation_annotation` channels are mandatory. The annotations are single-channel PNG images. The format works as long as the metadata (modes) in the image helps the algorithm read the annotation images into a single-channel 8-bit unsigned integer. For more information on our support for modes, see the Python Image Library documentation. We recommend using the 8-bit pixel, true color P mode.

The image that is encoded is a simple 8-bit integer when using modes. To get from this mapping to a map of a label, the algorithm uses one mapping file per channel, called the `label map`. The label map is used to map the values in the image with actual label indices. In the default label map, which is provided by default if you don’t provide one, the pixel value in an annotation matrix (image) directly index the label. These images can be grayscale PNG files or 8-bit indexed PNG files. The label map file for the unscaled default case is the following:

```json
{
 "scale": "1"
}
```

To provide some contrast for viewing, some annotation software scales the label images by a constant amount. To support this, the SageMaker semantic segmentation algorithm provides a rescaling option to scale down the values to actual label values. When scaling down doesn’t convert the value to an appropriate integer, the algorithm defaults to the greatest integer less than or equal to the scale value. The following code shows how to set the scale value to rescale the label values:

```json
{
 "scale": "3"
}
```

The following example shows how this `scale` value is used to rescale the `encoded_label` values of the input annotation image when they are mapped to the `mapped_label` values to be used in training.
The label values in the input annotation image are 0, 3, 6, with scale 3, so they are mapped to 0, 1, 2 for training:

```plaintext
encoded_label = [0, 3, 6]
mapped_label = [0, 1, 2]
```

In some cases, you might need to specify a particular color mapping for each class. Use the map option in the label mapping as shown in the following example of a label_map file:

```json
{
  "map": {
    "0": 5,
    "1": 0,
    "2": 2
  }
}
```

This label mapping for this example is:

```plaintext
encoded_label = [0, 5, 2]
mapped_label = [1, 0, 2]
```

With label mappings, you can use different annotation systems and annotation software to obtain data without a lot of preprocessing. You can provide one label map per channel. The files for a label map in the label_map channel must follow the naming conventions for the four directory structure. If you don't provide a label map, the algorithm assumes a scale of 1 (the default).

**Training with the Augmented Manifest Format**

The augmented manifest format enables you to do training in Pipe mode using image files without needing to create RecordIO files. The augmented manifest file contains data objects and should be in JSON Lines format, as described in the `CreateTrainingJob` request. Each line in the manifest is an entry containing the Amazon S3 URI for the image and the URI for the annotation image.

Each JSON object in the manifest file must contain a `source-ref` key. The `source-ref` key should contain the value of the Amazon S3 URI to the image. The labels are provided under the `AttributeNames` parameter value as specified in the `CreateTrainingJob` request. It can also contain additional metadata under the `metadata` tag, but these are ignored by the algorithm. In the example below, the `AttributeNames` are contained in the list of image and annotation references ["source-ref", "city-streets-ref"]. These names must have -ref appended to them. When using the Semantic Segmentation algorithm with Augmented Manifest, the value of the `RecordWrapperType` parameter must be "RecordIO" and value of the `ContentType` parameter must be application/x-recordio.

```json
{"source-ref": "S3 bucket location", "city-streets-ref": "S3 bucket location", "city-streets-metadata": {"job-name": "label-city-streets", }}
```

For more information on augmented manifest files, see [Provide Dataset Metadata to Training Jobs with an Augmented Manifest File (p. 1828)].

**Incremental Training**

You can also seed the training of a new model with a model that you trained previously using SageMaker. This incremental training saves training time when you want to train a new model with the same or similar data. Currently, incremental training is supported only for models trained with the built-in SageMaker Semantic Segmentation.
To use your own pre-trained model, specify the ChannelName as "model" in the InputDataConfig for the CreateTrainingJob request. Set the ContentType for the model channel to application/x-sagemaker-model. The backbone, algorithm, crop_size, and num_classes input parameters that define the network architecture must be consistently specified in the input hyperparameters of the new model and the pre-trained model that you upload to the model channel. For the pretrained model file, you can use the compressed (.tar.gz) artifacts from SageMaker outputs. You can only use Image formats for input data. For more information on incremental training and for instructions on how to use it, see Incremental Training in Amazon SageMaker (p. 1819).

**Produce Inferences**

To query a trained model that is deployed to an endpoint, you need to provide an image and an AcceptType that denotes the type of output required. The endpoint takes JPEG images with an image/jpeg content type. If you request an AcceptType of image/png, the algorithm outputs a PNG file with a segmentation mask in the same format as the labels themselves. If you request an accept type of application/x-recordio-protobuf, the algorithm returns class probabilities encoded in recordio-protobuf format. The latter format outputs a 3D tensor where the third dimension is the same size as the number of classes. This component denotes the probability of each class label for each pixel.

**EC2 Instance Recommendation for the Semantic Segmentation Algorithm**

The SageMaker semantic segmentation algorithm only supports GPU instances for training, and we recommend using GPU instances with more memory for training with large batch sizes. The algorithm can be trained using P2/P3 EC2 Amazon Elastic Compute Cloud (Amazon EC2) instances in single machine configurations. It supports the following GPU instances for training:

- ml.p2.xlarge
- ml.p2.8xlarge
- ml.p2.16xlarge
- ml.p3.2xlarge
- ml.p3.8xlarge
- ml.p3.16xlarge

For inference, you can use either CPU instances (such as c5 and m5) and GPU instances (such as p2 and p3) or both. For information about the instance types that provide varying combinations of CPU, GPU, memory, and networking capacity for inference, see Amazon SageMaker ML Instance Types.

**Semantic Segmentation Hyperparameters**

The following tables list the hyperparameters supported by the Amazon SageMaker semantic segmentation algorithm for network architecture, data inputs, and training. You specify Semantic Segmentation for training in the AlgorithmName of the CreateTrainingJob request.

**Network Architecture Hyperparameters**

</table>
| mini_batch_size | The batch size for training. Using a large `mini_batch_size` usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the `mini_batch_size` and `image_shape` parameters, and the backbone architecture.  
**Optional**  
Valid values: positive integer  
Default value: 16 |
| momentum | The momentum for the `sgd` optimizer. When you use other optimizers, the semantic segmentation algorithm ignores this parameter.  
**Optional**  
Valid values: $0 < \text{float} \leq 1$  
Default value: 0.9 |
| optimizer | The type of optimizer. For more information about an optimizer, choose the appropriate link:  
- `adam`: Adaptive momentum estimation  
- `adagrad`: Adaptive gradient descent  
- `nag`: Nesterov accelerated gradient  
- `rmsprop`: Root mean square propagation  
- `sgd`: Stochastic gradient descent  
**Optional**  
Valid values: `adam`, `adagrad`, `nag`, `rmsprop`, `sgd`  
Default value: `sgd` |
| syncbn | If set to `True`, the batch normalization mean and variance are computed over all the samples processed across the GPUs.  
**Optional**  
Valid values: `True`, `False`  
Default value: `False` |
**Parameter Name** | **Description**
--- | ---
validation_mini_batch_size | The batch size for validation. A large mini_batch_size usually results in faster training, but it might cause you to run out of memory. Memory usage is affected by the values of the mini_batch_size and image_shape parameters, and the backbone architecture.

- To score the validation on the entire image without cropping the images, set this parameter to 1. Use this option if you want to measure performance on the entire image as a whole.

**Note**
Setting the validation_mini_batch_size parameter to 1 causes the algorithm to create a new network model for every image. This might slow validation and training.

- To crop images to the size specified in the crop_size parameter, even during evaluation, set this parameter to a value greater than 1.

Optional
Valid values: positive integer
Default value: 16

weight_decay | The weight decay coefficient for the sgd optimizer. When you use other optimizers, the algorithm ignores this parameter.

Optional
Valid values: 0 < float < 1
Default value: 0.0001

---

**Tuning a Semantic Segmentation Model**

*Automatic model tuning*, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

**Metrics Computed by the Semantic Segmentation Algorithm**

The semantic segmentation algorithm reports two validation metrics. When tuning hyperparameter values, choose one of these metrics as the objective.

<table>

**Sequence-to-Sequence Algorithm**

Amazon SageMaker Sequence to Sequence is a supervised learning algorithm where the input is a sequence of tokens (for example, text, audio) and the output generated is another sequence of tokens. Example applications include: machine translation (input a sentence from one language and predict what that sentence would be in another language), text summarization (input a longer string of words and predict a shorter string of words that is a summary), speech-to-text (audio clips converted into output sentences in tokens). Recently, problems in this domain have been successfully modeled with deep neural networks that show a significant performance boost over previous methodologies. Amazon SageMaker seq2seq uses Recurrent Neural Networks (RNNs) and Convolutional Neural Network (CNN) models with attention as encoder-decoder architectures.

**Topics**
- Input/Output Interface for the Sequence-to-Sequence Algorithm (p. 1469)
- EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm (p. 1470)
- Sequence-to-Sequence Sample Notebooks (p. 1470)
- How Sequence-to-Sequence Works (p. 1471)
- Sequence-to-Sequence Hyperparameters (p. 1471)
- Tune a Sequence-to-Sequence Model (p. 1479)

**Input/Output Interface for the Sequence-to-Sequence Algorithm**

**Training**

SageMaker seq2seq expects data in RecordIO-Protobuf format. However, the tokens are expected as integers, not as floating points, as is usually the case.

A script to convert data from tokenized text files to the protobuf format is included in the seq2seq example notebook. In general, it packs the data into 32-bit integer tensors and generates the necessary vocabulary files, which are needed for metric calculation and inference.

After preprocessing is done, the algorithm can be invoked for training. The algorithm expects three channels:

- **train**: It should contain the training data (for example, the train.rec file generated by the preprocessing script).
• **validation**: It should contain the validation data (for example, the `val.rec` file generated by the preprocessing script).
• **vocab**: It should contain two vocabulary files (`vocab.src.json` and `vocab.trg.json`)

If the algorithm doesn't find data in any of these three channels, training results in an error.

**Inference**

For hosted endpoints, inference supports two data formats. To perform inference using space separated text tokens, use the `application/json` format. Otherwise, use the `recordio-protobuf` format to work with the integer encoded data. Both modes support batching of input data. `application/json` format also allows you to visualize the attention matrix.

• **application/json**: Expects the input in JSON format and returns the output in JSON format. Both content and accept types should be `application/json`. Each sequence is expected to be a string with whitespace separated tokens. This format is recommended when the number of source sequences in the batch is small. It also supports the following additional configuration options:

  ```json
  configuration: {attention_matrix: true}: Returns the attention matrix for the particular input sequence.
  ```

• **application/x-recordio-protobuf**: Expects the input in `recordio-protobuf` format and returns the output in `recordio-protobuf` format. Both content and accept types should be `application/x-recordio-protobuf`. For this format, the source sequences must be converted into a list of integers for subsequent protobuf encoding. This format is recommended for bulk inference.

For batch transform, inference supports JSON Lines format. Batch transform expects the input in JSON Lines format and returns the output in JSON Lines format. Both content and accept types should be `application/jsonlines`. The format for input is as follows:

```json
content-type: application/jsonlines

{"source": "source_sequence_0"}
{"source": "source_sequence_1"}
```

The format for response is as follows:

```json
accept: application/jsonlines

{"target": "predicted_sequence_0"}
{"target": "predicted_sequence_1"}
```

For additional details on how to serialize and deserialize the inputs and outputs to specific formats for inference, see the [Sequence-to-Sequence Sample Notebooks](p. 1470).

**EC2 Instance Recommendation for the Sequence-to-Sequence Algorithm**

Currently Amazon SageMaker seq2seq is only supported on GPU instance types and is only set up to train on a single machine. But it does also offer support for multiple GPUs.

**Sequence-to-Sequence Sample Notebooks**

For a sample notebook that shows how to use the SageMaker Sequence to Sequence algorithm to train a English-German translation model, see [Machine Translation English-German Example Using SageMaker Seq2Seq](p. 1470). For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see [Use Amazon SageMaker Notebook Instances](p. 119). Once you have created a notebook instance and opened it, select the **SageMaker Examples** tab to see a list of all the
How Sequence-to-Sequence Works

Typically, a neural network for sequence-to-sequence modeling consists of a few layers, including:

- **An embedding layer.** In this layer, the input matrix, which is input tokens encoded in a sparse way (for example, one-hot encoded) are mapped to a dense feature layer. This is required because a high-dimensional feature vector is more capable of encoding information regarding a particular token (word for text corpora) than a simple one-hot-encoded vector. It is also a standard practice to initialize this embedding layer with a pre-trained word vector like FastText or Glove or to initialize it randomly and learn the parameters during training.

- **An encoder layer.** After the input tokens are mapped into a high-dimensional feature space, the sequence is passed through an encoder layer to compress all the information from the input embedding layer (of the entire sequence) into a fixed-length feature vector. Typically, an encoder is made of RNN-type networks like long short-term memory (LSTM) or gated recurrent units (GRU). (Colah's blog explains LSTM in a great detail.)

- **A decoder layer.** The decoder layer takes this encoded feature vector and produces the output sequence of tokens. This layer is also usually built with RNN architectures (LSTM and GRU).

The whole model is trained jointly to maximize the probability of the target sequence given the source sequence. This model was first introduced by Sutskever et al. in 2014.

**Attention mechanism.** The disadvantage of an encoder-decoder framework is that model performance decreases as and when the length of the source sequence increases because of the limit of how much information the fixed-length encoded feature vector can contain. To tackle this problem, in 2015, Bahdanau et al. proposed the attention mechanism. In an attention mechanism, the decoder tries to find the location in the encoder sequence where the most important information could be located and uses that information and previously decoded words to predict the next token in the sequence.

For more in details, see the whitepaper Effective Approaches to Attention-based Neural Machine Translation by Luong, et al. that explains and simplifies calculations for various attention mechanisms. Additionally, the whitepaper Google's Neural Machine Translation System: Bridging the Gap between Human and Machine Translation by Wu, et al. describes Google's architecture for machine translation, which uses skip connections between encoder and decoder layers.

## Parameter Name | Description
--- | ---
training_metric | Metrics to track on training on validation data. Optional
| Valid values: String. Either perplexity or accuracy.
| Default value: perplexity
weight_decay | Weight decay constant. Optional
| Valid values: float
| Default value: 0
weight_init_scale | Weight initialization scale (for uniform and xavier initialization). Optional
| Valid values: float
| Default value: 2.34
weight_init_type | Type of weight initialization. Optional
| Valid values: String. Either uniform or xavier.
| Default value: xavier
xavier_factor_type | Xavier factor type. Optional
| Valid values: String. One of in, out, or avg.
| Default value: in

### Tune a Sequence-to-Sequence Model

_Automatic model tuning_, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your dataset. You choose the tunable hyperparameters, a range of values for each, and an objective metric. You choose the objective metric from the metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the objective metric.

For more information about model tuning, see _Perform Automatic Model Tuning with SageMaker_ (p. 1715).

### Metrics Computed by the Sequence-to-Sequence Algorithm

The sequence to sequence algorithm reports three metrics that are computed during training. Choose one of them as an objective to optimize when tuning the hyperparameter values.
Use built-in algorithms

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Optimization Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation:accuracy</td>
<td>Accuracy computed on the validation dataset.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:bleu</td>
<td>Bleu score computed on the validation dataset. Because BLEU computation is expensive, you can choose to compute BLEU on a random subsample of the validation dataset to speed up the overall training process. Use the <code>bleu_sample_size</code> parameter to specify the subsample.</td>
<td>Maximize</td>
</tr>
<tr>
<td>validation:perplexity</td>
<td>Perplexity, is a loss function computed on the validation dataset. Perplexity measures the cross-entropy between an empirical sample and the distribution predicted by a model and so provides a measure of how well a model predicts the sample values. Models that are good at predicting a sample have a low perplexity.</td>
<td>Minimize</td>
</tr>
</tbody>
</table>

**Tunable Sequence-to-Sequence Hyperparameters**

You can tune the following hyperparameters for the SageMaker Sequence to Sequence algorithm. The hyperparameters that have the greatest impact on sequence to sequence objective metrics are: `batch_size`, `optimizer_type`, `learning_rate`, `num_layers_encoder`, and `num_layers_decoder`.

<table>

### XGBoost Algorithm

The XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining an ensemble of estimates from a set of simpler and weaker models. The XGBoost algorithm performs well in machine learning competitions because of its robust handling of a variety of data types, relationships, distributions, and the variety of hyperparameters that you can fine-tune. You can use XGBoost for regression, classification (binary and multiclass), and ranking problems.

You can use the new release of the XGBoost algorithm either as a Amazon SageMaker built-in algorithm or as a framework to run training scripts in your local environments. This implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics than the original versions. It provides an XGBoost estimator that executes a training script in a managed XGBoost environment. The current release of SageMaker XGBoost is based on the original XGBoost versions 0.90, 1.0, and 1.2.

#### Supported versions

- Framework (open source) mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2
- Algorithm mode: 0.90-1, 0.90-2, 1.0-1, 1.2-1, 1.2-2

Note

XGBoost 1.1 is not supported on SageMaker because XGBoost 1.1 has a broken capability to run prediction when the test input has fewer features than the training data in LIBSVM inputs. This capability has been restored in XGBoost 1.2. Consider using SageMaker XGBoost 1.2-2.

How to Use SageMaker XGBoost

With SageMaker, you can use XGBoost as a built-in algorithm or framework. By using XGBoost as a framework, you have more flexibility and access to more advanced scenarios, such as k-fold cross-validation, because you can customize your own training scripts.

- Use XGBoost as a framework

Use XGBoost as a framework to run your customized training scripts that can incorporate additional data processing into your training jobs. In the following code example, you can find how SageMaker Python SDK provides the XGBoost API as a framework in the same way it provides other framework APIs, such as TensorFlow, MXNet, and PyTorch.

SageMaker Python SDK v1

```python
import boto3
import sagemaker
from sagemaker.xgboost.estimator import XGBoost
from sagemaker.session import s3_input, Session

# initialize hyperparameters
hyperparameters = {
    "max_depth": "5",
    "eta": "0.2",
    "gamma": "4",
    "min_child_weight": "6",
    "subsample": "0.7",
    "verbosity": "1",
    "objective": "reg:linear",
    "num_round": "50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-framework'
output_path = 's3://{}/{}/output'.format(bucket, prefix, 'abalone-xgb-framework')

# construct a SageMaker XGBoost estimator
# specify the entry_point to your xgboost training script
estimator = XGBoost(entry_point = "your_xgboost_abalone_script.py",
    framework_version='1.2-2',
    hyperparameters=hyperparameters,
    role=sagemaker.get_execution_role(),
    instance_count=1,
    instance_type='ml.m5.2xlarge',
    output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}/{}/{}".format(bucket, prefix, 'train'),
    content_type=content_type)
validation_input = s3_input("s3://{}/{}/{}".format(bucket, prefix, 'validation'),
    content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```
### Use built-in algorithms

For an end-to-end example of using SageMaker XGBoost as a framework, see Regression with Amazon SageMaker XGBoost.

- **Use XGBoost as a built-in algorithm**

  Use the XGBoost built-in algorithm to build an XGBoost training container as shown in the following code example. You can automatically spot the XGBoost built-in algorithm image URI using the SageMaker image_uris.retrieve API (or the get_image_uri API if using Amazon SageMaker Python SDK version 1). If you want to ensure if the image_uris.retrieve API finds the correct URI, see Common parameters for built-in algorithms and look up xgboost from the full list of built-in algorithm image URIs and available regions.

  After specifying the XGBoost image URI, you can use the XGBoost container to construct an estimator using the SageMaker Estimator API and initiate a training job. This XGBoost built-in algorithm mode does not incorporate your own XGBoost training script and runs directly on the input datasets.
SageMaker Python SDK v1

```python
import sagemaker
import boto3
from sagemaker.amazon.amazon_estimator import get_image_uri
from sagemaker.session import Session

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
    "subsample":"0.7",
    "objective":"reg:squarederror",
    "num_round":"50"
}

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}/output'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = get_image_uri(boto3.Session().region_name,
                                   'xgboost',
                                   repo_version='1.2-2')

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_name=xgboost_container,
                                           hyperparameters=hyperparameters,
                                           role=sagemaker.get_execution_role(),
                                           instance_count=1,
                                           instance_type='ml.m5.2xlarge',
                                           train_volume_size=5,  # 5 GB
                                           output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = s3_input("s3://{}/{}/{}/{}".format(bucket, prefix, 'train',
                                                    content_type=content_type))
validation_input = s3_input("s3://{}/{}/{}/{}".format(bucket, prefix, 'validation',
                                                      content_type=content_type))

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

SageMaker Python SDK v2

```python
import sagemaker
import boto3
from sagemaker import image_uris
from sagemaker.session import Session
from sagemaker.inputs import TrainingInput

# initialize hyperparameters
hyperparameters = {
    "max_depth":"5",
    "eta":"0.2",
    "gamma":"4",
    "min_child_weight":"6",
```
Use built-in algorithms

```python
"subsample":"0.7",
"objective":"reg:squarederror",
"num_round":"50"

# set an output path where the trained model will be saved
bucket = sagemaker.Session().default_bucket()
prefix = 'DEMO-xgboost-as-a-built-in-algo'
output_path = 's3://{}/{}/{}'.format(bucket, prefix, 'abalone-xgb-built-in-algo')

# this line automatically looks for the XGBoost image URI and builds an XGBoost container.
# specify the repo_version depending on your preference.
xgboost_container = sagemaker.image_uris.retrieve("xgboost", region, "1.2-2")

# construct a SageMaker estimator that calls the xgboost-container
estimator = sagemaker.estimator.Estimator(image_uri=xgboost_container,
                                         hyperparameters=hyperparameters,
                                         role=sagemaker.get_execution_role(),
                                         instance_count=1,
                                         instance_type='ml.m5.2xlarge',
                                         volume_size=5, # 5 GB
                                         output_path=output_path)

# define the data type and paths to the training and validation datasets
content_type = "libsvm"
train_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'train'),
                           content_type=content_type)
validation_input = TrainingInput("s3://{}/{}/{}".format(bucket, prefix, 'validation'),
                                content_type=content_type)

# execute the XGBoost training job
estimator.fit({'train': train_input, 'validation': validation_input})
```

For more information about how to set up the XGBoost as a built-in algorithm, see the following notebook examples.

- Managed Spot Training for XGBoost
- Regression with Amazon SageMaker XGBoost (Parquet input)

### Input/Output Interface for the XGBoost Algorithm

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.
- For Inference ContentType, valid inputs are `text/libsvm` (default) or `text/csv`.

**Note**

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record.

For CSV inference, the algorithm assumes that CSV input does not have the label column. For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: `<label> <index0>:<value0> <index1>:<value1> ...`. Inference requests for libsvm might not have labels in the libsvm format.
This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it’s not required, but we recommend it.

SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()
model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For `text/libsvm` input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For `text/csv` input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Algorithm**

SageMaker XGBoost 1.0-1 or earlier currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M5) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

SageMaker XGBoost version 1.2 or later supports single-instance GPU training. Despite higher per-instance costs, GPUs train more quickly, making them more cost effective. To take advantage of GPU training, specify the instance type as one of the GPU instances (for example, P3) and set the `tree_method` hyperparameter to `gpu_hist` in your existing XGBoost script. SageMaker currently does not support multi-GPU training.

**XGBoost Sample Notebooks**

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker XGBoost algorithm.
<table>
<thead>
<tr>
<th>Notebook Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>How to Create a Custom XGBoost container?</td>
<td>This notebook shows you how to build a custom XGBoost Container with Amazon SageMaker Batch Transform.</td>
</tr>
<tr>
<td>An Introduction to Feature Processing, Training and Inference</td>
<td>This notebook shows you how to build a Machine Learning (ML) Pipeline using Spark Feature Transformers and do real-time inference using Amazon SageMaker Batch Transform.</td>
</tr>
<tr>
<td>Regression with XGBoost using Parquet</td>
<td>This notebook shows you how to use the Abalone dataset in Parquet to train a XGBoost model.</td>
</tr>
<tr>
<td>How to Train and Host a Multiclass Classification Model?</td>
<td>This notebook shows how to use the MNIST dataset to train and host a multiclass classification model.</td>
</tr>
<tr>
<td>How to train a Model for Customer Churn Prediction?</td>
<td>This notebook shows how to train a model to Predict Mobile Customer Departure in an effort to identify unhappy customers.</td>

<td>How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs?</td>
<td>This notebook shows you how to use Amazon SageMaker Debugger to monitor training jobs to detect inconsistencies.</td>
</tr>
<tr>
<td>How to use Amazon SageMaker Debugger to debug XGBoost Training Jobs in Real-Time?</td>
<td>This notebook shows you how to use the MNIST dataset and Amazon SageMaker Debugger to perform real-time analysis of XGBoost training jobs while training jobs are running.</td>
</tr>
</tbody>
</table>

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The topic modeling example notebooks using the linear learning algorithm are located in the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab and choose Create copy.

How XGBoost Works

XGBoost is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm, which attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models.

When using gradient boosting for regression, the weak learners are regression trees, and each regression tree maps an input data point to one of its leaves that contains a continuous score. XGBoost minimizes a regularized (L1 and L2) objective function that combines a convex loss function (based on the difference between the predicted and target outputs) and a penalty term for model complexity (in other words, the regression tree functions). The training proceeds iteratively, adding new trees that predict the residuals or errors of prior trees that are then combined with previous trees to make the final prediction. It’s called gradient boosting because it uses a gradient descent algorithm to minimize the loss when adding new models.

Below is a brief illustration on how gradient tree boosting works.
For more detail on XGBoost, see:

- XGBoost: A Scalable Tree Boosting System
- Gradient Tree Boosting
- Introduction to Boosted Trees

**XGBoost Hyperparameters**

The following table contains the subset of hyperparameters that are required or most commonly used for the Amazon SageMaker XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source DMLC XGBoost package. Currently SageMaker supports version 1.2-2. For details about full set of hyperparameter that can be configured for this version of XGBoost, see XGBoost Parameters.

</table>
### Parameter Name | Description
---|---
**skip_drop** | Probability of skipping the dropout procedure during a boosting iteration.  
  **Optional**  
  Valid values: Float. Range: [0.0, 1.0].  
  Default value: 0.0

**subsample** | Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting.  
  **Optional**  
  Valid values: Float. Range: [0,1].  
  Default value: 1

**tree_method** | The tree construction algorithm used in XGBoost.  
  **Optional**  
  Valid values: One of auto, exact, approx, hist, or gpu_hist.  
  Default value: auto

**tweedie_variance_power** | Parameter that controls the variance of the Tweedie distribution.  
  **Optional**  
  Valid values: Float. Range: (1, 2).  
  Default value: 1.5

**updater** | A comma-separated string that defines the sequence of tree updaters to run. This provides a modular way to construct and to modify the trees.  
  For a full list of valid inputs, please refer to XGBoost Parameters.  
  **Optional**  
  Valid values: comma-separated string.  
  Default value: grow_colmaker, prune

**verbosity** | Verbosity of printing messages.  
  Valid values: 0 (silent), 1 (warning), 2 (info), 3 (debug).  
  **Optional**  
  Default value: 1
Tune an XGBoost Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

Note
Automatic model tuning for XGBoost 0.90 is only available from the Amazon SageMaker SDKs, not from the SageMaker console.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

Evaluation Metrics Computed by the XGBoost Algorithm

The XGBoost algorithm computes the following metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>
<thead>
<tr>
<th>Metric Name</th>

Tunable XGBoost Hyperparameters

Tune the XGBoost model with the following hyperparameters. The hyperparameters that have the greatest effect on optimizing the XGBoost evaluation metrics are: alpha, min_child_weight, subsample, eta, and num_round.

XGBoost Previous Versions

This page contains links to the documentation for previous versions of Amazon SageMaker XGBoost.

Topics
- XGBoost Version 0.72 (p. 1497)

XGBoost Version 0.72

Important
The XGBoost 0.72 is deprecated by Amazon SageMaker. You can still use this old version of XGBoost (as a built-in algorithm) by pulling its image URI as shown in the following code sample. For XGBoost, the image URI ending with :1 is for the old version.

SageMaker Python SDK v1

```python
import boto3
```
Use built-in algorithms

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
xgb_image_uri = get_image_uri(boto3.Session().region_name, "xgboost",
repo_version="1")
```

SageMaker Python SDK v2

```python
import boto3
from sagemaker import image_uris
xgb_image_uri = image_uris.retrieve("xgboost", boto3.Session().region_name, "1")
```

If you want to use newer versions, you have to explicitly specify the image URI tags (see Supported versions (p. 1481)).

This previous release of the Amazon SageMaker XGBoost algorithm is based on the 0.72 release. XGBoost (eXtreme Gradient Boosting) is a popular and efficient open-source implementation of the gradient boosted trees algorithm. Gradient boosting is a supervised learning algorithm that attempts to accurately predict a target variable by combining the estimates of a set of simpler, weaker models. XGBoost has done remarkably well in machine learning competitions because it robustly handles a variety of data types, relationships, and distributions, and because of the large number of hyperparameters that can be tweaked and tuned for improved fits. This flexibility makes XGBoost a solid choice for problems in regression, classification (binary and multiclass), and ranking.

Customers should consider using the new release of XGBoost Algorithm (p. 1481). They can use it as a SageMaker built-in algorithm or as a framework to run scripts in their local environments as they would typically, for example, do with a Tensorflow deep learning framework. The new implementation has a smaller memory footprint, better logging, improved hyperparameter validation, and an expanded set of metrics. The earlier implementation of XGBoost remains available to customers if they need to postpone migrating to the new version. But this previous implementation will remain tied to the 0.72 release of XGBoost.

Input/Output Interface for the XGBoost Release 0.72

Gradient boosting operates on tabular data, with the rows representing observations, one column representing the target variable or label, and the remaining columns representing features.

The SageMaker implementation of XGBoost supports CSV and libsvm formats for training and inference:

- For Training ContentType, valid inputs are text/libsvm (default) or text/csv.
- For Inference ContentType, valid inputs are text/libsvm or (the default) text/csv.

Note

For CSV training, the algorithm assumes that the target variable is in the first column and that the CSV does not have a header record. For CSV inference, the algorithm assumes that CSV input does not have the label column.

For libsvm training, the algorithm assumes that the label is in the first column. Subsequent columns contain the zero-based index value pairs for features. So each row has the format: `<label> <index0>:<value0> <index1>:<value1> ...` Inference requests for libsvm may or may not have labels in the libsvm format.

This differs from other SageMaker algorithms, which use the protobuf training input format to maintain greater consistency with standard XGBoost data formats.

For CSV training input mode, the total memory available to the algorithm (Instance Count * the memory available in the InstanceType) must be able to hold the training dataset. For libsvm training input mode, it's not required, but we recommend it.
SageMaker XGBoost uses the Python pickle module to serialize/deserialize the model, which can be used for saving/loading the model.

**To use a model trained with SageMaker XGBoost in open source XGBoost**

- Use the following Python code:

```python
import pickle as pkl
import tarfile
import xgboost

t = tarfile.open('model.tar.gz', 'r:gz')
t.extractall()

model = pkl.load(open(model_file_path, 'rb'))

# prediction with test data
pred = model.predict(dtest)
```

**To differentiate the importance of labelled data points use Instance Weight Supports**

- SageMaker XGBoost allows customers to differentiate the importance of labelled data points by assigning each instance a weight value. For text/libsvm input, customers can assign weight values to data instances by attaching them after the labels. For example, `label:weight idx_0:val_0 idx_1:val_1...`. For text/csv input, customers need to turn on the `csv_weights` flag in the parameters and attach weight values in the column after labels. For example: `label,weight,val_0,val_1,...`.

**EC2 Instance Recommendation for the XGBoost Release 0.72**

SageMaker XGBoost currently only trains using CPUs. It is a memory-bound (as opposed to compute-bound) algorithm. So, a general-purpose compute instance (for example, M4) is a better choice than a compute-optimized instance (for example, C4). Further, we recommend that you have enough total memory in selected instances to hold the training data. Although it supports the use of disk space to handle data that does not fit into main memory (the out-of-core feature available with the libsvm input mode), writing cache files onto disk slows the algorithm processing time.

**XGBoost Release 0.72 Sample Notebooks**

For a sample notebook that shows how to use the latest version of SageMaker XGBoost as a built-in algorithm to train and host a regression model, see Regression with Amazon SageMaker XGBoost algorithm. To use the 0.72 version of XGBoost, you need to change the version in the sample code to 0.72. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). Once you have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all the SageMaker samples. The topic modeling example notebooks using the XGBoost algorithms are located in the Introduction to Amazon algorithms section. To open a notebook, click on its Use tab and select Create copy.

**XGBoost Release 0.72 Hyperparameters**

The following table contains the hyperparameters for the XGBoost algorithm. These are parameters that are set by users to facilitate the estimation of model parameters from data. The required hyperparameters that must be set are listed first, in alphabetical order. The optional hyperparameters that can be set are listed next, also in alphabetical order. The SageMaker XGBoost algorithm is an implementation of the open-source XGBoost package. Currently SageMaker supports version 0.72. For more detail about hyperparameter configuration for this version of XGBoost, see XGBoost Parameters.
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

<tr>
<td>skip_drop</td>
<td>Probability of skipping the dropout procedure during a boosting iteration. <strong>Optional</strong> Valid values: Float. Range: [0.0, 1.0]. Default value: 0.0</td>
</tr>
<tr>
<td>subsample</td>
<td>Subsample ratio of the training instance. Setting it to 0.5 means that XGBoost randomly collects half of the data instances to grow trees. This prevents overfitting. <strong>Optional</strong> Valid values: Float. Range: [0,1]. Default value: 1</td>
</tr>
<tr>
<td>tree_method</td>
<td>The tree construction algorithm used in XGBoost. <strong>Optional</strong> Valid values: One of auto, exact, approx, or hist. Default value: auto</td>
</tr>
<tr>
<td>tweedie_variance_power</td>
<td>Parameter that controls the variance of the Tweedie distribution. <strong>Optional</strong> Valid values: Float. Range: (1, 2). Default value: 1.5</td>
</tr>
</tbody>
</table>
Tune an XGBoost Release 0.72 Model

Automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many jobs that test a range of hyperparameters on your training and validation datasets. You choose three types of hyperparameters:

- a learning objective function to optimize during model training
- an eval_metric to use to evaluate model performance during validation
- a set of hyperparameters and a range of values for each to use when tuning the model automatically

You choose the evaluation metric from set of evaluation metrics that the algorithm computes. Automatic model tuning searches the hyperparameters chosen to find the combination of values that result in the model that optimizes the evaluation metric.

For more information about model tuning, see Perform Automatic Model Tuning with SageMaker (p. 1715).

Metrics Computed by the XGBoost Release 0.72 Algorithm

The XGBoost algorithm based on version 0.72 computes the following nine metrics to use for model validation. When tuning the model, choose one of these metrics to evaluate the model. For full list of valid eval_metric values, refer to XGBoost Learning Task Parameters

<table>

Use Reinforcement Learning with Amazon SageMaker

Reinforcement learning (RL) combines fields such as computer science, neuroscience, and psychology to determine how to map situations to actions to maximize a numerical reward signal. This notion of a reward signal in RL stems from neuroscience research into how the human brain makes decisions about which actions maximize reward and minimize punishment. In most situations, humans are not given explicit instructions on which actions to take, but instead must learn both which actions yield the most immediate rewards, and how those actions influence future situations and consequences.

The problem of RL is formalized using Markov decision processes (MDPs) that originate from dynamical systems theory. MDPs aim to capture high-level details of a real problem that a learning agent encounters over some period of time in attempting to achieve some ultimate goal. The learning agent should be able to determine the current state of its environment and identify possible actions that affect the learning agent’s current state. Furthermore, the learning agent’s goals should correlate...
strongly to the state of the environment. A solution to a problem formulated in this way is known as a reinforcement learning method.

**What are the differences between reinforcement, supervised, and unsupervised learning paradigms?**

Machine learning can be divided into three distinct learning paradigms: supervised, unsupervised, and reinforcement.

In supervised learning, an external supervisor provides a training set of labeled examples. Each example contains information about a situation, belongs to a category, and has a label identifying the category to which it belongs. The goal of supervised learning is to generalize in order to predict correctly in situations that are not present in the training data.

In contrast, RL deals with interactive problems, making it infeasible to gather all possible examples of situations with correct labels that an agent might encounter. This type of learning is most promising when an agent is able to accurately learn from its own experience and adjust accordingly.

In unsupervised learning, an agent learns by uncovering structure within unlabeled data. While a RL agent might benefit from uncovering structure based on its experiences, the sole purpose of RL is to maximize a reward signal.

**Topics**

- Why is Reinforcement Learning Important? (p. 1508)
- Markov Decision Process (MDP) (p. 1508)
- Key Features of Amazon SageMaker RL (p. 1509)
- Reinforcement Learning Sample Notebooks (p. 1511)
- Sample RL Workflow Using Amazon SageMaker RL (p. 1511)
- RL Environments in Amazon SageMaker (p. 1512)
- Distributed Training with Amazon SageMaker RL (p. 1514)
- Hyperparameter Tuning with Amazon SageMaker RL (p. 1514)

**Why is Reinforcement Learning Important?**

RL is well-suited for solving large, complex problems, such as supply chain management, HVAC systems, industrial robotics, game artificial intelligence, dialog systems, and autonomous vehicles. Because RL models learn by a continuous process of receiving rewards and punishments for every action taken by the agent, it is possible to train systems to make decisions under uncertainty and in dynamic environments.

**Markov Decision Process (MDP)**

RL is based on models called Markov Decision Processes (MDPs). An MDP consists of a series of time steps. Each time step consists of the following:

**Environment**

Defines the space in which the RL model operates. This can be either a real-world environment or a simulator. For example, if you train a physical autonomous vehicle on a physical road, that would be a real-world environment. If you train a computer program that models an autonomous vehicle driving on a road, that would be a simulator.

**State**

Specifies all information about the environment and past steps that is relevant to the future. For example, in an RL model in which a robot can move in any direction at any time step, the position
of the robot at the current time step is the state, because if we know where the robot is, it isn't necessary to know the steps it took to get there.

**Action**

What the agent does. For example, the robot takes a step forward.

**Reward**

A number that represents the value of the state that resulted from the last action that the agent took. For example, if the goal is for a robot to find treasure, the reward for finding treasure might be 5, and the reward for not finding treasure might be 0. The RL model attempts to find a strategy that optimizes the cumulative reward over the long term. This strategy is called a *policy*.

**Observation**

Information about the state of the environment that is available to the agent at each step. This might be the entire state, or it might be just a part of the state. For example, the agent in a chess-playing model would be able to observe the entire state of the board at any step, but a robot in a maze might only be able to observe a small portion of the maze that it currently occupies.

Typically, training in RL consists of many *episodes*. An episode consists of all of the time steps in an MDP from the initial state until the environment reaches the terminal state.

**Key Features of Amazon SageMaker RL**

To train RL models in SageMaker RL, use the following components:

- An RL environment. You can use custom environments, open-source environments, or commercial environments. For information, see [RL Environments in Amazon SageMaker](p. 1512).

The following diagram shows the RL components that are supported in SageMaker RL.
Reinforcement Learning Sample Notebooks

The following table outlines a variety of sample notebooks that address different use cases of Amazon SageMaker reinforcement learning.

<table>

Sample RL Workflow Using Amazon SageMaker RL

The following example describes the steps for developing RL models using Amazon SageMaker RL.

For complete code examples, see the sample notebooks at https://github.com/awslabs/amazon-sagemaker-examples/tree/master/reinforcement-learning.

1. **Formulate the RL problem**—First, formulate the business problem into an RL problem. For example, auto scaling enables services to dynamically increase or decrease capacity depending on conditions that you define. Currently, this requires setting up alarms, scaling policies, thresholds, and other manual steps. To solve this with RL, we define the components of the Markov Decision Process:
   a. **Objective**—Scale instance capacity so that it matches the desired load profile.
   b. **Environment**—A custom environment that includes the load profile. It generates a simulated load with daily and weekly variations and occasional spikes. The simulated system has a delay between when new resources are requested and when they become available for serving requests.
   c. **State**—The current load, number of failed jobs, and number of active machines.
   d. **Action**—Remove, add, or keep the same number of instances.
   e. **Reward**—A positive reward for successful transactions and a high penalty for failing transactions beyond a specified threshold.

2. **Define the RL environment**—The RL environment can be the real world where the RL agent interacts or a simulation of the real world. You can connect open source and custom environments developed using Gym interfaces and commercial simulation environments such as MATLAB and Simulink.

3. **Define the presets**—The presets configure the RL training jobs and define the hyperparameters for the RL algorithms.

4. **Write the training code**—Write training code as a Python script and pass the script to a SageMaker training job. In your training code, import the environment files and the preset files, and then define the `main()` function.

5. **Train the RL Model**—Use the SageMaker `RLEstimator` in the Amazon SageMaker Python SDK to start an RL training job. If you are using local mode, the training job runs on the notebook instance.
When you use SageMaker for training, you can select GPU or CPU instances. Store the output from the training job in a local directory if you train in local mode, or on Amazon S3 if you use SageMaker training.

The RLEstimator requires the following information as parameters.

a. The source directory where the environment, presets, and training code are uploaded.
b. The path to the training script.
c. The RL toolkit and deep learning framework you want to use. This automatically resolves to the Amazon ECR path for the RL container.
d. The training parameters, such as the instance count, job name, and S3 path for output.
e. Metric definitions that you want to capture in your logs. These can also be visualized in CloudWatch and in SageMaker notebooks.

6. **Visualize training metrics and output**—After a training job that uses an RL model completes, you can view the metrics you defined in the training jobs in CloudWatch. You can also plot the metrics in a notebook by using the Amazon SageMaker Python SDK analytics library. Visualizing metrics helps you understand how the performance of the model as measured by the reward improves over time.

   **Note**
   If you train in local mode, you can't visualize metrics in CloudWatch.

7. **Evaluate the model**—Checkpointed data from the previously trained models can be passed on for evaluation and inference in the checkpoint channel. In local mode, use the local directory. In SageMaker training mode, you need to upload the data to S3 first.

8. **Deploy RL models**—Finally, deploy the trained model on an endpoint hosted on SageMaker containers or on an edge device by using AWS IoT Greengrass.

For more information on RL with SageMaker, see [Using RL with the SageMaker Python SDK](#).

**RL Environments in Amazon SageMaker**

Amazon SageMaker RL uses environments to mimic real-world scenarios. Given the current state of the environment and an action taken by the agent or agents, the simulator processes the impact of the action, and returns the next state and a reward. Simulators are useful in cases where it is not safe to train an agent in the real world (for example, flying a drone) or if the RL algorithm takes a long time to converge (for example, when playing chess).

The following diagram shows an example of the interactions with a simulator for a car racing game.
The simulation environment consists of an agent and a simulator. Here, a convolutional neural network (CNN) consumes images from the simulator and generates actions to control the game controller. With multiple simulations, this environment generates training data of the form state_t, action, state_t+1, and reward_t+1. Defining the reward is not trivial and impacts the RL model quality. We want to provide a few examples of reward functions, but would like to make it user-configurable.

**Topics**
- Use OpenAI Gym Interface for Environments in SageMaker RL (p. 1513)
- Use Open-Source Environments (p. 1514)
- Use Commercial Environments (p. 1514)

**Use OpenAI Gym Interface for Environments in SageMaker RL**

To use OpenAI Gym environments in SageMaker RL, use the following API elements. For more information about OpenAI Gym, see https://gym.openai.com/docs/.

- `env.action_space`—Defines the actions the agent can take, specifies whether each action is continuous or discrete, and specifies the minimum and maximum if the action is continuous.
- `env.observation_space`—Defines the observations the agent receives from the environment, as well as minimum and maximum for continuous observations.
- `env.reset()`—Initializes a training episode. The `reset()` function returns the initial state of the environment, and the agent uses the initial state to take its first action. The action is then sent to `step()` repeatedly until the episode reaches a terminal state. When `step()` returns `done = True`, the episode ends. The RL toolkit re-initializes the environment by calling `reset()`.
- `step()`—Takes the agent action as input and outputs the next state of the environment, the reward, whether the episode has terminated, and an info dictionary to communicate debugging information. It is the responsibility of the environment to validate the inputs.
- `env.render()`—Used for environments that have visualization. The RL toolkit calls this function to capture visualizations of the environment after each call to the `step()` function.
Use Open-Source Environments

You can use open-source environments, such as EnergyPlus and RoboSchool, in SageMaker RL by building your own container. For more information about EnergyPlus, see https://energyplus.net/. For more information about RoboSchool, see https://github.com/openai/roboschool. The HVAC and RoboSchool examples in the SageMaker examples repository show how to build a custom container to use with SageMaker RL:

Use Commercial Environments

You can use commercial environments, such as MATLAB and Simulink, in SageMaker RL by building your own container. You need to manage your own licenses.

Distributed Training with Amazon SageMaker RL

Amazon SageMaker RL supports multi-core and multi-instance distributed training. Depending on your use case, training and/or environment rollout can be distributed. For example, SageMaker RL works for the following distributed scenarios:

- Single training instance and multiple rollout instances of the same instance type. For an example, see the Neural Network Compression example in the SageMaker examples repository.
- Single trainer instance and multiple rollout instances, where different instance types for training and rollouts. For an example, see the AWS DeepRacer / AWS RoboMaker example in the SageMaker examples repository.
- Single trainer instance that uses multiple cores for rollout. For an example, see the Roboschool example in the SageMaker examples repository. This is useful if the simulation environment is lightweight and can run on a single thread.
- Multiple instances for training and rollouts. For an example, see the Roboschool example in the SageMaker examples repository.

Hyperparameter Tuning with Amazon SageMaker RL

You can run a hyperparameter tuning job to optimize hyperparameters for Amazon SageMaker RL. The Roboschool example in the sample notebooks in the SageMaker examples repository shows how you can do this with RL Coach. The launcher script shows how you can abstract parameters from the Coach preset file and optimize them.

Manage Machine Learning with Amazon SageMaker Experiments

Amazon SageMaker Experiments is a capability of Amazon SageMaker that lets you organize, track, compare, and evaluate your machine learning experiments.

Machine learning is an iterative process. You need to experiment with multiple combinations of data, algorithm and parameters, all the while observing the impact of incremental changes on model accuracy. Over time this iterative experimentation can result in thousands of model training runs and model versions. This makes it hard to track the best performing models and their input configurations. It’s also difficult to compare active experiments with past experiments to identify opportunities for further incremental improvements.

SageMaker Experiments automatically tracks the inputs, parameters, configurations, and results of your iterations as trials. You can assign, group, and organize these trials into experiments. SageMaker
Experiments is integrated with Amazon SageMaker Studio providing a visual interface to browse your active and past experiments, compare trials on key performance metrics, and identify the best performing models.

SageMaker Experiments comes with its own Experiments Python SDK which makes the analytics capabilities easily accessible in Amazon SageMaker Notebooks. Because SageMaker Experiments enables tracking of all the steps and artifacts that went into creating a model, you can quickly revisit the origins of a model when you are troubleshooting issues in production, or auditing your models for compliance verifications.

## SageMaker Experiments Features

The following sections provide a brief overview of the features provided by SageMaker Experiments.

**Topics**
- Organize Experiments (p. 1515)
- Track Experiments (p. 1515)
- Compare and Evaluate Experiments (p. 1516)
- Amazon SageMaker Autopilot (p. 1516)

### Organize Experiments

Amazon SageMaker Experiments offers a structured organization scheme to help users group and organize their machine learning iterations. The top level entity, an experiment, is a collection of trials that are observed, compared, and evaluated as a group. A trial is a set of steps called trial components. Each trial component can include a combination of inputs such as datasets, algorithms, and parameters, and produce specific outputs such as models, metrics, datasets, and checkpoints. Examples of trial components are data pre-processing jobs, training jobs, and batch transform jobs.

The goal of an experiment is to determine the trial that produces the best model. Multiple trials are performed, each one isolating and measuring the impact of a change to one or more inputs, while keeping the remaining inputs constant. By analyzing the trials, you can determine which features have the most effect on the model.

### Track Experiments

Amazon SageMaker Experiments enables tracking of experiments.

**Automated Tracking**

SageMaker Experiments automatically tracks Amazon SageMaker Autopilot jobs as experiments with their underlying training jobs tracked as trials. SageMaker Experiments also automatically tracks
SageMaker independently executed training, batch transform, and processing jobs as trial components, whether assigned to a trial or left unassigned. Unassigned trial components can be associated with a trial at a later time. All experiment artifacts including datasets, algorithms, hyperparameters, and model metrics are tracked and recorded. This data allows customers to trace the complete lineage of a model which helps with model governance, auditing, and compliance verifications.

**Manual Tracking**

SageMaker Experiments provides tracking APIs for recording and tracking machine learning workflows running locally on SageMaker Studio notebooks, including classic SageMaker notebooks. These experiments must be part of a SageMaker training, batch transform, or processing job.

**Compare and Evaluate Experiments**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Studio. When you use SageMaker Studio, SageMaker Experiments automatically tracks your experiments and trials, and presents visualizations of the tracked data and an interface to search the data.

SageMaker Experiments automatically organizes, ranks, and sorts trials based on a chosen metric using the concept of a trial leaderboard. SageMaker Studio produces real-time data visualizations, such as metric charts and graphs, to quickly compare and identify the best performing models. These are updated in real-time as the experiment progresses.

**Amazon SageMaker Autopilot**

Amazon SageMaker Experiments is integrated with Amazon SageMaker Autopilot. When you perform an Autopilot job, SageMaker Experiments creates an experiment for the job, and trials for each of the different combinations of the available trial components, parameters, and artifacts. You can visually drill into all trials and components using SageMaker Studio.

**Create an Amazon SageMaker Experiment**

Create an Amazon SageMaker experiment to track your SageMaker training, processing, and transform jobs.

The following procedure shows you how to create a SageMaker experiment for a SageMaker training, processing, or transform job. Steps labeled as (Studio) describe how to view the experiment in Amazon SageMaker Studio. You don't have to run the experiment in Studio to view the experiment in Studio.

For a tutorial that shows this functionality in an existing SageMaker Studio notebook, see Track and Compare Tutorial (p. 1523).

1. Import the `sys` module to install the SDKs.

   ```python
   import sys
   ```

2. (Optional) The Amazon SageMaker Python SDK, comes preinstalled in SageMaker Studio. If you plan to run your code outside Studio, install the SageMaker Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker
   ```

3. Install the SageMaker Experiments Python SDK.

   ```bash
   !{sys.executable} -m pip install sagemaker-experiments
   ```

4. Import modules.

1516
import time
from time import strftime
import sagemaker
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker

5. Get the execution role and create the SageMaker session.

```python
role = sagemaker.get_execution_role()
sm_sess = sagemaker.session.Session()
```

6. Create a SageMaker experiment. The experiment name must be unique in your account.

   **Note**
   The `tags` parameter is optional. You can search for the tag using Studio, the SageMaker console, and the SDK. Tags can also be applied to trials and trial components. For information on how to search tags using Studio, see [Search by Tag](p. 1533).

```python
create_date = strftime("%Y-%m-%d-%H-%M-%S")
demo_experiment = Experiment.create(experiment_name = "DEMO-{}.format(create_date),
                                 description = "Demo experiment",
                                 tags = [{'Key': 'demo-experiments', 'Value': 'demo1'}])
```

7. (Studio) To view the experiment in SageMaker Studio, in the left sidebar, choose the **Components and registries** icon (öffnen). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

   After the code runs, the experiment list contains the new experiment. It might take a moment for the list to refresh and display the experiment. The filter on the experiment tag is also displayed. Only experiments that have a matching tag are displayed. Your list should look similar to the following:
8. Create a trial for the experiment. The trial name must be unique in your account.

```python
demo_trial = Trial.create(trial_name = "DEMO-{}".format(create_date),
                      experiment_name = demo_experiment.experiment_name,
                      tags = [{'Key': 'demo-trials', 'Value': 'demo1'}])
```

9. (Studio) In the experiment list, double-click the experiment to display a list of the trials in the experiment (this example has one trial). Your list should look similar to the following:
10. Create a trial component as part of the trial. The trial component is the SageMaker job.

Add the `ExperimentConfig` parameter to the appropriate method. The SageMaker jobs listed in the following table are supported.

<table>
<thead>
<tr>
<th>Job</th>
<th>SageMaker Python SDK method</th>
<th>Boto3 method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td><code>Estimator.fit</code></td>
<td><code>CreateTrainingJob</code></td>
</tr>
<tr>
<td>Processing</td>
<td><code>Processor.run</code></td>
<td><code>CreateProcessingJob</code></td>
</tr>
<tr>
<td>Transform</td>
<td><code>Transformer.transform</code></td>
<td><code>CreateTransformJob</code></td>
</tr>
</tbody>
</table>

The following examples are for a training job. The `Tags` parameter adds a tag to the trial component. `ExperimentName` isn't specified because the trial was associated with the experiment when the trial was created in an earlier step.

**Using the SageMaker Python SDK**

```python
sagemaker.estimator.Estimator(
    ...
    sagemaker_session = sm_sess,
    tags = [{'Key': 'demo-jobs', 'Value': 'demo2'}])

estimator.fit(
    ...,
    experiment_config = {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    })
```

**Using Boto3**
create_training_job(
    ...
    "ExperimentConfig": {
        # "ExperimentName"
        "TrialName" : demo_trial.trial_name,
        "TrialComponentDisplayName" : "TrainingJob",
    },
    "Tags": [{"Key": 'demo-jobs', 'Value': 'demo2'}])

11. (Studio) In the trial list, double-click the trial to display a list of the components in the trial (this example has one trial). Your list should look similar to the following:

12. (Studio) To view information about the experiment, trial, and job (trial component), see View and Compare Amazon SageMaker Experiments, Trials, and Trial Components (p. 1520).

To clean up the resources you created, see Clean Up Amazon SageMaker Experiment Resources (p. 1534).

View and Compare Amazon SageMaker Experiments, Trials, and Trial Components

An Amazon SageMaker experiment consists of multiple trials with a related objective. A trial consists of one or more trial components, such as a data preprocessing job and a training job.

You use the experiments browser to display a list of these entities. You can filter the list by entity name, type, and tags. The entities are presented in a hierarchical view (that is, experiments > trials > trial components). Double-click an entity to see other entities that are at a lower level in the hierarchy. Use the breadcrumbs above the list to move to a higher level in the hierarchy.

For a tutorial using a SageMaker example notebook, see Track and Compare Tutorial (p. 1523). For an overview of the Studio user interface, see Amazon SageMaker Studio UI Overview (p. 71).

Topics
- View Experiments, Trials, and Trial Components (p. 1521)
- Compare Experiments, Trials, and Trial Components (p. 1522)
View Experiments, Trials, and Trial Components

Amazon SageMaker Studio provides an experiments browser that you can use to view lists of experiments, trials, and trial components. You can choose one of these entities to view detailed information about the entity or choose multiple entities for comparison.

To view experiments, trials, and trial components

1. In the left sidebar of Studio, choose the **Components and registries** icon ( ![Components and registries icon](image)). In the drop-down menu, select **Experiments and trials** to display the experiments browser.

   A list of experiments and their properties is displayed. The list includes all the SageMaker experiments in your account, including experiments created outside of SageMaker Studio.

   **Note**
   To view all the properties, you might have to expand the width of the experiments browser by dragging the right border.

2. In the experiments list, double-click an experiment to display a list of the trials in the experiment.

3. Double-click a trial to display a list of the components in the trial.
4. Double-click one of the components to open the **Describe Trial Component** tab.

5. On the **Describe Trial Component** tab, choose any of the following column headings to see available information about each trial component:

   - **Charts** – Build your own charts.
   - **Metrics** – Metrics that are logged by a Tracker during a trial run.
   - **Parameters** – Hyperparameter values and instance information.
   - **Artifacts** – Amazon S3 bucket storage locations for the input dataset and the output model.
   - **AWS Settings** – Job name, ARN, status, creation time, training time, billable time, instance information, and others.
   - **Debugger** – A list of debugger rules and any issues found.
   - **Trial Mappings**

For information about comparing Experiments entities, see **View and Compare Amazon SageMaker Experiments, Trials, and Trial Components** (p. 1520).

**Compare Experiments, Trials, and Trial Components**

You can compare experiments, trials, and trial components by selecting the entities and opening them in the trial components list. The trial components list is referred to as the Studio Leaderboard. In the Leaderboard you can do the following:

   - View detailed information about the entities
   - Compare entities
• Stop a training job
• Deploy a model

To compare experiments, trials, and trial components

1. In the left sidebar of SageMaker Studio, choose the SageMaker Experiment List icon ( ).
2. In the Experiments browser, choose either the experiment or trial list. For more information, see View Experiments, Trials, and Trial Components (p. 1521).
3. Choose the experiments or trials that you want to compare, right-click the selection, and then choose Open in trial component list. The Leaderboard opens and lists the associated Experiments entities as shown in the following screenshot.

The Leaderboard has a TABLE PROPERTIES pane on the right side. Use the Settings icon ( ) to open and close the pane. You can hide or display properties by category or by individual columns. When you display a chart, the pane changes to display chart properties.

For information on searching the Experiments entities, see Search Experiments Using Amazon SageMaker Studio (p. 1529).

Track and Compare Tutorial

This tutorial demonstrates how to visually track and compare trials in a model training experiment using Amazon SageMaker Studio. The basis of the tutorial is the MNIST Handwritten Digits Classification Experiment notebook.

It is intended that this topic be viewed alongside Studio with the MNIST notebook open. As you run through the cells, the sections in this document highlight the relevant code and show you how to observe the results in Studio. Some of the code snippets have been edited for brevity.

To clean up the resources created by the notebook, see Clean Up Amazon SageMaker Experiment Resources (p. 1534).

For a tutorial that showcases additional features of Studio, see Amazon SageMaker Studio Tour (p. 53).

Prerequisites
A local copy of the MNIST example notebook and the companion mnist.py file. Both files are available from the sagemaker_experiments/mnist-handwritten-digits-classification-experiment folder in the aws/amazon-sagemaker-examples repository. To download the files, choose each link, right-click on the Raw button, and then choose Save as.

An AWS SSO or IAM account to sign-on to SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).

Topics

- Open the Notebook in Studio (p. 1524)
- Install the Experiments SDK and Import Modules (p. 1524)
- Transform and Track the Input Data (p. 1525)
- Create and Track an Experiment (p. 1525)
- Compare and Analyze Trials (p. 1527)

Open the Notebook in Studio

To open the notebook

1. Sign-on to Studio.
2. In the left sidebar, choose the File Browser icon ( ).
3. At the top of the file browser pane, choose the Up arrow icon and then a File Upload dialog opens. Browse to and choose your local versions of the mnist-handwritten-digits-classification-experiment.ipynb and mnist.py files, and then choose Open.
4. The two files are listed in the file browser. Double-click the uploaded notebook file to open the notebook in a new tab.
5. At the top right of the notebook, make sure the kernel is Python 3 (Data Science). If not, choose the current kernel name to open the Select Kernel dropdown. Choose Python 3 (Data Science) and then choose Select.

Install the Experiments SDK and Import Modules

The Amazon SageMaker Experiments Python SDK is separate from the Amazon SageMaker Python SDK, which comes preinstalled in SageMaker Studio. Run the first few cells in the notebook to install the Experiments SDK and import the Experiments modules. The relevant sections of the notebook cells are displayed below.

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import sagemaker
from sagemaker import get_execution_role
from sagemaker.session import Session
from sagemaker.analytics import ExperimentAnalytics
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent
from smexperiments.tracker import Tracker
```
Transform and Track the Input Data

The next few cells create an Amazon S3 bucket and a folder in the bucket named `mnist`. In Studio, the file browser displays the `mnist` folder. The input data is downloaded to the `mnist/MNIST/raw` folder, normalized, and then the transformed data is uploaded to the `mnist/MNIST/processed` folder. You can drill down into the `mnist` folder to display, but not open, the data files.

Your screen should look similar to the following:

![Image of an Amazon SageMaker Studio interface with a file browser displaying the 'mnist' folder, showing 'mnist/MNIST/raw' and 'mnist/MNIST/processed' folders.]

The last cell in the Dataset section creates a Tracker for the transform job. The tracker logs the normalization parameters and the URI of the Amazon S3 bucket where the transformed dataset is stored. In a later section, we show how to find this information in Studio. In the next section, the tracker is used to track the experiment and trial runs.

```python
with Tracker.create(display_name="Preprocessing", sagemaker_boto_client=sm) as tracker:
    tracker.log_parameters(
        {
            "normalization_mean": 0.1307,
            "normalization_std": 0.3081,
        }
    )
    tracker.log_input(name="mnist-dataset", media_type="s3/uri", value=inputs)
```

Create and Track an Experiment

The following procedure creates and tracks an experiment to determine the effect of the model's `num_hidden_channel` hyperparameter. As part of the experiment, five trials are created inside a loop, one for each value of the `num_hidden_channel` hyperparameter. Later in the notebook, you'll compare the results of these five trials.

1. In the left sidebar of Studio, choose the SageMaker Components and registries icon (🚀). In the dropdown menu, choose Experiments and trials to display the list of experiments in your account.
2. Run the following cell.

```python
mnist_experiment = Experiment.create(  
    experiment_name=f"mnist-hand-written-digits-classification-{int(time.time())}" ,  
    description="Classification of mnist hand-written digits",  
    sagemaker_boto_client=sm)
print(mnist_experiment)
```

Output:

```
Experiment(sagemaker_boto_client=<botocore.client.SageMaker object at 0x7f7152b326d8>,  
    experiment_name='mnist-hand-written-digits-classification-1575947870',  
    description='Classification of mnist hand-written digits',  
```

After the code runs, the experiments list contains an entry for the experiment. It might take a moment to display and you might have to refresh the experiments list. Your screen should look similar to the following:
3. Run the following cell.

```python
preprocessing_trial_component = tracker.trial_component
```

After the code runs, the experiments list contains an entry labeled **Unassigned trial components**. The trial component entry is the data preprocessing step previously created. Double-click the trial component for verification. The trial component isn’t associated with an experiment at this time. Your screen should look similar to the following:

4. Choose the **Home** icon in the navigation breadcrumb at the top on the experiments browser. From there, double-click on your experiment to display a list of the trials in the experiment.

5. The following code create trials for the experiment. Each trial trains a model using a different number for the `num_hidden_channel` hyperparameter. The preprocessing trial component is added to each trial for complete tracking (for example, for auditing purposes). The code also specifies definitions for the following metrics:

- Train loss
- Test loss
- Test accuracy

The definitions tell SageMaker to capture those metrics from the algorithm's log output. The metrics are used later to evaluate and compare the models.

```python
preprocessing_trial_component = tracker.trial_component

for i, num_hidden_channel in enumerate([2, 5, 10, 20, 32]):
    trial_name = f"cnn-training-job-{num_hidden_channel}-hidden-channels-{int(time.time())}"
    cnn_trial = Trial.create(
        trial_name=trial_name,
        experiment_name=mnist_experiment.experiment_name,
        sagemaker_boto_client=sm,
    )
    hidden_channel_trial_name_map[num_hidden_channel] = trial_name
    cnn_trial.add_trial_component(preprocessing_trial_component)
```
estimator = PyTorch(
    py_version='py3',
    framework_version='1.1.0',
    ...
    hyperparameters={
        'hidden_channels': num_hidden_channel,
        ...
    },
    metric_definitions=[
        {'Name':'train:loss', 'Regex':'Train Loss: (.*)'},
        {'Name':'test:loss', 'Regex':'Test Average loss: (.*)'},
        {'Name':'test:accuracy', 'Regex':'Test Accuracy: (.*)'}
    ],
    enable_sagemaker_metrics=True,
)

cnn_training_job_name = "cnn-training-job-{}.format(int(time.time()))
estimator.fit(
    inputs={'training': inputs},
    job_name=cnn_training_job_name,
    experiment_config={
        "TrialName": cnn_trial.trial_name,
        "TrialComponentDisplayName": "Training",
    },
)

The trial list automatically updates as each training job runs. It takes a few minutes for each trial to be displayed. Your screen should look similar to the following:

**Compare and Analyze Trials**

This section deviates from the notebook and shows you how to compare and analyze the trained models using the SageMaker Studio UI.

**To view the details of a trial**

1. Double-click one of the trials to display a list of the trial components associated with the trial. There's a preprocessing job and training job for each trial. Double-click one of the components to open a new tab that displays information about each component.

2. Under **Trial stages**, choose **Preprocessing**. On the **Describe Trial Component** menu, choose **Parameters** to display the normalization parameters that were previously logged. Next, choose **Artifacts** to display the URI of the Amazon S3 bucket where the transformed dataset was stored.

3. Under **Trial stages**, choose **Training**. On the **Describe Trial Component** menu, choose the following items to display information about the training job trial component.
• **Metrics** – test:loss, test:accuracy, and train:loss
• **Parameters** – hyperparameter values and instance information
• **Artifacts** – Amazon S3 storage for the input dataset and the output model
• **AWS Settings** – job name, ARN, status, creation time, training time, billable time, instance information, and others

**To view a list of trials ordered by test:accuracy**

1. Choose the experiment name on the navigation breadcrumb above **TRIAL COMPONENTS** to display the trial list.
2. Choose all five trials. Hold down the CTRL/CMD key and select each trial. Right-click the selection and then choose **Open in trial component list**. A new tab opens that displays each trial and trial component.
3. If the **TABLE PROPERTIES** pane isn't open, choose the **Settings** icon (▲) in the upper right corner to open it. Deselect everything except **Trial**, **Metrics**, and **Training job**. Choose the **Settings** icon to close the pane.
4. Choose the **test:accuracy** column header to sort the list by decreasing maximum test accuracy. Your screen should look similar to the following:

![Trial Component List](image)

**To view a chart of test:loss versus num_hidden_channel**

1. In the **TRIAL COMPONENTS** pane, choose all five trials and then choose **Add chart**. Select inside the chart area to open the preferences pane for **CHART PROPERTIES**.
2. In **CHART PROPERTIES**, choose the following:
   • **Data type** - Summary statistics
   • **Chart type** - Line
   • **X-axis** - hidden-channels
   • **Y-axis** - test:loss_last
• Color - None

Your screen should look similar to the following:

Search Experiments Using Amazon SageMaker Studio

You can search your experiments, trials, and trial components using the experiments browser. After choosing the entities, you can search on properties of these entities on the Amazon SageMaker Leaderboard.

Topics
• Search Experiments, Trials, and Trial Components (p. 1529)
• Search the SageMaker Studio Leaderboard (p. 1530)
• Search by Tag (p. 1533)

Search Experiments, Trials, and Trial Components

You can search and create multiple filters to display a subset of experiments, trials, and trial components in the experiments browser. After you search and filter your list, you can open the entities in the Leaderboard and search on additional properties.

To search for experiments, trials, and trial components, and apply filters

For more information about the following steps, along with screenshots, see Search the SageMaker Studio Leaderboard (p. 1530).

1. In the experiments browser, navigate to the entity type you want to search for: experiment, trial, or trial component.
2. Place your cursor in the search box to display the list of column that are searchable.
3. Choose the column that you want to search on and one of the following dialog boxes opens that's specific to the column you chose:
• **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.

• **Discrete values** – Choose one or more property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values.

• **Date** – Enter a date in **From Date** and **To Date**, or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified date range.

• **Tag** – In **Search tag key**, start entering the tag's key. A list of tag keys is filtered to only those keys with a name that starts with the text string that you enter. Choose the tag key that you want to search on from the list. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

4. To create the filter, choose **Apply**.

5. To apply additional filters, repeat the preceding steps. You can have a maximum of 20 filters. An entity must match all filters to be displayed.

**Search the SageMaker Studio Leaderboard**

The Amazon SageMaker Studio trial components list is referred to as the Leaderboard. You can use the Leaderboard to compare your trials and experiments. The Leaderboard lists properties of the trials, such as the trial status, debugger status, tags, metrics, hyperparameters, and input and output artifacts.

You can search the Leaderboard to find specific trial components. You apply the results of a search to create a filter that displays only those components that satisfy the filter. You can apply up to 20 filters. A component is displayed only if it matches all filters. To remove a filter, choose the X that displays to the right of the filter.

**To search the Leaderboard and apply filters**

1. If the TABLE PROPERTIES pane isn't open in SageMaker Studio, choose the **Settings** icon ( ) in the upper-right corner to open it.

2. In the **Settings** pane, select the check boxes for the columns that you want to view, and then choose the **Settings** icon to close the pane.

3. Place your cursor in the **Search column name** box to display the following list of TABLE PROPERTIES column names that are searchable:

   **Summary section**
   - Trial component name
   - Trial component type
   - Created
   - Last modified
   - Created by
   - Tags

   **Detail sections** (all columns)
   - Metrics
   - Parameters
   - Input artifacts
   - Output artifacts
4. To limit the column names when you search the detail sections, start typing the column name. The list displays only those columns with a name that starts with the text string that you enter.

5. Choose the column that you want to search on. This opens a dialog that's specific to the type of data in that column.

6. Enter your search criteria in the dialog for the appropriate data type:
   - **String** – Enter a text string in the search dialog box that opens. Enter a string of at least three characters that's part of the component's property value. This filter limits the list to those components with a property value that contains the text string.
   - **Discrete values** – Choose one or more of the property values from the list. This filter limits the list to those components with a property value that matches at least one of the chosen values. For the **Trial component type** column, **Others** matches components with no value in the column.
• **Date** – Enter a date in From Date and To Date or select the dates from the calendar. This filter limits the list to those components that were created or last modified in the specified data range.

• **Created by** – Select Me or Everyone else. This filter limits the list to those components that were created by the currently signed-in user or everyone but the currently signed-in user.

• **Tag** – Choose the tag to search. For more information, see Search by Tag (p. 1533).

• **Detail columns** – Specify the conditions that the component's property value must satisfy.
7. To create the filter, choose **Apply**.
8. To apply additional filters, repeat the preceding steps. A component must match all filters to be displayed. You can have a maximum of 20 filters.

**Search by Tag**

You can add searchable tags to experiments, trials, and trial components when the entities are created or afterwards using the **AddTags** API. A tag consists of a unique case-sensitive key and an optional value. Multiple tags can be added to an entity. You can add the same tag to multiple entities.

**To search by tag and apply filters**

1. If the **TABLE PROPERTIES** pane isn’t open in SageMaker Studio, choose the **Settings** icon (⚙️) in the upper-right corner to open it.
2. In the **Settings** pane, select **Tags** if it isn’t selected, and then choose the **Settings** icon to close the pane.
3. Place your cursor in the **Search column name** box and then choose **Tags**.
4. In **Search tag key**, start entering the tag’s key. A list of tag keys displays only those keys with a name that starts with the text string that you enter.
5. Choose the tag key that you want to search on from the list.
6. In **Search tag value**, enter the complete tag value, and then choose **Apply**.

7. The trial component list displays only those components that have tags that match the key-value pair you chose.

8. To add more tag filters, repeat the previous steps. A tag must match all filters for the component to be displayed.

**Clean Up Amazon SageMaker Experiment Resources**

To avoid incurring unnecessary charges, delete the Amazon SageMaker Experiment resources you no longer need. You can't delete Experiment resources through the SageMaker Management Console or the Amazon SageMaker Studio UI. This topic shows you how to clean up these resources using Boto3 and the Experiments SDK. For more information about the Experiments SDK, see [sagemaker-experiments](#).

To delete the experiment, you must delete all trials in the experiment. To delete a trial, you must remove all trial components from the trial. To delete a trial component, you must remove the component from all trials.

**Note**

Trial components can exist independent of trials and experiments. You do not have to delete them. If you want to reuse them, comment out `tc.delete()` in the code.
Clean Up Using the Experiments SDK

To clean up using the Experiments SDK

```python
import sys
!{sys.executable} -m pip install sagemaker-experiments

import time
from smexperiments.experiment import Experiment
from smexperiments.trial import Trial
from smexperiments.trial_component import TrialComponent

def cleanup_sme_sdk(experiment):
    for trial_summary in experiment.list_trials():
        trial = Trial.load(trial_name=trial_summary.trial_name)
        for trial_component_summary in trial.list_trial_components():
            tc = TrialComponent.load(
                trial_component_name=trial_component_summary.trial_component_name)
            trial.remove_trial_component(tc)
            try:
                # comment out to keep trial components
                tc.delete()
            except:
                # tc is associated with another trial
                continue
            # to prevent throttling
            time.sleep(.5)
            trial.delete()
            experiment_name = experiment.experiment_name
            experiment.delete()
            print(f"\nExperiment {experiment_name} deleted")

cleanup_sme_sdk(experiment_to_cleanup)
```

Clean Up Using the Python SDK (Boto3)

To clean up using Boto 3

```python
import boto3
sm = boto3.Session().client('sagemaker')

def cleanup_boto3(experiment):
    # Use experiment name not display name
    experiment_name="experiment-name"
    experiment.delete()
```

Call cleanup_boto3

```python
cleanup_boto3(experiment_to_cleanup)
```
Search Using the Amazon SageMaker Console and API

Developing a machine learning model typically requires extensive experimenting with different datasets, algorithms, and hyperparameter values. To manage up to thousands of machine learning model experiments, use the search capabilities in SageMaker.

You can use SageMaker search to:

- Organize, find, and evaluate training jobs using properties, hyperparameters, performance metrics, or any metadata.
- Find the best performing model by reviewing training job and model metrics, such as training loss or validation accuracy.
- Trace a model's lineage to the training job and its related resources, such as the training datasets.

This topic covers searching from the SageMaker console and the SageMaker API. For information on searching in Amazon SageMaker Studio, see Search Experiments Using Studio (p. 1529).

**Topics**

- Sample Notebooks for Managing ML Experiments (p. 1537)
- Organize, Find, and Evaluate Training Jobs (Console) (p. 1537)
- Find and Evaluate Training Jobs (API) (p. 1539)
- Verify the Datasets Used by Your Training Jobs (p. 1540)
Sample Notebooks for Managing ML Experiments

For a sample notebook that uses Amazon SageMaker model tracking capability to manage ML experiments, see Managing ML Experimentation using Amazon SageMaker Model Tracking Capability.

For instructions on how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all of the SageMaker samples. The notebook for managing ML experiments is located in the Advanced Functionality section. To open a notebook, choose its Use tab, and choose Create copy. If you have questions, post them on the Amazon Machine Learning Developer Forum.

Organize, Find, and Evaluate Training Jobs (Console)

To organize training jobs, assign one or more tags to them.

To find a specific training job, model, or resource, use model tracking to search on keywords assigned to any searchable items. Searchable items include training jobs, models, hyperparameters, metadata, tags, and URLs. To refine your tracking results, you can search using multiple criteria.

To choose the best model for deployment, evaluate how all models performed against one or more metrics. You can use model tracking results to list, sort, and evaluate the performance of the models in your experiments.

Topics

- Use Tags to Track Training Jobs (Console) (p. 1537)
- Find Training Jobs (Console) (p. 1538)
- Evaluate Models (Console) (p. 1538)

Use Tags to Track Training Jobs (Console)

To group training jobs, create tags with descriptive keys and a value. For example, create tag keys for: project, owner, customer, and industry.

Add tags to training jobs (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Training jobs and Create training job.
3. Scroll to the bottom of the page and enter a key and value for the tag.
4. To add another tag, choose Add tag, and add another key-value pair.
Find Training Jobs (Console)

You can search for training jobs using a variety of job attributes. Note that some search parameters appear only if you have created a training job with that attribute. For example, **Tags** appears only if you have added a tag for a training job.

**To find training jobs (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Search**.
3. Add **Parameters**.
   a. In the search box, enter a parameter and choose a parameter type, for example **TrainingJobName**.
   b. Choose a conditional operation. For numeric values, use operators such as **is equals to**, **lesser than**, or **or greater than**. For text-based values, use operators such as **equals to** or **contains**.
   c. Enter a value for the parameter.
4. (Optional) To refine your search, add additional search criteria. Choose **Add row** and enter the parameter values.
5. Choose **Search**.

Evaluate Models (Console)

To evaluate a model's performance, review its metadata, hyperparameters, and metrics. To highlight metrics, adjust the view to show only metrics and important hyperparameters.

**To evaluate a model (console)**

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose **Search** and search for training jobs by specifying relevant parameters. The results are displayed in a table.

<table>
<thead>
<tr>
<th>HyperParameter</th>
<th>Metric</th>
<th>Metric</th>
<th>Metric</th>
<th>Metric</th>
</tr>
</thead>
<tbody>
<tr>
<td>mini_batch_size</td>
<td>train:binary_f_beta</td>
<td>train:progress</td>
<td>train:objective_loss</td>
<td>train:objective_loss</td>
</tr>
<tr>
<td>300</td>
<td>binary_classifier</td>
<td>0.966639518737793</td>
<td>100</td>
<td>0.02381423674523</td>
</tr>
<tr>
<td>100</td>
<td>binary_classifier</td>
<td>0.9652714133262634</td>
<td>100</td>
<td>0.02350491285324</td>
</tr>
<tr>
<td>200</td>
<td>binary_classifier</td>
<td>0.9647442698478699</td>
<td>100</td>
<td>0.02325980737805</td>
</tr>
</tbody>
</table>

3. Open the preferences window by choosing the settings icon in the search results table.
4. To show or hide a hyperparameter or metric, turn it on or off by choosing **Hyperparameter** or **Metric**.

5. Make necessary changes, then choose **Update view**.

6. After viewing metrics and important hyperparameters, you can compare and contrast the result. Then, you can choose the best model to host or investigate the models that are performing poorly.

**Find and Evaluate Training Jobs (API)**

To find and evaluate training jobs or to get suggestions for items used in experiments that are searchable, you can use the **Search API**.

**Topics**
- Find Training Jobs (API) (p. 1539)
- Evaluate Models (API) (p. 1539)
- Get Suggestions for a Search (API) (p. 1540)

**Find Training Jobs (API)**

To find training jobs, create a search parameter using the `search_params` parameter. Then use the `search` function in the `smclient` subprocess in the AWS SDK for Python (Boto3).

The following example shows how to use the **Search API** to find training jobs.

```python
import boto3

search_params=
"MaxResults": 10,
"Resource": "TrainingJob",
"SearchExpression": {
  "Filters": [{
    "Name": "Tags.Project",
    "Operator": "Equals",
    "Value": "Project_Binary_Classifier"
  }],
  "SortBy": "Metrics.train:binary_classification_accuracy",
  "SortOrder": "Descending"
}

smclient = boto3.client(service_name='sagemaker')
results = smclient.search(**search_params)
```

**Evaluate Models (API)**

To evaluate models, run a search as described in **Find Training Jobs (API)** (p. 1539), review model metrics, then, use the AWS SDK for Python (Boto3) to create a table and plot it.

The following example shows how to evaluate models and to display the results in a table.

```python
import pandas

headers=['Training Job Name', 'Training Job Status', 'Batch Size', 'Binary Classification Accuracy']
rows=[]
for result in results['Results']:
    trainingJob = result['TrainingJob']
    metrics = trainingJob['FinalMetricDataList']
```
Get Suggestions for a Search (API)

To get suggestions for a search, use the `GetSearchSuggestions` API.

The following example for AWS SDK for Python (Boto3) is a `get_search_suggestions` request for items containing linear.

```python
search_suggestion_params={
    "Resource": "TrainingJob",
    "SuggestionQuery": {
        "PropertyNameQuery": {
            "PropertyNameHint": "linear"
        }
    }
}
```

The following is an example response for a `get_search_suggestions` request.

```json
{
    "PropertyNameSuggestions": [
        {'PropertyName': 'hyperparameters.linear_init_method'},
        {'PropertyName': 'hyperparameters.linear_init_value'},
        {'PropertyName': 'hyperparameters.linear_init_sigma'},
        {'PropertyName': 'hyperparameters.linear_lr'},
        {'PropertyName': 'hyperparameters.linear_wd'}
    ]
}
```

After getting search suggestions, you can use one of the property names in a search.

Verify the Datasets Used by Your Training Jobs

You can use model tracking capability to verify which datasets were used in training, where holdout datasets were used, and other details about training jobs. For example, use model tracking capability to verify that a specific dataset was used in a training job for an audit or to verify compliance.

To check whether a specific dataset was used in a training job, you search for the URL to its location in Amazon Simple Storage Service (Amazon S3). Model tracking capability returns the training jobs that used the dataset that you specify. If your search doesn't return the dataset (the result is empty), the dataset wasn't used in a training job. An empty result confirms, for example, that a holdout dataset wasn't used.

Trace Model Lineage

You can use model tracking capability to get information about the lineage of training jobs and the model resources that were used for them, including the dataset, algorithm, hyperparameters, and metrics. For example, if you find that the performance of a hosted model has declined, you can review its training job and the resources it used to determine what's causing the problem.
Topics

• Trace Model Lineage (Console) (p. 1541)
• Trace Model Lineage (API) (p. 1541)

Trace Model Lineage (Console)

To trace a model's lineage (console)

1. Open the Amazon SageMaker console.
2. In the navigation pane, choose Endpoints, and choose the relevant endpoint.
3. Scroll to the Endpoint configuration settings section. This section lists all of the model versions deployed at the endpoint, with a hyperlink to the training job that created each.

Trace Model Lineage (API)

To trace a model's lineage, get the model's name, then use it to search for training jobs.

The following example shows how to trace a model's lineage using the API.

```python
# Get the name of model deployed at endpoint
endpoint_config = smclient.describe_endpoint_config(EndpointConfigName=endpointName)
model_name = endpoint_config['ProductionVariants'][0]['ModelName']

# Get the model's name
model = smclient.describe_model(ModelName=model_name)

# Search the training job by the location of model artifacts in Amazon S3
search_params={
    "MaxResults": 1,
    "Resource": "TrainingJob",
    "SearchExpression": {
        "Filters": [
            {
                "Name": "ModelArtifacts.S3ModelArtifacts",
                "Operator": "Equals",
                "Value": model['PrimaryContainer']['ModelDataUrl']
            }
        ]
    }
}
results = smclient.search(**search_params)
```

After finding the training job, you can review the resources used to train the model.

Amazon SageMaker Debugger

Debug, monitor, and profile training jobs in real time, detect non-converging conditions, optimize resource utilization by eliminating bottlenecks, improve training time, and reduce costs of your machine learning models using Amazon SageMaker Debugger.

Amazon SageMaker Debugger Features

A machine learning (ML) training job can have problems such as system bottlenecks, overfitting, saturated activation functions, and vanishing gradients, which can compromise model performance.
SageMaker Debugger profiles and debugs training jobs to help resolve such problems and improve your ML model's compute resource utilization and performance. Debugger offers tools to send alerts when training anomalies are found, take actions against the problems, and identify the root cause of them by visualizing collected metrics and tensors.

SageMaker Debugger supports Apache MXNet, TensorFlow, PyTorch, and XGBoost. For more information about available frameworks and versions, see Supported Frameworks and Algorithms (p. 1543).

The high-level Debugger workflow is as follows:

1. Configure a SageMaker training job with Debugger.
   - Configure using the SageMaker Estimator API (for Python SDK).
   - Configure using the SageMaker CreateTrainingJob request (for Boto3 or CLI).
   - Configure custom training containers (p. 1644) with Debugger.
2. Start a training job and monitor training issues in real time.
   - SageMaker Studio Debugger dashboards in Studio Experiments and trials (p. 1658).
   - List of Debugger Built-in Rules (p. 1598).
3. Get alerts and take prompt actions against the training issues.
   - Receive texts and emails and stop training jobs when training issues are found using Debugger Built-in Actions for Rules (p. 1648).
   - Set up your own actions using Amazon CloudWatch Events and AWS Lambda (p. 1653).
4. Receive training reports, suggestions to fix the issues, and insights into your training jobs.
   - Studio Debugger Insights dashboard for deep learning frameworks
   - Deep learning framework profiling report
   - SageMaker XGBoost training report
5. Explore deep analysis of the training issues and bottlenecks.
   - For profiling training jobs, see Analyze Data Using the SMDebug Client Library (p. 1697).
   - For debugging model parameters, see Visualize Debugger Output Tensors in TensorBoard (p. ).
6. Fix the issues, considering the suggestions provided by Debugger, and repeat steps 1–5 until you optimize your model and achieve target accuracy.

The SageMaker Debugger developer guide walks you through the following topics.

Topics
- Supported Frameworks and Algorithms (p. 1543)
- Amazon SageMaker Debugger Architecture (p. 1544)

</table>

- **Monitoring system bottlenecks** – Monitor the system utilization rate for resources such as CPU, GPU, memories, network, and data I/O metrics. This is a framework and model agnostic feature and available for any training jobs in SageMaker.
• **Profiling deep learning framework operations** – Profile the deep learning operations of the TensorFlow and PyTorch frameworks, such as step durations, data loaders, forward and backward operations, Python profiling metrics, and framework-specific metrics.

• **Debugging model parameters** – Track and debug model parameters, such as weights, gradients, biases, and scalar values of your training job. Available deep learning frameworks are Apache MXNet, TensorFlow, PyTorch, and XGBoost.

If the framework or algorithm that you want to train and debug is not listed in the table, go to the AWS Discussion Forum and leave feedback on SageMaker Debugger.

### Use Debugger with Custom Training Containers

Bring your training containers to SageMaker and gain insights into your training jobs using Debugger. Maximize your work efficiency by optimizing your model on Amazon EC2 instances using the monitoring and debugging features.

For more information about how to build your training container with the `SMDebug` client library, push it to the Amazon Elastic Container Registry (Amazon ECR), and monitor and debug, see Use Debugger with Custom Training Containers (p. 1644).

### Debugger Open-Source GitHub Repositories

Debugger APIs are provided through the SageMaker Python SDK and designed to construct Debugger hook and rule configurations for the SageMaker `CreateTrainingJob` and `DescribeTrainingJob` API operations. The `SMDebug` client library provides tools to register hooks and access the training data through its `trial` feature, all through its flexible and powerful API operations. It supports the machine learning frameworks TensorFlow, PyTorch, MXNet, and XGBoost on Python 3.6 and later.

For direct resources about the Debugger and `SMDebug` API operations, see the following links:

- The Amazon SageMaker Python SDK documentation
- The Amazon SageMaker Debugger APIs
- The `SMDebug` open source client library
- The `SMDebug` PyPI

If you use the SDK for Java to conduct SageMaker training jobs and want to configure Debugger APIs, see the following references:

- Amazon SageMaker Debugger API Operations (p. 1710)
- Configure Debugger Using Amazon SageMaker API (p. 1588)

### Amazon SageMaker Debugger Architecture

This topic walks you through a high-level overview of the Amazon SageMaker Debugger workflow.

Debugger supports profiling functionality for *performance optimization* to identify computation issues, such as system bottlenecks and underutilization, and to help optimize hardware resource utilization at scale.

Debugger’s debugging functionality for *model optimization* is about analyzing non-converging training issues that can arise while minimizing the loss functions using optimization algorithms, such as gradient descent and its variations.

The following diagram shows the architecture of SageMaker Debugger. The blocks with bold boundary lines are what Debugger manages to analyze your training job.
Debugger stores the following data from your training jobs in your secured Amazon S3 bucket:

- **System metrics** – Hardware resource utilization data, such as CPU, GPU, CPU and GPU memory, network, and data input and output (I/O) metrics.
- **Framework metrics** – Metrics to track each framework operation per call or sampling, such as convolutional layer operations in the forward pass, batch normalization operations in the backward pass, data loader processes between steps, and gradient descent algorithm operations to calculate and update the loss function.
- **Output tensors** – Collections of scalars and model parameters that are continuously updated during the forward and backward passes while training ML models. The output tensors include scalar values (accuracy and loss) and matrices (weights, gradients, input layers, and output layers).

**Note**

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics.
every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured Amazon S3 bucket.

The Debugger built-in rules run on processing containers, which are designed to evaluate machine learning models by processing the training data collected in your S3 bucket (see Process Data and Evaluate Models). The built-in rules are fully managed by Debugger. You can also create your own rules customized to your model to watch for any issues you want to monitor.

See the following topics for best practices to improve the performance of your model using SageMaker Debugger.

**Get Started with Debugger Tutorials**

The following topics walk you through tutorials from the basics to advanced use cases of monitoring, profiling, and debugging SageMaker training jobs using Debugger. Explore the Debugger features and learn how you can debug and improve your machine learning models efficiently by using Debugger.

**Topics**

- Debugger Tutorial Videos (p. 1546)
- Debugger Example Notebooks (p. 1547)
- Debugger Advanced Demos and Visualization (p. 1549)

**Debugger Tutorial Videos**

The following videos provide a tour of Amazon SageMaker Debugger capabilities using SageMaker Studio and SageMaker notebook instances.

**Topics**

- Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger (p. 1546)
- Debug Models with Amazon SageMaker Debugger in Studio (p. 1546)
- Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor (p. 1547)

**Analyze, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger**

*Emily Webber, AWS Machine Learning Specialist | Length: 13 minutes 54 seconds*

This tutorial video gives you a tour of Amazon SageMaker Debugger to capture, debug, and visualize model output data from a training model with MXNet. Learn how Amazon SageMaker Debugger makes the training process transparent by automatically capturing metrics, analyzing training runs, and detecting problems.

**Analyse, Detect, and Get Alerted on Problems with Training Runs Using Amazon SageMaker Debugger**

You can find the example notebook in this video at Visualizing Debugging Tensors of MXNet training in the Amazon SageMaker Examples GitHub repository.

**Debug Models with Amazon SageMaker Debugger in Studio**

*Julien Simon, AWS Technical Evangelist | Length: 14 minutes 17 seconds*
This tutorial video demonstrates how to use Amazon SageMaker Debugger to capture and inspect debugging information from a training model. The example training model used in this video is a simple convolutional neural network (CNN) based on Keras with the TensorFlow backend. SageMaker in a TensorFlow framework and Debugger enable you to build an estimator directly using the training script and debug the training job.

Debug Models with Amazon SageMaker Debugger (part 1)

You can find the example notebook in the video in this Studio Demo repository provided by the author. You need to clone the debugger.ipynb notebook file and the mnist_keras_tf.py training script to your SageMaker Studio or a SageMaker notebook instance. After you clone the two files, specify the path keras_script_path to the mnist_keras_tf.py file inside the debugger.ipynb notebook. For example, if you cloned the two files in the same directory, set it as keras_script_path = "mnist_keras_tf.py".

Deep Dive on Amazon SageMaker Debugger and SageMaker Model Monitor

Julien Simon, AWS Technical Evangelist | Length: 44 minutes 34 seconds

This video session explores advanced features of Debugger and SageMaker Model Monitor that help boost productivity and the quality of your models. First, this video shows how to detect and fix training issues, visualize tensors, and improve models with Debugger. Next, at 22:41, the video shows how to monitor models in production and identify prediction issues such as missing features or data drift using SageMaker Model Monitor. Finally, it offers cost optimization tips to help you make the most of your machine learning budget.

Debug Models with Debugger (part 2)

You can find the example notebook in the video in this AWS Dev Days 2020 repository offered by the author.

Debugger Example Notebooks

SageMaker Debugger example notebooks are provided in the aws/amazon-sagemaker-examples repository. The Debugger example notebooks walk you through basic to advanced use cases of debugging and profiling training jobs.

We recommend that you run the example notebooks on SageMaker Studio or a SageMaker Notebook instance because most of the examples are designed for training jobs in the SageMaker ecosystem, including Amazon EC2, Amazon S3, and Amazon SageMaker Python SDK.

To clone the example repository to SageMaker Studio, follow the instructions at Amazon SageMaker Studio Tour.

To find the examples in a SageMaker Notebook instance, follow the instructions at SageMaker Notebook Instance Example Notebooks.

Important

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Debugger Example Notebooks for Profiling Training Jobs

The following list shows Debugger example notebooks introducing Debugger's adaptability to monitor and profile training jobs for various machine learning models, datasets, and frameworks.
This notebook provides an introduction to interactive analysis of profiled data captured by SageMaker Debugger. Explore the full functionality of the SMDebug interactive analysis tools.

Profile TensorFlow 1-D CNN for sentiment analysis of IMDB data that consists of movie reviews labeled as having positive or negative sentiment. Explore the Studio Debugger insights and Debugger profiling report.

Run TensorFlow training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.

Run TensorFlow training jobs with various distributed training settings, monitor system resource utilization, and profile model performance using Debugger.

To find advanced visualizations of model parameters and use cases, see the next topic at Debugger Advanced Demos and Visualization (p. 1549).

## Debugger Advanced Demos and Visualization

The following demos walk you through advanced use cases and visualization scripts using Debugger.

### Topics
- **Train and Tune Your Models with Amazon SageMaker Experiments and Debugger** (p. 1549)
- **Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training** (p. 1552)
- **Using SageMaker Debugger to Monitor Attentions in BERT Model Training** (p. 1552)
- **Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)** (p. 1555)

### Train and Tune Your Models with Amazon SageMaker Experiments and Debugger

*Dr. Nathalie Rauschmayr, AWS Applied Scientist | Length: 49 minutes 26 seconds*

Train and Prune Models with SageMaker Experiments and Debugger

Find out how Amazon SageMaker Experiments and Debugger can simplify the management of your training jobs. Amazon SageMaker Debugger provides transparent visibility into training jobs and saves training metrics into your Amazon S3 bucket. SageMaker Experiments enables you to call the training information as trials through SageMaker Studio and supports visualization of the training job. This helps you keep model quality high while reducing less important parameters based on importance rank.

This video demonstrates a *model pruning* technique that makes pre-trained ResNet50 and AlexNet models lighter and affordable while keeping high standards for model accuracy.
SageMaker Estimator trains those algorithms supplied from the PyTorch model zoo in an AWS Deep Learning Containers with PyTorch framework, and Debugger extracts training metrics from the training process.

The video also demonstrates how to set up a Debugger custom rule to watch the accuracy of a pruned model, to trigger an Amazon CloudWatch event and an AWS Lambda function when the accuracy hits a threshold, and to automatically stop the pruning process to avoid redundant iterations.

Learning objectives are as follows:

- Learn how to use SageMaker to accelerate ML model training and improve model quality.
- Understand how to manage training iterations with SageMaker Experiments by automatically capturing input parameters, configurations, and results.
- Discover how Debugger makes the training process transparent by automatically capturing real-time tensor data from metrics such as weights, gradients, and activation outputs of convolutional neural networks.
- Use CloudWatch to trigger Lambda when Debugger catches issues.
- Master the SageMaker training process using SageMaker Experiments and Debugger.

You can find the notebooks and training scripts used in this video from SageMaker Debugger PyTorch Iterative Model Pruning.

The following image shows how the iterative model pruning process reduces the size of AlexNet by cutting out the 100 least significant filters based on importance rank evaluated by activation outputs and gradients.

The pruning process reduced the initial 50 million parameters to 18 million. It also reduced the estimated model size from 201 MB to 73 MB.

**Pruning iteration: 0**

Total params: 58,883,321
Trainable params: 58,883,321
Non-trainable params: 0

Input size (MB): 0.57
Forward/backward pass size (MB): 7.27
Params size (MB): 194.18
Estimated Total Size (MB): 201.95
You also need to track model accuracy, and the following image shows how you can plot the model pruning process to visualize changes in model accuracy based on the number of parameters in SageMaker Studio.

In SageMaker Studio, choose the **Experiments** tab, select a list of tensors saved by Debugger from the pruning process, and then compose a **Trial Component List** panel. Select all ten iterations and then choose **Add chart** to create a **Trial Component Chart**. After you decide on a model to deploy, choose the trial component and choose a menu to perform an action or choose **Deploy model**.

**Note**
To deploy a model through SageMaker Studio using the following notebook example, add a line at the end of the train function in the `train.py` script.

```python
# In the train.py script, look for the train function in line 58.
def train(epochs, batch_size, learning_rate):
    ...
    print('acc:{:.4f}'.format(correct/total))
    hook.save_scalar("accuracy", correct/total, sm_metric=True)

    # Add the following code to line 128 of the train.py script to save the pruned models
    # under the current SageMaker Studio model directory
    torch.save(model.state_dict(), os.environ['SM_MODEL_DIR'] + '/model.pt')
```

Using SageMaker Debugger to Monitor a Convolutional Autoencoder Model Training

This notebook demonstrates how SageMaker Debugger visualizes tensors from an unsupervised (or self-supervised) learning process on a MNIST image dataset of handwritten numbers.

The training model in this notebook is a convolutional autoencoder with the MXNet framework. The convolutional autoencoder has a bottleneck-shaped convolutional neural network that consists of an encoder part and a decoder part.

The encoder in this example has two convolution layers to produce compressed representation (latent variables) of the input images. In this case, the encoder produces a latent variable of size (1, 20) from an original input image of size (28, 28) and significantly reduces the size of data for training by 40 times.

The decoder has two deconvolutional layers and ensures that the latent variables preserve key information by reconstructing output images.

The convolutional encoder powers clustering algorithms with smaller input data size and the performance of clustering algorithms such as k-means, k-NN, and t-Distributed Stochastic Neighbor Embedding (t-SNE).

This notebook example demonstrates how to visualize the latent variables using Debugger, as shown in the following animation. It also demonstrates how the t-SNE algorithm classifies the latent variables into ten clusters and projects them into a two-dimensional space. The scatter plot color scheme on the right side of the image reflects the true values to show how well the BERT model and t-SNE algorithm organize the latent variables into the clusters.

Using SageMaker Debugger to Monitor Attentions in BERT Model Training

Bidirectional Encode Representations from Transformers (BERT) is a language representation model. As the name of model reflects, the BERT model builds on transfer learning and the Transformer model for natural language processing (NLP).

The BERT model is pre-trained on unsupervised tasks such as predicting missing words in a sentence or predicting the next sentence that naturally follows a previous sentence. The training data contains 3.3 billion words (tokens) of English text, from sources such as Wikipedia and electronic books. For a simple example, the BERT model can give a high attention to appropriate verb tokens or pronoun tokens from a subject token.
The pre-trained BERT model can be fine-tuned with an additional output layer to achieve state-of-the-art model training in NLP tasks, such as automated responses to questions, text classification, and many others.

Debugger collects tensors from the fine-tuning process. In the context of NLP, the weight of neurons is called attention.

This notebook demonstrates how to use the pre-trained BERT model from the GluonNLP model zoo on the Stanford Question and Answering dataset and how to set up SageMaker Debugger to monitor the training job.

Plotting attention scores and individual neurons in the query and key vectors can help to identify causes of incorrect model predictions. With SageMaker Debugger, you can retrieve the tensors and plot the attention-head view in real time as training progresses and understand what the model is learning.

The following animation shows the attention scores of the first 20 input tokens for ten iterations in the training job provided in the notebook example.
Using SageMaker Debugger to Visualize Class Activation Maps in Convolutional Neural Networks (CNNs)

This notebook demonstrates how to use SageMaker Debugger to plot class activation maps for image detection and classification in convolutional neural networks (CNNs). In deep learning, a convolutional neural network (CNN or ConvNet) is a class of deep neural networks, most commonly applied to analyzing visual imagery. One of the applications that adopts the class activation maps is self-driving cars, which require instantaneous detection and classification of images such as traffic signs, roads, and obstacles.

In this notebook, the PyTorch ResNet model is trained on the German Traffic Sign Dataset, which contains more than 40 classes of traffic-related objects and more than 50,000 images in total.

During the training process, SageMaker Debugger collects tensors to plot the class activation maps in real time. As shown in the animated image, the class activation map (also called as a saliency map) highlights regions with high activation in red color.

Using tensors captured by Debugger, you can visualize how the activation map evolves during the model training. The model starts by detecting the edge on the lower-left corner at the beginning of the training job. As the training progresses, the focus shifts to the center and detects the speed limit sign, and the model successfully predicts the input image as Class 3, which is a class of speed limit 60km/h signs, with a 97% confidence level.

Configure Debugger Using Amazon SageMaker Python SDK

To configure Debugger, use Amazon SageMaker Python SDK and specify Debugger-specific parameters while constructing SageMaker estimators. There are three parameters you need to configure: profiler_config, debugger_hook_config, and rules.

Note

By default, Debugger monitors and debugs SageMaker training jobs without any Debugger-specific parameters configured in SageMaker estimators. Debugger collects system metrics every 500 milliseconds and basic output tensors (scalar outputs such as loss and accuracy) every 500 steps. It also runs the ProfilerReport rule to analyze the system metrics and aggregate the Studio Debugger insights dashboard and a profiling report. Debugger saves the output data in your secured S3 bucket.
Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter Notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Construct a SageMaker Estimator with Debugger

The following example codes show how to construct a SageMaker estimator with the Debugger-specific parameters depending on a framework of your choice. Throughout the documentation in the following topics, you can find more information about how to configure the Debugger-specific parameters that you can mix and match as you want.

Note
The following example codes are not directly executable. You need to proceed to the next sections and configure the Debugger-specific parameters.

TensorFlow

To access the deep profiling feature for TensorFlow, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker TensorFlow estimator
import boto3
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule, rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)  
deauber_hook_config=DebuggerHookConfig(...)
rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=TensorFlow(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```
PyTorch

To access the deep profiling feature for PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI as shown in the following example code:

```python
# An example of constructing a SageMaker PyTorch estimator
import boto3
import sagemaker
from sagemaker.pytorch import PyTorch
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

session=boto3.session.Session()
region=session.region_name

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=PyTorch(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    image_uri=f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04",
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)
```

MXNet

```python
# An example of constructing a SageMaker MXNet estimator
import sagemaker
from sagemaker.mxnet import MXNet
from sagemaker.debugger import ProfilerConfig, DebuggerHookConfig, Rule, ProfilerRule,
rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)

rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=MXNet(
    entry_point="directory/to/your_training_script.py",
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.7.0",
    py_version="py37",
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
```

1557
# Debugger-specific parameters

```python
profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)  
```

```
Rules=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]
```

```
estimator=XGBoost(
    entry_point=directory/to/your_training_script.py,
    role=sagemaker.get_execution_role(),
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.p3.2xlarge",
    framework_version="1.2-1",
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)
```

```
estimator.fit(wait=False)
```

**Note**

For XGBoost, when configuring the `profiler_config` parameter, you can only configure for system monitoring. Profiling framework metrics is not supported for XGBoost.

---

**XGBoost**

---

**Generic estimator**

---
region=boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",

    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

estimator.fit(wait=False)

Where you configure the following parameters:

- **profiler_config** parameter – Configure Debugger to collect system metrics and framework metrics from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the profiler_config parameter, see Configure Debugger Monitoring Hardware System Resource Utilization (p. 1560) and Configure Debugger Framework Profiling (p. 1560).

- **debugger_hook_config** parameter – Configure Debugger to collect output tensors from your training job and save into your secured S3 bucket URI or local machine. To learn how to configure the debugger_hook_config parameter, see Configure Debugger Hook to Save Tensors (p. 1564).

- **rules** parameter – Configure this parameter to enable Debugger built-in rules that you want to run in parallel. The rules automatically analyze your training job and find training issues. The ProfilerReport rule saves the Debugger profiling reports in your secured S3 bucket URI. To learn how to configure the rules parameter, see Configure Debugger Built-in Rules (p. 1570).

**Note**

Debugger securely saves output data in subfolders of your default S3 bucket. For example, the format of the default S3 bucket URI is s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/<debugger-subfolders>/. There are three subfolders created by Debugger: debug-output, profiler-output, and rule-output. You can also retrieve the default S3 bucket URIs using the SageMaker estimator classmethods (p. 1587).

See the following topics to find out how to configure the Debugger-specific parameters in detail.

**Topics**

- Configure Debugger Monitoring Hardware System Resource Utilization (p. 1560)
- Configure Debugger Framework Profiling (p. 1560)
- Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1564)
- Configure Debugger Hook to Save Tensors (p. 1564)
- Configure Debugger Built-in Rules (p. 1570)
- Turn Off Debugger (p. 1586)
- Useful SageMaker Estimator Classmethods for Debugger (p. 1587)
Configure Debugger Monitoring Hardware System Resource Utilization

To adjust Debugger system monitoring time intervals, use the ProfilerConfig API operation to create a parameter object while constructing a SageMaker framework or generic estimator depending on your preference.

**Note**
By default, for all SageMaker training jobs, Debugger collects hardware system utilization data from Amazon EC2 instances every 500 milliseconds for system monitoring, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the system metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

The following example code shows how to set up the profiler_config parameter with a system monitoring time interval of 1000 milliseconds.

```python
from sagemaker.debugger import ProfilerConfig
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000
)
```

- `system_monitor_interval_millis` (int) – Specify the monitoring intervals in milliseconds to record system metrics. Available values are 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds. The default value is 500 milliseconds.

To see the progress of system monitoring, see Open Amazon SageMaker Debugger Insights Dashboard (p. 1659).

Configure Debugger Framework Profiling

To enable Debugger framework profiling, configure the framework_profile_params parameter when you construct an estimator. Debugger framework profiling collects framework metrics, such as data from initialization stage, data loader processes, Python operators of deep learning frameworks and training scripts, detailed profiling within and between steps, with cProfile or Pyinstrument options. Using the FrameworkProfile class, you can configure custom framework profiling options.

**Note**
Before getting started with Debugger framework profiling, verify that the framework used to build your model is supported by Debugger for framework profiling. For more information, see Supported Frameworks and Algorithms (p. 1543).

Debugger saves the framework metrics in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/profiler-output/`.

Start a Training Job with the Default System Monitoring and Framework Profiling

The following example code is the simplest profiler_config parameter setting to start the default system monitoring and the default framework profiling. The FrameworkProfile class in the following example code initiates the default framework profiling when a training job starts. Debugger framework profiling includes the following options: detailed profiling, data loader profiling, and Python profiling.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
```
Configure Debugger Using SageMaker Python SDK

```python
profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile()
)
```

With this `profiler_config` parameter configuration, Debugger calls the default settings of monitoring and profiling. Debugger monitors system metrics every 500 milliseconds; profiles the fifth step with the detailed profiling option; the seventh step with the data loader profiling option; and the ninth, tenth, and eleventh steps with the Python profiling option.

To find available profiling configuration options, the default parameter settings, and examples of how to configure them, see Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options (p. 1562) and SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

If you want to change the system monitoring interval and enable the default framework profiling, you can specify the `system_monitor_interval_millis` parameter explicitly with the `framework_profile_params` parameter. For example, to monitor every 1000 milliseconds and enable the default framework profiling, use the following example code.

```python
from sagemaker.debugger import ProfilerConfig, FrameworkProfile
profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile()
)
```

For more information about the `FrameworkProfile` class, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

Start a Training Job with the Default System Monitoring and Customized Framework Profiling for Target Steps or a Target Time Range

If you want to specify target steps or target time intervals to profile your training job, you need to specify parameters for the `FrameworkProfile` class. The following code examples show how to specify the target ranges for profiling along with system monitoring.

- **For a target step range**

  With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

  With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target step range from step 5 to step 15 (for 10 steps).

  ```python
  from sagemaker.debugger import ProfilerConfig, FrameworkProfile
  profiler_config=ProfilerConfig(
      system_monitor_interval_millis=1000,
      framework_profile_params=FrameworkProfile(start_step=5, num_steps=10)
  )
  ```

- **For a target time range**
With the following example configuration, Debugger monitors the entire training job every 500 milliseconds (the default monitoring) and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

With the following example configuration, Debugger monitors the entire training job every 1000 milliseconds and profiles a target time range from the current Unix time for 600 seconds.

```python
import time
from sagemaker.debugger import ProfilerConfig, FrameworkProfile

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=1000,
    framework_profile_params=FrameworkProfile(start_unix_time=int(time.time()), duration=600)
)
```

The framework profiling is performed for all of the profiling options at the target step or time range.

To find more information about available profiling options, see SageMaker Debugger APIs – FrameworkProfile in the Amazon SageMaker Python SDK.

The next section shows you how to script the available profiling options.

### Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options

You can use the following profiling configuration classes to manage the framework profiling options:

- **DetailedProfilingConfig** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  Detailed profiling might significantly increase GPU memory consumption. We do not recommend enabling detailed profiling for more than a couple of steps.

- **DataloaderProfilingConfig** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.

  **Note**
  Data loader profiling might lower the training performance while collecting information from data loaders. We don't recommend enabling data loader profiling for more than a couple of steps.
  Debugger is preconfigured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes from any other custom or external training containers.

- **PythonProfilingConfig** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.
• **cProfile** – The standard Python profiler. cProfile collects information for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation for each function call, providing complete detail about Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function call executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

• **Pyinstrument** – Pyinstrument is a low-overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wall-clock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noise (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute-intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

**Note**
Enabling Python profiling might slow down the overall training time. cProfile profiles the most frequently called Python operators at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

The following example configuration shows the full structure when you use the different profiling options with specified values.

```python
import time
from sagemaker.debugger import (ProfilerConfig,
                                 FrameworkProfile,
                                 DetailedProfilingConfig,
                                 DataloaderProfilingConfig,
                                 PythonProfilingConfig)

profiler_config=ProfilerConfig(
    system_monitor_interval_millis=500,
    framework_profile_params=FrameworkProfile(
        detailed_profiling_config=DetailedProfilingConfig(
            start_step=5,
            num_steps=1
        ),
        dataloader_profiling_config=DataloaderProfilingConfig(
            start_step=7,
            num_steps=1
        ),
    python_profiling_config=PythonProfilingConfig(
        start_step=9,
        num_steps=1,
        python_profiler="cProfile",
        cprofile_timer="total_time"
    )
)
```

For more information about available profiling options, see `DetailedProfilingConfig`, `DataloaderProfilingConfig`, and `PythonProfilingConfig` in the Amazon SageMaker Python SDK.
Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running

If you want to enable or update the Debugger monitoring and profiling configuration for a training job that is currently running, use the following SageMaker estimator extension methods:

- To enable Debugger system monitoring for a running training job and receive a Debugger profiling report, use the following:
  
  ```python
  estimator.enable_default_profiling()
  ```
  
  When you use the `enable_default_profiling` method, Debugger initiates the default system monitoring and the `ProfileReport` built-in rule, which generates a comprehensive profiling report at the end of the training job. This method can be called only if the current training job is running without both Debugger monitoring and profiling.

  For more information, see `estimator.enable_default_profiling` in the Amazon SageMaker Python SDK.

- To enable Debugger built-in rules, system monitoring, and framework profiling with customizable configuration parameters, use the following:
  
  ```python
  estimator.update_profiler(
      rules=[ProfilerRule.sagemaker(rule_configs.BuiltInRule()),
             system_monitor_interval_millis=500,
             framework_profile_params=FrameworkProfile()
           )
  ```

  For more information, see `estimator.update_profiler` in the Amazon SageMaker Python SDK.

Configure Debugger Hook to Save Tensors

Tensors are data collections of updated parameters from the backward and forward pass of each training iteration, and Debugger collects output tensors to analyze the state of a training job. The Amazon SageMaker Debugger `CollectionConfig` and `DebuggerHookConfig` API operations provide methods for grouping tensors into `collections` and saving them to a target S3 bucket.

**Note**

By default, for all SageMaker training jobs, Debugger collects loss and accuracy output scalars from the training jobs every 500 steps, without any Debugger-specific parameters specified in SageMaker estimators. Debugger saves the output data in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

While constructing a SageMaker estimator, enable Debugger by specifying the hook configuration parameter, `debugger_hook_config`. The following steps include examples of how to set up the `debugger_hook_config` using the `CollectionConfig` and `DebuggerHookConfig` API operations to pull tensors out of your training jobs and save them. If you use Debugger-supported AWS containers for zero script change, you can simply run the training job without changing your training script. You can also use Debugger for training jobs running in any other Debugger-supported AWS containers with script mode, making minimal changes to your training script.

Configure Debugger Tensor Collections Using the Collectivisation API Operation

Use the `CollectionConfig` API operation to configure tensor collections. Debugger provides pre-built tensor collections that cover a variety of regular expressions (regex) of parameters if using Debugger-supported deep learning frameworks and machine learning algorithms. As shown in the following example code, add the built-in tensor collections you want to debug.
from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients")
]

The preceding collections set up the Debugger hook to save the tensors every 500 steps based on the default "save_interval" value.

For a full list of available Debugger built-in collections, see Debugger Built-in Collections.

If you want to customize the built-in collections, such as changing the save intervals and tensor regex, use the following CollectionConfig template to adjust parameters.

from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="tensor_collection",
        parameters=
            {
                "key_1": "value_1",
                "key_2": "value_2",
                ...
                "key_n": "value_n"
            }
    )
]

For more information about available parameter keys, see CollectionConfig in the Amazon SageMaker Python SDK. For example, the following code example shows how you can adjust the save intervals of the "losses" tensor collection at different phases of training: save loss every 100 steps in training phase and validation loss every 10 steps in validation phase.

from sagemaker.debugger import CollectionConfig

collection_configs=[
    CollectionConfig(
        name="losses",
        parameters=
            {
                "train.save_interval": "100",
                "eval.save_interval": "10"
            }
    )
]

Tip
This tensor collection configuration object can be used for both DebuggerHookConfig and Rule API operations.

Configure Debugger Hook to Save Tensors

Use the DebuggerHookConfig class to create a debugger_hook_config object using the collection_configs object you created in the previous step.

from sagemaker.debugger import DebuggerHookConfig

db_hook_config=DebuggerHookConfig("weights", "gradients")
Debugger saves the model training output tensors into the default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/debug-output/`.

If you want to specify an exact S3 bucket URI, use the following code example:

```python
from sagemaker.debugger import DebuggerHookConfig
debuger_hook_config=DebuggerHookConfig(
    s3_output_path="specify-your-s3-bucket-uri",
    collection_configs=collection_configs
)
```

For more information, see `DebuggerHookConfig` in the Amazon SageMaker Python SDK.

**Example Notebooks and Code Samples to Configure Debugger Hook**

The following sections provide notebooks and code examples of how to use Debugger hook to save, access, and visualize output tensors.

**Topics**

- Tensor Visualization Example Notebooks (p. 1566)
- Save Tensors Using Debugger Built-in Collections (p. 1568)
- Save Tensors Using Debugger Modified Built-in Collections (p. 1569)
- Save Tensors Using Debugger Custom Collections (p. 1569)

**Tensor Visualization Example Notebooks**

The following two notebook examples show advanced use of Amazon SageMaker Debugger for visualizing tensors. Debugger provides a transparent view into training deep learning models.

- **Interactive Tensor Analysis in SageMaker Studio Notebook with MXNet**

  This notebook example shows how to visualize saved tensors using Amazon SageMaker Debugger. By visualizing the tensors, you can see how the tensor values change while training deep learning algorithms. This notebook includes a training job with a poorly configured neural network and uses Amazon SageMaker Debugger to aggregate and analyze tensors, including gradients, activation outputs, and weights. For example, the following plot shows the distribution of gradients of a convolutional layer that is suffering from a vanishing gradient problem.
This notebook also illustrates how a good initial hyperparameter setting improves the training process by generating the same tensor distribution plots.

- Visualizing and Debugging Tensors from MXNet Model Training

This notebook example shows how to save and visualize tensors from an MXNet Gluon model training job using Amazon SageMaker Debugger. It illustrates that Debugger is set to save all tensors to an Amazon S3 bucket and retrieves ReLu activation outputs for the visualization. The following figure shows a three-dimensional visualization of the ReLu activation outputs. The color scheme is set to blue to indicate values close to 0 and yellow to indicate values close to 1.

In this notebook, the TensorPlot class imported from tensor_plot.py is designed to plot convolutional neural networks (CNNs) that take two-dimensional images for inputs. The tensor_plot.py script provided with the notebook retrieves tensors using Debugger and visualizes
the CNN. You can run this notebook on SageMaker Studio to reproduce the tensor visualization and implement your own convolutional neural network model.

- **Real-time Tensor Analysis in a SageMaker Notebook with MXNet**

This example guides you through installing required components for emitting tensors in an Amazon SageMaker training job and using the Debugger API operations to access those tensors while training is running. A gluon CNN model is trained on the Fashion MNIST dataset. While the job is running, you will see how Debugger retrieves activation outputs of the first convolutional layer from each of 100 batches and visualizes them. Also, this will show you how to visualize weights after the job is done.

**Save Tensors Using Debugger Built-in Collections**

You can use built-in collections of tensors using the `CollectionConfig` API and save them using the `DebuggerHookConfig` API. The following example shows how to use the default settings of Debugger hook configurations to construct a SageMaker TensorFlow estimator. You can also utilize this for MXNet, PyTorch, and XGBoost estimators.

**Note**

In the following example code, the `s3_output_path` parameter for `DebuggerHookConfig` is optional. If you do not specify it, Debugger saves the tensors at `s3://<output_path>/debug-output/`, where the `<output_path>` is the default output path of SageMaker training jobs. For example:

```
"s3://sagemaker-us-east-1-111122223333/sagemaker-debugger-training-YYYY-MM-DD-HH-MM-SS-123/debug-output"
```

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call built-in collections
collection_configs=[
    CollectionConfig(name="weights"),
    CollectionConfig(name="gradients"),
    CollectionConfig(name="losses"),
    CollectionConfig(name="biases")
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-built-in-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
                                                                     LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",
```
Configure Debugger Using SageMaker Python SDK

# debugger-specific hook argument below
debuger_hook_config=hook_config

sagemaker_estimator.fit()

To see a list of Debugger built-in collections, see Debugger Built-in Collections.

Save Tensors Using Debugger Modified Built-in Collections

You can modify the Debugger built-in collections using the `CollectionConfig` API operation. The following example shows how to tweak the built-in `losses` collection and construct a SageMaker TensorFlow estimator. You can also use this for MXNet, PyTorch, and XGBoost estimators.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to call and modify built-in collections
collection_configs=[
    CollectionConfig(
        name="losses",
        parameters={"save_interval": "50"})
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-modified-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
    LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of `CollectionConfig` parameters, see Debugger CollectionConfig API.

Save Tensors Using Debugger Custom Collections

You can also save a reduced number of tensors instead of the full set of tensors (for example, if you want to reduce the amount of data saved in your Amazon S3 bucket). The following example shows how to customize the Debugger hook configuration to specify target tensors that you want to save. You can use this for TensorFlow, MXNet, PyTorch, and XGBoost estimators.

```
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import DebuggerHookConfig, CollectionConfig

# use Debugger CollectionConfig to create a custom collection

collection_configs=[
    CollectionConfig(
        name="custom_activations_collection",
        parameters={
            "include_regex": "relu|tanh", # Required
            "reductions": "mean,variance,max,abs_mean,abs_variance,abs_max"
        }
    )
]

# configure Debugger hook
# set a target S3 bucket as you want
sagemaker_session=sagemaker.Session()
BUCKET_NAME=sagemaker_session.default_bucket()
LOCATION_IN_BUCKET='debugger-custom-collections-hook'

hook_config=DebuggerHookConfig(
    s3_output_path='s3://{BUCKET_NAME}/{LOCATION_IN_BUCKET}'.format(BUCKET_NAME=BUCKET_NAME,
    LOCATION_IN_BUCKET=LOCATION_IN_BUCKET),
    collection_configs=collection_configs
)

# construct a SageMaker TensorFlow estimator
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-demo-job',
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.3.0",
    py_version="py37",

    # debugger-specific hook argument below
    debugger_hook_config=hook_config
)

sagemaker_estimator.fit()

For a full list of CollectionConfig parameters, see Debugger CollectionConfig.

### Configure Debugger Built-in Rules

Amazon SageMaker Debugger rules analyze tensors emitted during the training of a model. Debugger offers the Rule API operation that monitors training job progress and errors for the success of training your model. For example, the rules can detect whether gradients are getting too large or too small, whether a model is overfitting or overtraining, and whether a training job does not decrease loss function and improve. To see a full list of available built-in rules, see List of Debugger Built-in Rules (p. 1598).

**Note**

The built-in rules are prepared in Amazon SageMaker processing containers and fully managed by SageMaker Debugger. By default, Debugger initiates the ProfilerReport (p. 1601) rule for all SageMaker training jobs, without any Debugger-specific rule parameter specified to the SageMaker estimators. The ProfilerReport rule invokes all of the following built-in rules for monitoring system bottlenecks and profiling framework metrics:

- BatchSize (p. 1602)
Debugger saves the profiling report in a default S3 bucket. The format of the default S3 bucket URI is `s3://sagemaker-<region>-<12digit_account_id>/<training-job-name>/rule-output/`. For more information about how to download the profiling report, see SageMaker Debugger Profiling Report (p. 1674). SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

In the following topics, learn how to use the Debugger built-in rules.

**Topics**
- Use Debugger Built-in Rules with the Default Parameter Settings (p. 1571)
- Use Debugger Built-in Rules with Custom Parameter Values (p. 1572)
- Example Notebooks and Code Samples to Configure Debugger Rules (p. 1573)

**Use Debugger Built-in Rules with the Default Parameter Settings**

To specify Debugger built-in rules in an estimator, you need to configure a `rules` list object. The following example code shows the basic structure of listing the Debugger built-in rules:

```python
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules=[
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_1()),
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_2()),
    ...
    ProfilerRule.sagemaker(rule_configs.BuiltinProfilerRuleName_n()),
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```

For more information about default parameter values and descriptions of the built-in rule, see List of Debugger Built-in Rules (p. 1598).

For example, to inspect the overall training performance and progress of your model, construct a SageMaker estimator with the following built-in rule configuration:

```python
from sagemaker.debugger import Rule, rule_configs

rules=[
    ...
    Rule.sagemaker(rule_configs.built_in_rule_name_n())
]
```
When you start the training job, Debugger collects system resource utilization data every 500 milliseconds and the loss and accuracy values every 500 steps by default. Debugger analyzes the resource utilization to identify if your model is having bottleneck problems. The `loss_not_decreasing`, `overfit`, `overtraining`, and `stalled_training_rule` monitors if your model is optimizing the loss function without those training issues. If the rules detect training anomalies, the rule evaluation status changes to `IssueFound`. You can set up automated actions, such as notifying training issues and stopping training jobs using Amazon CloudWatch Events and AWS Lambda. For more information, see Action on Amazon SageMaker Debugger Rules (p. 1648).

**Use Debugger Built-in Rules with Custom Parameter Values**

If you want to adjust the built-in rule parameter values and customize tensor collection regex, configure the `base_config` and `rule_parameters` parameters for the `ProfilerRule.sagemaker` and `Rule.sagemaker` class methods. In case of the `Rule.sagemaker` class methods, you can also customize tensor collections through the `collections_to_save` parameter. The instruction of how to use the `CollectionConfig` class is provided in Configure Debugger Tensor Collections Using the Collectivisation API Operation (p. 1564).

Use the following configuration template for built-in rules to customize parameter values. By changing the rule parameters as you want, you can adjust the sensitivity of the rules to be triggered.

- The `base_config` argument is where you call the built-in rule methods.
- The `rule_parameters` argument is to adjust the default key values of the built-in rules listed in List of Debugger Built-in Rules (p. 1598).
- The `collections_to_save` argument takes in a tensor configuration through the `CollectionConfig` API, which requires `name` and `parameters` arguments.
  - To find available tensor collections for `name`, see Debugger Built-in Tensor Collections.
  - For a full list of adjustable `parameters`, see Debugger CollectionConfig API.

For more information about the Debugger rule class, methods, and parameters, see SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.
The parameter descriptions and value customization examples are provided for each rule at List of Debugger Built-in Rules (p. 1598).

Example Notebooks and Code Samples to Configure Debugger Rules

In the following sections, notebooks and code samples of how to use Debugger rules to monitor SageMaker training jobs are provided.

Topics

- Debugger Built-in Rules Example Notebooks (p. 1573)
- Debugger Built-in Rules Example Code (p. 1574)
- Use Debugger Built-in Rules with Parameter Modifications (p. 1575)

Debugger Built-in Rules Example Notebooks

The following example notebooks show how to use Debugger built-in rules when running training jobs with Amazon SageMaker:

- Using a SageMaker Debugger built-in rule with TensorFlow
- Using a SageMaker Debugger built-in rule with Managed Spot Training and MXNet
- Using a SageMaker Debugger built-in rule with XGBoost
- Using a SageMaker Debugger built-in rule with parameter modifications for a real-time training job analysis with XGBoost

While running the example notebooks in SageMaker Studio, you can find the training job trial created on the Studio Experiment List tab. For example, as shown in the following screenshot, you can find and open a Describe Trial Component window of your current training job. On the Debugger tab, you can check if the Debugger rules, vanishing_gradient() and loss_not_decreasing(), are monitoring the training session in parallel. For a full instruction of how to find your training job trial components in the Studio UI, see SageMaker Studio - View Experiments, Trials, and Trial Components.
There are two ways of using the Debugger built-in rules in the SageMaker environment: deploy the built-in rules as it is prepared or adjust their parameters as you want. The following topics show you how to use the built-in rules with example codes.

**Debugger Built-in Rules Example Code**

The following code sample shows how to set the Debugger built-in rules using the `Rule.sagemaker` method. To specify built-in rules that you want to run, use the `rules_config` API operation to call the built-in rules. To find a full list of Debugger built-in rules and default parameter values, see List of Debugger Built-in Rules (p. 1598).

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call built-in rules that you want to use.
built_in_rules=[
    Rule.sagemaker(rule_configs.vanishing_gradient()),
    Rule.sagemaker(rule_configs.loss_not_decreasing())
]

# construct a SageMaker estimator with the Debugger built-in rules
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name='debugger-built-in-rules-demo',
    rules=built_in_rules
)
```
instance_count=1,
instance_type="ml.m4.xlarge",
framework_version="2.1.0",
py_version="py3",

# debugger-specific arguments below
rules=built_in_rules
}
sagemaker_estimator.fit()

Note
The Debugger built-in rules run in parallel with your training job. The maximum number of built-in rule containers for a training job is 20.

For more information about the Debugger rule class, methods, and parameters, see the SageMaker Debugger Rule class in the Amazon SageMaker Python SDK.

To find an example of how to adjust the Debugger rule parameters, see the following Use Debugger Built-in Rules with Parameter Modifications (p. 1575) section.

Use Debugger Built-in Rules with Parameter Modifications

The following code example shows the structure of built-in rules to adjust parameters. In this example, the stalled_training_rule collects the losses tensor collection from a training job at every 50 steps and an evaluation stage at every 10 steps. If the training process starts stalling and not collecting tensor outputs for 120 seconds, the stalled_training_rule stops the training job.

```python
import sagemaker
from sagemaker.tensorflow import TensorFlow
from sagemaker.debugger import Rule, CollectionConfig, rule_configs

# call the built-in rules and modify the CollectionConfig parameters
base_job_name_prefix= 'smdebug-stalled-demo-' + str(int(time.time()))
built_in_rules_modified = [
    Rule.sagemaker(
        base_config=rule_configs.stalled_training_rule(),
        rule_parameters={
            'threshold': '120',
            'training_job_name_prefix': base_job_name_prefix,
            'stop_training_on_fire' : 'True'
        }
    )
]
collections_to_save = [
    CollectionConfig(
        name="losses",
        parameters={
            "train.save_interval": "50",
            "eval.save_interval": "10"
        }
    )
]

# construct a SageMaker estimator with the modified Debugger built-in rule
sagemaker_estimator=TensorFlow(
    entry_point='directory/to/your_training_script.py',
    role=sm.get_execution_role(),
    base_job_name=base_job_name_prefix,
    instance_count=1,
    instance_type="ml.m4.xlarge",
    framework_version="2.1.0",
    )
```
py_version="py3",
    # debugger-specific arguments below
    rules=built_in_rules_modified
  )
sagemaker_estimator.fit()

For an advanced configuration of the Debugger built-in rules using the CreateTrainingJob API, see

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure CreateTrainingJob, UpdateTrainingJob, Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.

Topics

• JSON (AWS CLI) (p. 1588)
  • AWS Boto3 (p. 1593)

JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the DebugHookConfig, DebugRuleConfiguration, ProfilerConfig, and ProfilerRuleConfiguration objects through the SageMaker CreateTrainingJob API operation. You need to specify the right image URI in the RuleEvaluatorImage parameter, and the following examples walk you through how to set up the JSON strings to request CreateTrainingJob.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as debugger-training-job-cli.json.

Note
Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711).

```json
{
  "TrainingJobName": "debugger-aws-cli-test",
  "RoleArn": "arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-YYYYMMDDTT123456",
  "AlgorithmSpecification": {
    // Specify a training Docker container image URI (Deep Learning Container
    or your own training container) to TrainingImage.
    "TrainingInputMode": "File",
    "EnableSageMakerMetricsTimeSeries": false
  }
}
```
After saving the JSON file, run the following command in your terminal. (Use `!` at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```

To configure a Debugger rule for debugging model parameters, the following code samples show how to configure a built-in **VanishingGradient** rule using this SageMaker API.
To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
"DebugHookConfig": {

  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",

  "CollectionConfigurations": [

    {
      "CollectionName": "gradients",

      "CollectionParameters": {
          "save_interval": "500"
        }
    }

  ]

}
```

This will make the training job save the tensor collection, *gradients*, every `save_interval` of 500 steps. To find available `CollectionName` values, see Debugger Built-in Collections in the *SMDebug client library documentation*. To find available `CollectionParameters` parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the *SageMaker Python SDK documentation*.

To enable Debugger rules for debugging the output tensors

The following `DebugRuleConfigurations` API example shows how to run the built-in VanishingGradient rule on the saved *gradients* collection.

```
"DebugRuleConfigurations": [

  {
    "RuleConfigurationName": "VanishingGradient",

    "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",

    "RuleParameters": {
      "rule_to_invoke": "VanishingGradient",

      "threshold": "20.0"
    }

  }

]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of *gradients* tensor. To find a complete list of available Docker images for using the Debugger rules, see *Use Debugger Docker Images for Built-in or Custom Rules* (p. 1711). To find the key-value pairs for `RuleParameters`, see *List of Debugger Built-in Rules* (p. 1598).
Configure Debugger Using SageMaker Python SDK

"S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",

// Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
"ProfilingIntervalInMilliseconds": 500,

"ProfilingParameters": {

  "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "MetricsRegex": ".*" },

  "DetailedProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10 }",

  // For PythonProfilingConfig,
  // available ProfilerName options: cProfile, Pyinstrument
  // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time

  "PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer": "total_time" },

  // Optional. Local path for profiling outputs
  "LocalPath": "/opt/ml/output/profiler/"

}

Target Time Duration

"ProfilerConfig": {

  // Optional. Path to an S3 bucket to save profiling outputs
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",

  // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
  "ProfilingIntervalInMilliseconds": 500,

  "ProfilingParameters": {

    "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "MetricsRegex": ".*" }",

    "DetailedProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10 }",

    // For PythonProfilingConfig,
    // available ProfilerName options: cProfile, Pyinstrument
    // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time

    "PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer": "total_time" }",

    // Optional. Local path for profiling outputs
    "LocalPath": "/opt/ml/output/profiler/"

  }

}
To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

**Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation**

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```json
{
  "ProfilerConfig": {
    "DisableProfiler": boolean,
    "ProfilingIntervalInMilliseconds": number,
    "ProfilingParameters": {
      "string" : "string"
    }
  },
  "ProfilerRuleConfigurations": [
    {
      "RuleConfigurationName": "string",
      "RuleEvaluatorImage": "string",
      "RuleParameters": {
        "string" : "string"
      }
    }
  ],
  "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```

**Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation**

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects in the CreateTrainingJob API operation. The following code sample shows how to configure a custom ImproperActivation rule written with the smdebug library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.
Configure Debugger Using SageMaker Python SDK

```
"RuleConfigurationName": "improper_activation_job",

"RuleEvaluatorImage": "552407032007.dkr.ecr.ap-south-1.amazonaws.com/

sagemaker-debugger-rule-evaluator:latest",

"InstanceType": "ml.c4.xlarge",

"VolumeSizeInGB": 400,

"RuleParameters": {

  "source_s3_uri": "s3://bucket/custom_rules.py",

  "rule_to_invoke": "ImproperActivation",

  "collection_names": "relu_activations"

}

}

]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

AWS Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the create_training_job() function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the RuleEvaluatorImage parameter, and the following examples walk you through how to set up the request body for the create_training_job() function.

The following code shows a complete example of how to configure Debugger for the create_training_job() request body and start a training job in us-west-2, assuming that a training script entry_point/train.py is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

```
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()

region = session.boto_region_name

bucket = session.default_bucket()
```
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+project+'/'+source,
        'sagemaker_program': '/entry_point/train.py' # training script file
    },
    AlgorithmSpecification={
        'TrainingInputMode': 'File',
        'EnableSageMakerMetricsTimeSeries': False
    },
    RoleArn='arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20201014T161125',
    OutputDataConfig={'S3OutputPath': 's3://'+bucket+'/'+project+'/output'},
    ResourceConfig={
        'InstanceType': 'ml.p3.8xlarge',
        'InstanceCount': 1,
        'VolumeSizeInGB': 30
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 86400
    },
    DebugHookConfig={
        'S3OutputPath': 's3://'+bucket+'/'+project+'/debug-output',
        'CollectionConfigurations': [
            {'CollectionName': 'losses',
            'CollectionParameters': {'train.save_interval': 500, 'eval.save_interval': 50}}
        ],
        'DebugRuleConfigurations': [
            {'RuleConfigurationName': 'LossNotDecreasing',
             'RuleParameters': {'rule_to_invoke': 'LossNotDecreasing'}}
        ],
        'ProfilerConfig': {'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
                           'ProfilingIntervalInMilliseconds': 500,
                           'ProfilingParameters': {'DataloaderProfilingConfig': {'StartStep': 5, 'NumSteps': 3, 'MetricsRegex': '.*'}, 'DetailedProfilingConfig': {'StartStep': 5, 'NumSteps': 3}, 'PythonProfilingConfig': {'StartStep': 5, 'NumSteps': 3, 'ProfilerName': 'cprofile', 'cProfileTimer': 'total_time'}, 'LocalPath': '/opt/ml/output/profiler/'},
        'ProfilerRuleConfigurations': [
            {'RuleConfigurationName': 'ProfilerReport',
             'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}}
        ]
    }
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```python
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {'CollectionName': 'gradients',
         'CollectionParameters': {
             'train.save_interval': '500',
             'eval.save_interval': '50'}
        ]
    }
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the `sagemaker.debugger.CollectionConfig` class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```python
DebugRuleConfigurations=[
    {
        'RuleConfigurationName': 'VanishingGradient',
    }
]
```

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.
To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "MetricsRegex": ".*"
        },
        'DetailedProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3
        },
        'PythonProfilingConfig': '{
            "StartStep": 5,
            "NumSteps": 3,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time" # Include only when using cprofile. Available options: cpu, off_cpu, total_time
        },
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
    }
}
```

Target Time Duration

```
ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs
    # Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "MetricsRegex": ".*"
        },
        'DetailedProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10
        },
        'PythonProfilingConfig': '{
            "StartTimeInSecSinceEpoch": 12345567789,
            "DurationInSeconds": 10,
            "ProfilerName": "cprofile", # Available options: cprofile, pyinstrument
            "cProfileTimer": "total_time" # Include only when using cprofile. Available options: cpu, off_cpu, total_time
        },
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
    }
}
```
To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

```
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleParameters': {
            'rule_to_invoke': 'ProfilerReport',
            'CPUBottleneck_cpu_threshold': '90',
            'IOBottleneck_threshold': '90'
        }
    }
]
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

**Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation**

Debugger profiling configuration can be updated while your training job is running by using the update_training_job() function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
ProfilerConfig=
{
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string' : 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string': 'string'
        }
    }
]
```

Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects using the AWS Boto3 SageMaker client's create_training_job() function. The following code sample shows how to configure a custom ImproperActivation rule written with the smdebug library using this SageMaker API operation. This example assumes that you’ve written the custom rule in custom_rules.py file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.
Configure Debugger Using SageMaker Python SDK

```python
DebugHookConfig=

'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',

'CollectionConfigurations': [

  {
    'CollectionName': 'relu_activations',
    'CollectionParameters': {
      'include_regex': 'relu',
      'save_interval': '500',
      'end_step': '5000'
    }
  }
],

DebugRulesConfigurations=[

  {
    'RuleConfigurationName': 'improper_activation_job',
    'InstanceType': 'ml.c4.xlarge',
    'VolumeSizeInGB': 400,
    'RuleParameters': {
      'source_s3_uri': 's3://bucket/custom_rules.py',
      'rule_to_invoke': 'ImproperActivation',
      'collection_names': 'relu_activations'
    }
  }
],
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

**Turn Off Debugger**

If you want to completely turn off Debugger, do one of the following:

• Before starting a training job, do the following:
  - To disable both monitoring and profiling, include the `disable_profiler` parameter to your `estimator` and set it to `True`.
  - To disable debugging, set the `debugger_hook_config` parameter to `False`.

  Warning: If you disable it, you won’t be able to view the comprehensive Studio Debugger insights dashboard and the autogenerated profiling report.

  ```python
  estimator=Estimator(...
  disable_profiler=True
  debugger_hook_config=False)
  ```

  For more information about the Debugger-specific parameters, see SageMaker Estimator in the Amazon SageMaker Python SDK.

• While a training job is running, do the following:

  ```python
  1586
  ```
To disable both monitoring and profiling while your training job is running, use the following estimator classmethod:

```python
estimator.disable_profiling()
```

To disable framework profiling only and keep system monitoring, use the `update_profiler` method:

```python
estimator.update_profiler(disable_framework_metrics=True)
```

For more information about the estimator extension methods, see the `estimator.disable_profiling` and `estimator.update_profiler` classmethods in the Amazon SageMaker Python SDK documentation.

### Useful SageMaker Estimator Classmethods for Debugger

The following estimator class methods are useful for accessing your SageMaker training job information and retrieving output paths of training data collected by Debugger. The following methods are executable after you initiate a training job with the `estimator.fit()` method.

- To check the base S3 bucket URI of a SageMaker training job:
  ```python
estimator.output_path
  ```

- To check the base job name of a SageMaker training job:
  ```python
estimator.latest_training_job.job_name
  ```

- To see a full `CreateTrainingJob` API operation configuration of a SageMaker training job:
  ```python
estimator.latest_training_job.describe()
  ```

- To check a full list of the Debugger rules while a SageMaker training job is running:
  ```python
estimator.latest_training_job.rule_job_summary()
  ```

- To check the S3 bucket URI where the model parameter data (output tensors) are saved:
  ```python
  estimator.latest_job_debugger_artifacts_path()
  ```

- To check the S3 bucket URI at where the model performance data (system and framework metrics) are saved:
  ```python
  estimator.latest_job_profiler_artifacts_path()
  ```

- To check the Debugger rule configuration for debugging output tensors:
  ```python
  estimator.debugger_rule_configs
  ```

- To check the list of the Debugger rules for debugging while a SageMaker training job is running:
  ```python
  estimator.debugger_rules
  ```

- To check the Debugger rule configuration for monitoring and profiling system and framework metrics:
estimator.profiler_rule_configs

- To check the list of the Debugger rules for monitoring and profiling while a SageMaker training job is running:

estimator.profiler_rules

For more information about the SageMaker estimator class and its methods, see Estimator API in the Amazon SageMaker Python SDK.

Configure Debugger Using Amazon SageMaker API

The preceding topics focus on using Debugger through Amazon SageMaker Python SDK, which is a wrapper around AWS SDK for Python (Boto3) and SageMaker API operations. This offers a high-level experience of accessing the Amazon SageMaker API operations. In case you need to manually configure the SageMaker API operations using AWS Boto3 or AWS Command Line Interface (CLI) for other SDKs, such as Java, Go, and C++, this guide covers how to configure CreateTrainingJob, UpdateTrainingJob, Debugger configuration APIs, and their parameters to use the Debugger built-in and custom rules.

Topics
- JSON (AWS CLI) (p. 1588)
- AWS Boto3 (p. 1593)

JSON (AWS CLI)

Amazon SageMaker Debugger built-in rules can be configured for a training job using the DebugHookConfig, DebugRuleConfiguration, ProfilerConfig, and ProfilerRuleConfiguration objects through the SageMaker CreateTrainingJob API operation. You need to specify the right image URI in the RuleEvaluatorImage parameter, and the following examples walk you through how to set up the JSON strings to request CreateTrainingJob.

The following code shows a complete JSON template to run a training job with required settings and Debugger configurations. Save the template as a JSON file in your working directory and run the training job using AWS CLI. For example, save the following code as debugger-training-job-cli.json.

Note
Ensure that you use the correct Docker container images. To find AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711).

```
{
    "TrainingJobName": "debugger-aws-cli-test",
    "RoleArn": "arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-YYYMMDDT123456",
    "AlgorithmSpecification": {
        "TrainingInputMode": "File",
        "EnableSageMakerMetricsTimeSeries": false
    },
    "HyperParameters": {
        "sagemaker_program": "entry_point/tf-hvd-train.py",
```
"sagemaker_submit_directory": "s3://sagemaker-us-west-2-11112223333/debugger-boto3-profiling-test/source.tar.gz",
"OutputDataConfig": {
  "S3OutputPath": "s3://sagemaker-us-west-2-11112223333/debugger-aws-cli-test/output"
},
"DebugHookConfig": {
  "S3OutputPath": "s3://sagemaker-us-west-2-11112223333/debugger-aws-cli-test/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "losses",
      "CollectionParameters": {
        "train.save_interval": "50"
      }
    }
  ]
},
"DebugRuleConfigurations": [
  {
    "RuleConfigurationName": "LossNotDecreasing",
    "RuleParameters": {"rule_to_invoke": "LossNotDecreasing"}
  }
],
"ProfilerConfig": {
  "S3OutputPath": "s3://sagemaker-us-west-2-11112223333/debugger-aws-cli-test/profile-output",
  "ProfilingIntervalInMilliseconds": 500,
  "ProfilingParameters": {
    "DataloaderProfilingConfig": "{"StartStep": 5, "NumSteps": 3, "MetricsRegex": serviceregex},",
    "DetailedProfilingConfig": "{"StartStep": 5, "NumSteps": 3, "," PythonProfilingConfig": "{"StartStep": 5, "NumSteps": 3, "," ProfilerName": "cprofile", "," cProfileTimer": "total_time"},",
    "LocalPath": "/opt/ml/output/profiler/"
  }
},
"ProfilerRuleConfigurations": [
  {
    "RuleConfigurationName": "ProfilerReport",
    "RuleParameters": {"rule_to_invoke": "ProfilerReport"}
  }
],
"ResourceConfig": {
  "InstanceType": "ml.p3.8xlarge",
  "InstanceCount": 1,
  "VolumeSizeInGB": 30
},
"StoppingCondition": {
  "MaxRuntimeInSeconds": 86400
}]

After saving the JSON file, run the following command in your terminal. (Use ! at the beginning of the line if you use a Jupyter notebook.)

```
aws sagemaker create-training-job --cli-input-json file://debugger-training-job-cli.json
```
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
"DebugHookConfig": {
  "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
  "CollectionConfigurations": [
    {
      "CollectionName": "gradients",
      "CollectionParameters": {
        "save_interval": "500"
      }
    }
  ]
}
```

This will make the training job save the tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
"DebugRuleConfigurations": [
  {
    "RuleConfigurationName": "VanishingGradient",
    "RuleEvaluatorImage": "503895931360.dkr.ecr.us-east-1.amazonaws.com/sagemaker-debugger-rules:latest",
    "RuleParameters": {
      "rule_to_invoke": "VanishingGradient",
      "threshold": "20.0"
    }
  }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
"ProfilerConfig": {
  "ProfilerConfig": {
```
// Optional. Path to an S3 bucket to save profiling outputs
"S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
// Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
"ProfilingIntervalInMilliseconds": 500,
"ProfilingParameters": {
    "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "MetricsRegex": ".*" },
    "DetailedProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10 }",
// For PythonProfilingConfig,
// available ProfilerName options: cProfile, Pyinstrument
// available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
"PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer": "total_time" },
// Optional. Local path for profiling outputs
"LocalPath": "/opt/ml/output/profiler/"
}
}

Target Time Duration

"ProfilerConfig": {
    // Optional. Path to an S3 bucket to save profiling outputs
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/profiler-output",
    // Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.
    "ProfilingIntervalInMilliseconds": 500,
    "ProfilingParameters": {
        "DataloaderProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "MetricsRegex": ".*" },
        "DetailedProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10 }",
        // For PythonProfilingConfig,
        // available ProfilerName options: cProfile, Pyinstrument
        // available cProfileTimer options only when using cProfile: cpu, off_cpu, total_time
        "PythonProfilingConfig": "{ "StartTimeInSecSinceEpoch": 12345567789, "DurationInSeconds": 10, "ProfilerName": "cProfile", "cProfileTimer": "total_time" },
        // Optional. Local path for profiling outputs
        "LocalPath": "/opt/ml/output/profiler/"
    }
}

To enable Debugger rules for profiling the metrics

The following example code shows how to configure the ProfilerReport rule.

"ProfilerRuleConfigurations": [
    {
        "RuleConfigurationName": "ProfilerReport",
        "RuleParameters": {
            "rule_to_invoke": "ProfilerReport",
            "CPUBottleneck_cpu_threshold": "90",
            "IOBottleneck_threshold": "90"
        }
    }
]
To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

**Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation**

Debugger profiling configuration can be updated while your training job is running by using the UpdateTrainingJob API operation. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
{
    "ProfilerConfig": {
        "DisableProfiler": boolean,
        "ProfilingIntervalInMilliseconds": number,
        "ProfilingParameters": {
            "string": "string"
        }
    },
    "ProfilerRuleConfigurations": [
        {
            "RuleConfigurationName": "string",
            "RuleEvaluatorImage": "string",
            "RuleParameters": {
                "string": "string"
            }
        }
    ],
    "TrainingJobName": "your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
}
```

**Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation**

A custom rule can be configured for a training job using the DebugHookConfig and DebugRuleConfiguration objects in the CreateTrainingJob API operation. The following code sample shows how to configure a custom ImproperActivation rule written with the smdebug library using this SageMaker API operation. This example assumes that you’ve written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.

```
"DebugHookConfig": {
    "S3OutputPath": "s3://<default-bucket>/<training-job-name>/debug-output",
    "CollectionConfigurations": [
        {
            "CollectionName": "relu_activations",
            "CollectionParameters": {
                "include_regex": "relu",
                "save_interval": "500",
                "end_step": "5000"
            }
        }
    ]
},
"DebugRulesConfigurations": [
    {
        "RuleConfigurationName": "improper_activation_job",
        "RuleEvaluatorImage": "552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rule-evaluator:latest"
    }
]
```
Configure Debugger Using SageMaker API

```
"InstanceType": "ml.c4.xlarge",
"VolumeSizeInGB": 400,
"RuleParameters": {
  "source_s3_uri": "s3://bucket/custom_rules.py",
  "rule_to_invoke": "ImproperActivation",
  "collection_names": "relu_activations"
}
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

AWS Boto3

Amazon SageMaker Debugger built-in rules can be configured for a training job using the `create_training_job()` function of the AWS Boto3 SageMaker client. You need to specify the right image URI in the `RuleEvaluatorImage` parameter, and the following examples walk you through how to set up the request body for the `create_training_job()` function.

The following code shows a complete example of how to configure Debugger for the `create_training_job()` request body and start a training job in `us-west-2`, assuming that a training script `entry_point/train.py` is prepared using TensorFlow. To find an end-to-end example notebook, see Profiling TensorFlow Multi GPU Multi Node Training Job with Amazon SageMaker Debugger (Boto3).

**Note**

Ensure that you use the correct Docker container images. To find available AWS Deep Learning Container images, see Available Deep Learning Containers Images. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711).

```python
import sagemaker, boto3
import datetime, tarfile

# Start setting up a SageMaker session and a Boto3 SageMaker client
session = sagemaker.Session()
region = session.boto_region_name
bucket = session.default_bucket()

# Upload a training script to a default Amazon S3 bucket of the current SageMaker session
source = 'source.tar.gz'
project = 'debugger-boto3-test'
tar = tarfile.open(source, 'w:gz')
tar.add('entry_point/train.py') # Specify the directory and name of your training script
tar.close()
s3 = boto3.client('s3')
s3.upload_file(source, bucket, project+'/'+source)

# Set up a Boto3 session client for SageMaker
sm = boto3.Session(region_name=region).client("sagemaker")

# Start a training job
sm.create_training_job(
    TrainingJobName='debugger-boto3-'+datetime.datetime.now().strftime('%Y-%m-%d-%H-%M-%S'),
    HyperParameters={
        'sagemaker_submit_directory': 's3://'+bucket+'/'+source,
        'sagemaker_program': 'entry_point/train.py' # training scrip file location and name under the sagemaker_submit_directory
```
AlgorithmSpecification={
    # Specify a training Docker container image URI (Deep Learning Container or your
    # own training container) to TrainingImage.
    'TrainingImage': '763104351884.dkr.ecr.us-west-2.amazonaws.com/tensorflow-

    'S3OutputPath': 's3://'+bucket+'/'+project+'/profiler-output',
    'ProfilingIntervalInMilliseconds': 500,
    'ProfilingParameters': {
        'DataloaderProfilingConfig': {'"StartStep": 5, "NumSteps": 3, "MetricsRegex":
        ".*", },',
        'DetailedProfilingConfig': {'"StartStep": 5, "NumSteps": 3, },',
        'PythonProfilingConfig': {'"StartStep": 5, "NumSteps": 3, "ProfilerName":
        "cprofile", "cProfileTimer": "total_time"},
        'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling
        outputs
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'ProfilerReport',
        'RuleEvaluatorImage': '895741380848.dkr.ecr.us-west-2.amazonaws.com/sagemaker-
        debugger-rules:latest',
        'RuleParameters': {'rule_to_invoke': 'ProfilerReport'}
    }
]
To configure a Debugger rule for debugging model parameters

The following code samples show how to configure a built-in VanishingGradient rule using this SageMaker API.

To enable Debugger to collect output tensors

Specify the Debugger hook configuration as follows:

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {'CollectionName': 'gradients',
         'CollectionParameters': {
             'train.save_interval': '500',
             'eval.save_interval': '50'
         }
        ]
    }
}
```

This will make the training job save a tensor collection, gradients, every save_interval of 500 steps. To find available CollectionName values, see Debugger Built-in Collections in the SMDebug client library documentation. To find available CollectionParameters parameter keys and values, see the sagemaker.debugger.CollectionConfig class in the SageMaker Python SDK documentation.

To enable Debugger rules for debugging the output tensors

The following DebugRuleConfigurations API example shows how to run the built-in VanishingGradient rule on the saved gradients collection.

```
DebugRuleConfigurations=[
    {'RuleConfigurationName': 'VanishingGradient',
     'RuleParameters': {
         'rule_to_invoke': 'VanishingGradient',
         'threshold': '20.0'
     }
    }
]
```

With a configuration like the one in this sample, Debugger starts a rule evaluation job for your training job using the VanishingGradient rule on the collection of gradients tensor. To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

To configure a Debugger built-in rule for profiling system and framework metrics

The following example code shows how to specify the ProfilerConfig API operation to enable collecting system and framework metrics.

To enable Debugger profiling to collect system and framework metrics

Target Step

```
ProfilerConfig={
```
Configure Debugger Using SageMaker API

'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs

# Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.

'ProfilingIntervalInMilliseconds': 500,

'ProfilingParameters': {
    'DataloaderProfilingConfig': '{
        "StartTime": 5,
        "NumSteps": 3,
        "MetricsRegex": ".*"
    },
    'DetailedProfilingConfig': '{
        "StartTime": 5,
        "NumSteps": 3
    },
    'PythonProfilingConfig': '{
        "StartTime": 5,
        "NumSteps": 3,
        "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
        "cProfileTimer": "total_time"  # Include only when using cprofile.
        Available options: cpu, off_cpu, total_time
    }
},

'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
}

**Target Time Duration**

ProfilerConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/profiler-output', # Optional. Path to an S3 bucket to save profiling outputs

# Available values for ProfilingIntervalInMilliseconds: 100, 200, 500, 1000 (1 second), 5000 (5 seconds), and 60000 (1 minute) milliseconds.

'ProfilingIntervalInMilliseconds': 500,

'ProfilingParameters': {
    'DataloaderProfilingConfig': '{
        "StartTime": 12345567789,
        "DurationInSeconds": 10,
        "MetricsRegex": ".*"
    },
    'DetailedProfilingConfig': '{
        "StartTime": 12345567789,
        "DurationInSeconds": 10
    },
    'PythonProfilingConfig': '{
        "StartTime": 12345567789,
        "DurationInSeconds": 10,
        "ProfilerName": "cprofile",  # Available options: cprofile, pyinstrument
        "cProfileTimer": "total_time"  # Include only when using cprofile.
        Available options: cpu, off_cpu, total_time
    },

'LocalPath': '/opt/ml/output/profiler/' # Optional. Local path for profiling outputs
}

**To enable Debugger rules for profiling the metrics**

The following example code shows how to configure the ProfilerReport rule.

ProfilerRuleConfigurations=[

```python
ProfilerRuleConfigurations=[
```
Configure Debugger Using SageMaker API

```
{
    'RuleConfigurationName': 'ProfilerReport',
    'RuleParameters': {
        'rule_to_invoke': 'ProfilerReport',
        'CPUBottleneck_cpu_threshold': '90',
        'IOBottleneck_threshold': '90'
    }
}
```

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

**Update Debugger Profiling Configuration Using the UpdateTrainingJob API Operation**

Debugger profiling configuration can be updated while your training job is running by using the `update_training_job()` function of the AWS Boto3 SageMaker client. Configure new ProfilerConfig and ProfilerRuleConfiguration objects, and specify the training job name to the TrainingJobName parameter.

```
ProfilerConfig={
    'DisableProfiler': boolean,
    'ProfilingIntervalInMilliseconds': number,
    'ProfilingParameters': {
        'string': 'string'
    }
},
ProfilerRuleConfigurations=[
    {
        'RuleConfigurationName': 'string',
        'RuleEvaluatorImage': 'string',
        'RuleParameters': {
            'string': 'string'
        }
    }
],
TrainingJobName='your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS'
```

**Add Debugger Custom Rule Configuration to the CreateTrainingJob API Operation**

A custom rule can be configured for a training job using the `DebugHookConfig` and `DebugRuleConfiguration` objects using the AWS Boto3 SageMaker client's `create_training_job()` function. The following code sample shows how to configure a custom ImproperActivation rule written with the `smdebug` library using this SageMaker API operation. This example assumes that you've written the custom rule in `custom_rules.py` file and uploaded it to an Amazon S3 bucket. The example provides pre-built Docker images that you can use to run your custom rules. These are listed at Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712). You specify the URL registry address for the pre-built Docker image in the RuleEvaluatorImage parameter.

```
DebugHookConfig={
    'S3OutputPath': 's3://<default-bucket>/<training-job-name>/debug-output',
    'CollectionConfigurations': [
        {
            'CollectionName': 'relu_activations',
            'CollectionParameters': {
            }
        }
    ],
```

1597
DebugRulesConfigurations=[
    {
        'RuleConfigurationName': 'improper_activation_job',
        'InstanceType': 'ml.c4.xlarge',
        'VolumeSizeInGB': 400,
        'RuleParameters': {
            'source_s3_uri': 's3://bucket/custom_rules.py',
            'rule_to_invoke': 'ImproperActivation',
            'collection_names': 'relu_activations'
        }
    }
]

To find a complete list of available Docker images for using the Debugger rules, see Use Debugger Docker Images for Built-in or Custom Rules (p. 1711). To find the key-value pairs for RuleParameters, see List of Debugger Built-in Rules (p. 1598).

List of Debugger Built-in Rules

Use the Debugger built-in rules provided by Amazon SageMaker Debugger and analyze tensors emitted while training your models. The Debugger built-in rules monitor various common conditions that are critical for the success of a training job. You can call the built-in rules using Amazon SageMaker Python SDK or the low-level SageMaker API operations. Depending on deep learning frameworks of your choice, there are four scopes of validity for the built-in rules as shown in the following table.

**Note**

The maximum numbers of built-in rules for a training job are 20 for ProfilerRule and 20 for Rule. SageMaker Debugger fully manages the built-in rules and analyzes your training job in parallel. For more information about billing, see the Amazon SageMaker Studio is available at no additional charge section of the Amazon SageMaker Pricing page.

**Important**

To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Debugger ProfilerRule**

The following rules are the Debugger built-in rules that are callable using the ProfilerRule.sagemaker classmethod.

</tbody>
</table>

To use the built-in rules with default parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [  
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_1()),  
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_2()),  
    ...  
    ProfilerRule.sagemaker(rule_configs.BuiltInRuleName_n()),  
    Rule.sagemaker(rule_configs.built_in_rule_name_1()),  
    Rule.sagemaker(rule_configs.built_in_rule_name_2()),  
    ...  
    Rule.sagemaker(rule_configs.built_in_rule_name_n())  
]
```

To use the built-in rules with customizing the parameter values – use the following configuration format:

```
from sagemaker.debugger import Rule, ProfilerRule, rule_configs

rules = [  
    ProfilerRule.sagemaker(  
        base_config=rule_configs.BuiltInRuleName(),  
        rule_parameters={  
            "key": "value"  
        }  
    )  
    Rule.sagemaker(  
        base_config=rule_configs.built_in_rule_name(),  
        rule_parameters={  
            "key": "value"  
        }  
    )  
    collections_to_save=[  
        CollectionConfig(  
            name="tensor_collection_name",  
            parameters={  
                "key": "value"  
            }  
        )  
    ]  
]
```

To find available keys for the `rule_parameters` parameter, see the parameter description tables.

Sample rule configuration codes are provided for each built-in rule below the parameter description tables.
For a full instruction and examples of using the Debugger built-in rules, see Debugger Built-in Rules Example Code (p. 1574).

For a full instruction of using the built-in rules with the low-level SageMaker API operations, see Configure Debugger Using Amazon SageMaker API (p. 1588).

ProfilerReport

The ProfilerReport rule invokes all of the built-in rules for monitoring and profiling. It creates a profiling report and updates when the individual rules are triggered. You can download a comprehensive profiling report while a training job is running or after the training job is complete. You can adjust the rule parameter values to customize sensitivity of the built-in monitoring and profiling rules. The following example code shows the basic format to adjust the built-in rule parameters through the ProfilerReport rule.

```python
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            <BuiltInRuleName>_<parameter_name> = value
        )
    )
]
```

If you trigger this ProfilerReport rule without any customized parameter as shown in the following example code, then the ProfilerReport rule triggers all of the built-in rules for monitoring and profiling with their default parameter values.

```python
rules=[ProfilerRule.sagemaker(rule_configs.ProfilerReport())]
```

The following example code shows how to specify and adjust the CPUBottleneck rule's cpu_threshold parameter and the IOBottleneck rule's threshold parameter.

```python
rules=[
    ProfilerRule.sagemaker(
        rule_configs.ProfilerReport(
            CPUBottleneck_cpu_threshold = 90,
            IOBottleneck_threshold = 90
        )
    )
]
```

Parameter Descriptions for the OverallSystemUsage Rule

<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
</tbody>
</table>

**BatchSize**

The BatchSize rule helps detect if GPU is underutilized due to a small batch size. To detect this issue, this rule monitors the average CPU utilization, GPU utilization, and GPU memory utilization. If utilization on CPU, GPU, and GPU memory is low on average, it may indicate that the training job can either run on a smaller instance type or can run with a bigger batch size. This analysis does not work for frameworks that heavily overallocate memory. However, increasing the batch size can lead to processing or data loading bottlenecks because more data preprocessing time is required in each iteration.

**Parameter Descriptions for the BatchSize Rule**

<table>
<thead>
<tr>

The first several steps of training jobs usually show high volume of data processes, so keep the rule patient and prevent it from being invoked too soon with a given number of profiling data that you specify with this parameter.</td>
</tr>
<tr>
<td>scan_interval_us</td>
<td>Time interval that timeline files are scanned.</td>
</tr>
</tbody>
</table>

**LoadBalancing**

The LoadBalancing rule helps detect issues in workload balancing among multiple GPUs.

**Parameter Descriptions for the LoadBalancing Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>

<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default values: 60000000 (in microseconds)</td>
</tr>
</tbody>
</table>

**LowGPUUtilization**

The LowGPUUtilization rule helps detect if GPU utilization is low or suffers from fluctuations. This is checked for each GPU on each worker. Rule returns True if 95th quantile is below threshold_p95 which indicates underutilization. Rule returns true if 95th quantile is above threshold_p95 and 5th quantile is below threshold_p5 which indicates fluctuations.

**Parameter Descriptions for the LowGPUUtilization Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>

Optional  
Valid values: Integer  
Default values: 60000000 (in microseconds) |

### OverallSystemUsage

The OverallSystemUsage rule measures overall system usage per worker node. The rule currently only aggregates values per node and computes their percentiles.

**Parameter Descriptions for the OverallSystemUsage Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| base_trial     | The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.  
Required  
Valid values: String |
| scan_interval_us | Time interval to scan timeline files.  
Optional  
Valid values: Integer  
Default values: 60000000 (in microseconds) |
MaxInitializationTime

The MaxInitializationTime rule helps detect if the training initialization is taking too much time. The rule waits until the first step is available.

Parameter Descriptions for the MaxInitializationTime Rule

</table>
CreateXgboostReport

The CreateXgboostReport rule collects output tensors from an XGBoost training job and autogenerates a comprehensive training report. You can download a comprehensive profiling report while a training job is running or after the training job is complete, and check progress of training or the final result of the training job. The CreateXgboostReport rule collects the following output tensors by default:

- `hyperparameters` – Saves at the first step
- `metrics` – Saves loss and accuracy every 5 steps
- `feature_importance` – Saves every 5 steps
- `predictions` – Saves every 5 steps
- `labels` – Saves every 5 steps

Parameter Descriptions for the CreateXgboostReport Rule

```

DeadRelu

This rule detects when the percentage of rectified linear unit (ReLU) activation functions in a trial are considered dead because their activation activity has dropped below a threshold. If the percent of inactive ReLUs in a layer is greater than the `threshold_layer` value of inactive ReLUs, the rule returns True.

Parameter Descriptions for the DeadRelu Rule

<table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.exploding_tensor(),
        rule_parameters={
            "tensor_regex": ".*gradient",
            "only_nan": "False"
        }
    )
]```
For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

Note
This rule is not available for the XGBoost algorithm.

PoorWeightInitialization

This rule detects if your model parameters have been poorly initialized.

Good initialization breaks the symmetry of the weights and gradients in a neural network and maintains commensurate activation variances across layers. Otherwise, the neural network doesn't learn effectively. Initializers like Xavier aim to keep variance constant across activations, which is especially relevant for training very deep neural nets. Too small an initialization can lead to vanishing gradients. Too large an initialization can lead to exploding gradients. This rule checks the variance of activation inputs across layers, the distribution of gradients, and the loss convergence for the initial steps to determine if a neural network has been poorly initialized.

Parameter Descriptions for the PoorWeightInitialization Rule

                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).
**Note**
This rule is not available for the XGBoost algorithm.

**SaturatedActivation**

This rule detects if the tanh and sigmoid activation layers are becoming saturated. An activation layer is saturated when the input of the layer is close to the maximum or minimum of the activation function. The minimum and maximum of the tanh and sigmoid activation functions are defined by their respective min_threshold and max_threshold values. If the activity of a node drops below the threshold_inactivity percentage, it is considered saturated. If more than a threshold_layer percent of the nodes are saturated, the rule returns True.

**Parameter Descriptions for the SaturatedActivation Rule**

### threshold_layer

Returns `True` if the number of saturated activations in a layer is greater than the `threshold_layer` percentage.

Returns `False` if the number of saturated activations in a layer is less than the `threshold_layer` percentage.

**Optional**

Valid values: Float

Default values: `50.0`

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.saturated_activation(),
        rule_parameters={
            "tensor_regex": ".*tanh_input|.*sigmoid_input",
            "threshold_tanh_min": "-9.4999",
            "threshold_tanh_max": "9.4999",
            "threshold_sigmoid_min": "-23",
            "threshold_sigmoid_max": "16.99999",
            "threshold_inactivity": "1.0",

                name="custom_activations_collection",
                parameters={
                    "include_regex": ".*tanh_input|.*sigmoid_input",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#).

**Note**

This rule is not available for the XGBoost algorithm.

### VanishingGradient

This rule detects if the gradients in a trial become extremely small or drop to a zero magnitude. If the mean of the absolute values of the gradients drops below a specified `threshold`, the rule returns `True`.

#### Parameters Descriptions for the VanishingGradient Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
</tbody>
</table>

**Required**
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold</td>
<td>The value at which the gradient is determined to be vanishing.</td>
</tr>
<tr>
<td></td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Float</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.0000001</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.vanishing_gradient(),
        rule_parameters={
            "threshold": "0.0000001"
        },
        collections_to_save=[
            CollectionConfig(
                name="gradients",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

**Note**
This rule is not available for the XGBoost algorithm.

**WeightUpdateRatio**

This rule keeps track of the ratio of updates to weights during training and detects if that ratio gets too large or too small. If the ratio of updates to weights is larger than the large_threshold value or if this ratio is smaller than small_threshold, the rule returns True.

Conditions for training are best when the updates are commensurate to gradients. Excessively large updates can push the weights away from optimal values, and very small updates result in very slow convergence. This rule requires weights to be available for two training steps, and train.save_interval needs to be set equal to num_steps.

**Parameter Descriptions for the WeightUpdateRatio Rule**

<table>
<thead>

</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.weight_update_ratio(),
        rule_parameters={
            "num_steps": "100",
            "large_threshold": "10.0",
            "small_threshold": "0.00000001",
            "epsilon": "0.000000001"
        },
        collections_to_save=
```
CollectionConfig(
    name="weights",
    parameters={
        "train.save_interval": "100"
    }
)
]
]

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

**Note**
This rule is not available for the XGBoost algorithm.

### AllZero

This rule detects if all or a specified percentage of the tensor values are zero.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

#### Parameters Descriptions for the AllZero Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

<td>Specifies the percentage of values in the tensor that needs to be zero for this rule to be invoked. Optional&lt;br&gt;Valid values: Float&lt;br&gt;Default value: 100 (in percentage)</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.all_zero(),
        rule_parameters={
            "tensor_regex": ".*",
            "threshold": "100"
        },
        collections_to_save=[
            CollectionConfig(
                name="all",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

### ClassImbalance

This rule measures sampling imbalances between classes and throws errors if the imbalance exceeds a threshold or if too many mispredictions for underrepresented classes occur as a result of the imbalance.

Classification models require well-balanced classes in the training dataset or a proper weighting/sampling of classes during training. The rule performs the following checks:

- It counts the occurrences per class. If the ratio of number of samples between smallest and largest class is larger than the `threshold_imbalance`, an error is thrown.
- It checks the prediction accuracy per class. If resampling or weighting has not been correctly applied, then the model can reach high accuracy for the class with many training samples, but low accuracy for the classes with few training samples. If a fraction of mispredictions for a certain class is above `threshold_misprediction`, an error is thrown.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).
## Parameter Descriptions for the ClassImbalance Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.class_imbalance(),
        rule_parameters={
            "threshold_imbalance": "10",
            "threshold_misprediction": "0.7",
            "samples": "500",
            "argmax": "False",
            "labels_regex": ".*labels",
            "predictions_regex": ".*predictions"
        },
        collections_to_save=[
            CollectionConfig(
                name="custom_output_collection",
                parameters={
                    "include_regex": ".*labels|.*predictions",
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

**LossNotDecreasing**

This rule detects when the loss is not decreasing in value at an adequate rate. These losses must be scalars.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules](#).  

**Parameter Descriptions for the LossNotDecreasing Rule**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td><strong>Parameter Name</strong></td>

                }
            )
        ]
    )
]
```

**Overfit**

This rule detects if your model is being overfit to the training data by comparing the validation and training losses.
This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

Note
A standard way to prevent overfitting is to regularize your model.

Parameter Descriptions for the Overfit Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>

<tr>
<td></td>
<td>Valid values: List of strings or a comma-separated string</td>
</tr>
<tr>
<td></td>
<td>Default value: None</td>
</tr>
<tr>
<td>start_step</td>
<td>The step from which to start comparing the validation and training loss.</td>
</tr>
<tr>
<td></td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td>patience</td>
<td>The number of steps for which the ratio_threshold is allowed to exceed the value set before the model is considered to be overfit.</td>
</tr>
<tr>
<td></td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 1</td>
</tr>
<tr>
<td>ratio_threshold</td>
<td>The maximum ratio of the difference between the mean validation loss and mean training loss to the mean training loss. If this threshold is exceeded for a patience number of steps, the model is being overfit and the rule returns True.</td>
</tr>
</tbody>
</table>
Overtraining

This rule detects if a model is being overtrained. After a number of training iterations on a well-behaved model (both training and validation loss decrease), the model approaches to a minimum of the loss function and does not improve anymore. If the model continues training it can happen that validation loss starts increasing, because the model starts overfitting. This rule sets up thresholds and conditions to determine if the model is not improving, and prevents overfitting problems due to overtraining.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

Note
Overtraining can be avoided by early stopping. For information on early stopping, see Stop Training Jobs Early (p. 1732). For an example that shows how to use spot training with Debugger, see Enable Spot Training with Amazon SageMaker Debugger.

                }
            )
        ]
    )
]
```

**SimilarAcrossRuns**

This rule compares tensors gathered from a base trial with tensors from another trial.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

                }
            )
        ]
    )
]```

1630
StalledTrainingRule

StalledTrainingRule detects if there is no progress made on training job, and stops the training job if the rule fires. This rule requires tensors to be periodically saved in a time interval defined by its threshold parameter. This rule keeps on monitoring for new tensors, and if no new tensor has been emitted for threshold interval rule gets fired.

Parameter Descriptions for the StalledTrainingRule Rule

<table>
<thead>
<tr>

```
built_in_rules = [
    Rule.sagemaker(
```
TensorVariance

This rule detects if you have tensors with very high or low variances. Very high or low variances in a tensor could lead to neuron saturation, which reduces the learning ability of the neural network. Very high variance in tensors can also eventually lead to exploding tensors. Use this rule to detect such issues early.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the collection_names or tensor_regex parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

                } )
        ]
    )
]
```

**UnchangedTensor**

This rule detects whether a tensor is no longer changing across steps.

This rule runs the `numpy.allclose` method to check if the tensor isn't changing.

This rule can be applied either to one of the supported deep learning frameworks (TensorFlow, MXNet, and PyTorch) or to the XGBoost algorithm. You must specify either the `collection_names` or `tensor_regex` parameter. If both the parameters are specified, the rule inspects the union of tensors from both sets.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

</tbody>
</table>
### List of Built-in Rules

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>atol</td>
<td>The absolute tolerance parameter to be passed to the <code>numpy.allclose</code> method.</td>
</tr>
<tr>
<td>equal_nan</td>
<td>Whether to compare NaNs as equal. If True, NaNs in input array a are considered equal to NaNs in input array b in the output array. This parameter is passed to the <code>numpy.allclose</code> method.</td>
</tr>
</tbody>
</table>

**Default values:**
- Default value: `1e-05`
- Default value: `1e-08`

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.unchanged_tensor(),
        rule_parameters={
            "collection_names": "losses",
            "tensor_regex": "",
            "num_steps": "3",
            "rtol": "1e-05",
            "atol": "1e-08",
            "equal_nan": "False"
        },
        collections_to_save=[
            CollectionConfig(
                name="losses",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

#### CheckInputImages

This rule checks if input images have been correctly normalized. Specifically, it detects if the mean of the sample data differs by more than a threshold value from zero. Many computer vision models require that input data has a zero mean and unit variance.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see [Configure Debugger Built-in Rules (p. 1570)](#).
## Parameter Descriptions for the `checkInputImages` Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base_trial</td>
<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td></td>
<td><strong>Required</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td>threshold_mean</td>
<td>A threshold that defines by how much mean of the input data can differ from 0.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Float</td>
</tr>
<tr>
<td></td>
<td>Default value: 0.2</td>
</tr>
<tr>
<td>threshold_samples</td>
<td>The number of images that have to be sampled before an error can be thrown. If the value is too low, the estimation of the dataset mean will be inaccurate.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 500</td>
</tr>
<tr>
<td>regex</td>
<td>The name of the input data tensor.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: String</td>
</tr>
<tr>
<td></td>
<td>Default value: &quot;.*hybridsequential0_input_0&quot; (the name of the input tensor for Apache MXNet models using HybridSequential)</td>
</tr>
<tr>
<td>channel</td>
<td>The position of the color channel in the input tensor shape array.</td>
</tr>
<tr>
<td></td>
<td><strong>Optional</strong></td>
</tr>
<tr>
<td></td>
<td>Valid values: Integer</td>
</tr>
<tr>
<td></td>
<td>Default value: 1 (for example, MXNet expects input data in the form of (batch_size, channel, height, width))</td>
</tr>
</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.check_input_images(),
        rule_parameters={
            "threshold_mean": "0.2",
            "threshold_samples": "500",
        }
    ),
]```
NLPSequenceRatio

This rule calculates the ratio of specific tokens given the rest of the input sequence that is useful for optimizing performance. For example, you can calculate the percentage of padding end-of-sentence (EOS) tokens in your input sequence. If the number of EOS tokens is too high, an alternate bucketing strategy should be performed. You also can calculate the percentage of unknown tokens in your input sequence. If the number of unknown words is too high, an alternate vocabulary could be used.

This rule is applicable to deep learning applications.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

            CollectionConfig(
                name="custom_inputs_collection",
                parameters=s[
                    "include_regex": ".*embedding0_input_0"
                ]
            )
        ]
    )
]
```

## Confusion

This rule evaluates the goodness of a confusion matrix for a classification problem.

It creates a matrix of size `category_no*category_no` and populates it with data coming from `(labels, predictions)` pairs. For each `(labels, predictions)` pair, the count in `confusion[labels][predictions]` is incremented by 1. When the matrix is fully populated, the ratio of data on-diagonal values and off-diagonal values are evaluated as follows:

- For elements on the diagonal: `confusion[i][i]/sum_j(confusion[j][j]) >= min_diag`
- For elements off the diagonal: `confusion[j][i]/sum_j(confusion[j][j]) <= max_off_diag`

This rule can be applied to the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

        },
        collections_to_save=[
            CollectionConfig(name="labels",
                             parameters={
                             "save_interval": "500"}
                      ),
            CollectionConfig(name="predictions",
                             parameters={
                             "include_regex": "500"}
                      )
        ]
    )
]
```

**Note**

This rule infers default values for the optional parameters if their values aren't specified.

**FeatureImportanceOverweight**

This rule accumulates the weights of the n largest feature importance values per step and ensures that they do not exceed the threshold. For example, you can set the threshold for the top 3 features to not hold more than 80 percent of the total weights of the model.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).
### Parameter Descriptions for the FeatureImportanceOverweight Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>

</tbody>
</table>

```python
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.feature_importance_overweight(),
        rule_parameters={
            "threshold": "0.8",
            "nfeatures": "3",
            "tensor_regex": ".*feature_importance/weight"
        },
        collections_to_save=[
            CollectionConfig(
                name="feature_importance",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]```
TreeDepth

This rule measures the depth of trees in an XGBoost model. XGBoost rejects splits if they do not improve loss. This regularizes the training. As a result, the tree might not grow as deep as defined by the depth parameter.

This rule is valid only for the XGBoost algorithm.

For an example of how to configure and deploy a built-in rule, see Configure Debugger Built-in Rules (p. 1570).

Parameter Descriptions for the TreeDepth Rule

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>The base trial training job name. This parameter is automatically set to the current training job by Amazon SageMaker Debugger.</td>
</tr>
<tr>
<td>depth</td>
<td>The depth of the tree. The depth of the tree is obtained by computing the base 2 logarithm of the largest node ID.</td>
</tr>
</tbody>
</table>

```
built_in_rules = [
    Rule.sagemaker(
        base_config=rule_configs.tree_depth(),
        rule_parameters={
            "depth": "4"
        },
        collections_to_save=[
            CollectionConfig(
                name="tree",
                parameters={
                    "save_interval": "500"
                }
            )
        ]
    )
]
```

Create Debugger Custom Rules for Training Job Analysis

You can create custom rules to monitor your training job using the Debugger Rule APIs and the open source smdebug Python library that provide tools to build your own rule containers.

Topics
• Prerequisites for Creating Debugger Custom Rules (p. 1643)
• Use the Debugger Client Library \texttt{smddebug} to Create a Custom Rule Python Script (p. 1643)
• Use the Debugger APIs to Run Your Own Custom Rules (p. 1643)

Prerequisites for Creating Debugger Custom Rules

To create Debugger custom rules, you need the following prerequisites.

- SageMaker Debugger Rule\texttt{.custom} API
- The open source \texttt{smddebug} Python library
- Your own custom rule python script
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712)

Use the Debugger Client Library \texttt{smddebug} to Create a Custom Rule Python Script

The \texttt{smddebug} Rule API provides an interface to set up your own custom rules. The following python script is a sample of how to construct a custom rule, \texttt{CustomGradientRule}. This tutorial custom rule watches if the gradients are getting too large and set the default threshold as 10. The custom rule takes a base trial created by a SageMaker estimator when it initiates training job.

```python
from smdebug.rules.rule import Rule

class CustomGradientRule(Rule):
    def __init__(self, base_trial, threshold=10.0):
        super().__init__(base_trial)
        self.threshold = float(threshold)

    def invoke_at_step(self, step):
        for tname in self.base_trial.tensor_names(collection="gradients"):
            t = self.base_trial.tensor(tname)
            abs_mean = t.reduction_value(step, "mean", abs=True)
            if abs_mean > self.threshold:
                return True
        return False
```

You can add multiple custom rule classes as many as you want in the same python script and deploy them to any training job trials by constructing custom rule objects in the following section.

Use the Debugger APIs to Run Your Own Custom Rules

The following code sample shows how to configure a custom rule with the Amazon SageMaker Python SDK. This example assumes that the custom rule script you created in the previous step is located at `'path/to/my_custom_rule.py'`.

```python
from sagemaker.debugger import Rule, CollectionConfig

custom_rule = Rule.custom(
    name='MyCustomRule',
    image_uri='759209512951.dkr.ecr.us-west-2.amazonaws.com/sagemaker-debugger-rule-evaluator:latest',
    instance_type='ml.t3.medium',
    source='path/to/my_custom_rule.py',
)```
The following list explains the Debugger Rule.custom API arguments.

- **name** (str): Specify a custom rule name as you want.
- **image_uri** (str): This is the image of the container that has the logic of understanding your custom rule. It sources and evaluates the specified tensor collections you save in the training job. You can find the list of open source SageMaker rule evaluator images from Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712).
- **instance_type** (str): You need to specify an instance to build a rule docker container. This spins up the instance in parallel with a training container.
- **source** (str): This is the local path or the Amazon S3 URI to your custom rule script.
- **rule_to_invoke** (str): This specifies the particular Rule class implementation in your custom rule script. SageMaker supports only one rule to be evaluated at a time in a rule job.
- **collections_to_save** (str): This specifies which tensor collections you will save for the rule to run.
- **rule_parameters** (dictionary): This accepts parameter inputs in a dictionary format. You can adjust the parameters that you configured in the custom rule script.

After you set up the custom_rule object, you can use it for building a SageMaker estimator for any training jobs. Specify the entry_point to your training script. You do not need to make any change of your training script.

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(
    role=sagemaker.get_execution_role(),
    base_job_name='smdebug-custom-rule-demo-tf-keras',
    entry_point='path/to/your_training_script.py',
    train_instance_type='ml.p2.xlarge',
    ...  
    # debugger-specific arguments below
    rules = [custom_rule]
)

estimator.fit()
```

For more variations and advanced examples of using Debugger custom rules, see the following example notebooks.

- Monitor your training job with Amazon SageMaker Debugger custom rules
- PyTorch iterative model pruning of ResNet and AlexNet
- Trigger Amazon CloudWatch Events using Debugger Rules to Take an Action Based on Training Status with TensorFlow

### Use Debugger with Custom Training Containers

Amazon SageMaker Debugger is available for any deep learning models that you bring to Amazon SageMaker. The AWS CLI, SageMaker Estimator API, and the Debugger APIs enable you to use any Docker base images to build and customize containers to train your models. To use Debugger with
customized containers, you need to make a minimal change to your training script to implement the Debugger hook callback and retrieve tensors from training jobs.

You need the following resources to build a customized container with Debugger.

- Amazon SageMaker Python SDK
- The SMDebug open source client library
- A Docker base image of your choice
- Your training script with a Debugger hook registered – For more information about registering a Debugger hook to your training script, see Register Debugger Hook to Your Training Script (p. 1645).

For an end-to-end example of using Debugger with a custom training container, see the following example notebook.

- Build a Custom Training Container and Debug Training Jobs with Debugger

**Tip**

This custom container with Debugger guide is an extension of the Adapting Your Own Training Container (p. 2107) guide which walks you thorough how to build and push your custom training container to Amazon ECR.

### Prepare to Build a Custom Training Container

To build a docker container, the basic structure of files should look like the following:

```bash
### debugger_custom_container_test_notebook.ipynb      # a notebook to run python snippet codes
### debugger_custom_container_test_folder              # this is a docker folder
    ### your-training-script.py                       # your training script with Debugger hook
    ### Dockerfile                                    # a Dockerfile to build your own container
```

### Register Debugger Hook to Your Training Script

To debug your model training, you need to add a Debugger hook to your training script.

**Note**

This step is required to collect model parameters (output tensors) for debugging your model training. If you only want to monitor and profile, you can skip this hook registration step and exclude the `debugger_hook_config` parameter when constructing an estimator.

The following example code shows the structure of a training script using the Keras ResNet50 model and how to pass the Debugger hook as a Keras callback for debugging. To find a complete training script, see TensorFlow training script with SageMaker Debugger hook.

```python
# An example of training script (your-training-script.py)
import tensorflow.comapt.v2 as tf
from tensorflow.keras.applications.resnet50 import ResNet50
import smdebug.tensorflow as smd

def train(batch_size, epoch, model, hook):
    ...  
    model.fit(X_train, Y_train,
              batch_size=batch_size,
              epochs=epoch,
```
validation_data=(X_valid, Y_valid),
shuffle=True,

callback
# smdebug modification: Pass the Debugger hook in the main() as a Keras callback
callbacks=[hook])

def main():
    parser=argparse.ArgumentParser(description="Train resnet50 cifar10")

    # hyperparameter settings
    parser.add_argument(...)

    args = parser.parse_args()

    model=ResNet50(weights=None, input_shape=(32,32,3), classes=10)

    # Add the following line to register the Debugger hook for Keras.
    hook=smd.KerasHook.create_from_json_file()

    # Start the training.
    train(args.batch_size, args.epoch, model, hook)

if __name__ == "__main__":
    main()
The SageMaker PyTorch estimator is already in script mode by default. In the notebook, the line to activate `script_mode` is not included in the estimator configuration.

This notebook shows detailed steps to change an original PyTorch training script to a modified version with Debugger enabled. Additionally, this example shows how you can use Debugger built-in rules to detect training issues such as the vanishing gradients problem, and the Debugger trial features to call and analyze the saved tensors.

### Create and Configure a Dockerfile

Open your SageMaker JupyterLab and create a new folder, `debugger_custom_container_test_folder` in this example, to save your training script and Dockerfile. The following code example is a Dockerfile that includes essential docker build commands. Paste the following code into the Dockerfile text file and save it. Upload your training script to the same folder.

```
# Specify a docker base image
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3
RUN /usr/bin/python3 -m pip install --upgrade pip
RUN pip install --upgrade protobuf

# Install required packages to enable the SageMaker Python SDK and the smdebug library
RUN pip install sagemaker-training
RUN pip install smdebug

CMD ['bin/bash']
```

If you want to use a pre-built AWS Deep Learning Container image, see Available AWS Deep Learning Containers Images.

### Build and Push the Custom Training Container to Amazon ECR

Create a test notebook, `debugger_custom_container_test_notebook.ipynb`, and run the following code in the notebook cell. This will access the `debugger_byoc_test_docker` directory, build the docker with the specified `algorithm_name`, and push the docker container to your Amazon ECR.

```
import boto3

account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-debugger-mnist-byoc-tf2'
tag = ':latest'

region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix, ecr_repository + tag)

!docker build -t $ecr_repository docker
!$(aws ecr get-login --region $region --registry-ids $account_id --no-include-email)
!aws ecr create-repository --repository-name $ecr_repository
!docker tag {ecr_repository + tag} $byoc_image_uri
!docker push $byoc_image_uri
```

**Tip**

If you use one of the AWS Deep Learning Container base images, run the following code to log in to Amazon ECR and access to the Deep Learning Container image repository.
Run and Debug Training Jobs Using the Custom Training Container

After you build and push your docker container to Amazon ECR, configure a SageMaker estimator with your training script and the Debugger-specific parameters. After you execute the `estimator.fit()`, Debugger will collect output tensors, monitor them, and detect training issues. Using the saved tensors, you can further analyze the training job by using the `smdebug` core features and tools. Configuring a workflow of Debugger rule monitoring process with Amazon CloudWatch Events and AWS Lambda, you can automate a stopping training job process whenever the Debugger rules spots training issues.

```python
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker.debugger import Rule, DebuggerHookConfig, CollectionConfig, rule_configs

profiler_config=ProfilerConfig(...)
debugger_hook_config=DebuggerHookConfig(...)
rule_configs=[
    Rule.sagemaker(rule_configs.built_in_rule()),
    ProfilerRule.sagemaker(rule_configs.BuiltInRule())
]

estimator=Estimator(
    image_uri=byoc_image_uri,
    entry_point="./debugger_custom_container_test_folder/your-training-script.py",
    role=sagemaker.get_execution_role(),
    base_job_name='debugger-custom-container-test',
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    # Debugger-specific parameters
    profiler_config=profiler_config,
    debugger_hook_config=debugger_hook_config,
    rules=rules
)

# start training
estimator.fit()
```

Action on Amazon SageMaker Debugger Rules

Based on the Debugger rule evaluation status, you can set up automated actions such as stopping a training job and sending notifications using Amazon Simple Notification Service (Amazon SNS). You can also create your own actions using Amazon CloudWatch Events and AWS Lambda. To learn how to set up automated actions based on the Debugger rule evaluation status, see the following topics.

Topics
- Debugger Built-in Actions for Rules (p. 1648)
- Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1653)

Debugger Built-in Actions for Rules

Use Debugger built-in actions to respond to issues found by Debugger Rule (p. 1599). The Debugger rule_configs class provides tools to configure a list of actions, including automatically stopping...
training jobs and sending notifications using Amazon Simple Notification Service (Amazon SNS) when the Debugger rules find training issues.

Step 1: Set Up Amazon SNS, Create an SMDebugRules Topic, and Subscribe to the Topic

This section walks you through how to set up an Amazon SNS SMDebugRules topic, subscribe to it, and confirm the subscription to receive notifications from the Debugger rules.

**Note**
For more information about billing for Amazon SNS, see Amazon SNS pricing and Amazon SNS FAQs.

**To create a SMDebugRules topic**

2. In the left navigation pane, choose Topics.
3. On the Topics page, choose Create topic.
4. On the Create topic page, in the Details section, do the following:
   a. For Type, choose Standard for topic type.
   b. In Name, enter SMDebugRules.
5. Skip all other optional settings and choose Create topic. If you want to learn more about the optional settings, see Creating an Amazon SNS topic.

**To subscribe to the SMDebugRules topic**

2. In the left navigation pane, choose Subscriptions.
3. On the Subscriptions page, choose Create subscription.
4. On the Create subscription page, in the Details section, do the following:
   b. For Protocol, choose Email or SMS.
   c. For Endpoint, enter the endpoint value, such as an email address or a phone number that you want to receive notifications.

   **Note**
   Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.
5. Skip all other optional settings and choose Create subscription. If you want to learn more about the optional settings, see Subscribing to an Amazon SNS topic.

After you subscribe to the SMDebugRules topic, you receive the following confirmation message in email or by phone:
Step 2: Set Up Your IAM Role to Attach Required Policies

In this step, you add the required policies to your IAM role.

To add the required policies to your IAM role

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the left navigation pane, choose Policies, and choose Create policy.
3. On the Create policy page, do the following to create a new sns-access policy:
   a. Choose the JSON tab.
   b. Paste the JSON strings formatted in bold in the following code into the "Statement", replacing the 12-digit AWS account ID with your AWS account ID.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "sns:Publish",
        "sns:CreateTopic",
        "sns:Subscribe"
      ],
      "Resource": "arn:aws:sns:*:111122223333:SMDebugRules"
    }
  ]
}
```
   c. At the bottom of the page, choose Review policy.
   d. On the Review policy page, for Name, enter sns-access.
   e. At the bottom of the page, choose Create policy.
4. Go back to the IAM console, and choose Roles in the left navigation pane.
5. Look up the IAM role that you use for SageMaker model training and choose that IAM role.
6. On the Permissions tab of the Summary page, choose Attach policies.
7. Search for the sns-access policy, select the check box next to the policy, and then choose Attach policy.
For more examples of setting up IAM policies for Amazon SNS, see Example cases for Amazon SNS access control.

**Step 3: Configure Debugger Rules with the Built-in Actions**

After successfully finishing the required settings in the preceding steps, you can configure the Debugger built-in actions for debugging rules as shown in the following example script. You can choose which built-in actions to use while building the actions list object. The `rule_configs` is a helper module that provides high-level tools to configure Debugger built-in rules and actions. The following built-in actions are available for Debugger:

- `rule_configs.StopTraining()` – Stops a training job when the Debugger rule finds an issue.
- `rule_configs.Email("abc@abc.com")` – Sends a notification via email when the Debugger rule finds an issue. Use the email address that you used when you set up your SNS topic subscription.
- `rule_configs.SMS("+1234567890")` – Sends a notification via text message when the Debugger rule finds an issue. Use the phone number that you used when you set up your SNS topic subscription.

**Note**

Make sure you type the correct email address and phone number. Phone numbers must include +, a country code, and a phone number, with no special characters or spaces. For example, the phone number +1 (222) 333-4444 is formatted as +12223334444.

You can use all of the built-in actions or a subset of actions by wrapping up using the `rule_configs.ActionList()` method, which takes the built-in actions and configures a list of actions.

**To add all of the three built-in actions to a single rule**

If you want to assign all of the three built-in actions to a single rule, configure a Debugger built-in action list while constructing an estimator. Use the following template to construct the estimator, and Debugger will stop training jobs and send notifications through email and text for any rules that you use to monitor your training job progress.

```python
from sagemaker.debugger import Rule, rule_configs

# Configure an action list object for Debugger rules
actions = rule_configs.ActionList(
    rule_configs.StopTraining(),
    rule_configs.Email("abc@abc.com"),
    rule_configs.SMS("+1234567890")
)

# Configure rules for debugging with the actions parameter
rules = [
    Rule.sagemaker(
        base_config=rule_configs.built_in_rule(),
        rule_parameters={"paramter_key": value },
        actions=actions
    )
]

estimator = Estimator(
    ...
    rules = rules
)

estimator.fit(wait=False)
```

**To create multiple built-in action objects to assign different actions to a single rule**
If you want to assign the built-in actions to be triggered at different threshold values of a single rule, you can create multiple built-in action objects as shown in the following script. To avoid a conflict error by running the same rule, you must submit different rule job names (specify different strings for the rules' name attribute) as shown in the following example script template. This example shows how to set up StalledTrainingRule (p. 1631) to take two different actions: send an email to abc@abc.com when a training job stalls for 60 seconds, and stop the training job if stalling for 120 seconds.

```python
from sagemaker.debugger import Rule, rule_configs
time
base_job_name_prefix = 'smdebug-stalled-demo-' + str(int(time.time()))

# Configure an action object for StopTraining
action_stop_training = rule_configs.ActionList(
    rule_configs.StopTraining()
)

# Configure an action object for Email
action_email = rule_configs.ActionList(
    rule_configs.Email("abc@abc.com")
)

# Configure a rule with the Email built-in action to trigger if a training job stalls for 60 seconds
stalled_training_job_rule_email = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "60",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_email
)

stalled_training_job_rule_email.name = "StalledTrainingJobRuleEmail"

# Configure a rule with the StopTraining built-in action to trigger if a training job stalls for 120 seconds
stalled_training_job_rule = Rule.sagemaker(
    base_config=rule_configs.stalled_training_rule(),
    rule_parameters={
        "threshold": "120",
        "training_job_name_prefix": base_job_name_prefix
    },
    actions=action_stop_training
)

stalled_training_job_rule.name = "StalledTrainingJobRuleStopTraining"

estimator = Estimator(
    ...
    rules = [stalled_training_job_rule_email, stalled_training_job_rule]
)

estimator.fit(wait=False)
```

While the training job is running, the Debugger built-in action sends notification emails and text messages whenever the rule finds issues with your training job. The following screenshot shows an example of email notification for a training job that has a stalled training job issue.
The following screenshot shows an example text notification that Debugger sends when the rule finds a StalledTraining issue.

Considerations for Using the Debugger Built-in Actions

- To use the Debugger built-in actions, an internet connection is required. This feature is not supported in the network isolation mode provided by Amazon SageMaker or Amazon VPC.
- The built-in actions cannot be used for Debugger ProfilerRule (p. 1598).
- The built-in actions cannot be used on training jobs with spot training interruptions.
- In email or text notifications, None appears at the end of messages. This does not have any meaning, so you can disregard the text None.

Create Actions on Rules Using Amazon CloudWatch and AWS Lambda

Amazon CloudWatch collects Amazon SageMaker model training job logs and Amazon SageMaker Debugger rule processing job logs. Configure Debugger with Amazon CloudWatch Events and AWS Lambda to take action based on Debugger rule evaluation status.

CloudWatch Logs for Debugger Rules and Training Jobs

To find training job logs and Debugger rule job logs

2. In the left navigation pane under the Log node, choose Log Groups.
3. In the log groups list, do the following:
   - Choose /aws/sagemaker/TrainingJobs for training job logs.
Choose `/aws/sagemaker/ProcessingJobs` for Debugger rule job logs.

You can use the training and Debugger rule job status in the CloudWatch logs to take further actions when there are training issues.

For more information about monitoring training jobs using CloudWatch, see Monitor Amazon SageMaker.

**Set Up Debugger for Automated Training Job Termination Using CloudWatch and Lambda**

The Debugger rules monitor training job status, and a CloudWatch Events rule watches the Debugger rule training job evaluation status.

**Step 1: Create a Lambda Function**

**To create a Lambda function**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In the left navigation pane, choose **Functions** and then choose **Create function**.
3. On the **Create function** page, choose **Author from scratch** option.
4. In the **Basic information** section, enter a **Function name** (for example, `debugger-rule-stop-training-job`).
5. For **Runtime**, choose **Python 3.7**.
6. For **Permissions**, expand the drop down option, and choose **Change default execution role**.
7. For **Execution role**, choose **Use an existing role** and choose the IAM role that you use for training jobs on SageMaker.

   **Note**
   
   Make sure you use the execution role with `AmazonSageMakerFullAccess` and `AWSLambdaBasicExecutionRole` attached. Otherwise, the Lambda function won't properly react to the Debugger rule status changes of the training job. If you are unsure which execution role is being used, run the following code in a Jupyter notebook cell to retrieve the execution role output:
   
   ```python
   import sagemaker
   sagemaker.get_execution_role()
   ```

8. At the bottom of the page, choose **Create function**.
   
   The following figure shows an example of the **Create function** page with the input fields and selections completed.
Step 2: Configure the Lambda function

To configure the Lambda function

1. In the **Function code** section of the configuration page, paste the following Python script in the Lambda code editor pane. The `lambda_handler` function monitors the Debugger rule evaluation status collected by CloudWatch and triggers the `StopTrainingJob` API operation. The AWS SDK for Python (Boto3) client for SageMaker provides a high-level method, `stop_training_job`, which triggers the `StopTrainingJob` API operation.

```python
import json
import boto3
import logging

logger = logging.getLogger()
logger.setLevel(logging.INFO)

def lambda_handler(event, context):
    training_job_name = event.get("detail").get("TrainingJobName")
    logging.info(f' Evaluating Debugger rules for training job: {training_job_name}')
```
eval_statuses = event.get("detail").get("DebugRuleEvaluationStatuses", None)

if eval_statuses is None or len(eval_statuses) == 0:
    logging.info("Couldn't find any debug rule statuses, skipping...")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

# should only attempt stopping jobs with InProgress status
training_job_status = event.get("detail").get("TrainingJobStatus", None)
if training_job_status != 'InProgress':
    logging.debug(f"Current Training job status({training_job_status}) is not 'InProgress'. Exiting")
    return {
        'statusCode': 200,
        'body': json.dumps('Nothing to do')
    }

client = boto3.client('sagemaker')

for status in eval_statuses:
    logging.info(status.get("RuleEvaluationStatus") + ', RuleEvaluationStatus=' + str(status))
    if status.get("RuleEvaluationStatus") == "IssuesFound":
        secondary_status = event.get("detail").get("SecondaryStatus", None)
        logging.info(
            f'About to stop training job, since evaluation of rule configuration {status.get("RuleConfigurationName")} resulted in "IssuesFound". ' +
            f'\ntraining job "{training_job_name}" status is "{training_job_status}", secondary status is "{secondary_status}" ' +
            f'\nAttempting to stop training job "{training_job_name}"' +
        )
        try:
            client.stop_training_job(
                TrainingJobName=training_job_name
            )
        except Exception as e:
            logging.error(
                "Encountered error while trying to " +
                "stop training job {}": {}").format(
                    training_job_name, str(e)
                )
        raise e

return None

For more information about the Lambda code editor interface, see Creating functions using the AWS Lambda console editor.

2. Skip all other settings and choose Save at the top of the configuration page.

Step 3: Create a CloudWatch Events Rule and Link to the Lambda Function for Debugger

To create a CloudWatch Events rule and link to the Lambda function for Debugger

2. In the left navigation pane, choose Rules under the Events node.
3. Choose Create rule.
4. In the **Event Source** section of the **Step 1: Create rule** page, choose **SageMaker** for **Service Name**, and choose **SageMaker Training Job State Change** for **Event Type**. The Event Pattern Preview should look like the following example JSON strings:

```json
{
    "source": ["aws.sagemaker"],
    "detail-type": ["SageMaker Training Job State Change"]
}
```

5. In the **Targets** section, choose **Add target***, and choose the **debugger-rule-stop-training-job** Lambda function that you created. This step links the CloudWatch Events rule with the Lambda function.

6. Choose **Configure details** and go to the **Step 2: Configure rule details** page.

7. Specify the CloudWatch rule definition name. For example, **debugger-cw-event-rule**.

8. Choose **Create rule** to finish.

9. Go back to the Lambda function configuration page and refresh the page. Confirm that it's configured correctly in the **Designer** panel. The CloudWatch Events rule should be registered as a trigger for the Lambda function. The configuration design should look like the following example:

![CloudWatch Events Designer panel](image)

### Run Example Notebooks to Test Automated Training Job Termination

You can run the following example notebooks, which are prepared for experimenting with stopping a training job using Debugger's built-in rules.

- **Amazon SageMaker Debugger - Reacting to CloudWatch Events from Debugger rules**
This example notebook runs a training job that has a vanishing gradient issue. The Debugger VanishingGradient (p. 1618) built-in rule is used while constructing the SageMaker TensorFlow estimator. When the Debugger rule detects the issue, the training job is terminated.

- Detect stalled training and stop training job using Debugger rule

This example notebook runs a training script with a code line that forces it to sleep for 10 minutes. The Debugger StalledTrainingRule (p. 1631) built-in rule invokes issues and stops the training job.

Disable the CloudWatch Events Rule to Stop Using the Automated Training Job Termination

If you want to disable the automated training job termination, you need to disable the CloudWatch Events rule. In the Lambda Designer panel, choose the EventBridge (CloudWatch Events) block linked to the Lambda function. This shows an EventBridge panel below the Designer panel (for example, see the previous screen shot). Select the check box next to EventBridge (CloudWatch Events): debugger-cw-event-rule, and then choose Disable. If you want to use the automated termination functionality later, you can enable the CloudWatch Events rule again.

SageMaker Debugger on Studio

Use Debugger dashboards on Studio to analyze your model performance and system bottlenecks while running training jobs on Amazon Elastic Compute Cloud instances. Gain insights into your training jobs and improve your model training performance and accuracy with the Debugger dashboards. By default, Debugger monitors system metrics (CPU, GPU, CPU and GPU memory, Network, and data I/O) every 500 milliseconds and basic output tensors (loss and accuracy) every 500 iterations for training jobs. You can also further customize Debugger configuration parameter values and adjust the saving intervals through the Studio UI or using the Amazon SageMaker Python SDK.

Important
If using existing SageMaker Studio apps, you need to restart them to use the new features.
For instructions on how to restart and update your Studio environment, see Update Amazon SageMaker Studio.

Topics
- Open Amazon SageMaker Debugger Insights Dashboard (p. 1659)
Open Amazon SageMaker Debugger Insights Dashboard

Open the Debugger insights dashboard on Studio to see profiling progress and results of resource utilization and system bottlenecks of your training job running on EC2 instances.

**Note**

Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

**Important**

When you are done using the Debugger insights dashboard, you must shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the SageMaker Debugger Insights Instance (p. 1670).

To open the Debugger insights dashboard

1. Choose the SageMakerComponents and registries icon ( ).
2. Open the drop down menu, and choose Experiments and trials.
3. Look up your training job name. If you have not assigned a SageMaker Experiments trial component to the training job, the job is collected under the Unassigned trial components list.
4. Right-click (or an equivalent UI interaction) to open the context menu of the training job trial component. There are two menu items to access the Debugger features on Studio: Open Debugger for insights and Open in trial details.
5. Choose **Open Debugger for insights**. This opens a **Debug [your-training-job-name]** tab. In this tab, Debugger provides an overview of your model training performance on EC2 instances and identifies system bottleneck problems. While **monitoring** the system resource utilization, you can also enable **profiling** to capture framework metrics that consist of data from neural network operations executed during forward and backward pass and data loading. For more information about how to enable **profiling** using the Debugger insights dashboard controller, see *Enable and Configure Debugger Profiling for Detailed Insights* (p. 1661).

Debugger correlates the system resource utilization metrics with the framework metrics and helps identify resource-intensive operators that might be the root cause of the system bottlenecks. You can also download an aggregated Debugger profiling report. For more information, see *SageMaker Debugger Insights Dashboard Controller* (p. 1660).

**SageMaker Debugger Insights Dashboard Controller**

There are different components of the Debugger Controller for monitoring and profiling. In this guide, you learn about the Debugger controller components.

**Note**

Studio Debugger insights dashboard runs a Studio app on an **ml.m5.4xlarge** instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the **ml.m5.4xlarge** instance usage. For information about pricing, see the *Amazon SageMaker Pricing* page.

**Important**

When you are done using the Debugger insights dashboard, you must shut down the **ml.m5.4xlarge** instance to avoid accruing charges. For instructions on how to shut down the instance, see *Shut Down the SageMaker Debugger Insights Instance* (p. 1670).

**SageMaker Debugger Insights Controller UI**

Using the Debugger controller located at the upper-left corner of the insights dashboard, you can refresh the dashboard, configure or update Debugger settings for monitoring system metrics and profiling framework metrics, stop training job, and download Debugger profiling report.

- If you want to manually refresh the **Debug [your-training-job-name]** page, choose the refresh button (the round arrow at the upper-left corner) as shown in the preceding screenshot.
- **Monitoring** is on by default for any SageMaker training job. By monitoring your training job, Debugger only collects system metrics to detect resource utilization problems, such as CPU bottlenecks and GPU underutilization. For a complete list of resource utilization problems that Debugger monitors, see *Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics)* (p. 1599).
To download a comprehensive Debugger profiling report with details and analysis of a training job, choose **Download report**. For more information about the Debugger profiling report, see *SageMaker Debugger Profiling Report (p. 1674)*.

**Enable and Configure Debugger Profiling for Detailed Insights**

When you enable **Profiling**, Debugger starts collecting framework metrics. Framework metrics are model data collected from ML framework operations of your model, such as forward pass, backward pass, batch normalization, and data loader processes. Debugger correlates system performance bottlenecks with the framework operations and runs the **Debugger Built-in Rules for Profiling Framework Metrics (p. 1599)**.

**Note**

After you've enabled profiling, Debugger collects every framework operation call that's executed in each step: operations for convolving down input layers during forward pass, updating weights of millions of neurons during backward pass, and data loader processes. While profiling enables you to understand model performance at a deeper level, collecting framework metrics might impact your training time and performance. We recommend that you enable profiling to inspect your model up to two steps at a time. For more information about how to configure Debugger for framework profiling using *Amazon SageMaker Python SDK*, see *Configure Debugger Framework Profiling (p. 1560)* and *Updating Debugger System Monitoring and Framework Profiling Configuration while a Training Job is Running (p. 1564)*.

If you want to enable profiling while your training job is running, use the following steps to start profiling.

1. In *SageMaker Studio*, turn on **Profiling** to enable Debugger framework profiling. This opens a Debugger monitoring and profiling configuration page.

```
[Image of Debugger monitoring and profiling configuration page]
```

2. In *Configure Debugger monitoring and profiling*, **S3 bucket URI** and **Collect monitoring data every** are already set to the default values.

You can choose to change the monitoring interval using the drop down menu and selecting among the following available options: 100 milliseconds, 200 milliseconds, 500 milliseconds (default), 1 second, 5 seconds, and 1 minute.
The following fields need to be specified:

- **S3 bucket URI** – Specify the base S3 bucket URI.
- **Collect monitoring data every** – Select a time interval to collect system metrics.

  **Note**
  If you choose one of the lower time intervals, you increase the granularity of monitoring system metrics. It allows you to capture spikes and anomalies with a higher time resolution. However, as the size of system metrics to process proportionally increases, it might impact the overall training and processing time.

3. **In Advanced settings for profiling**, configure framework metrics profiling options. Specify **Start step** (or **Start time**) and **Number of steps to profile** (or **Time duration to profile**) to profile. You can also leave the input fields blank. The default values will be automatically configured to use the current step and for 1 step duration.
• **Detailed profiling** – Specify a target step or time range to profile framework operations using the native framework profilers (TensorFlow profiler and PyTorch profiler). For example, if using TensorFlow, the Debugger hooks enable the TensorFlow profiler to collect TensorFlow-specific framework metrics. Detailed profiling enables you to profile all framework operators at a pre-step (before the first step), within steps, and between steps of a training job.

  **Note**
  The detailed profiling might significantly increase GPU memory consumption. It is not recommended to enable the detailed profiling for more than a couple of steps.

• **Python profiling** – Specify a target step or time range to profile Python functions. You can also choose between two Python profilers: cProfile and Pyinstrument.

  • cProfile – The standard Python profiler. cProfile collects for every Python operator called during training. With cProfile, Debugger saves cumulative time and annotation of each function call, providing a complete detail of Python functions. In deep learning, for example, the most frequently called functions might be the convolutional filters and backward pass operators, and cProfile profiles every single of them. For the cProfile option, you can further select a timer option: total time, CPU time, and off-CPU time. While you can profile every function calls executing on processors (both CPU and GPU) in CPU time, you can also identify I/O or network bottlenecks with the off-CPU time option. The default is total time, and Debugger profiles both CPU and off-CPU time. With cProfile, you are able to drill down to every single functions when analyzing the profile data.

  • Pyinstrument – Pyinstrument is a low overhead Python profiler that works based on sampling. With the Pyinstrument option, Debugger samples profiling events every millisecond. Because Pyinstrument measures elapsed wallclock time instead of CPU time, the Pyinstrument option can be a better choice over the cProfile option for reducing profiling noises (filtering out irrelevant function calls that are cumulatively fast) and capturing operators that are actually compute intensive (cumulatively slow) for training your model. With Pyinstrument, you are able to see a tree of function calls and better understand the structure and root cause of the slowness.

  **Note**
  Enabling Python profiling might result in slowing down the overall training time. In case of cProfile, Python operators that are the most frequently called are profiled at every call, so the processing time on profiling increases with respect to the number of calls. For Pyinstrument, the cumulative profiling time increases with respect to time because of its sampling mechanism.

• **Dataloader profiling** – Specify a target step or time range to profile deep learning framework data loader processes. Debugger collects every data loader event of the frameworks.
Note
The data loader profiling can lower the training performance while collecting information from data loaders. We don't recommend that you enable the data loader profiling for more than a couple of steps. Debugger is pre-configured to annotate data loader processes only for the AWS deep learning containers. Debugger cannot profile data loader processes on any other custom or external containers.

4. Choose Confirm to finish your profiling configuration. When the configuration is successfully updated, you should be able to see the following confirmation message.

SageMaker Debugger Insights Dashboard Walkthrough

When you initiate a SageMaker training job, Debugger starts monitoring hardware system resource utilization of EC2 instances by default. You can track the system utilization rate, statistics overview, and bottleneck detection status and results through the Studio. This guide walks you through every component of the Studio Debugger insights dashboard.

Note
Studio Debugger insights dashboard runs a Studio app on an ml.m5.4xlarge instance to process and render the visualizations. Each Debugger insights tab runs one Studio kernel session. Multiple kernel sessions for multiple Debugger insights tabs run on the single instance. When you close a Debugger insights tab, the corresponding kernel session is also closed. A Studio app remains active and accrue charges for the ml.m5.4xlarge instance usage. For information about pricing, see the Amazon SageMaker Pricing page.

Important
When you are done using the Debugger insights dashboard, you must shut down the ml.m5.4xlarge instance to avoid accruing charges. For instructions on how to shut down the instance, see Shut Down the SageMaker Debugger Insights Instance (p. 1670).

Topics
- Debugger Insights – Overview (p. 1664)
- Debugger Insights – Nodes (p. 1667)

Debugger Insights – Overview

On the Overview tab, you can find a training job summary, resource utilization summary, resource intensive operations, and insights.

Training job summary

The Training job summary section shows the overall training time spent on different phases of training: initialization, training loop, and finalization. The pie chart shows the time usage percentage and absolute time amount spent on the different training phases. For example, you can have a high-level overview of how long it takes for initializing a training job, check if the initialization is taking too long due to data downloading, leaving the GPUs idle.
This section has the following features:

- The Training progress over time chart shows the timeline of the different training phase over time. If using spot training, you can also find the spot interruptions in the timeline chart.

- The Training job details panel shows the exact time stamps and utilization rate percentage numbers.
  - Start time – The exact time when the training job started.
  - End time – The exact time when the training job finished.
  - Job duration – The total training time from the Start time to the End time.
  - Training loop start – The exact time when the first step of the first epoch has started.
  - Training loop end – The exact time when the last step of the last epoch has finished.
  - Training loop duration – The total time between the Training loop start time and the Training loop end time.
  - Initialization – Time spent on initializing the training job, such as compiling the training script, initiating EC2 instances, and downloading training data.
  - Finalization – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances.
  - Initialization (%) – The percentage of time spent on Initialization over the total Job duration.
  - Training loop (%) – The percentage of time spent on Training loop over the total Job duration.
  - Finalization (%) – The percentage of time spent on Finalization over the total Job duration.

Resource utilization summary

This summary table shows hardware system resource utilization statistics of all workers (algo-n). System metrics include total CPU utilization, total GPU utilization, total CPU memory utilization, total GPU memory utilization, total I/O wait time, and total Network in bytes. The table shows the minimum and the maximum values, and p99, p90, and p50 percentiles.
Resource intensive operations

The Resource intensive operations section provides more detailed profiling results that show what operations of the training job were compute intensive. In the following example, it shows that the convolutional neural network backward pass operators were the most resource intensive on the GPUs.

<table>
<thead>
<tr>
<th>Node</th>
<th>Type</th>
<th>Value</th>

</tbody>
</table>

Insights

In the Insights pane, you can find training issues detected by Debugger built-in rules. You can expand each of the list to find useful insights, suggestions, a description of the rule, and criteria of triggering the rule.

For more information about the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1598).
Insights
The following list shows a summary of Debugger rule analysis on your training job. Expand the following rule items to find suggestions and additional details, such as the number of times each rule triggered, the rule parameters, and the default threshold values to evaluate your training job performance.
Showing 8 suggestions

- GPUMemoryIncrease - Issue Found
- BatchSize - Issue Found
- LowGPUtilization - Issue Found
- CPUBottleneck - Issue Found
- IOBottleneck - No Issue Found
- StepOutlier - No Issue Found
- MaxInitializationTime - No Issue Found
- LoadBalancing - No Issue Found

Debugger Insights – Nodes

On the Studio Debugger Insight Nodes tab, Debugger provides detailed graphs that track each compute node on which your training jobs are running.

CPU and Network utilization

The first two graphs show CPU utilization and network utilization over time. By default, the graphs show the mean values: the average of CPU and network utilization over the total number of CPU cores. You can select one or more CPU cores, by selecting on the labels, to graph them on single chart and compare utilization across cores. The timeline graphs are interactive, and the two graphs are synced up. You can drag and zoom in and out to see specific time windows that you want to have a closer look.
The following graphs show GPU utilization and GPU memory utilization over time. By default, the graphs show the mean utilization rate over time. You can select the GPU core labels to see the utilization rate of each core. Taking the mean of utilization rate over the total number of GPU cores shows the mean utilization of the entire hardware system resource. By looking at the mean utilization rate, you can check the overall system resource usage of EC2 instance. The following figure shows an example training job on an ml.p3.16xlarge instance with 8 GPU cores. You can monitor if the training job is well distributed, fully utilizing all GPUs.
Overall system utilization over time

The following heatmap shows the entire system utilization over time projected onto the two-dimensional plot. Every CPU and GPU cores are listed in the vertical axis, and the utilization is recorded over time with colors. See the labeled colorbar on the right side of the plot to find out what color level corresponds to what utilization rate. For example, in the following heatmap, after initialization phase has ended around Sun 23:18, you can find that the training job fully utilizes an ml.p3.16xlarge instance: the GPU cores are fully utilized and the CPUs are moderately used for processing Python operations. There were several CPU bottleneck problems scattered across the CPUs at different times.

System resource utilization over time and framework event phase

The System metrics over time graph shows the overall CPU, GPU, and data I/O utilization. The Framework metrics over time graph shows the framework metrics, which are the framework event phases that you can correlate with the System metrics over time graph.

You can select a time interval of interest in the system resource usage timeline, and the framework event phase spots the interval to show what events happened during the selected time interval. In each event phase block, you can find what time interval was actually spent for training loop, and break the training loop into backward pass and forward pass events. Overall, you can see that actual training time intervals are occupying only a small percentage over the entire training time.
Time spent in training

In the following graph, framework metrics from the last 30 steps of the last training loop are captured. This graph shows cumulative time spent by different events in each step.

Shut Down the SageMaker Debugger Insights Instance

When you are not using the Debugger insights dashboard, it is important to shut down the instance on which it runs to avoid incurring additional fees.

To shut down the Debugger insights instance in Studio
1. In Studio, select the Running Instances and Kernels icon ( ).
2. Under the RUNNING APPS list, look for the sagemaker-debugger-1.0 app. Select the shut down icon ( ) next to the app. The Debugger insights dashboards run on an ml.m5.4xlarge instance. This instance also disappears from the RUNNING INSTANCES when you shut down the sagemaker-debugger-1.0 app.

SageMaker Debugger on Studio Experiments

In this section, you learn how to use the Debugger in Studio Experiments. You can select any training jobs from the Experiment trial list to see the model output data graphs, such as accuracy and loss curves, debugging built-in rule status, and Debugger configuration information for debugging.

Visualize Tensors Using SageMaker Debugger and Studio

SageMaker Studio provides visualizations to interpret tensor outputs that are captured by Debugger.

Loss Curves While Training Is in Progress

The following screenshot shows visualizations of loss curves for training. The training is in progress.
Analyzing Training Jobs: Comparing Loss Curves Across Multiple Jobs

SageMaker Studio enables you to compare across multiple jobs (in this case, the loss). This helps you identify the best-performing training jobs.

Rules Triggering and Logs from Jobs

When rules are triggered for anomalous conditions, SageMaker Studio presents logs for the failing rule. This enables you to analyze the causes of the condition.
SageMaker Debugger Interactive Reports

Receive training and profiling reports autogenerated by Debugger. The Debugger reports provide insights into your training jobs and suggest recommendations to improve your model performance. The following screenshot shows a collage of the Debugger profiling report. To learn more, see SageMaker Debugger Profiling Report (p. 1674).

**Note**
You can download a Debugger reports while your training job is running or after the job has finished. During training, Debugger concurrently updates the report reflecting the current rules’ evaluation status. You can download a complete Debugger report only after the training job has completed.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Topics**
- SageMaker Debugger Profiling Report (p. 1674)
- SageMaker Debugger XGBoost Training Report (p. 1684)
SageMaker Debugger Profiling Report

For any SageMaker training jobs, the Debugger ProfilerReport (p. 1601) rule invokes all of the monitoring and profiling rules (p. 1599) and aggregates the rule analysis into a comprehensive report. Following this guide, download the report using the Amazon SageMaker Python SDK or the S3 console, and learn what you can interpret from the profiling results.

Important
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

Topics

- Download a Debugger Profiling Report (p. 1674)
- Debugger Profiling Report Walkthrough (p. 1677)

Download a Debugger Profiling Report

Download the Debugger profiling report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

Tip
You can also download the report with one click and no additional scripting through the SageMaker Studio Debugger insights dashboard. To find out how to download the report from Studio, see Open Amazon SageMaker Debugger Insights Dashboard (p. 1659).
Download using SageMaker Python SDK and AWS CLI

1. Check the current job’s default S3 output base URI.

   ```python
   estimator.output_path
   ```

2. Check the current job name.

   ```python
   estimator.latest_training_job.job_name
   ```

3. The Debugger profiling report is stored under `<default-s3-output-base-uri>/
   <training-job-name>/rule-output`. Configure the rule output path as follows:

   ```python
   rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + 
   "rule-output"
   ```

4. To check if the report is generated, list directories and files recursively under the
   `rule_output_path` using `aws s3 ls` with the `--recursive` option.

   ```bash
   ! aws s3 ls {rule_output_path} --recursive
   ```

   This should return a complete list of files under an autogenerated folder that’s named
   as `ProfilerReport-1234567890`. The folder name is a combination of strings:
   `ProfilerReport` and a unique 10-digit tag based on the Unix timestamp when the
   `ProfilerReport` rule is initiated.

   The `profiler-report.html` is an autogenerated profiling report by Debugger. The remaining
   files are the built-in rule analysis components stored in JSON and a Jupyter notebook that are
   used to aggregate them into the report.

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule
   output files to the `ProfilerReport-1234567890` folder under the current working directory.

   ```bash
   ! aws s3 cp {rule_output_path} ./ --recursive
   ```

   **Tip**
   
   If using a Jupyter notebook server, run `!pwd` to double check the current working
   directory.

6. Under the `/ProfilerReport-1234567890/profiler-output` directory, open `profiler-
   report.html`. If using JupyterLab, choose Trust HTML to see the autogenerated Debugger
   profiling report.

7. Open the `profiler-report.ipynb` file to explore how the report is generated. You can also
   customize and extend the profiling report using the Jupyter notebook file.
Download using Amazon S3 Console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven't specified any base job name, the base S3 bucket name should be in the following format: sagemaker-<region>-111122223333. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by specifying your job name prefix into the Find objects by prefix input field. Choose the training job name.

4. In the training job's S3 bucket, there must be three subfolders for training data collected by Debugger: debug-output/, profiler-output/, and rule-output/. Choose rule-output/.

5. In the rule-output/ folder, choose ProfilerReport-1234567890, and choose profiler-output/ folder. The profiler-output/ folder contains profiler-report.html (the autogenerated profiling report in html), profiler-report.ipynb (a Jupyter notebook with scripts that are used for generating the report), and a profiler-report/ folder (contains rule analysis JSON files that are used as components of the report).

6. Select the profiler-report.html file, choose Actions, and Download.
7. Open the downloaded `profiler-report.html` file in a web browser.

**Note**
If you started your training job without configuring the Debugger-specific parameters, Debugger generates the report based only on the system monitoring rules because the Debugger parameters are not configured to save framework metrics. To enable framework metrics profiling and receive an extended Debugger profiling report, configure the `profiler_config` parameter when constructing or updating SageMaker estimators.
To learn how to configure the `profiler_config` parameter before starting a training job, see Configure Debugger Framework Profiling (p. 1560).
To update the current training job and enable framework metrics profiling, see Update Debugger Framework Profiling Configuration (p. 1564).

**Debugger Profiling Report Walkthrough**
This section walks you through the Debugger profiling report section by section. The profiling report is generated based on the built-in rules for monitoring and profiling. The report shows result plots only for the rules that found issues.

**Topics**
- Training Job Summary (p. 1678)
- System Usage Statistics (p. 1679)
- Framework metrics summary (p. 1679)
- Rules Summary (p. 1681)
- Analyzing the Training Loop – Step Durations (p. 1682)
- GPU Utilization Analysis (p. 1682)
Training Job Summary

At the beginning of the report, Debugger provides a summary of your training job. In this section, you can overview the time durations and timestamps at different training phases.

<table>
<thead>
<tr>
<th>#</th>
<th>Job Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start time 20:12:43 11/29/2020</td>
</tr>
<tr>
<td>1</td>
<td>End time 20:24:59 11/29/2020</td>
</tr>
<tr>
<td>2</td>
<td>Job duration 757 seconds</td>
</tr>
<tr>
<td>3</td>
<td>Training/loop start 23:17:31 11/29/2020</td>
</tr>
<tr>
<td>4</td>
<td>Training/loop end 20:04:59 11/29/2020</td>
</tr>
<tr>
<td>5</td>
<td>Training/loop duration 448 seconds</td>
</tr>
<tr>
<td>6</td>
<td>Initialization time 288 seconds</td>
</tr>
<tr>
<td>7</td>
<td>Finalization time 9 seconds</td>
</tr>
<tr>
<td>8</td>
<td>Initialization 30 %</td>
</tr>
<tr>
<td>9</td>
<td>Training/loop 80 %</td>
</tr>
<tr>
<td>10</td>
<td>Finalization 0 %</td>
</tr>
</tbody>
</table>

The summary table contains the following information:

- **start_time** – The exact time when the training job started.
- **end_time** – The exact time when the training job finished.
- **job_duration_in_seconds** – The total training time from the start_time to the end_time.
- **training_loop_start** – The exact time when the first step of the first epoch has started.
- **training_loop_end** – The exact time when the last step of the last epoch has finished.
- **training_loop_duration_in_seconds** – The total time between the training loop start time and the training loop end time.
- **initialization_in_seconds** – Time spent on initializing the training job. The initialization phase covers the period from the start_time to the training_loop_start time. The initialization time is spent on compiling the training script, starting the training script, creating and initializing the model, initiating EC2 instances, and downloading training data.
- **finalization_in_seconds** – Time spent on finalizing the training job, such as finishing the model training, updating the model artifacts, and closing the EC2 instances. The finalization phase covers the period from the training_loop_end time to the end_time.
- **initialization (%)** – The percentage of time spent on initialization over the total job_duration_in_seconds.
- **training loop (%)** – The percentage of time spent on training loop over the total job_duration_in_seconds.
- **finalization (%)** – The percentage of time spent on finalization over the total job_duration_in_seconds.
System Usage Statistics

In this section, you can see an overview of system utilization statistics.

System usage statistics

The 99th quantile of the total GPU utilization on node algo-2 is 74%. GPUs on node algo-2 are well utilized.

The following table shows usage statistics per worker node such as total CPU and GPU utilization, total CPU and memory footprint. The table also includes total IO wait time and total sent/received bytes. The table shows min and max values as well as p99, p95 and p50 percentiles.

<table>

</tr>
</tbody>
</table>

The Debugger profiling report includes the following information:

- **node** – Lists the name of nodes. If using distributed training on multi nodes (multiple EC2 instances), the node names are in format of algo-n.
- **metric** – The system metrics collected by Debugger: CPU, GPU, CPU memory, GPU memory, I/O, and Network metrics.
- **unit** – The unit of the system metrics.
- **max** – The maximum value of each system metric.
- **p99** – The 99th percentile of each system utilization.
- **p95** – The 95th percentile of each system utilization.
- **p50** – The 50th percentile (median) of each system utilization.
- **min** – The maximum value of each system metric.

Framework metrics summary

In this section, the following pie charts show the breakdown of framework operations on CPUs and GPUs.
Each of the pie charts analyzes the collected framework metrics in various aspects as follows:

- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
- **Ratio between CPU/GPU operators** – Shows the ratio between time spent on operators running on CPU or GPU, such as convolutional operators.
- **General metrics recorded in framework** – Shows the ratio between time spent on major framework metrics, such as data loading, forward and backward pass.

**Overview: CPU Operators**

This section provides information of the CPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called CPU operators.
Overview: GPU Operators

This section provides information of the GPU operators in detail. The table shows the percentage of the time and the absolute cumulative time spent on the most frequently called GPU operators.

Overview: GPU operators

The following table shows a list of operators that your training job run on GPU. The most expensive operator on GPU was "CudnnConvolutionBackward" with 34 %

<table>

Rules Summary

In this section, Debugger aggregates all of the rule evaluation results, analysis, rule descriptions, and suggestions.

Rules summary

The following table shows a summary of the executed profiler rules. The table is sorted by the rules that triggered most frequently. In your training job this was the case for rule LoadBalancing. It has processed 5467 datapoints and triggered 263 times.

<table>
<thead>
<tr>
<th>Rule parameters</th>
<th>Description</th>
<th>Recommendations</th>
<th>Number of times rule triggered</th>
<th>Number of datapoints</th>
<th>Rule parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoadBalancing</td>
<td>Detect issues in weight balance between multiple GPUs. Weight imbalance can be a cause of training failures when gradients are accumulated on primary GPU or on the GPU with the highest weights. This can lead to large spikes in the cost of training.</td>
<td>Choose different distributed training strategy or different distributed learning framework.</td>
<td>263</td>
<td>5467</td>
<td>Increase 10% of stop epochs.</td>
</tr>
<tr>
<td>LoadResNet</td>
<td>Checks if GPU utilization is low or suffers from fluctuations. This can happen if there are bottlenecks, many blocking calls due to synchronization or batch size too small.</td>
<td>Check for bottlenecks, minimize blocking calls, change distributed training strategy, increase batch size.</td>
<td>264</td>
<td>5467</td>
<td>Increase 10% of stop epochs.</td>
</tr>
<tr>
<td>BatchSize</td>
<td>Checks if GPU is under-utilized because of the batch size being too small. To detect this the rule analyzes the average GPU memory footprint, CPU and GPU utilization.</td>

</table>
Analyzing the Training Loop – Step Durations

In this section, you can find a detailed statistics of step durations on each GPU core of each node. Debugger evaluates mean, maximum, p99, p95, p50, and minimum values of step durations, and evaluate step outliers. The following histogram shows the step durations captured on different worker nodes and GPUs. You can enable or disable the histogram of each worker by choosing the legends on the right side. You can check if there is a particular GPU that's causing step duration outliers.

GPU Utilization Analysis

This section shows the detailed statistics about GPU core utilization based on LowGPUUtilization rule. It also summarizes the GPU utilization statistics, mean, p95, and p5 to determine if the training job is underutilizing GPUs.

Batch Size

This section shows the detailed statistics of total CPU utilization, individual GPU utilizations, and GPU memory footprints. The BatchSize rule determines if you need to change the batch size to better utilize the GPUs. You can check whether the batch size is too small resulting in underutilization or too large causing overutilization and out of memory issues. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.
CPU Bottlenecks

In this section, you can drill down into the CPU bottlenecks that the CPUBottleneck rule detected from your training job. The rule checks if the CPU utilization is above `cpu_threshold` (90% by default) and also if the GPU utilization is below `gpu_threshold` (10% by default).

The pie charts show the following information:

- **Low GPU usage caused by CPU bottlenecks** – Shows the ratio of data points between the ones with GPU utilization above and below the threshold and the ones that matches the CPU bottleneck criteria.
- **Ratio between TRAIN/EVAL phase and others** – Shows the ratio between time durations spent on different training phases.
- **Ratio between forward and backward pass** – Shows the ratio between time durations spent on forward and backward pass in the training loop.
• **Ratio between CPU/GPU operators** – Shows the ratio between time durations spent on GPUs and CPUs by Python operators, such as data loader processes and forward and backward pass operators.

• **General metrics recorded in framework** – Shows major framework metrics and the ratio between time durations spent on the metrics.

I/O Bottlenecks

In this section, you can find a summary of IO bottlenecks.

**LoadBalancing in Multi-GPU Training**

In this section, you can identify workload balancing issue across GPUs.

![LoadBalancing in Multi-GPU Training](image)

**GPU Memory Analysis**

In this section, you can analyze the GPU memory utilization collected by the GPUMemoryIncrease rule. In the plot, the boxes show the p25 and p75 percentile ranges (filled with dark purple and bright yellow respectively) from the median (p50), and the error bars show the 5th percentile for the lower bound and 95th percentile for the upper bound.

![GPU Memory Analysis](image)

**SageMaker Debugger XGBoost Training Report**

For SageMaker XGBoost training jobs, use the Debugger `CreateXgboostReport` (p. 1611) rule to receive a comprehensive training report of the training progress and results. Following this guide, specify the `CreateXgboostReport` (p. 1611) rule while constructing an XGBoost estimator, download the report using...
the Amazon SageMaker Python SDK or the Amazon S3 console, and then you can interpret the profiling results.

**Important**
To use the new Debugger features, you need to upgrade the SageMaker Python SDK and the SMDebug client library. In your iPython kernel, Jupyter notebook, or JupyterLab environment, run the following code to install the latest versions of the libraries and restart the kernel.

```python
import sys
import IPython
!{sys.executable} -m pip install -U sagemaker smdebug
IPython.Application.instance().kernel.do_shutdown(True)
```

**Topics**
- Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule (p. 1685)
- Download the Debugger XGBoost Training Report (p. 1686)
- Debugger XGBoost Training Report Walkthrough (p. 1688)

**Construct a SageMaker XGBoost Estimator with the Debugger XGBoost Report Rule**

When you construct a SageMaker estimator for an XGBoost training job, specify the rule as shown in the following example code.

The `CreateXgboostReport` (p. 1611) rule collects the following output tensors from your training job:

- `hyperparameters` – Saves at the first step.
- `metrics` – Saves loss and accuracy every 5 steps.
- `feature_importance` – Saves every 5 steps.
- `predictions` – Saves every 5 steps.
- `labels` – Saves every 5 steps.

The output tensors are saved at a default S3 bucket. For example, `s3://sagemaker-<region>-<12digit_account_id>/<base-job-name>/debug-output/`.

Using the SageMaker generic estimator

```python
import boto3
import sagemaker
from sagemaker.estimator import Estimator
from sagemaker import image_uris
from sagemaker.debugger import Rule, rule_configs

rules=[
    Rule.sagemaker(rule_configs.create_xgboost_report())
]

region = boto3.Session().region_name
xgboost_container=sagemaker.image_uris.retrieve("xgboost", region, "1.2-1")

estimator=Estimator(
    role=sagemaker.get_execution_role(),
    image_uri=xgboost_container,
    base_job_name="debugger-xgboost-report-demo",
    instance_count=1,
    instance_type="ml.m5.2xlarge",
)
```
# Add the Debugger XGBoost report rule

```python
rules=rules
```

estimator.fit(wait=False)

## Download the Debugger XGBoost Training Report

Download the Debugger XGBoost training report while your training job is running or after the job has finished using the Amazon SageMaker Python SDK and AWS Command Line Interface (CLI).

### Download using the SageMaker Python SDK and AWS CLI

1. Check the current job’s default S3 output base URI.

```python
estimator.output_path
```

2. Check the current job name.

```python
estimator.latest_training_job.job_name
```

3. The Debugger XGBoost report is stored under `<default-s3-output-base-uri>/
<training-job-name>/rule-output`. Configure the rule output path as follows:

```python
rule_output_path = estimator.output_path + estimator.latest_training_job.job_name + "/rule-output"
```

4. To check if the report is generated, list directories and files recursively under the `rule_output_path` using `aws s3 ls` with the `--recursive` option.

```bash
! aws s3 ls {rule_output_path} --recursive
```

This should return a complete list of files under autogenerated folders that are named `CreateXgboostReport` and `ProfilerReport-1234567890`. The XGBoost training report is stored in the `CreateXgboostReport`, and the profiling report is stored in the `ProfilerReport-1234567890` folder. To learn more about the profiling report generated by default with the XGBoost training job, see SageMaker Debugger Profiling Report (p. 1674).

5. Download the files recursively using `aws s3 cp`. The following command saves all of the rule output files to the `ProfilerReport-1234567890` folder under the current working directory.

```bash
! aws s3 cp {rule_output_path} . --recursive
```

The `xgboost_report.html` is an autogenerated XGBoost training report by Debugger. The `xgboost_report.ipynb` is a Jupyter notebook that’s used to aggregate training results into the report. You can download all of the files, browse the HTML report file, and modify the report using the notebook.
Tip
If you are using a Jupyter notebook server, run `!pwd` to verify the current working directory.

6. Under the `/CreateXgboostReport` directory, open `xgboost_report.html`. If you are using JupyterLab, choose Trust HTML to see the autogenerated Debugger training report.

7. Open the `xgboost_report.ipynb` file to explore how the report is generated. You can customize and extend the training report using the Jupyter notebook file.

Download using the Amazon S3 console

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. Search for the base S3 bucket. For example, if you haven’t specified any base job name, the base S3 bucket name should be in the following format: `sagemaker-<region>-111122223333`. Look up the base S3 bucket through the Find bucket by name field.

3. In the base S3 bucket, look up the training job name by entering your job name prefix in Find objects by prefix and then choosing the training job name.
4. In the training job’s S3 bucket, choose `rule-output/` subfolder. There must be three subfolders for training data collected by Debugger: `debug-output/`, `profiler-output/`, and `rule-output/`.

5. In the `rule-output/` folder, choose the `CreateXgboostReport/` folder. The folder contains `xbgoost_report.html` (the autogenerated report in html) and `xbgoost_report.ipynb` (a Jupyter notebook with scripts that are used for generating the report).

6. Choose the `xbgoost_report.html` file, choose `Download actions`, and then choose `Download`.

7. Open the downloaded `xbgoost_report.html` file in a web browser.

**Debugger XGBoost Training Report Walkthrough**

This section walks you through the Debugger XGBoost training report. The report is automatically aggregated depending on the output tensor regex, recognizing what type of your training job is among binary classification, multiclass classification, and regression.

**Topics**
- Distribution of True Labels of the Dataset (p. 1689)
• Loss versus Step Graph (p. 1689)
• Feature Importance (p. 1690)
• Confusion Matrix (p. 1691)
• Evaluation of the Confusion Matrix (p. 1692)
• Accuracy Rate of Each Diagonal Element Over Iteration (p. 1693)
• Receiver Operating Characteristic Curve (p. 1694)
• Distribution of Residuals at the Last Saved Step (p. 1695)
• Absolute Validation Error per Label Bin Over Iteration (p. 1696)

Distribution of True Labels of the Dataset

This histogram shows the distribution of labeled classes (for classification) or values (for regression) in your original dataset. Skewness in your dataset could contribute to inaccuracies. This visualization is available for the following model types: binary classification, multiclassification, and regression.

 Loss versus Step Graph

This is a line chart that shows the progression of loss on training data and validation data throughout training steps. The loss is what you defined in your objective function, such as mean squared error. You can gauge whether the model is overfit or underfit from this plot. This section also provides insights that you can use to determine how to resolve the overfit and underfit problems. This visualization is available for the following model types: binary classification, multiclassification, and regression.
Feature Importance

There are three different types of feature importance visualizations provided: Weight, Gain and Coverage. We provide detailed definitions for each of the three in the report. Feature importance visualizations help you learn what features in your training dataset contributed to the predictions. Feature importance visualizations are available for the following model types: binary classification, multiclassification, and regression.
Confusion Matrix

This visualization is only applicable to binary and multiclass classification models. Accuracy alone might not be sufficient for evaluating the model performance. For some use cases, such as healthcare and fraud detection, it’s also important to know the false positive rate and false negative rate. A confusion matrix gives you the additional dimensions for evaluating your model performance.
Evaluation of the Confusion Matrix

This section provides you with more insights on the micro, macro, and weighted metrics on precision, recall, and F1-score for your model.
Overall Accuracy

Overall Accuracy: 0.919

Micro Performance Metrics

Performance metrics calculated globally by counting the total true positives, false negatives, and false positives.

- Micro Precision: 0.919
- Micro Recall: 0.919
- Micro F1-score: 0.919

Macro Performance Metrics

Performance metrics calculated for each label, and find their unweighted mean. This does not take the class imbalance problem into account.

- Macro Precision: 0.919
- Macro Recall: 0.918
- Macro F1-score: 0.918

Weighted Performance Metrics

Performance metrics calculated for each label and their average weighted by support (the number of true instances for each label). This extends the macro option to take the class imbalance into account. It might result in an F-score that is not between precision and recall.

- Weighted Precision: 0.92
- Weighted Recall: 0.919
- Weighted F1-score: 0.919

Classification Report

The summary of the precision, recall, and F1-score for each class.

<table>
<thead>
<tr>

</table>

| accuracy  | 0.92   | 12000    |
| macro avg | 0.92   | 0.92     | 12000   |
| weighted avg | 0.92 | 0.92     | 0.92    | 12000   |

Accuracy Rate of Each Diagonal Element Over Iteration

This visualization is only applicable to binary classification and multiclass classification models. This is a line chart that plots the diagonal values in the confusion matrix throughout the training steps for each class. This plot shows you how the accuracy of each class progresses throughout the training steps. You can identify the under-performing classes from this plot.
Receiver Operating Characteristic Curve

This visualization is only applicable to binary classification models. The Receiver Operating Characteristic curve is commonly used to evaluate binary classification model performance. The y-axis of the curve is True Positive Rate (TPF) and x-axis is false positive rate (FPR). The plot also displays the value for the area under the curve (AUC). The higher the AUC value, the more predictive your classifier. You can also use the ROC curve to understand the trade-off between TPR and FPR and identify the optimum classification threshold for your use case. The classification threshold can be adjusted to tune the behavior of the model to reduce more of one or another type of error (FP/FN).
Distribution of Residuals at the Last Saved Step

This visualization is a column chart that shows the residual distributions in the last step Debugger captures. In this visualization, you can check whether the residual distribution is close to normal distribution that’s centered at zero. If the residuals are skewed, your features may not be sufficient for predicting the labels.
Absolute Validation Error per Label Bin Over Iteration

This visualization is only applicable to regression models. The actual target values are split into 10 intervals. This visualization shows how validation errors progress for each interval throughout the training steps in line plots. Absolute validation error is the absolute value of difference between prediction and actual during validation. You can identify the underperforming intervals from this visualization.
Analyze Data Using the SMDebug Client Library

While your training job is running or after it has completed, you can access the training data collected by Debugger using the Amazon SageMaker Python SDK and the SMDebug client library. The SMDebug library provides analysis and visualization tools that enable you to drill down into your training job data.

To install the library and use the SMDebug analysis tools (in a JupyterLab notebook or an iPython kernel)

```bash
pip install -U smdebug
```

The following topics walk you through how to use the SMDebug tools to visualize and analyze the training data collected by Debugger.

Analyze system and framework metrics

- Access the Monitoring and Profiling Data (p. 1697)
- Plot the System Metrics and Framework Metrics Data (p. 1698)
- Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1699)
- Access the Python Profiling Stats Data (p. 1699)
- Merge Timelines of Different Profiling Trace Files (p. 1702)
- Profiling Data Loader (p. 1704)

Access the Monitoring and Profiling Data

The SMDebug `TrainingJob` class reads data from the S3 bucket where the system and framework metrics are saved.

To set up a `TrainingJob` object and retrieve profiling event files of a training job

```python
from smdebug.profiler.analysis.notebook_utils.training_job import TrainingJob
tj = TrainingJob(training_job_name, region)
```

Tip

You need to specify the `training_job_name` and `region` parameters to log to a training job. There are two ways to specify the training job information:

- Use the SageMaker Python SDK while the estimator is still attached to the training job.

  ```python
  import sagemaker
  training_job_name=estimator.latest_training_job.job_name
  region=sagemaker.Session().boto_region_name
  ```

- Pass strings directly.

  ```python
  training_job_name="your-training-job-name-YYYY-MM-DD-HH-MM-SS-SSS"
  region="us-west-2"
  ```

To retrieve a description of the training job description and the S3 bucket URI where the metric data are saved

```python
tj.describe_training_job()
tj.get_config_and_profiler_s3_output_path()
```
To check if the system and framework metrics are available from the S3 URI

```python
tj.wait_for_sys_profiling_data_to_be_available()
tj.wait_for_framework_profiling_data_to_be_available()
```

To create system and framework reader objects after the metric data become available

```python
system_metrics_reader = tj.get_systems_metrics_reader()
framework_metrics_reader = tj.get_framework_metrics_reader()
```

To refresh and retrieve the latest training event files

The reader objects have an extended method, `refresh_event_file_list()`, to retrieve the latest training event files.

```python
system_metrics_reader.refresh_event_file_list()
framework_metrics_reader.refresh_event_file_list()
```

Plot the System Metrics and Framework Metrics Data

You can use the system and algorithm metrics objects for the following visualization classes to plot timeline graphs and histograms.

**Note**

To visualize the data with narrowed-down metrics in the following visualization object plot methods, specify `select_dimensions` and `select_events` parameters. For example, if you specify `select_dimensions=['GPU']`, the plot methods filter the metrics that include the "GPU" keyword. If you specify `select_events=['total']`, the plot methods filter the metrics that include the "total" event tags at the end of the metric names. If you enable these parameters and give the keyword strings, the visualization classes return the charts with filtered metrics.

- **The MetricsHistogram class**

  ```python
  from smdebug.profiler.analysis.notebook_utils.metrics_histogram import MetricsHistogram
  metrics_histogram = MetricsHistogram(system_metrics_reader)
  metrics_histogram.plot(
    starttime=0,
    endtime=system_metrics_reader.get_timestamp_of_latest_available_file(),
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'] # optional
  )
  ```

- **The StepTimelineChart class**

  ```python
  from smdebug.profiler.analysis.notebook_utils.step_timeline_chart import StepTimelineChart
  view_step_timeline_chart = StepTimelineChart(framework_metrics_reader)
  ```

- **The StepHistogram class**

  ```python
  from smdebug.profiler.analysis.notebook_utils.step_histogram import StepHistogram
  step_histogram = StepHistogram(framework_metrics_reader)
  step_histogram.plot(
    starttime=step_histogram.last_timestamp - 5 * 1000 * 1000,
  )
  ```
• The TimelineCharts class

```python
from smdebug.profiler.analysis.notebook_utils.timeline_charts import TimelineCharts

view_timeline_charts = TimelineCharts(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'] # optional
)
view_timeline_charts.plot_detailed_profiler_data([700,710])
```

• The Heatmap class

```python
from smdebug.profiler.analysis.notebook_utils.heatmap import Heatmap

view_heatmap = Heatmap(
    system_metrics_reader,
    framework_metrics_reader,
    select_dimensions=['CPU', 'GPU', 'I/O'], # optional
    select_events=['total'], # optional
    plot_height=450
)
```

Access the Profiling Data Using the Pandas Data Parsing Tool

The following PandasFrame class provides tools to convert the collected profiling data to Pandas data frame.

```python
from smdebug.profiler.analysis.utils.profiler_data_to_pandas import PandasFrame

pf = PandasFrame(tj.profiler_s3_output_path)
system_metrics_df = pf.get_all_system_metrics()
framework_metrics_df = pf.get_all_framework_metrics(
    selected_framework_metrics=[
        'Step:ModeKeys.TRAIN',
        'Step:ModeKeys.GLOBAL'
    ]
)
```

Access the Python Profiling Stats Data

The Python profiling provides framework metrics related to Python functions and operators in your training scripts and the SageMaker deep learning frameworks.

Training Modes and Phases for Python Profiling

To profile specific intervals during training to partition statistics for each of these intervals, Debugger provides tools to set modes and phases.
For training modes, use the following `PythonProfileModes` class:

```python
from smdebug.profiler.python_profile_utils import PythonProfileModes
```

This class provides the following options:

- `PythonProfileModes.TRAIN` – Use if you want to profile the target steps in the training phase. This mode option available only for TensorFlow.
- `PythonProfileModes.EVAL` – Use if you want to profile the target steps in the evaluation phase. This mode option available only for TensorFlow.
- `PythonProfileModes.PREDICT` – Use if you want to profile the target steps in the prediction phase. This mode option available only for TensorFlow.
- `PythonProfileModes.GLOBAL` – Use if you want to profile the target steps in the global phase, which includes the previous three phases. This mode option available only for PyTorch.
- `PythonProfileModes.PRE_STEP_ZERO` – Use if you want to profile the target steps in the initialization stage before the first training step of the first epoch starts. This phase includes the initial job submission, uploading the training scripts to EC2 instances, preparing the EC2 instances, and downloading input data. This mode option available for both TensorFlow and PyTorch.
- `PythonProfileModes.POST_HOOK_CLOSE` – Use if you want to profile the target steps in the finalization stage after the training job has done and the Debugger hook is closed. This phase includes profiling data while the training jobs are finalized and completed. This mode option available for both TensorFlow and PyTorch.

For training phases, use the following `StepPhase` class:

```python
from smdebug.profiler.analysis.utils.python_profile_analysis_utils import StepPhase
```

This class provides the following options:

- `StepPhase.START` – Use to specify the start point of the initialization phase.
- `StepPhase.STEP_START` – Use to specify the start step of the training phase.
- `StepPhase.FORWARD_PASS_END` – Use to specify the steps where the forward pass ends. This option is available only for PyTorch.
- `StepPhase.STEP_END` – Use to specify the end steps in the training phase. This option is available only for TensorFlow.
- `StepPhase.END` – Use to specify the ending point of the finalization (post-hook-close) phase. If the callback hook is not closed, the finalization phase profiling does not occur.

**Python Profiling Analysis Tools**

Debugger supports the Python profiling with two profiling tools:

- `cProfile` – The standard python profiler. `cProfile` collects framework metrics on CPU time for every function called when profiling was enabled.
- `Pyinstrument` – This is a low overhead Python profiler sampling profiling events every milliseconds.

To learn more about the Python profiling options and what's collected, see [Start a Training Job with the Default System Monitoring and Customized Framework Profiling with Different Profiling Options](p. 1562).

The following methods of the `PythonProfileAnalysis`, `cProfileAnalysis`, `PyinstrumentAnalysis` classes are provided to fetch and analyze the Python profiling data. Each function loads the latest data from the default S3 URI.
To set Python profiling objects for analysis, use the cProfileAnalysis or PyinstrumentAnalysis classes as shown in the following example code. It shows how to set a cProfileAnalysis object, and if you want to use PyinstrumentAnalysis, replace the class name.

```python
python_analysis = cProfileAnalysis(
    local_profile_dir=tf_python_stats_dir,
    s3_path=tj.profiler_s3_output_path
)
```

The following methods are available for the cProfileAnalysis and PyinstrumentAnalysis classes to fetch the Python profiling stats data:

- `python_analysis.fetch_python_profile_stats_by_time(start_time_since_epoch_in_secs, end_time_since_epoch_in_secs)` – Takes in a start time and end time, and returns the function stats of step stats whose start or end times overlap with the provided interval.

- `python_analysis.fetch_python_profile_stats_by_step(start_step, end_step, mode, start_phase, end_phase)` – Takes in a start step and end step and returns the function stats of all step stats whose profiled step satisfies start_step <= step < end_step.

- `python_analysis.fetch_pre_step_zero_profile_stats()` – Fetches the stats from the Python profiling until step 0.

- `python_analysis.fetch_post_hook_close_profile_stats()` – Fetches stats from the Python profiling after the hook is closed.

- `python_analysis.fetch_profile_stats_between_modes(start_mode, end_mode)` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are (PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE). All stats files within each of these combinations are aggregated.

- `python_analysis.list_profile_stats()` – Returns a DataFrame of the Python profiling stats. Each row holds the metadata for each instance of profiling and the corresponding stats file (one per step).

- `python_analysis.list_available_node_ids()` – Returns a list the available node IDs for the Python profiling stats.

The cProfileAnalysis class specific methods:

- `fetch_profile_stats_by_training_phase()` – Fetches and aggregates the Python profiling stats for every possible combination of start and end modes. For example, if a training and validation phases are done while detailed profiling is enabled, the combinations are (PRE_STEP_ZERO, TRAIN), (TRAIN, TRAIN), (TRAIN, EVAL), (EVAL, EVAL), and (EVAL, POST_HOOK_CLOSE). All stats files within each of these combinations are aggregated.
- `fetch_profile_stats_by_job_phase()` — Fetches and aggregates the Python profiling stats by job phase. The job phases are initialization (profiling until step 0), training_loop (training and validation), and finalization (profiling after the hook is closed).

**Merge Timelines of Different Profiling Trace Files**

The SMDebug client library provide profiling analysis and visualization tools for merging timelines of system metrics, framework metrics, and Python profiling data collected by Debugger.

**Tip**
Before proceeding, you need to set a TrainingJob object that will be utilized throughout the examples in this page. For more information about setting up a TrainingJob object, see Access the Monitoring and Profiling Data (p. 1697).

The `MergedTimeline` class provides tools to integrate and correlate different profiling information in a single timeline. After Debugger captures profiling data and annotations from different phases of a training job, JSON files of trace events are saved in a default `tracefolder` directory.

- For annotations in the Python layers, the trace files are saved in `*pythontimeline.json`.
- For annotations in the TensorFlow C++ layers, the trace files are saved in `*model_timeline.json`.
- Tensorflow profiler saves events in a `*trace.json.gz` file.

**Tip**
If you want to list all of the JSON trace files, use the following AWS CLI command:

```
! aws s3 ls {tj.profiler_s3_output_path} --recursive | grep '\.json$'
```

As shown in the following animated screenshot, putting and aligning the trace events captured from the different profiling sources in a single plot can provide an overview of the entire events occurring in different phases of the training job.
Tip
To interact with the merged timeline on the tracing app using a keyboard, use the W key for zooming in, the A key for shifting to the left, the S key for zooming out, and the D key for shifting to the right.

The multiple event trace JSON files can be merged into one trace event JSON file using the following MergedTimeline API operation and class method from the smdebug.profiler.analysis.utils.merge_timelines module.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(path, file_suffix_filter, output_directory)
combined_timeline.merge_timeline(start, end, unit)
```

The MergedTimeline API operation passes the following parameters:

- `path` (str) – Specify a root folder (/profiler-output) that contains system and framework profiling trace files. You can locate the profiler-output using the SageMaker estimator classmethod or the TrainingJob object. For example, estimator.latest_job_profiler_artifacts_path() or tj.profiler_s3_output_path.
- `file_suffix_filter` (list) – Specify a list of file suffix filters to merge timelines. Available suffix filters are ["model_timeline.json", "pythontimeline.json", "trace.json.gz"]. If this parameter is not manually specified, all of the trace files are merged by default.
- `output_directory` (str) – Specify a path to save the merged timeline JSON file. The default is to the directory specified for the `path` parameter.

The `merge_timeline()` classmethod passes the following parameters to execute the merging process:

- `start` (int) – Specify start time (in microseconds and in Unix time format) or start step to merge timelines.
- `end` (int) – Specify end time (in microseconds and in Unix time format) or end step to merge timelines.
- `unit` (str) – Choose between "time" and "step". The default is "time".

Using the following example codes, execute the `merge_timeline()` method and download the merged JSON file.

- Merge timeline with the "time" unit option. The following example code merges all available trace files between the Unix start time (the absolute zero Unix time) and the current Unix time, which means that you can merge the timelines for the entire training duration.

```python
import time
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
from smdebug.profiler.profiler_constants import CONVERT_TO_MICROSECS
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(0, int(time.time() * CONVERT_TO_MICROSECS))
```

- Merge timeline with the "step" unit option. The following example code merges all available timelines between step 3 and step 9.

```python
from smdebug.profiler.analysis.utils.merge_timelines import MergedTimeline
combined_timeline = MergedTimeline(tj.profiler_s3_output_path, output_directory="./")
combined_timeline.merge_timeline(3, 9, unit="step")
```
Open the Chrome tracing app at `chrome://tracing` on a Chrome browser, and open the JSON file. You can explore the output to plot the merged timeline.

### Profiling Data Loader

In PyTorch, data loader iterators, such as `SingleProcessingDataLoaderIter` and `MultiProcessingDataLoaderIter`, are initiated at the beginning of every iteration over a dataset. During the initialization phase, PyTorch turns on worker processes depending on the configured number of workers, establishes data queue to fetch data and `pin_memory` threads.

To use the PyTorch data loader profiling analysis tool, import the following `PT_dataloader_analysis` class:

```python
from smdebug.profiler.analysis.utils.pytorch_dataloader_analysis import PT_dataloader_analysis
```

Pass the profiling data retrieved as a Pandas frame data object in the Access the Profiling Data Using the Pandas Data Parsing Tool (p. 1699) section:

```python
pt_analysis = PT_dataloader_analysis(pf)
```

The following functions are available for the `pt_analysis` object:

The SMDebug S3SystemMetricsReader class reads the system metrics from the S3 bucket specified to the `s3_trial_path` parameter.

- `pt_analysis.analyze_dataloaderIterInitialization()`
  
  The analysis outputs the median and maximum duration for these initializations. If there are outliers, (i.e duration is greater than 2 * median), the function prints the start and end times for those durations. These can be used to inspect system metrics during those time intervals.

  The following list shows what analysis is available from this class method:
  - Which type of data loader iterators were initialized.
  - The number of workers per iterator.
  - Inspect whether the iterator was initialized with or without `pin_memory`.
  - Number of times the iterators were initialized during training.

- `pt_analysis.analyze_dataloaderWorkers()`
  
  The following list shows what analysis is available from this class method:
  - The number of worker processes that were spun off during the entire training.
  - Median and maximum duration for the worker processes.
  - Start and end time for the worker processes that are outliers.

- `pt_analysis.analyze_dataloader_getnext()`
  
  The following list shows what analysis is available from this class method:
  - Number of GetNext calls made during the training.
  - Median and maximum duration in microseconds for GetNext calls.
  - Start time, End time, duration and worker id for the outlier GetNext call duration.

- `pt_analysis.analyze_batchtime(start_timestamp, end_timestamp, select_events=".*", select_dimensions=".*")`

  Debugger collects the start and end times of all the GetNext calls. You can find the amount of time spent by the training script on one batch of data. Within the specified time window, you can identify the calls that are not directly contributing to the training. These calls can be from the following
operations: computing the accuracy, adding the losses for debugging or logging purposes, and printing the debugging information. Operations like these can be compute intensive or time consuming. We can identify such operations by correlating the Python profiler, system metrics, and framework metrics.

The following list shows what analysis is available from this class method:

- Profile time spent on each data batch, BatchTime_in_seconds, by finding the difference between start times of current and subsequent GetNext calls.
- Find the outliers in BatchTime_in_seconds and start and end time for those outliers.
- Obtain the system and framework metrics during those BatchTime_in_seconds timestamps. This indicates where the time was spent.
- pt_analysis.plot_the_window()

Plots a timeline charts between a start timestamp and the end timestamp.

Visualize Amazon SageMaker Debugger Output Tensors in TensorBoard

Use SageMaker Debugger to create output tensor files that are compatible with TensorBoard. Load the files to visualize in TensorBoard and analyze your SageMaker training jobs. Debugger automatically generates output tensor files that are compatible with TensorBoard. For any hook configuration you customize for saving output tensors, Debugger has the flexibility to create scalar summaries, distributions, and histograms that you can import to TensorBoard.

You can enable this by passing DebuggerHookConfig and TensorBoardOutputConfig objects to an estimator.

The following procedure explains how to save scalars, weights, and biases as full tensors, histograms, and distributions that can be visualized with TensorBoard. Debugger saves them to the training container’s local path (the default path is /opt/ml/output/tensors) and syncs to the Amazon S3 locations passed through the Debugger output configuration objects.

To save TensorBoard compatible output tensor files using Debugger

1. Set up a tensorboard_output_config configuration object to save TensorBoard output using the Debugger TensorBoardOutputConfig class. For the s3_output_path parameter, specify the
default S3 bucket of the current SageMaker session or a preferred S3 bucket. This example does not add the container local output path parameter; instead, it is set to the default local path / opt/ml/output/tensors.

```python
import sagemaker
from sagemaker.debugger import TensorBoardOutputConfig

bucket = sagemaker.Session().default_bucket()
tensorboard_output_config = TensorBoardOutputConfig(
    s3_output_path='s3://{}'.format(bucket)
)
```

For additional information, see the Debugger TensorBoardOutputConfig API in the Amazon SageMaker Python SDK.

2. Configure the Debugger hook and customize the hook parameter values. For example, the following code configures a Debugger hook to save all scalar outputs every 100 steps in training phases and 10 steps in validation phases, the weights parameters every 500 steps (the default save_interval value for saving tensor collections is 500), and the bias parameters every 10 global steps until the global step reaches 500.

```python
from sagemaker.debugger import CollectionConfig, DebuggerHookConfig

hook_config = DebuggerHookConfig(
    hook_parameters={
        "train.save_interval": "100",
        "eval.save_interval": "10"
    },
    collection_configs=[
        CollectionConfig("weights"),
        CollectionConfig(
            name="biases",
            parameters={
                "save_interval": "10",
                "end_step": "500",
                "save_histogram": "True"
            }
        )
    ],
)
```

For more information about the Debugger configuration APIs, see the Debugger CollectionConfig and DebuggerHookConfig APIs in the Amazon SageMaker Python SDK.

3. Construct a SageMaker estimator with the Debugger parameters passing the configuration objects. The following example template shows how to create a generic SageMaker estimator. You can replace `Estimator` with other SageMaker frameworks’ estimator parent classes and estimator classes. Available SageMaker framework estimators for this functionality are TensorFlow, PyTorch, and MXNet.

```python
from sagemaker.estimator import Estimator

estimator = Estimator(
    ...
    # Debugger parameters
deploy_to_sagemaker=True,
tensorboard_output_config=tensorboard_output_config
)
estimator.fit()
```
The `estimator.fit()` method starts a training job, and Debugger writes the output tensor files in real time to the Debugger S3 output path and to the TensorBoard S3 output path. To retrieve the output paths, use the following estimator methods:

- For the Debugger S3 output path, use
  ```python
  estimator.latest_job_debugger_artifacts_path()
  ```
- For the TensorBoard S3 output path, use
  ```python
  estimator.latest_job_tensorboard_artifacts_path()
  ```

4. After the training has completed, check the names of saved output tensors:

```python
from smdebug.trials import create_trial
trial = create_trial(estimator.latest_job_debugger_artifacts_path())
trial.tensor_names()
```

5. Check the TensorBoard output data in Amazon S3:

```bash
s3 = estimator.latest_job_tensorboard_artifacts_path()
p = s3 ls {s3_output_path} /
```

6. Download the TensorBoard output data to your notebook instance. For example, the following AWS CLI command downloads the TensorBoard files to `/logs/fit` under the current working directory of your notebook instance.

```bash
!aws s3 cp --recursive {s3_output_path} ./logs/fit
```

7. Compress the file directory to a TAR file to download to your local machine.

```bash
!tar -cf logs.tar logs
```

8. Download and extract the TensorBoard TAR file to a directory on your device, launch a Jupyter notebook server, open a new notebook, and run the TensorBoard app.

```bash
!tar -xf logs.tar
%load_ext tensorboard
%tensorboard --logdir logs/fit
```

---

### Best Practices for Amazon SageMaker Debugger

Use the following guidelines when you run training jobs with Debugger.

**Topics**

- [Choose a Machine Learning Framework](#) (p. 1708)
- [Use Studio Debugger Insights Dashboard](#) (p. 1708)
- [Download Debugger Reports and Gain More Insights](#) (p. 1708)
- [Capture Data from Your Training Job and Save Data to Amazon S3](#) (p. 1708)
- [Analyze the Data with a Fleet of Debugger Built-in Rules](#) (p. 1708)
- [Take Actions Based on the Built-in Rule Status](#) (p. 1708)
- [Dive Deep into the Data Using the SMDebug Client Library](#) (p. 1708)
- [Monitoring System Utilization and Detect Bottlenecks](#) (p. 1709)
- [Profiling Framework Operations](#) (p. 1709)
Choose a Machine Learning Framework

You can choose a machine learning framework and use SageMaker pre-built training containers or your own containers. Use Debugger to detect training and performance issues, and analyze training progress of your training job in SageMaker. SageMaker provides you options to use pre-built containers that are prepared for a number of machine learning framework environments to train your model on Amazon EC2. Any training job can be adapted to run in AWS Deep Learning Containers, SageMaker training containers, and custom containers. To learn more, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1555) and Use Debugger with Custom Training Containers (p. 1644).

Use Studio Debugger Insights Dashboard

With Studio Debugger insights dashboard, you are in control of your training jobs. Use the Studio Debugger dashboards to keep your model performance on Amazon EC2 instances in control and optimized. For any SageMaker training jobs running on Amazon EC2 instance, Debugger monitors resource utilization and basic model output data (loss and accuracy values). Through the Studio Debugger dashboards, gain insights into your training jobs and improve your model training performance. To learn more, see SageMaker Debugger on Studio (p. 1658).

Download Debugger Reports and Gain More Insights

You can view aggregated results and gain insights in Debugger reports. Debugger aggregates training and profiling results collected from the built-in rule analysis into a report per training job. You can find more detailed information about your training results through the Debugger reports. To learn more, see SageMaker Debugger Interactive Reports (p. 1673).

Capture Data from Your Training Job and Save Data to Amazon S3

You can use a Debugger hook to save output tensors. After you choose a container and a framework that fit your training script, use a Debugger hook to configure which tensors to save and to which directory to save them, such as a Amazon S3 bucket. A Debugger hook helps you to build the configuration and to keep it in your account to use in subsequent analyses, where it is secured for use with the most privacy-sensitive applications. To learn more, see Configure Debugger Hook to Save Tensors (p. 1564).

Analyze the Data with a Fleet of Debugger Built-in Rules

You can use Debugger built-in rules to inspect tensors in parallel with a training job. To analyze the training performance data, Debugger provides built-in rules that watch for abnormal training process behaviors. For example, a Debugger rule detects issues when the training process suffers from system bottleneck issues or training issues, such as vanishing gradients, exploding tensors, overfitting, or overtraining. If necessary, you can also build customized rules by creating a rule definition with your own criteria to define a training issue. To learn more about the Debugger rules, see Configure Debugger Built-in Rules (p. 1570) for detailed instructions of using the Amazon SageMaker Python SDK. For a full list of the Debugger built-in rules, see List of Debugger Built-in Rules (p. 1598). If you want to create a custom rule, see Create Debugger Custom Rules for Training Job Analysis (p. 1642).

Take Actions Based on the Built-in Rule Status

You can use Debugger with Amazon CloudWatch Events and AWS Lambda. You can automate actions based on the rule status, such as stopping training jobs early and setting up notifications through email or text. When the Debugger rules detect problems and triggers an "IssuesFound" evaluation status,
CloudWatch Events detects the rule status changes and invokes the Lambda function to take actions. To configure automated actions to your training issues, see Create Actions on Rules Using Amazon CloudWatch and AWS Lambda (p. 1653).

Dive Deep into the Data Using the SMDebug Client Library

You can use the SMDebug tools to access and analyze training data collected by Debugger. The `TrainingJob` and `create_trial` classes load the metrics and tensors saved by Debugger. These classes provide extended class methods to analyze the data in real time or after the training has finished. The SMDebug library also provides visualization tools: merge timelines of framework metrics to aggregate different profiling, line charts and heatmap to track the system utilization, and histograms to find step duration outliers. To learn more about the SMDebug library tools, see Analyze Data Using the SMDebug Client Library (p. 1697).

Monitoring System Utilization and Detect Bottlenecks

With Amazon SageMaker Debugger monitoring, you can measure hardware system resource utilization of Amazon EC2 instances. Monitoring is available for any SageMaker training job constructed with the SageMaker framework estimators (TensorFlow, PyTorch, and MXNet) and the generic SageMaker estimator (SageMaker built-in algorithms and your own custom containers). Debugger built-in rules for monitoring detect system bottleneck issues and notify you when they detect the bottleneck issues.

To learn how to enable Debugger system monitoring, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1555) and then Configure Debugger Monitoring Hardware System Resource Utilization (p. 1560).

For a full list of available built-in rules for monitoring, see Debugger Built-in Rules for Monitoring Hardware System Resource Utilization (System Metrics) (p. 1599).

Profiling Framework Operations

With Amazon SageMaker Debugger profiling you can profile deep learning frameworks operations. You can profile your model training with the SageMaker TensorFlow training containers, the SageMaker PyTorch framework containers, and your own training containers. Using the profiling feature of Debugger, you can drill down into the Python operators and functions that are executed to perform the training job. Debugger supports detailed profiling, Python profiling, data loader profiling, and Horovod distributed training profiling. You can merge the profiled timelines to correlate with the system bottlenecks. Debugger built-in rules for profiling watch framework operation related issues, including excessive training initialization time due to data downloading before training starts and step duration outliers in training loops.

To learn how to configure Debugger for framework profiling, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1555) and then Configure Debugger Framework Profiling (p. 1560).

For a complete list of available built-in rules for profiling, see Debugger Built-in Rules for Profiling Framework Metrics (p. 1599).

Debugging Model Parameters

Debugging is available for deep learning frameworks using AWS Deep Learning Containers and the SageMaker training containers. For fully supported framework versions (see the versions at Supported Frameworks and Algorithms (p. 1543)), Debugger automatically registers hooks to collect output tensors, and you can directly run your training script. For the versions with one asterisk sign, you need to manually register the hooks to collect tensors. Debugger provides preconfigured tensor collections with generalized names that you can utilize across the different frameworks. If you want to customize output tensor configuration, you can also use the CollectionConfig and DebuggerHookConfig API operations and

1709
the Amazon SageMaker Python SDK to configure your own tensor collections. Debugger built-in rules for debugging analyze the output tensors and identifies model optimization problems that blocks your model from minimizing the loss function. For example, the rules identify overfitting, overtraining, loss not decreasing, exploding tensors, and vanishing gradients.

To learn how to configure Debugger for debugging output tensors, see Configure Debugger Using Amazon SageMaker Python SDK (p. 1555) and then Configure Debugger Hook to Save Tensors (p. 1564).

For a full list of available built-in rules for debugging, see Debugger Built-in Rules for Debugging Model Training Data (Output Tensors) (p. 1599).

Amazon SageMaker Debugger Advanced Topics and Reference Documentation

The following sections contain advanced topics, reference documentation for the API operations, exceptions, and known limitations for Debugger.

Topics
- Amazon SageMaker Debugger API Operations (p. 1710)
- Use Debugger Docker Images for Built-in or Custom Rules (p. 1711)
- Amazon SageMaker Debugger Exceptions (p. 1713)
- Considerations for Amazon SageMaker Debugger (p. 1714)

Amazon SageMaker Debugger API Operations

Amazon SageMaker Debugger has API operations in several locations that are used to implement its monitoring and analysis of model training.

Amazon SageMaker Debugger also provides the open source SMDebug Python library at awslabs/sagemaker-debugger that is used to configure built-in rules, define custom rules, register hooks to collect output tensor data from training jobs.

The Amazon SageMaker Python SDK is a high-level SDK focused on machine learning experimentation. The SDK can be used to deploy built-in or custom rules defined with the SMDebug Python library to monitor and analyze these tensors using SageMaker estimators.

Debugger has added operations and types to the Amazon SageMaker API that enable the platform to use Debugger when training a model and to manage the configuration of inputs and outputs.

- CreateTrainingJob and UpdateTrainingJob use the following Debugger APIs to configure tensor collections, rules, rule images, and profiling options:
  - CollectionConfiguration
  - DebugHookConfig
  - DebugRuleConfiguration
  - TensorBoardOutputConfig
  - ProfilerConfig
  - ProfilerRuleConfiguration
- DescribeTrainingJob provides a full description of a training job including the following Debugger configurations and rule evaluation status:
  - DebugHookConfig
  - DebugRuleConfiguration
  - DebugRuleEvaluationStatus
The rule configuration API operations use the SageMaker Processing functionality when analyzing a model training. For more information about SageMaker Processing, see Process Data (p. 638).

### Use Debugger Docker Images for Built-in or Custom Rules

Amazon SageMaker provides two sets of Docker images for rules: one set for evaluating rules provided by SageMaker (built-in rules) and one set for evaluating custom rules provided in Python source files.

If you use the Amazon SageMaker Python SDK, you can simply use SageMaker high-level Debugger API operations with SageMaker Estimator API operations, without having to manually retrieve the Debugger Docker images and configure the ConfigureTrainingJob API.

If you are not using the SageMaker Python SDK, you have to retrieve a relevant pre-built container base image for the Debugger rules. Amazon SageMaker Debugger provides pre-built Docker images for built-in and custom rules, and the images are stored in Amazon Elastic Container Registry (Amazon ECR). To pull an image from an Amazon ECR repository (or to push an image to one), use the full name registry URL of the image using the CreateTrainingJob API. SageMaker uses the following URL patterns for the Debugger rule container image registry address.

```
<account_id>.dkr.ecr.<Region>.amazonaws.com/<ECR repository name>:<tag>
```

For the account ID in each AWS Region, Amazon ECR repository name, and tag value, see the following topics.

**Topics**
- Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators (p. 1711)
- Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators (p. 1712)

### Amazon SageMaker Debugger Registry URLs for Built-in Rule Evaluators

Use the following values for the components of the registry URLs for the images that provide built-in rules for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name:** sagemaker-debugger-rules

**Tag:** latest

**Example of a full registry URL:**

```
904829902805.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rules:latest
```

### Account IDs for Built-in Rules Container Images by AWS Region

<table>
<thead>
<tr>
<th>Region</th>
<th>account_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>af-south-1</td>
<td>314341159256</td>
</tr>
<tr>
<td>ap-east-1</td>
<td>199566480951</td>
</tr>
<tr>
<td>ap-northeast-1</td>
<td>430734990657</td>
</tr>
</tbody>
</table>
Amazon SageMaker Debugger Registry URLs for Custom Rule Evaluators

Use the following values for the components of the registry URL for the images that provide custom rule evaluators for Amazon SageMaker Debugger. For account IDs, see the following table.

**ECR Repository Name:** sagemaker-debugger-rule-evaluator

**Tag:** latest

**Example of a full registry URL:**

552407032007.dkr.ecr.ap-south-1.amazonaws.com/sagemaker-debugger-rule-evaluator:latest

**Account IDs for Custom Rules Container Images by AWS Region**

<table>
<thead>
<tr>
<th>Region</th>
<th>account_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>af-south-1</td>
<td>5159509971035</td>
</tr>
</tbody>
</table>
### Amazon SageMaker Debugger Exceptions

Amazon SageMaker Debugger is designed to be aware that tensors required to execute a rule might not be available at every step. As a result, it raises a few exceptions, which enable you to control what happens when a tensor is missing. These exceptions are available in the `smdebug.exceptions` module. You can import them as follows:

```python
from smdebug.exceptions import *
```

The following exceptions are available:

- **TensorUnavailableForStep** – The tensor requested is not available for the step. This might mean that this step might not be saved at all by the hook, or that this step might have saved some tensors but the requested tensor is not part of them. Note that when you see this exception, it means that this
A tensor can never become available for this step in the future. If the tensor has reductions saved for the step, it notifies you they can be queried.

- **TensorUnavailable** – This tensor is not being saved or has not been saved by the smdebug API. This means that this tensor is never seen for any step in smdebug.
- **StepUnavailable** – The step was not saved and Debugger has no data from the step.
- **StepNotYetAvailable** – The step has not yet been seen by smdebug. It might be available in the future if the training is still going on. Debugger automatically loads new data as it becomes available.
- **NoMoreData** – Raised when the training ends. Once you see this, you know that there are no more steps and no more tensors to be saved.
- **IndexReaderException** – The index reader is not valid.
- **InvalidWorker** – A worker was invoked that was not valid.
- **RuleEvaluationConditionMet** – Evaluation of the rule at the step resulted in the condition being met.
- **InsufficientInformationForRuleInvocation** – Insufficient information was provided to invoke the rule.

### Considerations for Amazon SageMaker Debugger

Consider the following when using Amazon SageMaker Debugger.

#### Considerations for Distributed Training

- **Horovod support**
  - For debugging – Debugger does not support Horovod distributed training for Keras.
  - For profiling – Debugger does not support Horovod distributed training for Keras and MXNet.
- **Parameter Server support** – Parameter server-based distributed training is not supported.

#### Considerations for Monitoring and Profiling

- For AWS TensorFlow, data loader metrics cannot be collected using the default `local_path` setting of the `FrameworkProfile` class. The path has to be manually configured ending in "/". For example:

  ```python
  FrameworkProfile(local_path="/opt/ml/output/profiler/")
  ```

  - For AWS TensorFlow, the data loader profiling configuration cannot be updated while training job is running.
  - For AWS TensorFlow, `NoneType` error might occur when you use analysis tools and notebook examples with TensorFlow 2.3 training jobs and the detailed profiling option.
  - Python profiling and detailed profiling are only supported for Keras API.

- To access the deep profiling feature for TensorFlow and PyTorch, currently you need to specify the latest AWS deep learning container images with CUDA 11. For example, you must specify the specific image URI in the TensorFlow and PyTorch estimator as follows:

  - For TensorFlow

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/tensorflow-training:2.3.1-gpu-py37-cu110-ubuntu18.04"
    ```

  - For PyTorch

    ```python
    image_uri = f"763104351884.dkr.ecr.{region}.amazonaws.com/pytorch-training:1.6.0-gpu-py36-cu110-ubuntu18.04"
    ```
Perform Automatic Model Tuning with SageMaker

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose.

For example, suppose that you want to solve a *binary classification* problem on a marketing dataset. Your goal is to maximize the *area under the curve (auc)* metric of the algorithm by training an XGBoost Algorithm (p. 1481) model. You don’t know which values of the *eta, alpha, min_child_weight,* and *max_depth* hyperparameters to use to train the best model. To find the best values for these hyperparameters, you can specify ranges of values that SageMaker hyperparameter tuning searches to find the combination of values that results in the training job that performs the best as measured by the objective metric that you chose. Hyperparameter tuning launches training jobs that use hyperparameter values in the ranges that you specified, and returns the training job with highest auc.

You can use SageMaker automatic model tuning with built-in algorithms, custom algorithms, and SageMaker pre-built containers for machine learning frameworks.

Amazon SageMaker automatic model tuning can use Amazon EC2 Spot instance to optimize costs when running training jobs. For more information on managed spot training, see [Managed Spot Training in Amazon SageMaker](p. 1823).

Before you start using hyperparameter tuning, you should have a well-defined machine learning problem, including the following:

- A dataset
- An understanding of the type of algorithm you need to train
- A clear understanding of how you measure success

You should also prepare your dataset and algorithm so that they work in SageMaker and successfully run a training job at least once. For information about setting up and running a training job, see [Get Started with Amazon SageMaker](p. 34).

**Topics**
- How Hyperparameter Tuning Works (p. 1715)
- Define Metrics (p. 1717)
- Define Hyperparameter Ranges (p. 1718)
- Tune Multiple Algorithms to Find the Best Model (p. 1719)
- Example: Hyperparameter Tuning Job (p. 1722)
- Stop Training Jobs Early (p. 1732)
- Run a Warm Start Hyperparameter Tuning Job (p. 1733)
- Resource Limits for Automatic Model Tuning (p. 1737)
- Best Practices for Hyperparameter Tuning (p. 1738)

**How Hyperparameter Tuning Works**

**Random Search**

In a random search, hyperparameter tuning chooses a random combination of values from within the ranges that you specify for hyperparameters for each training job it launches. Because the choice of hyperparameter values doesn’t depend on the results of previous training jobs, you can run the maximum number of concurrent training jobs without affecting the performance of the search.
For an example notebook that uses random search, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

**Bayesian Search**

Bayesian search treats hyperparameter tuning like a [regression] problem. Given a set of input features (the hyperparameters), hyperparameter tuning optimizes a model for the metric that you choose.

To solve a regression problem, hyperparameter tuning makes guesses about which hyperparameter combinations are likely to get the best results, and runs training jobs to test these values. After testing the first set of hyperparameter values, hyperparameter tuning uses regression to choose the next set of hyperparameter values to test.

Hyperparameter tuning uses a Amazon SageMaker implementation of Bayesian optimization.

When choosing the best hyperparameters for the next training job, hyperparameter tuning considers everything that it knows about this problem so far. Sometimes it chooses a combination of hyperparameter values close to the combination that resulted in the best previous training job to incrementally improve performance. This allows hyperparameter tuning to exploit the best known results. Other times, it chooses a set of hyperparameter values far removed from those it has tried. This allows it to explore the range of hyperparameter values to try to find new areas that are not well understood. The explore/exploit trade-off is common in many machine learning problems.

**Note**

Hyperparameter tuning might not improve your model. It is an advanced tool for building machine solutions, and, as such, should be considered part of the scientific development process.

When you build complex machine learning systems like deep learning neural networks, exploring all of the possible combinations is impractical. Hyperparameter tuning can accelerate
your productivity by trying many variations of a model, focusing on the most promising combinations of hyperparameter values within the ranges that you specify. To get good results, you need to choose the right ranges to explore. Because the algorithm itself is stochastic, it's possible that the hyperparameter tuning model will fail to converge on the best answer, even if the best possible combination of values is within the ranges that you choose.

Define Metrics

**Note**
When you use one of the Amazon SageMaker built-in algorithms, you don't need to define metrics. Built-in algorithms automatically send metrics to hyperparameter tuning. You do need to choose one of the metrics that the built-in algorithm emits as the objective metric for the tuning job. For a list of metrics that a built-in algorithm emits, see the *Metrics* table for the algorithm in Use Amazon SageMaker Built-in Algorithms (p. 691).

To optimize hyperparameters for a machine learning model, a tuning job evaluates the training jobs it launches by using a metric that the training algorithm writes to logs. Amazon SageMaker hyperparameter tuning parses your algorithm's `stdout` and `stderr` streams to find algorithm metrics, such as loss or validation-accuracy, that show how well the model is performing on the dataset.

**Note**
These are the same metrics that SageMaker sends to CloudWatch Logs. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 2470).

If you use your own algorithm for hyperparameter tuning, make sure that your algorithm emits at least one metric by writing evaluation data to `stderr` or `stdout`.

**Note**
Hyperparameter tuning sends an additional hyperparameter, `_tuning_objective_metric` to the training algorithm. This hyperparameter specifies the objective metric being used for the hyperparameter tuning job, so that your algorithm can use that information during training.

You can define up to 20 metrics for your tuning job to monitor. You choose one of those metrics to be the objective metric, which hyperparameter tuning uses to evaluate the training jobs. The hyperparameter tuning job returns the training job that returned the best value for the objective metric as the best training job.

You define metrics for a tuning job by specifying a name and a regular expression for each metric that your tuning job monitors. Design the regular expressions to capture the values of metrics that your algorithm emits. You pass these metrics to the `CreateHyperParameterTuningJob` operation in the `TrainingJobDefinition` parameter as the `MetricDefinitions` field of the `AlgorithmSpecification` field.

The following example defines 4 metrics:

```
=[
  {
    "Name": "loss",
    "Regex": "Loss = (.*);",
  },
  {
    "Name": "ganloss",
    "Regex": "GAN_loss=(.*);",
  },
  {
    "Name": "discloss",
    "Regex": "disc_train_loss=(.*);",
  },
  {
    "Name": "disc-combined",
    "Regex": "disc-combined=(.*);",
  },
]```
The following is an example of the log that the algorithm writes:

GAN_loss=0.138318;  Scaled_reg=2.654134; disc:\[-0.017371,0.102429\] real 93.3% gen 0.0% disc-combined=0.000000; disc_train_loss=1.374587;  Loss = 16.020744; Iteration 0 took 0.704s; Elapsed=0s

Use the regular expression (regex) to match the algorithm's log output and capture the numeric values of metrics. For example, in the regex for the loss metric defined above, the first part of the regex finds the exact text "Loss = ", and the expression (.*?); captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, \ means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Choose one of the metrics that you define as the objective metric for the tuning job. If you are using the API, specify the value of the name key in the HyperParameterTuningJobObjective field of the HyperParameterTuningJobConfig parameter that you send to the CreateHyperParameterTuningJob operation.

Define Hyperparameter Ranges

Hyperparameter tuning finds the best hyperparameter values for your model by searching over ranges of hyperparameters. You specify the hyperparameters and range of values over which to search by defining hyperparameter ranges for your tuning job. Choosing hyperparameters and ranges significantly affects the performance of your tuning job. For guidance on choosing hyperparameters and ranges, see Best Practices for Hyperparameter Tuning (p. 1738).

To define hyperparameter ranges by using the low-level API, you specify the names of hyperparameters and ranges of values in the ParameterRanges field of the HyperParameterTuningJobConfig parameter that you pass to the CreateHyperParameterTuningJob operation. The ParameterRanges field has three subfields, one for each of the categorical, integer, and continuous hyperparameter ranges. You can define up to 20 hyperparameters to search over. Each value of a categorical hyperparameter range counts as a hyperparameter against the limit. Hyperparameter ranges have the following structure:

```
"ParameterRanges": {  
  "CategoricalParameterRanges": [  
    {  
      "Name": "tree_method",  
      "Values": ["auto", "exact", "approx", "hist"]  
    }  
  ],  
  "ContinuousParameterRanges": [  
    {  
      "Name": "eta",  
      "MaxValue": "0.5",  
      "MinValue": "0",  
      "ScalingType": "Auto"  
    }  
  ],  
  "IntegerParameterRanges": [  
    {  
      "Name": "max_depth",  
      "MaxValue": "10",  
      "MinValue": "1",  
      "ScalingType": "Auto"  
    }  
  ]
```
Hyperparameter Scaling

For integer and continuous hyperparameter ranges, you can choose the scale you want hyperparameter tuning to use to search the range of values by specifying a value for the `ScalingType` field of the hyperparameter range. You can choose from the following scaling types:

Auto

SageMaker hyperparameter tuning chooses the best scale for the hyperparameter.

Linear

Hyperparameter tuning searches the values in the hyperparameter range by using a linear scale. Typically, you choose this if the range of all values from the lowest to the highest is relatively small (within one order of magnitude), because uniformly searching values from the range will give you a reasonable exploration of the entire range.

Logarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a logarithmic scale.

Logarithmic scaling works only for ranges that have only values greater than 0.

Choose logarithmic scaling when you are searching a range that spans several orders of magnitude. For example, if you are tuning a Tune a linear learner model (p. 1399) model, and you specify a range of values between 0.0001 and 1.0 for the `learning_rate` hyperparameter, searching uniformly on a logarithmic scale gives you a better sample of the entire range than searching on a linear scale would, because searching on a linear scale would, on average, devote 90 percent of your training budget to only the values between 0.1 and 1.0, leaving only 10 percent of your training budget for the values between 0.001 and 1.

ReverseLogarithmic

Hyperparameter tuning searches the values in the hyperparameter range by using a reverse logarithmic scale. reverse logarithmic scaling is supported only for continuous hyperparameter ranges. It is not supported for integer hyperparameter ranges.

Reverse logarithmic scaling works only for ranges that are entirely within the range 0<=x<1.0.

Choose reverse logarithmic scaling when you are searching a range that is highly sensitive to small changes that are very close to 1.

For an example notebook that uses hyperparameter scaling, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/xgboost_random_log/hpo_xgboost_random_log.ipynb.

Tune Multiple Algorithms to Find the Best Model

When you create a new hyperparameter optimization (HPO) job with Amazon SageMaker, you have the option of using the console or the API. You provide one or more job specifications for the different algorithms you're testing. These are called training definitions. Each training definition has a name, an algorithm source, metrics selection, an objective metric, and a configuration for a set of hyperparameter values. It also has a data configuration for setting up the input data channels for the algorithm you choose, and a setting for the output data location. You select the resources you want to use for the training run.

Topics
• Get Started (p. 1720)
• Managing Hyperparameter Tuning Jobs (p. 1720)
• Create a new single or multi-algorithm HPO tuning job (p. 1720)

Get Started

Using Multi-Algorithm HPO

To use multi-algorithm HPO you must add more than one training definition to your hyperparameter tuning job. Each training definition holds the configuration options for each algorithm you want to try.

In the console, you add training definitions when you create the HPO tuning job by choosing **Add training definition**, and then following the configuration steps for each algorithm that you want to use.

When you start the configuration steps, please note that the warm start and early stopping features are not available with multi-algorithm HPO. If you want to use these features, you can only tune a single algorithm at a time.

If you’re using an API request, instead of the single `TrainingJobDefinition`, you must provide a list of training definitions using `TrainingJobDefinitions`. You must use one or the other, not both.

Managing Hyperparameter Tuning Jobs

You can clone a job, add or edit tags, or create a new hyperparameter tuning job from the console. You can also use the search feature to find jobs by their name, creation time, and status.

Creating a Hyperparameter Tuning Job

To create a new job, open the Amazon SageMaker console, choose **Training**, choose **Hyperparameter tuning jobs**, and then choose **Create hyperparameter tuning job**.

For instructions on using the API to create a tuning job, see **Example: Hyperparameter Tuning Job**.

Cloning an existing training Job

You can save time by cloning a training job, which copies all of the job’s settings, including data channels, S3 bucket locations, algorithms, and the hyperparameter options.

To clone a training job

• On the **Training jobs** page or on the **Hyperparameter tuning jobs** page, choose **Actions** and then choose **Clone**.

Editing Tags

You enter tags as key-value pairs. Values are not required. You can use just the key. To see the keys associated with a job, choose the **Tags** tab on the tuning job’s details page.

Create a new single or multi-algorithm HPO tuning job

Defining job settings

Your tuning job settings are applied across all of the algorithms in the HPO tuning job. Warm start and early stopping are available only when tuning a single algorithm. After you define the job settings you will create individual training definitions for each algorithm or variation you want to tune.

Warm Start
If you cloned this job, you can choose to use the results from a previous tuning job to improve the performance of this tuning job. This is the warm start feature and it is only available when tuning a single algorithm. When you choose this option, you can choose up to five previous hyperparameter tuning jobs to use. Alternatively, you can use transfer learning to add additional data to the parent tuning job. When you select this option, you choose one previous tuning job as the parent.

Warm start is compatible with tuning jobs created after October 1, 2018. For more information, see Run a warm start job.

**Early Stopping**

Early stopping stops training jobs when they are unlikely to improve the current best objective metric of the hyperparameter tuning job. Like warm start, this feature is only available when tuning a single algorithm. This is an automatic feature without configuration options, and it's disabled by default.

**Tuning Strategy**

Tuning strategy can be either random or bayesian. It specifies how the automatic tuning searches over specified hyperparameter ranges. You specify the ranges in a later step. For more information, see How Hyperparameter Tuning Works.

**Training Definitions**

You must provide at least one training definition for each training job. Each training definition specifies the configuration for an algorithm. To create several definitions for your training job you can clone a definition.

**Name**

Provide a unique name for the training definition.

**Permissions**

Amazon SageMaker requires permissions to call other services on your behalf. Choose an IAM role or let AWS create a role that has the AmazonSageMakerFullAccess IAM policy attached.

**Optional Security Settings**

The network isolation setting prevents the container from making any outbound network calls. This is required for AWS Marketplace machine learning offerings.

You can also choose to use a private VPC.

**Note**

Inter-container encryption is only available when creating job definitions from the API.

**Algorithm Options**

You can choose one of the built-in algorithms, your own algorithm, your own container with an algorithm, or you can subscribe to an algorithm from AWS Marketplace.

If you choose a built-in algorithm, it has the ECR image information prepopulated. If you choose your own container, you must specify the ECR image information. You can select the input mode for the algorithm as file or pipe. If you plan to supply your data using a .CSV file from Amazon S3, you should select the file.

**Metrics**

When you choose a built-in algorithm, metrics are provided for you. If you choose your own algorithm, you need to define your metrics.

**Objective Metric**
To find the best training job, set an objective metric and tuning type. After the training job is complete, you can view the tuning job detail page for a summary of the best training job found using this objective metric.

**Hyperparameter Configuration**

When you choose a built-in algorithm, hyperparameters' default values are set for you, using ranges that are optimized for the particular algorithm. You can change these values as you see fit. Instead of a range, you can set a fixed value for a hyperparameter by setting the parameter's type to `static`. Each algorithm has different required and optional parameters. For more information, see best practices and ranges.

**Input Data Configuration**

Input data is defined by channels, each with their own source location (Amazon S3 or Amazon Elastic File System), compression, and format options. You can define up to 20 channels of input sources. If the algorithm you chose supports multiple input channels, you can specify those too.

For example, when using the XGBoost churn prediction notebook, you could add two channels: train and validation.

**Checkpoint Configuration**

Checkpoints are periodically generated during training. You must choose an Amazon S3 location for the checkpoints to be saved. Checkpoints are used in metrics reporting, and are also used to resume managed spot training jobs.

**Output Data Configuration**

You must define an Amazon S3 location for the artifacts of the training job to be stored. You have the option of adding encryption to the output using an AWS Key Management Service (AWS KMS) key.

**Resource Limits and Configuration**

Each training definition can have a different resource configuration. You choose the instance type and number of nodes.

**Finalizing the Job Settings**

You can run parallel jobs and limit the total number of jobs. The number of parallel jobs should not exceed the number of nodes you have requested across all of your training definitions. The total number of jobs can't exceed the number of jobs that your definitions are expected to run.

**Example: Hyperparameter Tuning Job**

This example shows how to create a new notebook for configuring and launching a hyperparameter tuning job. The tuning job uses the XGBoost Algorithm (p. 1481) to train a model to predict whether a customer will enroll for a term deposit at a bank after being contacted by phone.

You use the low-level AWS SDK for Python (Boto) to configure and launch the hyperparameter tuning job, and the AWS Management Console to monitor the status of hyperparameter tuning jobs. You can also use the Amazon SageMaker high-level Amazon SageMaker Python SDK to configure, run, monitor, and analyze hyperparameter tuning jobs. For more information, see https://github.com/aws/sagemaker-python-sdk.

**Prerequisites**

To run the code in this example, you need

- An AWS account and an administrator user (p. 34)
- An Amazon S3 bucket for storing your training dataset and the model artifacts created during training
- A running SageMaker notebook instance (p. 55)
Create a Notebook

Create a Jupyter notebook that contains a preinstalled environment with the default Anaconda installation and Python3.

To create a Jupyter notebook

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Open a running notebook instance, by choosing Open next to its name. The Jupyter notebook server page appears:

3. To create a notebook, choose Files, New, and conda_python3.
4. Name the notebook.

Next Step

Get the Amazon SageMaker Boto 3 Client (p. 1723)

Get the Amazon SageMaker Boto 3 Client

Import Amazon SageMaker Python SDK, AWS SDK for Python (Boto3), and other Python libraries. In a new Jupyter notebook, paste the following code to the first cell:

```python
import sagemaker
import boto3
import numpy as np  # For performing matrix operations and numerical processing
import pandas as pd  # For manipulating tabular data
from time import gmtime, strftime
import os

region = boto3.Session().region_name
smclient = boto3.Session().client('sagemaker')
```
The preceding code cell defines `region` and `smclient` objects that you will use to call the built-in XGBoost algorithm and set the SageMaker hyperparameter tuning job.

**Next Step**

Get the SageMaker Execution Role (p. 1724)

### Get the SageMaker Execution Role

Get the execution role for the notebook instance. This is the IAM role that you created for your notebook instance. You pass the role to the tuning job.

```python
from sagemaker import get_execution_role
role = get_execution_role()
print(role)
```

**Next Step**

Specify a S3 Bucket to Upload Training Datasets and Store Output Data (p. 1724)

### Specify a S3 Bucket to Upload Training Datasets and Store Output Data

Set up a S3 bucket to upload training datasets and save training output data.

**To use a default S3 bucket**

Use the following code to specify the default S3 bucket allocated for your SageMaker session. `prefix` is the path within the bucket where SageMaker stores the data for the current training job.

```python
sess = sagemaker.Session()
bucket = sess.default_bucket() # Set a default S3 bucket
prefix = 'DEMO-automatic-model-tuning-xgboost-dm'
```

**(Optional) To use a specific S3 bucket**

If you want to use a specific S3 bucket, use the following code and replace the strings to the exact name of the S3 bucket. The name of the bucket must contain `sagemaker`, and be globally unique. The bucket must be in the same AWS Region as the notebook instance that you use for this example.

```python
bucket = "sagemaker-your-preferred-s3-bucket"
```

**Note**

The name of the bucket doesn't need to contain `sagemaker` if the IAM role that you use to run the hyperparameter tuning job has a policy that gives the `S3FullAccess` permission.

**Next Step**

Download, Prepare, and Upload Training Data (p. 1724)

### Download, Prepare, and Upload Training Data

For this example, you use a training dataset of information about bank customers that includes the customer's job, marital status, and how they were contacted during the bank's direct marketing campaign. To use a dataset for a hyperparameter tuning job, you download it, transform the data, and then upload it to an Amazon S3 bucket.
For more information about the dataset and the data transformation that the example performs, see the `hpo_xgboost_direct_marketing_sagemaker_APIs` notebook in the Hyperparameter Tuning section of the SageMaker Examples tab in your notebook instance.

Download and Explore the Training Dataset

To download and explore the dataset, run the following code in your notebook:

```bash
!unzip -o bank-additional.zip
data = pd.read_csv('./bank-additional/bank-additional-full.csv', sep=';')
pd.set_option('display.max_columns', 500) # Make sure we can see all of the columns
pd.set_option('display.max_rows', 5)
data
```

Prepare and Upload Data

Before creating the hyperparameter tuning job, prepare the data and upload it to an S3 bucket where the hyperparameter tuning job can access it.

Run the following code in your notebook:

```python
data['no_previous_contact'] = np.where(data['pdays'] == 999, 1, 0) # Indicator variable to capture when pdays takes a value of 999
data['not_working'] = np.where(np.in1d(data['job'], ['student', 'retired', 'unemployed']), 1, 0) # Indicator for individuals not actively employed
model_data = pd.get_dummies(data)
# Convert categorical variables to sets of indicators
model_data = model_data.drop(['duration', 'emp.var.rate', 'cons.price.idx', 'cons.conf.idx', 'euribor3m', 'nr.employed'], axis=1)
train_data, validation_data, test_data = np.split(model_data.sample(frac=1, random_state=1729), [int(0.7 * len(model_data)), int(0.9*len(model_data))])
pd.concat([train_data['y_yes'], train_data.drop(['y_no', 'y_yes'], axis=1)]).to_csv('train.csv', index=False, header=False)
pd.concat([validation_data['y_yes'], validation_data.drop(['y_no', 'y_yes'], axis=1)]).to_csv('validation.csv', index=False, header=False)
pd.concat([test_data['y_yes'], test_data.drop(['y_no', 'y_yes'], axis=1)]).to_csv('test.csv', index=False, header=False)
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'train/train.csv')).upload_file('train.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(os.path.join(prefix, 'validation/validation.csv')).upload_file('validation.csv')
```

Next Step

Configure and Launch a Hyperparameter Tuning Job (p. 1725)

Configure and Launch a Hyperparameter Tuning Job

To configure and launch a hyperparameter tuning job, complete the following steps.

Topics
- Specify the Hyperparameter Tuning Job Settings (p. 1726)
- Configure the Training Jobs (p. 1727)
Specifying the Hyperparameter Tuning Job Settings

To specify settings for the hyperparameter tuning job, you define a JSON object. You pass the object as the value of the HyperParameterTuningJobConfig parameter to CreateHyperParameterTuningJob when you create the tuning job.

In this JSON object, you specify:

- The ranges of hyperparameters that you want to tune. For more information, see Define Hyperparameter Ranges (p. 1718).
- The limits of the resource that the hyperparameter tuning job can consume.
- The objective metric for the hyperparameter tuning job. An objective metric is the metric that the hyperparameter tuning job uses to evaluate the training job that it launches.

Note
To use your own algorithm for hyperparameter tuning, you need to define metrics for your algorithm. For information, see Define Metrics (p. 1717).

The hyperparameter tuning job defines ranges for the eta, alpha, min_child_weight, and max_depth hyperparameters of the XGBoost Algorithm (p. 1481) built-in algorithm. The objective metric for the hyperparameter tuning job maximizes the validation:auc metric that the algorithm sends to CloudWatch Logs.

tuning_job_config = {
    "ParameterRanges": {
        "CategoricalParameterRanges": [],
        "ContinuousParameterRanges": [
            {
                "MaxValue": "1",
                "MinValue": "0",
                "Name": "eta"
            },
            {
                "MaxValue": "2",
                "MinValue": "0",
                "Name": "alpha"
            },
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "min_child_weight"
            }
        ],
        "IntegerParameterRanges": [
            {
                "MaxValue": "10",
                "MinValue": "1",
                "Name": "max_depth"
            }
        ]
    },
    "ResourceLimits": {
        "MaxNumberOfTrainingJobs": 20,
        "MaxParallelTrainingJobs": 3
    },
    "Strategy": "Bayesian",
    "HyperParameterTuningJobObjective": {

Configure the Training Jobs

To configure the training jobs that the tuning job launches, define a JSON object that you pass as the value of the TrainingJobDefinition parameter of the CreateHyperParameterTuningJob call.

In this JSON object, you specify:

- Optional—Metrics that the training jobs emit.

  Note
  
  Define metrics only when you use a custom training algorithm. Because this example uses a built-in algorithm, you don't specify metrics. For information about defining metrics, see Define Metrics (p. 1717).

- The container image that specifies the training algorithm.
- The input configuration for your training and test data.
- The storage location for the algorithm's output. Specify the S3 bucket where you want to store the output of the training jobs.
- The values of algorithm hyperparameters that are not tuned in the tuning job.
- The type of instance to use for the training jobs.
- The stopping condition for the training jobs. This is the maximum duration for each training job.

In this example, we set static values for the eval_metric, num_round, objective, rate_drop, and tweedie_variance_power parameters of the XGBoost Algorithm (p. 1481) built-in algorithm.

SageMaker Python SDK v1

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
training_image = get_image_uri(region, 'xgboost', repo_version='1.0-1')

s3_input_train = 's3://{}{}train'.format(bucket, prefix)
s3_input_validation = 's3://{}{}validation/'.format(bucket, prefix)

training_job_definition = {
    "AlgorithmSpecification": {
        "TrainingImage": training_image,
        "TrainingInputMode": "File"
    },
    "InputDataConfig": [
        {
            "ChannelName": "train",
            "CompressionType": "None",

      "num_round": "100",
      "objective": "binary:logistic",
      "rate_drop": "0.3",
      "tweedie_variance_power": "1.4"
    },
    "StoppingCondition": {
      "MaxRuntimeInSeconds": 43200
    }
  }
}
```

Name and Launch the Hyperparameter Tuning Job

Now you can provide a name for the hyperparameter tuning job and then launch it by calling the `CreateHyperParameterTuningJob` API. Pass `tuning_job_config`, and `training_job_definition` that you created in previous steps as the values of the parameters.

```python
tuning_job_name = "MyTuningJob"
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName = tuning_job_name,
                                            HyperParameterTuningJobConfig = tuning_job_config,
                                            TrainingJobDefinition = training_job_definition)
```

Next Step

Monitor the Progress of a Hyperparameter Tuning Job (p. 1729)

Monitor the Progress of a Hyperparameter Tuning Job

To monitor the progress of a hyperparameter tuning job and the training jobs that it launches, use the Amazon SageMaker console.

Topics
- View the Status of the Hyperparameter Tuning Job (p. 1729)
- View the Status of the Training Jobs (p. 1730)
- View the Best Training Job (p. 1731)

View the Status of the Hyperparameter Tuning Job

To view the status of the hyperparameter tuning job

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Hyperparameter tuning jobs.
In the list of hyperparameter tuning jobs, check the status of the hyperparameter tuning job you launched. A tuning job can be:

- **Completed**—The hyperparameter tuning job successfully completed.
- **InProgress**—The hyperparameter tuning job is in progress. One or more training jobs are still running.
- **Failed**—The hyperparameter tuning job failed.
- **Stopped**—The hyperparameter tuning job was manually stopped before it completed. All training jobs that the hyperparameter tuning job launched are stopped.
- **Stopping**—The hyperparameter tuning job is in the process of stopping.

### View the Status of the Training Jobs

**To view the status of the training jobs that the hyperparameter tuning job launched**

1. In the list of hyperparameter tuning jobs, choose the job that you launched.
2. Choose **Training jobs**.

3. View the status of each training job. To see more details about a job, choose it in the list of training jobs. To view a summary of the status of all of the training jobs that the hyperparameter tuning job launched, see **Training job status counter**.
A training job can be:

- **Completed**—The training job successfully completed.
- **InProgress**—The training job is in progress.
- **Stopped**—The training job was manually stopped before it completed.
- **Failed (Retriable)**—The training job failed, but can be retried. A failed training job can be retried only if it failed because an internal service error occurred.
- **Failed (Non-retriable)**—The training job failed and can't be retried. A failed training job can't be retried when a client error occurs.

### View the Best Training Job

A hyperparameter tuning job uses the objective metric that each training job returns to evaluate training jobs. While the hyperparameter tuning job is in progress, the best training job is the one that has returned the best objective metric so far. After the hyperparameter tuning job is complete, the best training job is the one that returned the best objective metric.

To view the best training job, choose **Best training job**.

![Best Training Job](image)

To deploy the best training job as a model that you can host at a SageMaker endpoint, choose **Create model**.

### Next Step

**Clean up (p. 1731)**

### Clean up

To avoid incurring unnecessary charges, when you are done with the example, use the AWS Management Console to delete the resources that you created for it.

**Note**

If you plan to explore other examples, you might want to keep some of these resources, such as your notebook instance, S3 bucket, and IAM role.
1. Open the SageMaker console at https://console.aws.amazon.com/sagemaker/ and delete the notebook instance. Stop the instance before deleting it.

2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/ and delete the bucket that you created to store model artifacts and the training dataset.

3. Open the IAM console at https://console.aws.amazon.com/iam/ and delete the IAM role. If you created permission policies, you can delete them, too.

4. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/ and delete all of the log groups that have names starting with /aws/sagemaker/.

**Stop Training Jobs Early**

Stop the training jobs that a hyperparameter tuning job launches early when they are not improving significantly as measured by the objective metric. Stopping training jobs early can help reduce compute time and helps you avoid overfitting your model. To configure a hyperparameter tuning job to stop training jobs early, do one of the following:

- If you are using the AWS SDK for Python (Boto 3), set the `TrainingJobEarlyStoppingType` field of the `HyperParameterTuningJobConfig` object that you use to configure the tuning job to `AUTO`.
- If you are using the Amazon SageMaker Python SDK, set the `early_stopping_type` parameter of the `HyperParameterTuner` object to `Auto`.
- In the Amazon SageMaker console, in the `Create hyperparameter tuning job` workflow, under Early stopping, choose `Auto`.

For a sample notebook that demonstrates how to use early stopping, see https://github.com/awslabs/amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_early_stopping/hpo_image_classification_early_stopping.ipynb or open the `hpo_image_classification_early_stopping.ipynb` notebook in the Hyperparameter Tuning section of the SageMaker Examples in a notebook instance. For information about using sample notebooks in a notebook instance, see Example Notebooks (p. 130).

**How Early Stopping Works**

When you enable early stopping for a hyperparameter tuning job, SageMaker evaluates each training job the hyperparameter tuning job launches as follows:

- After each epoch of training, get the value of the objective metric.
- Compute the running average of the objective metric for all previous training jobs up to the same epoch, and then compute the median of all of the running averages.
- If the value of the objective metric for the current training job is worse (higher when minimizing or lower when maximizing the objective metric) than the median value of running averages of the objective metric for previous training jobs up to the same epoch, SageMaker stops the current training job.

**Algorithms That Support Early Stopping**

To support early stopping, an algorithm must emit objective metrics for each epoch. The following built-in SageMaker algorithms support early stopping:

- **Linear Learner Algorithm (p. 1399)**—Supported only if you use `objective_loss` as the objective metric.
- **XGBoost Algorithm (p. 1481)**
- **Image Classification Algorithm (p. 1356)**
Note
This list of built-in algorithms that support early stopping is current as of December 13, 2018. Other built-in algorithms might support early stopping in the future. If an algorithm emits a metric that can be used as an objective metric for a hyperparameter tuning job (preferably a validation metric), then it supports early stopping.

To use early stopping with your own algorithm, you must write your algorithms such that it emits the value of the objective metric after each epoch. The following list shows how you can do that in different frameworks:

TensorFlow
Use the `tf.keras.callbacks.ProgbarLogger` class. For information, see https://www.tensorflow.org/api_docs/python/tf/keras/callbacks/ProgbarLogger.

MXNet
Use the `mxnet.callback.LogValidationMetricsCallback`. For information, see https://mxnet.apache.org/api/python/callback/callback.html.

Chainer
Extend chainer by using the `extensions.Evaluator` class. For information, see https://docs.chainer.org/en/v1.24.0/reference/extensions.html#evaluator.

PyTorch and Spark
There is no high-level support. You must explicitly write your training code so that it computes objective metrics and writes them to logs after each epoch.

Run a Warm Start Hyperparameter Tuning Job

Use warm start to start a hyperparameter tuning job using one or more previous tuning jobs as a starting point. The results of previous tuning jobs are used to inform which combinations of hyperparameters to search over in the new tuning job. Hyperparameter tuning uses either Bayesian or random search to choose combinations of hyperparameter values from ranges that you specify. For more information, see How Hyperparameter Tuning Works (p. 1715). Using information from previous hyperparameter tuning jobs can help increase the performance of the new hyperparameter tuning job by making the search for the best combination of hyperparameters more efficient.

Note
Warm start tuning jobs typically take longer to start than standard hyperparameter tuning jobs, because the results from the parent jobs have to be loaded before the job can start. The increased time depends on the total number of training jobs launched by the parent jobs.

Reasons you might want to consider warm start include:

- You want to gradually increase the number of training jobs over several tuning jobs based on the results you see after each iteration.
- You get new data, and want to tune a model using the new data.
- You want to change the ranges of hyperparameters that you used in a previous tuning job, change static hyperparameters to tunable, or change tunable hyperparameters to static values.
- You stopped a previous hyperparameter job early or it stopped unexpectedly.
Types of Warm Start Tuning Jobs

There are two different types of warm start tuning jobs:

**IDENTICAL_DATA_AND_ALGORITHM**

The new hyperparameter tuning job uses the same input data and training image as the parent tuning jobs. You can change the hyperparameter ranges to search and the maximum number of training jobs that the hyperparameter tuning job launches. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. You cannot use a new version of the training algorithm, unless the changes in the new version do not affect the algorithm itself. For example, changes that improve logging or adding support for a different data format are allowed.

Use identical data and algorithm when you use the same training data as you used in a previous hyperparameter tuning job, but you want to increase the total number of training jobs or change ranges or values of hyperparameters.

When you run an warm start tuning job of type **IDENTICAL_DATA_AND_ALGORITHM**, there is an additional field in the response to `DescribeHyperParameterTuningJob` named `OverallBestTrainingJob`. The value of this field is the `TrainingJobSummary` for the training job with the best objective metric value of all training jobs launched by this tuning job and all parent jobs specified for the warm start tuning job.

**TRANSFER_LEARNING**

The new hyperparameter tuning job can include input data, hyperparameter ranges, maximum number of concurrent training jobs, and maximum number of training jobs that are different than those of its parent hyperparameter tuning jobs. You can also change hyperparameters from tunable to static, and from static to tunable, but the total number of static plus tunable hyperparameters must remain the same as it is in all parent jobs. The training algorithm image can also be a different version from the version used in the parent hyperparameter tuning job. When you use transfer learning, changes in the dataset or the algorithm that significantly affect the value of the objective metric might reduce the usefulness of using warm start tuning.

Warm Start Tuning Restrictions

The following restrictions apply to all warm start tuning jobs:

- A tuning job can have a maximum of 5 parent jobs, and all parent jobs must be in a terminal state (Completed, Stopped, or Failed) before you start the new tuning job.
- The objective metric used in the new tuning job must be the same as the objective metric used in the parent jobs.
- The total number of static plus tunable hyperparameters must remain the same between parent jobs and the new tuning job. Because of this, if you think you might want to use a hyperparameter as tunable in a future warm start tuning job, you should add it as a static hyperparameter when you create a tuning job.
- The type of each hyperparameter (continuous, integer, categorical) must not change between parent jobs and the new tuning job.
• The number of total changes from tunable hyperparameters in the parent jobs to static
hyperparameters in the new tuning job, plus the number of changes in the values of static
hyperparameters cannot be more than 10. Each value in a categorical hyperparameter counts against
this limit. For example, if the parent job has a tunable categorical hyperparameter with the possible
values red and blue, you change that hyperparameter to static in the new tuning job, that counts as
2 changes against the allowed total of 10. If the same hyperparameter had a static value of red in the
parent job, and you change the static value to blue in the new tuning job, it also counts as 2 changes.

• Warm start tuning is not recursive. For example, if you create MyTuningJob3 as a warm start tuning
job with MyTuningJob2 as a parent job, and MyTuningJob2 is itself an warm start tuning job with
a parent job MyTuningJob1, the information that was learned when running MyTuningJob1 is not
used for MyTuningJob3. If you want to use the information from MyTuningJob1, you must explicitly
add it as a parent for MyTuningJob3.

• The training jobs launched by every parent job in a warm start tuning job count against the 500
maximum training jobs for a tuning job.

• Hyperparameter tuning jobs created before October 1, 2018 cannot be used as parent jobs for warm
start tuning jobs.

Warm Start Tuning Sample Notebook

For a sample notebook that shows how to use warm start tuning, see https://github.com/awslabs/
amazon-sagemaker-examples/blob/master/hyperparameter_tuning/image_classification_warmstart/
hpo_image_classification_warmstart.ipynb. For instructions how to create and access Jupyter notebook
instances that you can use to run the example in SageMaker, see Example Notebooks (p. 130). Once you
have created a notebook instance and opened it, select the SageMaker Examples tab to see a list of all
the SageMaker samples. The warm start tuning example notebook is located in the Hyperparameter
tuning section, and is named hpo_image_classification_warmstart.ipynb. To open a notebook,
click on its Use tab and select Create copy.

Create a Warm Start Tuning Job

You can use either the low-level AWS SDK for Python (Boto 3) or the high-level SageMaker Python SDK
to create a warm start tuning job.

Topics
• Create a Warm Start Tuning Job ( Low-level SageMaker API for Python (Boto 3)) (p. 1735)
• Create a Warm Start Tuning Job (SageMaker Python SDK) (p. 1736)

Create a Warm Start Tuning Job ( Low-level SageMaker API for Python (Boto 3))

To use warm start tuning, you specify the values of a HyperParameterTuningJobWarmStartConfig
object, and pass that as the WarmStartConfig field in a call to CreateHyperParameterTuningJob.

The following code shows how to create a HyperParameterTuningJobWarmStartConfig object and
pass it to CreateHyperParameterTuningJob job by using the low-level SageMaker API for Python
(Boto 3).

Create the HyperParameterTuningJobWarmStartConfig object:

```python
code
warm_start_config = {
    "ParentHyperParameterTuningJobs" : [
        {"HyperParameterTuningJobName" : 'MyParentTuningJob'}
    ],
    "WarmStartType" : "IdenticalDataAndAlgorithm"
}
```
Create the warm start tuning job:

```python
smclient = boto3.Session().client('sagemaker')
smclient.create_hyper_parameter_tuning_job(HyperParameterTuningJobName =
    'MyWarmStartTuningJob',
    HyperParameterTuningJobConfig = tuning_job_config, # See notebook for tuning
    configuration
    TrainingJobDefinition = training_job_definition, # See notebook for job definition
    WarmStartConfig = warm_start_config)
```

Create a Warm Start Tuning Job (SageMaker Python SDK)

To use the Amazon SageMaker Python SDK to run a warm start tuning job, you:

- Specify the parent jobs and the warm start type by using a `WarmStartConfig` object.
- Pass the `WarmStartConfig` object as the value of the `warm_start_config` argument of a `HyperparameterTuner` object.
- Call the `fit` method of the `HyperparameterTuner` object.

For more information about using the Amazon SageMaker Python SDK for hyperparameter tuning, see https://github.com/aws/sagemaker-python-sdk#sagemaker-automatic-model-tuning.

This example uses an estimator that uses the Image Classification Algorithm (p. 1356) algorithm for training. The following code sets the hyperparameter ranges that the warm start tuning job searches within to find the best combination of values. For information about setting hyperparameter ranges, see Define Hyperparameter Ranges (p. 1718).

```python
hyperparameter_ranges = {'learning_rate': ContinuousParameter(0.0, 0.1),
                        'momentum': ContinuousParameter(0.0, 0.99)}
```

The following code configures the warm start tuning job by creating a `WarmStartConfig` object.

```python
from sagemaker.tuner import WarmStartConfig, WarmStartTypes
parent_tuning_job_name = "MyParentTuningJob"
warm_start_config = WarmStartConfig(type=WarmStartTypes.IDENTICAL_DATA_AND_ALGORITHM,
                                     parents=(parent_tuning_job_name))
```

Now set the values for static hyperparameters, which are hyperparameters that keep the same value for every training job that the warm start tuning job launches. In the following code, `imageclassification` is an estimator that was created previously.

```python
imageclassification.set_hyperparameters(num_layers=18,
                                        image_shape='3,224,224',
                                        num_classes=257,
                                        num_training_samples=15420,
                                        mini_batch_size=128,
                                        epochs=30,
                                        optimizer='sgd',
                                        top_k='2',
                                        precision_dtype='float32',
                                        augmentation_type='crop')
```

Now create the `HyperparameterTuner` object and pass the `WarmStartConfig` object that you previously created as the `warm_start_config` argument.

```python
tuner_warm_start = HyperparameterTuner(imageclassification,
```

1736
Finally, call the `fit` method of the `HyperparameterTuner` object to launch the warm start tuning job.

```python
tuner_warm_start.fit(
    {'train': s3_input_train, 'validation': s3_input_validation},
    include_cls_metadata=False)
```

## Resource Limits for Automatic Model Tuning

SageMaker sets the following default limits for resources used by automatic model tuning:

- Number of parallel (concurrent) hyperparameter tuning jobs: 100
- Number of hyperparameters that can be searched: 20
  
  **Note**
  Every possible value in a categorical hyperparameter counts against this limit.

- Number of metrics defined per hyperparameter tuning job: 20
- Number of parallel (concurrent) training jobs per hyperparameter tuning job: 10
  
  **Note**
  This can be increased to hundreds.

- [Bayesian search strategy] Number of training jobs per hyperparameter tuning job: 500
- [Random search strategy] Number of training jobs per hyperparameter tuning job: 500
  
  **Note**
  This can be increased up to ten thousand.

- Maximum run time for a hyperparameter tuning job: 30 days

When you plan hyperparameter tuning jobs, you also have to take into account the limits on training resources. For information about the default resource limits for SageMaker training jobs, see [SageMaker Limits](#). Every concurrent training instance on which all of your hyperparameter tuning jobs run counts against the total number of training instances allowed. For example, if you run 10 concurrent hyperparameter tuning jobs, each of those hyperparameter tuning jobs runs 100 total training jobs and 20 concurrent training jobs. Each of those training jobs runs on one `ml.m4.xlarge` instance. The following limits apply:

- Number of concurrent hyperparameter tuning jobs: You don't need to increase the limit, because 10 tuning jobs is below the limit of 100.
- Number of training jobs per hyperparameter tuning job: You don't need to increase the limit, because 100 training jobs is below the limit of 500.
- Number of concurrent training jobs per hyperparameter tuning job: You need to request a limit increase to 20, because the default limit is 10.
- SageMaker training `ml.m4.xlarge` instances: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
- SageMaker training total instance count: You need to request a limit increase to 200, because you have 10 hyperparameter tuning jobs, each of which is running 20 concurrent training jobs. The default limit is 20 instances.
To request a quota increase:

1. Open the AWS Support Center page, sign in if necessary, and then choose Create case.
2. On the Create case page, choose Service limit increase.
4. On the Requests panel for Request 1, select the Region, the resource Limit to increase and the New Limit value you are requesting. Select Add another request if you have additional requests for quota increases.
5. In the Case description panel, provide a description of your use case.
6. In the Contact options panel, select your preferred Contact methods (Web, Chat or Phone) and then choose Submit.

Best Practices for Hyperparameter Tuning

Hyperparameter optimization is not a fully-automated process. To improve optimization, use the following guidelines when you create hyperparameters.

Topics
- Choosing the Number of Hyperparameters (p. 1739)
- Choosing Hyperparameter Ranges (p. 1739)
- Using Logarithmic Scales for Hyperparameters (p. 1739)
Choosing the Number of Hyperparameters

The computational complexity of a hyperparameter tuning job depends primarily on the number of hyperparameters whose range of values Amazon SageMaker has to search through during optimization. Although you can simultaneously specify up to 20 hyperparameters to optimize for a tuning job, limiting your search to a much smaller number is likely to give you better results.

Choosing Hyperparameter Ranges

The range of values for hyperparameters that you choose to search can significantly affect the success of hyperparameter optimization. Although you might want to specify a very large range that covers every possible value for a hyperparameter, you get better results by limiting your search to a small range of values. If you know that you get the best metric values within a subset of the possible range, consider limiting the range to that subset.

Using Logarithmic Scales for Hyperparameters

During hyperparameter tuning, SageMaker attempts to figure out if your hyperparameters are log-scaled or linear-scaled. Initially, it assumes that hyperparameters are linear-scaled. If they are in fact log-scaled, it might take some time for SageMaker to discover that fact. If you know that a hyperparameter is log-scaled and can convert it yourself, doing so could improve hyperparameter optimization.

Choosing the Best Number of Concurrent Training Jobs

When setting the resource limit MaxParallelTrainingJobs for the maximum number of concurrent training jobs that a hyperparameter tuning job can launch, consider the following tradeoff. Running more hyperparameter tuning jobs concurrently gets more work done quickly, but a tuning job improves only through successive rounds of experiments. Typically, running one training job at a time achieves the best results with the least amount of compute time.

Running Training Jobs on Multiple Instances

When a training job runs on multiple instances, hyperparameter tuning uses the last-reported objective metric value from all instances of that training job as the value of the objective metric for that training job. Design distributed training jobs so that the objective metric reported is the one that you want.

Get Started with Distributed Training

If you’re familiar with distributed training, follow one of the links to your preferred strategy or framework to get started. Otherwise, continue on to the next section to learn some distributed training concepts.

SageMaker distributed training libraries:

- SageMaker's Distributed Data Parallel Library (p. 1747)
- SageMaker's Distributed Model Parallel (p. 1761)

Basic Distributed Training Concepts

SageMaker’s distributed training libraries use the following distributed training terms and features.

Datasets and Batches

- **Training Dataset**: All of the data you use to train the model.
- **Global batch size**: The number of records selected from the training dataset in each iteration to send to the GPUs in the cluster. This is the number of records over which the gradient is computed at each iteration. If data parallelism is used, it is equal to the total number of model replicas multiplied by the per-replica batch size: global batch size = # model replicas x per-replica batch size. A single batch of global batch size is often referred to as the *mini-batch* in machine learning literature.
- **Per-replica batch size**: When data parallelism is used, this is the number of records sent to each model replica. Each model replica performs a forward and backward pass with this batch to calculate weight updates. The resulting weight updates are synchronized (averaged) across all replicas before the next set of per-replica batches are processed.
- **Micro-batch**: A subset of the mini-batch or, if hybrid model and data parallelism is used, it is a subset of the per-replica sized batch. When you use SageMaker’s distributed model parallelism library, each micro-batch is fed into the training pipeline one-by-one and follows an *execution schedule* defined by the library’s runtime.

Training

- **Epoch**: One training cycle through the entire dataset. It is common to have multiple iterations per an epoch. The number of epochs you use in training is unique on your model and use case.
- **Iteration**: A single forward and backward pass performed using a global batch sized batch (a mini-batch) of training data. The number of iterations performed during training is determined by the global batch size and the number of epochs used for training. For example, if a dataset includes 5,000 samples, and you use a global batch size of 500, it will take 10 iterations to complete a single epoch.
- **Learning rate**: A variable that influences the amount that weights are changed in response to the calculated error of the model. The learning rate plays an important role in the model’s ability to converge as well as the speed and optimality of convergence.

Instances and GPUs

- **Instances**: An AWS machine learning compute instance. These are also referred to as *nodes*.
- **Cluster size**: When using SageMaker’s distributed training library, this is the number of instances multiplied by the number of GPUs in each instance. For example, if you use two ml.p3.8xlarge instances in a training job, which have 4 GPUs each, the cluster size is 8. While increasing cluster size can lead to faster training times, communication between instances must be optimized; Otherwise,
communication between the nodes can add overhead and lead to slower training times. The SageMaker distributed training library is designed to optimize communication between AWS ML compute instances, leading to higher device utilization and faster training times.

**Distributed Training Solutions**

- **Data parallelism**: A strategy in distributed training where a training dataset is split up across multiple processing nodes (such as AWS ML Instances), and each processing node contains a *replica* of the model. Each node receives different batches of training data, performs a forward and backward pass, and shares weight updates with the other nodes for synchronization before moving on to the next batch and ultimately another epoch.

- **Model parallelism**: A strategy in distributed training where the model partitioned across multiple processing nodes (such as AWS ML Instances). The model might be complex and have a large number of hidden layers and weights, making it unable to fit in the memory of a single node. Each node carries a subset of the model, through which the data flows and the transformations are shared and compiled. The efficiency of model parallelism, in terms of GPU utilization and training time, is heavily dependent on how the model is partitioned and the execution schedule used to perform forward and backward passes.

- **Pipeline Execution Schedule (Pipelining)**: The pipeline execution schedule determines the order in which computations (micro-batches) are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism and overcome the performance loss due to sequential computation by having the GPUs compute simultaneously on different data samples. To learn more, see Pipeline Execution Schedule.

**Example**

The following example demonstrates how these terms might be used to describe a training job that uses hybrid model and data parallelism:

A 2-way data parallelism and 4-way model parallelism training job is launched with a global batch size of 64 images. This training job requires a total of 8 GPUs. Each of the two model replicas processes a per-replica batch of size 32. During the forward and backward pass, a per-replica batch is further divided up into micro-batches. These micro-batches are processed in an interleaved fashion using a pipelined execution schedule.

The training dataset includes 640 images, and so a single epoch takes 10 iterations.

**Advanced Concepts**

Machine Learning (ML) practitioners commonly face two scaling challenges when training models: *scaling model size* and *scaling training data*. While model size and complexity can result in better accuracy, there is a limit to the model size you can fit into a single CPU or GPU. Furthermore, scaling model size may result in more computations and longer training times.

Not all models handle training data scaling equally well. Some algorithms need to ingest all the training data in memory for training. They only scale vertically, and to bigger and bigger instance types. Some algorithms have the disadvantage of scaling super-linearly with dataset size. For example, the computational load of a nearest-neighbor search for all records of an N-rows dataset scales in N squared. In most cases, scaling training data results in longer training times.

Deep Learning (DL) is a specific family of ML algorithms consisting of several layers of artificial neural networks. The most common training method is with mini-batch Stochastic Gradient Descent (SGD). In mini-batch SGD, the model is trained by conducting small iterative changes of its coefficients in the direction that reduces its error. Those iterations are conducted on equally sized subsamples of the training dataset called *mini-batches*. For each mini-batch, the model is run in each record of the mini-batch, its error measured and the gradient of the error estimated. Then the average gradient is measured...
across all the records of the mini-batch and provides an update direction for each model coefficient. One full pass over the training dataset is called an epoch. Model trainings commonly consist of dozens to hundreds of epochs. Mini-batch SGD has several benefits: First, its iterative design makes training time theoretically linear of dataset size. Second, in a given mini-batch each record is processed individually by the model without need for inter-record communication other than the final gradient average. The processing of a mini-batch is consequently particularly suitable for parallelization and distribution.

Parallelizing SGD training by distributing the records of a mini-batch over different computing devices is called data parallel distributed training, and is the commonly used DL distribution paradigm. Data parallel training is a relevant distribution strategy to scale the mini-batch size and process each mini-batch faster. However, data parallel training comes with the extra complexity of having to compute the mini-batch gradient average with gradients coming from all the workers and communicating it to all the workers, a step called allreduce that can represent a growing overhead, as the training cluster is scaled, and that can also drastically penalize training time if improperly implemented or implemented over improper hardware substracts.

Data parallel SGD still requires developers to be able to fit at least the model and a single record in a computing device, like a single CPU or GPU. When training very large models such as large transformers in Natural Language Processing (NLP), or segmentation models over high-resolution images, there may be situations in which this is not feasible. An alternative way to break up the workload is to partition the model over multiple computing devices, an approach called model-parallel distributed training.

**Strategies**

Distributed training is usually split by two approaches: data parallel and model parallel. Data parallel is the most common approach to distributed training: You have a lot of data, batch it up, and send blocks of data to multiple CPUs or GPUs (nodes) to be processed by the neural network or ML algorithm, then combine the results. The neural network is the same on each node. A model parallel approach is used with large models that won’t fit in a node’s memory in one piece; it breaks up the model and places different parts on different nodes. In this situation, you need to send your batches of data out to each node so that the data is processed on all parts of the model.

The terms network and model are often used interchangeably: A large model is really a large network with many layers and parameters. Training with a large network produces a large model, and loading the model back onto the network with all your pre-trained parameters and their weights loads a large model into memory. When you break apart a model to split it across nodes, you’re also breaking apart the underlying network. A network consists of layers, and to split up the network, you put layers on different compute devices.

A common pitfall of naively splitting layers across devices is severe GPU under-utilization. Training is inherently sequential in both forward and backward passes, and at a given time, only one GPU can actively compute, while the others wait on the activations to be sent. Modern model parallel libraries solve this problem by using pipeline execution schedules to improve device utilization. However, only the Amazon SageMaker's distributed model parallel library includes automatic model splitting. The two core features of the library, automatic model splitting and pipeline execution scheduling, simplifies the process of implementing model parallelism by making automated decisions that lead to efficient device utilization.

**Train with Data Parallel and Model Parallel**

If you are training with a large dataset, start with a data parallel approach. If you run out of memory during training, you may want to switch to a model parallel approach, or try hybrid model and data parallelism. You can also try the following to improve performance with data parallel:

- Change your model’s hyperparameters.
- Reduce the batch size.
- Keep reducing the batch size until it fits. If you reduce batch size to 1, and still run out of memory, then you should try model-parallel training.
Try gradient compression (fp16, fp8):

• On NVIDIA TensorCore-equipped hardware, using mixed-precision training creates both speed-up and memory consumption reduction.

Try reducing the input size:

• Reduce the NLP sequence length if you increase the sequence link, need to adjust the batch size down, or adjust the GPUs up to spread the batch.
• Reduce image resolution.

Check if you use batch normalization, since this can impact convergence. When you use distributed training, your batch is split across GPUs and the effect of a much lower batch size can be a higher error rate thereby disrupting the model from converging. For example, if you prototyped your network on a single GPU with a batch size of 64, then scaled up to using four p3dn.24xlarge, you now have 32 GPUs and your per-GPU batch size drops from 64 to 2. This will likely break the convergence you saw with a single node.

Start with model-parallel training when:

• Your model does not fit on a single device.
• Due to your model size, you’re facing limitations in choosing larger batch sizes, such as if your model weights take up most of your GPU memory and you are forced to choose a smaller, suboptimal batch size.

To learn more about the SageMaker distributed libraries, see the following:

• SageMaker's Distributed Data Parallel Library (p. 1747)
• SageMaker's Distributed Model Parallel (p. 1761)

Optimize Distributed Training

Customize hyperparameters for your use case and your data to get the best scaling efficiency. In the following discussion, we highlight some of the most impactful training variables and provide references to state-of-the-art implementations so you can learn more about your options. Also, we recommend that you refer to your preferred framework's distributed training documentation.

• Apache MXNet distributed training
• PyTorch distributed training
• TensorFlow distributed training

Batch Size

SageMaker distributed toolkits generally allow you to train on bigger batches. For example, if a model fits within a single device but can only be trained with a small batch size, using either model-parallel training or data parallel training enables you to experiment with larger batch sizes.

Be aware that batch size directly influences model accuracy by controlling the amount of noise in the model update at each iteration. Increasing batch size reduces the amount of noise in the gradient estimation, which can be beneficial when increasing from very small batches sizes, but can result in degraded model accuracy as the batch size increases to large values.

Tip
Adjust your hyperparameters to ensure that your model trains to a satisfying convergence as you increase its batch size.
A number of techniques have been developed to maintain good model convergence when batch is increased.

**Mini-Batch Size**

In SGD, the mini-batch size quantifies the amount of noise present in the gradient estimation. A small mini-batch results in a very noisy mini-batch gradient, which is not representative of the true gradient over the dataset. A large mini-batch results in a mini-batch gradient close to the true gradient over the dataset and potentially not noisy enough—likely to stay locked in irrelevant minima.

To learn more about these techniques, see the following papers:

- Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Goya et al.
- PowerAI DDL, Cho et al.
- Scale Out for Large Minibatch SGD: Residual Network Training on ImageNet-1K with Improved Accuracy and Reduced Time to Train, Codreanu et al.
- ImageNet Training in Minutes, You et al.
- Large Batch Training of Convolutional Networks, You et al.
- Large Batch Optimization for Deep Learning: Training BERT in 76 Minutes, You et al.
- Accelerated Large Batch Optimization of BERT Pretraining in 54 minutes, Zheng et al.
- Deep Gradient Compression, Lin et al.

**Scenarios**

The following sections cover scenarios in which you may want to scale up training, and how you can do so using AWS resources.

**Scaling from a Single GPU to Many GPUs**

The amount of data or the size of the model used in machine learning can create situations in which the time to train a model is longer than you are willing to wait. Sometimes, the training doesn't work at all because the model or the training data is too large. One solution is to increase the number of GPUs you use for training. On an instance with multiple GPUs, like a p3.16xlarge that has eight GPUs, the data and processing is split across the eight GPUs. When you use distributed training libraries, this can result in a near-linear speedup in the time it takes to train your model. It takes slightly over 1/8 the time it would have taken on p3.2xlarge with one GPU.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>GPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>p3.2xlarge</td>
<td>1</td>
</tr>
<tr>
<td>p3.8xlarge</td>
<td>4</td>
</tr>
<tr>
<td>p3.16xlarge</td>
<td>8</td>
</tr>
<tr>
<td>p3dn.24xlarge</td>
<td>8</td>
</tr>
</tbody>
</table>

**Note**

The ml instance types used by SageMaker training have the same number of GPUs as the corresponding p3 instance types. For example, ml.p3.8xlarge has the same number of GPUs as p3.8xlarge - 4.
Scaling from a Single Instance to Multiple Instances

If you want to scale your training even further, you can use more instances. However, you should choose a larger instance type before you add more instances. Review the previous table to see how many GPUs are in each p3 instance type.

If you have made the jump from a single GPU on a p3.2xlarge to four GPUs on a p3.8xlarge, but decide that you require more processing power, you may see better performance and incur lower costs if you choose a p3.16xlarge before trying to increase instance count. Depending on the libraries you use, when you keep your training on a single instance, performance is better and costs are lower than a scenario where you use multiple instances.

When you are ready to scale the number of instances, you can do this with SageMaker Python SDK's estimator function by setting your instance_count. For example, you can set instance_type = p3.16xlarge and instance_count = 2. Instead of the eight GPUs on a single p3.16xlarge, you have 16 GPUs across two identical instances. The following chart shows scaling and throughput starting with eight GPUs on a single instance and increasing to 64 instances for a total of 256 GPUs.
Availability Zones and Network Backplane

With multiple instances, it’s important to understand the network that connects the instances, how they read the training data, and how they share information between themselves (for example, communication between the nodes in the cluster when doing an `AllReduce` operation).

First, your instances need to be in the same Region and same Availability Zone. For example, instances in us-west-2 must all be in us-west-2a. When you use the SageMaker Python SDK, this is handled for you. If you use Amazon EC2 and orchestrate your own training clusters, you need to be aware of this, or your training speeds suffer.

Your training data should also be in the same Availability Zone. When you use a SageMaker estimator, you pass in the Region and the S3 bucket, and if the data is not in the Region you set, you get an error.

Optimized GPU, Network, and Storage

The `p3dn.24xlarge` instance type was designed for fast local storage and a fast network backplane with up to 100 gigabits, and we highly recommend it as the most performant option for distributed training. SageMaker supports streaming data modes from S3, referred to as `pipe` mode. For HPC loads like distributed training, we recommend Amazon Fsx for your file storage.

Custom Training Scripts

While SageMaker makes it simple to deploy and scale the number of instances and GPUs, depending on your framework of choice, managing the data and results can be very challenging, which is why external supporting libraries are often used. This most basic form of distributed training requires modification of your training script to manage the data distribution.

SageMaker also supports Horovod and implementations of distributed training native to each major deep learning framework. If you choose to use examples from these frameworks, you can follow SageMaker’s container guide for Deep Learning Containers, and various example notebooks that demonstrate implementations.

SageMaker Built-In Distributed Training Features

The SageMaker built-in libraries of algorithms consists of 18 popular machine learning algorithms. Many of them were rewritten from scratch to be scalable and distributed out of the box. If you want to use distributed deep learning training code, we recommend Amazon SageMaker’s distributed training libraries. SageMaker’s distributed training libraries make it easier for you to write highly scalable and cost-effective custom data parallel and model parallel deep learning training jobs.

SageMaker distributed training libraries offer both data parallel and model parallel training strategies. It combines software and hardware technologies to improve inter-GPU and inter-node communications. It extends SageMaker’s training capabilities with built-in options that require only small code changes to your training scripts.

- SageMaker’s Distributed Data Parallel Library (p. 1747)
- SageMaker’s Distributed Model Parallel (p. 1761)

SageMaker's Distributed Data Parallel Library

Important
To use new features with an existing notebook instance or Studio application, restart the notebook instance or Studio application to get the latest updates.
SageMaker's distributed data parallel library extends SageMaker's training capabilities on deep learning models with near-linear scaling efficiency, achieving fast time-to-train with minimal code changes.

- The library optimizes your training job for AWS network infrastructure and Amazon EC2 instance topology.
- The library takes advantage of gradient updates to communicate between nodes with a custom AllReduce algorithm.

When training a model on a large amount of data, machine learning practitioners often turn to distributed training to reduce the time to train. In some cases, where time is of the essence, the business requirement is to finish training as quickly as possible or at least within a constrained time period. Then, distributed training is scaled to use a cluster of multiple nodes—not just multiple GPUs in a computing instance, but multiple instances with multiple GPUs. As the cluster size increases, so does the significant drop in performance. This drop in performance is primarily caused by the communications overhead between nodes in a cluster.

SageMaker's distributed library offers two options for distributed training: model parallel and data parallel. This guide focuses on how to train models using a data parallel strategy. For more information on training with a model-parallel strategy, refer to SageMaker's Distributed Model Parallel (p. 1761).

Introduction to SageMaker's Distributed Data Parallel Library

Why Use SageMaker Distributed Data Parallel Library?

SageMaker's distributed data parallel library addresses communications overhead in two ways:

1. The library performs AllReduce, a key operation during distributed training that is responsible for a large portion of communication overhead.
2. The library performs optimized node-to-node communication by fully utilizing AWS's network infrastructure and Amazon EC2 instance topology.

Use this data parallel library to increase speed by up to 25% in training models such as BERT. While implementations like Horovod offer sub-linear performance at scale, this library offers near-linear performance at scale. This means that you get a faster training time and a lower cost to train a model.

Training Benchmarks

PyTorch with SageMaker's data parallel library
Using instance type `p3dn.24xlarge` and on 2, 4, and 8 node clusters:

- **BERT**: When used with PyTorch, the SageMaker library is 41%, 52%, and 13% faster than PyTorch-DDP.
- **MaskRCNN**: When used with PyTorch, the SageMaker library is 4%, 19%, and 15% faster than PyTorch-DDP.

These benchmarks were run on PyTorch v1.6 using `ml.p3dn.24xlarge` instances. You can find the training code on the SageMaker examples website. The examples website also has benchmark training code for these models using TensorFlow 2.3.

### Optimal Bandwidth Use with Balanced Fusion Buffer

SageMaker's distributed data parallel library uses a communication pattern similar to parameter servers to reduce the amount of data transferred and the number of steps involved in averaging gradients from multiple GPUs. It also uses a new technique called balanced fusion buffers to make optimal use of the bandwidth available across all nodes in the cluster.

One key disadvantage of traditional parameter servers is their suboptimal use of available network bandwidth. Parameter servers treat variables as atomic units and place each variable on one server. Since gradients become available sequentially during the backward pass, at any given instant, there is imbalance in the volume of data being sent and received from different servers. Some servers are receiving and sending more data, some less, and some none. This problem becomes worse as the number of parameter servers increases.

The library addresses these problems by introducing *balanced fusion buffers*. A balanced fusion buffer is a buffer in the GPU that holds the gradients until the size of the buffer exceeds a threshold. In a setup with N parameter servers, when the buffer exceeds the threshold, the balanced fusion buffer is copied to CPU memory, sharded into N parts, and the ith part is sent to the ith parameter server. Each server receives exactly the same number of bytes from a balanced fusion buffer. The ith server receives the ith partition of the balanced fusion buffer from all workers, sums them up, and sends the results back to all workers.

</tbody>
</table>
Since all the servers participate equally in averaging each balanced fusion buffer, server bandwidth is efficiently utilized.

**Optimal GPU Usage with Efficient `AllReduce` Overlapping with a Backward Pass**

SageMaker's distributed data parallel library achieves optimal overlapping of the `AllReduce` operation with the backward pass, significantly improving the GPU utilization, and achieves near-linear scaling efficiency and faster time to train by optimizing tasks between CPUs and GPUs. The library performs `AllReduce` in parallel while GPU is computing gradients without taking away additional GPU cycles, which makes the library faster.

- **Leverages CPUs:** The library uses CPUs to `AllReduce` gradients, offloading this task from the GPUs.
- **Improved GPU usage:** The cluster's GPUs focus on computing gradients, improving their utilization throughout training.

**Use the SageMaker Distributed Data Parallel API**

Use this page to learn how you can import and use SageMaker's distributed data parallel library. For API specifications, refer to distributed data parallel in the SageMaker Python SDK documentation.

**Use SageMaker's Distributed Data Parallel Library**

To use SageMaker's distributed data parallel library, you start with a training script. Just as with any training job on SageMaker, you use your training script to launch a SageMaker training job. To get started, we recommend that you use the SageMaker data parallel library in the following ways:

- Using a SageMaker notebook instance
- Using SageMaker Studio

With either option, you can then use the Distributed Training Jupyter Notebook Examples (p. 1783) provided with this documentation to get started.

**Use the Data Parallel Library with SageMaker's Python SDK**

To use SageMaker's distributed data parallel library, you must create a training script for one of the supported frameworks and launch the training job using the SageMaker Python SDK. To learn how you can incorporate the library into a training script, see Modify Your Training Script Using SageMaker's Distributed Model Parallel Library (p. 1770). The library API documentation is located in the SageMaker Python SDK. See SageMaker's data parallel API documentation.

SageMaker supports the following training environment configurations:

- You can use a prebuilt TensorFlow or PyTorch container.
- You can customize SageMaker prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example of how you can extend a pre-built container, see Extend a Prebuilt Container.

To extend a pre-built container, or adapt your own container to use the library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed data parallel library is included in all CUDA 11 (`cu11x`) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See Available Deep Learning Containers Images for a list of available images.

**Important**

It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed data parallel
library. All images that include TensorFlow 2.4.1 and PyTorch 1.8.1 versions and later support EFA instance types (ml.p3dn.24xlarge, ml.p4d.24xlarge).

For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a FROM statement similar to the following:

```
# SageMaker PyTorch image
FROM 762104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu111-ubuntu18.04
ENV PATH="/opt/ml/code:${PATH}"
# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py
# Defines cifar10.py as script entrypoint
ENV SAGEMAKER_PROGRAM cifar10.py
```

- You can adapt your own Docker container to work with SageMaker using the SageMaker Training toolkit. For an example, see Adapting Your Own Training Container.

In all cases, you launch your job using a SageMaker Python SDK Estimator.

If you are using the SageMaker pre-built PyTorch or TensorFlow containers, see the following section to learn how configure an Estimator to use the library.

If you bring your own container or extend a pre-built container, you can create an instance of the Estimator class with the desired Docker image.

**TensorFlow Estimator**

You can use SageMaker's distributed data parallel library API by specifying `smdistributed.dataparallel` as the distribution strategy in the SageMaker TensorFlow Estimator API. Refer to SageMaker TensorFlow Estimator API documentation for full details about the API.

```python
class sagemaker.tensorflow.estimator.TensorFlow(py_version=None, framework_version=None, model_dir=None, image_uri=None, distribution=None, kwargs)
```

The following two parameters of the SageMaker Python SDK TensorFlow estimator are required to use `smdistributed.dataparallel` with TensorFlow.

- **distribution(dict)(optional):** A dictionary with information on how to run distributed training (default: None).
  
  - To use `smdistributed.dataparallel` as a distribution strategy, use the following option:

    ```python
distribution = { "smdistributed": { "dataparallel": { "enabled": True } } }
```

  - **custom_mpi_options (str)(optional):** Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see Custom MPI Options (p. 1760).

    ```python
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```
**train_instance_type (str)(required)**: A type of Amazon EC2 instance to use.

- If the `smdistributed.dataparallel` distribution strategy is used, the allowed instance types are: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, it is recommended that you use an EFA supported instance, `ml.p3dn.24xlarge` or `ml.p4d.24xlarge`, with the latest supported version of PyTorch.

**Example**

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    base_job_name = "training_job_name_prefix",
    entry_point="tf-train.py",
    role="SageMakerRole",
    framework_version="2.4.1",
    # You must set py_version to py36
    py_version="py37",
    # For training with multi node distributed training, set this count.
    instance_count=2,
    # For training with p3dn instance use - ml.p3dn.24xlarge
    instance_type="ml.p3.16xlarge",
    # Training using smdistributed.dataparallel Distributed Training
    distribution={"smdistributed": {
              "dataparallel": {
                "enabled": True
              }
            }
    }
)
tf_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**

If you are using the SageMaker Python SDK 1.x, you need to use hyperparameters to specify to use `smdistributed dataparallel` as the distributed training strategy.

```python
from sagemaker.tensorflow import TensorFlow

tf_estimator = TensorFlow(
    ...  
    # Training using smdistributed.dataparallel Distributed Training
    hyperparameters={"sagemaker_distributed_dataparallel_enabled": True},
    ...
)
tf_estimator.fit("s3://bucket/path/to/training/data")
```

**PyTorch Estimator**

You can use SageMaker's distributed data parallel library API by specifying `smdistributed dataparallel` as the distribution strategy in SageMaker PyTorch Estimator API. Refer to the [SageMaker PyTorch Estimator API specification](#) for full details of the API.

```python
class sagemaker.pytorch.estimator.PyTorch(py_version=None, framework_version=None, model_dir=None, image_uri=None, hyperparameters=None, distribution=None, **kwargs)
```
The following two parameters of the SageMaker PyTorch Estimator are necessary for using smdistributed.dataparallel on SageMaker with PyTorch.

**distribution (dict)(optional):** A dictionary with information on how to run distributed training (default: None).

- To use smdistributed.dataparallel as a distribution strategy, use the following option:

  ```python
distribution={"smdistributed": { "dataparallel": { "enabled": True } } }
  ```

- **custom_mpi_options (str)(optional):** Custom MPI options. The following is an example of how you can use this parameter when defining distribution. To learn more, see Custom MPI Options (p. 1760).

  ```python
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
  ```

**train_instance_type (str)(required):** A type of Amazon EC2 instance to use.

- If the smdistributed.dataparallel distribution strategy is used, the allowed instance types are: `ml.p4d.24xlarge`, `ml.p3dn.24xlarge`, and `ml.p3.16xlarge`. For best performance, it is recommended that you use an EFA supported instance, `ml.p3dn.24xlarge` or `ml.p4d.24xlarge`, with the latest supported version of PyTorch.

**Example**

```python
from sagemaker.pytorch import PyTorch
pt_estimator = PyTorch(
    base_job_name="training_job_name_prefix",
    entry_point="pt-train.py",
    role="SageMakerRole",
    # You must set py_version to py36
    py_version="py36",
    # For training with multi node distributed training, set this count.
    # Example: 2,3,4,...8
    instance_count=2,
    # For training with p3dn instance use - ml.p3dn.24xlarge
    instance_type="ml.p3.16xlarge",
    # Training using smdistributed.dataparallel Distributed Training
    distribution="smdistributed": { "dataparallel": { "enabled": True } }
)
pt_estimator.fit("s3://bucket/path/to/training/data")
```

**Note**

If you are using SageMaker Python SDK 1.x, you need to use hyperparameters to specify smdistributed.dataparallel as the distributed training strategy.

```python
from sagemaker.pytorch import PyTorch
```
pt_estimator = PyTorch(  
...  
# Training using smdistributed.dataparallel Distributed Training  
Framework  
hyperparameters={"sagemaker_distributed_dataparallel_enabled": True},  
...  
)  
pt_estimator.fit("s3://bucket/path/to/training/data")

Modify Your Training Script using the SageMaker Data Parallel Library

Script Modification Overview

SageMaker's distributed data parallel library (the library) APIs are designed for ease of use, and to provide seamless integration with existing distributed training toolkits.

- **SageMaker Python SDK with the library API**: In most cases, all you have to change in your training script is the Horovod or other data parallel library import statements. Swap these out with the SageMaker data parallel library equivalents.
- **Focus on your model training without infrastructure management**: When training a deep learning model with the library on SageMaker, you can focus on your model training, while SageMaker does cluster management: brings up the nodes and creates the cluster, completes the training, then tears down the cluster.

To customize your own training script, you need to do the following:

- You must provide TensorFlow/PyTorch training scripts that are adapted to use the library. The following sections provide example code for this.
- Your input data must be in an S3 bucket or in FSx in the AWS Region that you will use to launch your training job. If you use the Jupyter Notebooks provided, create a SageMaker notebook instance in the same Region as the bucket that contains your input data. For more information about storing your training data, refer to the SageMaker Python SDK data inputs documentation.

Tip
Consider using FSx instead of Amazon S3 to increase training performance. It has higher throughput and lower latency than Amazon S3.

Use the following sections to see examples of training scripts that can be used to convert your TensorFlow or PyTorch training scripts. Then, use one of the example notebooks for your template to launch a training job. You'll need to swap your training script with the one that came with the notebook and modify any input functions as necessary. Once you have launched a training job, you can monitor it using Amazon CloudWatch.

Then you can see how to deploy your trained model to an endpoint by following one of the example notebooks for deploying a model.

Finally, you can follow an example notebook to test inference on your deployed model.

Modify a TensorFlow 2.x Training Script Using SMD Data Parallel

The following steps show you how to convert a TensorFlow 2.3.1 or 2.4.1 training script to utilize SageMaker's distributed data parallel library.

The library APIs are designed to be similar to Horovod APIs. Refer to the SageMaker distributed data parallel TensorFlow API documentation for additional details on each API that the library offers for TensorFlow.
1. **Import the library's TensorFlow client and initialize it:**

```python
import smdistributed.dataparallel.tensorflow as sdp
dsdp.init()
```

2. **Pin each GPU to a single `smdistributed.dataparallel` process with `local_rank`—this refers to the relative rank of the process within a given node. The `sdp.tensorflow.local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `sdp.local_rank()`.

   ```python
gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
    tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
    tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')
```

3. **Scale the learning rate by the number of workers. The `sdp.tensorflow.size()` API provides you the number of workers in the cluster. This is invoked in the next code block as `sdp.size()`.

   ```python
   learning_rate = learning_rate * sdp.size()
   ```

4. **Use the library's `DistributedGradientTape` to optimize AllReduce operations during training. This wraps `tf.GradientTape`.

   ```python
   with tf.GradientTape() as tape:
       output = model(input)
       loss_value = loss(label, output)
   # SageMaker data parallel: Wrap tf.GradientTape with the library's DistributedGradientTape
tape = sdp.DistributedGradientTape(tape)
   ```

5. **Broadcast the initial model variables from the leader node (rank 0) to all the worker nodes (ranks 1 through n). This is needed to ensure a consistent initialization across all the worker ranks. For this, you use the `sdp.tensorflow.broadcast_variables` API after the model and optimizer variables are initialized. This is invoked in the next code block as `sdp.broadcast_variables()`.

   ```python
   sdp.broadcast_variables(model.variables, root_rank=0)
sdp.broadcast_variables(opt.variables(), root_rank=0)
   ```

6. **Finally, modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.**

   ```python
   if sdp.rank() == 0:
       checkpoint.save(checkpoint_dir)
   ```

The following is an example TensorFlow2 training script for distributed training with the library:
import tensorflow as tf

# SageMaker data parallel: Import the library TF API
import smdistributed.dataparallel.tensorflow as sdp

# SageMaker data parallel: Initialize the library
sdp.init()

gpus = tf.config.experimental.list_physical_devices('GPU')
for gpu in gpus:
  tf.config.experimental.set_memory_growth(gpu, True)
if gpus:
  # SageMaker data parallel: Pin GPUs to a single library process
  tf.config.experimental.set_visible_devices(gpus[sdp.local_rank()], 'GPU')

# Prepare Dataset
dataset = tf.data.Dataset.from_tensor_slices(...)

# Define Model
mnist_model = tf.keras.Sequential(...)
loss = tf.losses.SparseCategoricalCrossentropy()

# SageMaker data parallel: Scale Learning Rate
# LR for 8 node run : 0.000125
# LR for single node run : 0.001
opt = tf.optimizers.Adam(0.000125 * sdp.size())

@tf.function
def training_step(images, labels, first_batch):
  with tf.GradientTape() as tape:
    probs = mnist_model(images, training=True)
    loss_value = loss(labels, probs)

    # SageMaker data parallel: Wrap tf.GradientTape with the library's
    # DistributedGradientTape
    tape = sdp.DistributedGradientTape(tape)

    grads = tape.gradient(loss_value, mnist_model.trainable_variables)
    opt.apply_gradients(zip(grads, mnist_model.trainable_variables))

  if first_batch:
    # SageMaker data parallel: Broadcast model and optimizer variables
    sdp.broadcast_variables(mnist_model.variables, root_rank=0)
    sdp.broadcast_variables(opt.variables(), root_rank=0)

  return loss_value

...
1. Import the library's PyTorch client and initialize it, then import the module for distributed training.

```python
import smdistributed.dataparallel.torch.distributed as dist
from smdistributed.dataparallel.torch.parallel.distributed import DistributedDataParallel as DDP
dist.init_process_group()
```

2. Pin each GPU to a single SageMaker data parallel library process with `local_rank`—this refers to the relative rank of the process within a given node.

   The `smdistributed.dataparallel.torch.get_local_rank()` API provides you the local rank of the device. The leader node is rank 0, and the worker nodes are rank 1, 2, 3, and so on. This is invoked in the next code block as `dist.get_local_rank()`.

```python
torch.cuda.set_device(dist.get_local_rank())
```

3. Wrap the PyTorch model with the library's DDP.

```python
model = ...
# Wrap model with the library's DistributedDataParallel
model = DDP(model)
```

4. Modify the `torch.utils.data.distributed.DistributedSampler` to include the cluster's information. Set `num_replicas` to the total number of GPUs participating in training across all the nodes in the cluster. This is called `world_size`. You can get `world_size` with the `smdistributed.dataparallel.torch.get_world_size()` API. This is invoked in the following code as `dist.get_world_size()`. Also supply the node rank using `smdistributed.dataparallel.torch.get_rank()`. This is invoked as `dist.get_rank()`.

```python
train_sampler = DistributedSampler(train_dataset, num_replicas=dist.get_world_size(), rank=dist.get_rank())
```

5. Modify your script to save checkpoints only on the leader node. The leader node has a synchronized model. This also avoids worker nodes overwriting the checkpoints and possibly corrupting the checkpoints.

The following is an example PyTorch training script for distributed training with the library:

```python
# SageMaker data parallel: Import the library PyTorch API
import smdistributed.dataparallel.torch.distributed as dist

# SageMaker data parallel: Import the library PyTorch DDP
from smdistributed.dataparallel.torch.parallel.distributed import DistributedDataParallel as DDP

# SageMaker data parallel: Initialize the library
dist.init_process_group()

class Net(nn.Module):
    ...
    # Define model
def train(...):
```
# Model training
def test(...):
    ...
    # Model evaluation
def main():

    # SageMaker data parallel: Scale batch size by world size
    batch_size //= dist.get_world_size() // 8
    batch_size = max(batch_size, 1)

    # Prepare dataset
    train_dataset = torchvision.datasets.MNIST(...)

    # SageMaker data parallel: Set num_replicas and rank in DistributedSampler
    train_sampler = torch.utils.data.distributed.DistributedSampler(
        train_dataset,
        num_replicas=dist.get_world_size(),
        rank=dist.get_rank())

    train_loader = torch.utils.data.DataLoader(..)

    # SageMaker data parallel: Wrap the PyTorch model with the library’s DDP
    model = DDP(Net().to(device))

    # SageMaker data parallel: Pin each GPU to a single library process.
    torch.cuda.set_device(local_rank)
    model.cuda(local_rank)

    # Train
    optimizer = optim.Adadelta(...)  
    scheduler = StepLR(...)  
    for epoch in range(1, args.epochs + 1):
        train(...)
        if rank == 0:
            test(...)
        scheduler.step()

    # SageMaker data parallel: Save model on master node.
    if dist.get_rank() == 0:
        torch.save(...)

    if __name__ == '__main__':
        main()

For more advanced usage, see the SageMaker distributed data parallel PyTorch API documentation.

**Launch a Training Job**

To launch the training job using your SageMaker distributed data parallel configured training script, you use the `Estimator.fit()` function. We recommend that you launch a training job using a SageMaker notebook instance or SageMaker Studio. To see an example of how you can launch a training job using a Studio or a notebook instance, see Distributed Training Jupyter Notebook Examples (p. 1783).

Use the following resources to learn more about using the SageMaker Python SDK with these frameworks:

- Use TensorFlow with the SageMaker Python SDK
- Using PyTorch with the SageMaker Python SDK
SageMaker distributed data parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using SageMaker's distributed data parallel library. This list includes tips that are applicable across frameworks.

Topics
- Data Preprocessing (p. 1759)
- Single vs Multiple Nodes (p. 1759)
- Debug Scaling Efficiency with Debugger (p. 1759)
- Batch Size (p. 1759)
- Custom MPI Options (p. 1760)

Data Preprocessing

If you pre-process data during training using an external library that utilizes the CPU, you may run into a CPU bottleneck because SageMaker distributed data parallel uses the CPU for all-reduce operations. You may be able to improve training time by moving pre-processing steps to a library that uses GPUs or by completing all pre-processing before training.

Single vs Multiple Nodes

It is recommended that you use this library with multiple nodes. The library can be used with a single-host, multi-device setup (for example, a single ML compute instance with multiple GPUs), however, when you use two or more nodes, the library's AllReduce operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node AllReduce efficiency.

Debug Scaling Efficiency with Debugger

You can use Amazon SageMaker Debugger to monitor and visualize CPU and GPU utilization, and other metrics of interest, during training. You can use Debugger built-in rules to monitor computational performance issues, such as CPU Bottleneck, Load Balancing, and Low GPU Utilization. You can specify these rules with Debugger configurations when you define an Amazon SageMaker Python SDK estimator. If you use AWS CLI and AWS Boto3 for training on SageMaker, you can enable Debugger as shown in Configure Debugger Using Amazon SageMaker API.

To see an example using Debugger in a SageMaker training job, you can reference one of the notebook examples in the SageMaker Notebook Examples GitHub repository. To learn more about Debugger, see Amazon SageMaker Debugger.

Batch Size

In distributed training, as more nodes are added, batch sizes should increase proportionally. To improve convergence speed as you add more nodes to your training job and increase the global batch size, increase the learning rate.

One way to achieve this is by using a gradual learning rate warmup where the learning rate is ramped up from a small to a large value as the training job progresses. This ramp avoids a sudden increase of the learning rate, allowing healthy convergence at the start of training. For example, you can use a "Linear Scaling Rule" where each time the mini-batch size is multiplied by k, the learning rate is also multiplied by k. To learn more about this technique, see the research paper, Accurate, Large Minibatch SGD: Training ImageNet in 1 Hour, Sections 2 and 3.
Custom MPI Options

The SageMaker distributed data parallel library employs Message Passing Interface (MPI), a popular standard for managing communication between nodes in a high-performance cluster, and uses NVIDIA's NCCL library for GPU-level communication. When you use the data parallel library with a TensorFlow or Pytorch Estimator, the respective container sets up the MPI environment and executes the mpirun command to start jobs on the cluster nodes.

You can set custom MPI operations using the custom_mpi_options parameter in the Estimator. Any mpirun flags passed in this field are added to the mpirun command and executed by Amazon SageMaker for training. For example, you may define the distribution parameter of an Estimator using the following to use the NCCL_DEBUG variable to print the NCCL version at the start of the program:

```
distribution = {'smdistributed':{'dataparallel':{'enabled': True, "custom_mpi_options": "-verbose -x NCCL_DEBUG=VERSION"}}}
```

Data Parallel Library FAQ

Use the following to find answers to commonly asked questions about SageMaker's data parallelism library.

Q: When using the library, how are the allreduce-supporting CPU instances managed? Do I have to create heterogeneous CPU-GPU clusters, or does the SageMaker service create extra CSs for jobs that use the library?

The library uses the CPUs available with GPU instances. No additional CS or CPU instances are launched; if your SageMaker training job is 8 node ml.p3dn.24xlarge clusters, only 8 ml.p3dn.24xlarge instances are used. No additional instances are provisioned.

Q: I have a training job taking 5 days on a single ml.p3.24xlarge instance with a set of hyperparameters H1 (learning rate, batch size, optimizer, etc). Is enabling SDP and using a 5x bigger cluster enough to experience an approximate 5x speedup? Or will I have to revisit its training hyperparameters after enabling SDP?

Enabling the library would change the overall batch size. The new overall batch size is scaled linearly with the number of training instances used. As a result of this, hyperparameters, such as learning rate, have to be changed to ensure convergence.

Q: Does the library support Spot?

Yes. You can use managed spot training. You specify the path to the checkpoint file in the SageMaker training job. You enable save/restore checkpoints in their training script as mentioned in the last step of the section called “Script Modification Overview” (p. 1754).

Q: What is the difference between the library's balanced fusion buffers and PyTorch Distributed Data Parallel (DDP) “Gradient Buckets”?

The primary difference is that DDP's fusion buffer is used for AllReduce and the library's balanced fusion buffer is used for parameter server style synchronization. The library is the first framework to shard fusion buffers in parameter server-based gradient synchronization.

From the PyTorch DDP documentation: “To improve communication efficiency, the Reducer organizes parameter gradients into buckets, and reduces one bucket at a time. Bucket size can be configured by setting the bucket_cap_mb argument in DDP constructor. The mapping from parameter gradients to buckets is determined at the construction time, based on the bucket size limit and parameter sizes.
Model parameters are allocated into buckets in (roughly) the reverse order of `Model.parameters()` from the given model. The reason for using the reverse order is because DDP expects gradients to become ready during the backward pass in approximately that order.

Q: Is the library relevant in single-host, multi-device setup?

The library can be used with a single-host, multi-device setup. However, in two or more nodes, the library’s `AllReduce` operation gives you significant performance improvement. Also, on a single host, NVLink already contributes to in-node `AllReduce` efficiency.

Q: Can the library be used with PyTorch Lightning?

No. However, with the library’s DDP for PyTorch, you can write custom DDP to achieve the functionality.

Q: Where should the training dataset be stored?

The training dataset can be stored in an S3 bucket or on an FSx drive. See this document for various supported input filesystem for a training job.

Q: When using the library, is it mandatory to have training data in FSx for Lustre? Can EFS and S3 be used?

We recommend using FSx to cut down the time to kickstart the training. It is not mandatory.

Q: Can the library be used with CPU nodes?

No. The library supports `ml.p3.16xlarge`, `ml.p3dn.24xlarge`, and `ml.p4d.24xlarge` instances at this time.

Q: What frameworks and framework versions are currently supported by the library at launch?

The library currently supports PyTorch v1.6 and Tensorflow v2.3.1. It doesn't currently support Tensorflow 1.x.

SageMaker's Distributed Model Parallel

Important

To use new features with an existing notebook instance or Studio app, restart it to get the latest updates.

Amazon SageMaker’s distributed model parallel library (the library) can be used to training large deep learning models that were previously difficult to train due to GPU memory limitations. The library automatically and efficiently splits a model across multiple GPUs and instances and coordinates model training, allowing you to increase prediction accuracy by creating larger models with more parameters.

You can use the library to automatically partition your existing TensorFlow and PyTorch workloads across multiple GPUs with minimal code changes. You can access the library's API through the SageMaker SDK.

Use the following sections to learn more about model parallelism and the SageMaker model parallel library. This library’s API documentation is located in the SageMaker Python SDK under Distributed Training APIs. To see the latest updates to the library, refer to the release notes.

Introduction to Model Parallelism

Model parallelism is the process of splitting a model up between multiple devices or nodes (such as GPU-equipped instances) and creating an efficient pipeline to train the model across these devices to maximize GPU utilization.

Use the sections on this page to learn more about model parallelism, including how it can be used to overcome issues that arise when training large ML models, and important considerations when integrating it into your ML training script.

What is Model Parallelism?

Increasing deep learning model size (layers and parameters) can result in better accuracy, however there is a limit to the maximum model size you can fit in a single GPU. When training deep learning models, GPU memory limitations can be a bottleneck in the following ways:

- They can limit the size of the model you train. Given that larger models tend to achieve higher accuracy, this directly translates to trained model accuracy.
- They can limit the batch size you train with, leading to lower GPU utilization and slower training.

To overcome the limitations associated with training a model on a single GPU, you can use model parallelism to distribute and train your model on multiple computing devices.

Important Considerations when Using Model Parallelism

When you use model parallelism, you must consider the following:

- **How you split your model across devices**: The computational graph of your model, sizes of model parameters and activations, and your resource constraints (for example, time vs. memory) determine the best partitioning strategy.

  To reduce the time and effort required to efficiently split your model, you can use automated model splitting features offered by Amazon SageMaker's distributed model parallel library.

- **Achieving parallelization**: Model training—that is, forward computations and backward propagation—is inherently sequential, where each operation must wait for its inputs to be computed by another operation. For this reason, forward and backward pass stages of deep learning training are not easily parallelizable, and naively splitting a model across multiple GPUs may lead to poor device utilization. For example, a layer on GPU $i+1$ has to wait for the output from a layer on GPU $i$, and so GPU $i+1$ remains idle during this waiting period.

  The model parallel library can achieve true parallelization by implementing pipelined execution by building an efficient computation schedule where different devices can work on forward and backward passes for different data samples at the same time.

To learn how you can use the library to efficiently split your model across devices and improve device utilization during training, see Core Features of SageMaker Distributed Model Parallel (p. 1762).

Core Features of SageMaker Distributed Model Parallel

Amazon SageMaker's distributed model parallel makes model parallelism more accessible by providing automated model splitting and sophisticated pipeline execution scheduling. The model splitting algorithms can optimize for speed or memory consumption. The library also supports manual
partitioning. When you use the library, training is executed in a pipelined fashion over microbatches to maximize GPU usage.

You can configure these features using a few lines of code when you create your training script and define your SageMaker PyTorch or Tensorflow Estimator. Use the following sections to learn more about these core features of the library.

**Automated Model Splitting**

When you use SageMaker's model parallel library, you can take advantage of automated model splitting, also referred to as automated model partitioning. The library uses a partitioning algorithm that balances memory, minimizes communication between devices, and optimizes performance. You can configure the automated partitioning algorithm to optimize for speed or memory.

Alternatively, you can use manual model splitting. We recommend automated model splitting, unless you are very familiar with the model architecture and have a good idea of how to efficiently partition your model.

**How It Works**

Auto-partitioning occurs during the first training step, when the `smp.step`-decorated function is first called. During this call, the library first constructs a version of the model on the CPU RAM (to avoid GPU memory limitations), and then analyzes the model graph and makes a partitioning decision. Based on this decision, each model partition is loaded on a GPU, and only then the first step is executed. Because of these analysis and partitioning steps, the first training step might take longer.

In either framework, the library manages the communication between devices through its own backend, which is optimized for AWS infrastructure.

The auto-partition design adapts to the characteristics of the framework, and the library does the partitioning at the granularity level that is more natural in each framework. For instance, in TensorFlow, each specific operation can be assigned to a different device, whereas in PyTorch, the assignment is done at the module level, where each module consists of multiple operations. The following section reviews the specifics of the design in each framework.

**Automated Model Splitting with PyTorch**

During the first training step, the model parallel library internally runs a tracing step that is meant to construct the model graph and determine the tensor and parameter shapes. After this tracing step, the library constructs a tree, which consists of the nested `nn.Module` objects in the model, as well as additional data gathered from tracing, such as the amount of stored `nn.Parameter` sizes, and execution time for each `nn.Module`.

Next, the library traverses this tree from the root and runs a partitioning algorithm that assigns each `nn.Module` to a device, which balances computational load (measured by module execution time) and memory use (measured by the total stored `nn.Parameter` size and activations). If multiple `nn.Modules` share the same `nn.Parameter`, then these modules are placed on the same device to avoid maintaining multiple versions of the same parameter. Once the partitioning decision is made, the assigned modules and weights are loaded to their devices.

**Automated Model Splitting with TensorFlow**

The model parallel library analyzes the sizes of the trainable variables and the graph structure, and internally uses a graph partitioning algorithm. This algorithm comes up with a device assignment for each operation, with the objective of minimizing the amount of communication needed across devices, subject to two constraints:

- Balancing the number of variables stored in each device
• Balancing the number of operations executed in each device

If you specify speed for optimize (in the model parallel parameters in the Python SDK), the library tries to balance the number of operations and tf.Variable objects in each device. Otherwise, it tries to balance the total size of tf.Variables.

Once the partitioning decision is made, the library creates a serialized representation of the subgraph that each device needs to execute and imports them onto each device. While partitioning, the library places operations that consume the same tf.Variable and operations that are part of the same Keras layer onto the same device. It also respects the colocation constraints imposed by TensorFlow. This means that, for example, if there are two Keras layers that share a tf.Variable, then all operations that are part of these layers are placed on a single device.

Comparison of Automated Model Splitting Between Frameworks

In TensorFlow, the fundamental unit of computation is a tf.Operation, and TensorFlow represents the model as a directed acyclic graph (DAG) of tf.Operations, and therefore model parallel library partitions this DAG so that each node goes to one device. Crucially, tf.Operation objects are sufficiently rich with customizable attributes, and they are universal in the sense that every model is guaranteed to consist of a graph of such objects.

PyTorch on the other hand, does not have an equivalent notion of operation that is sufficiently rich and universal. The closest unit of computation in PyTorch that has these characteristics is an nn.Module, which is at a much higher granularity level, and this is why the library does partitioning at this level in PyTorch.

Manual Model Splitting

If you want to manually specify how your model is partitioned across devices, you can use manual model splitting by using smp.partition context managers.

To use this option, set auto_partition to False, and define a default_partition in the SageMaker Python SDK. Any operation that is not explicitly placed on a partition through the smp.partition context manager is executed on the default_partition. In this case, the automated splitting logic is bypassed, and each operation is placed based on your specification. Based on the resulting graph structure, the model parallel library creates a pipelined execution schedule automatically.

Pipeline Execution Schedule

A core feature of SageMaker's distributed model parallel library is pipelined execution, which determines the order in which computations are made and data is processed across devices during model training. Pipelining is a technique to achieve true parallelization in model parallelism, by having the GPUs compute simultaneously on different data samples, and to overcome the performance loss due to sequential computation.

Pipelining is based on splitting a mini-batch into microbatches, which are fed into the training pipeline one-by-one and follow an execution schedule defined by the library runtime. A microbatch is a smaller subset of a given training mini-batch. The pipeline schedule determines which microbatch is executed by which device for every time slot.

For example, depending on the pipeline schedule and the model partition, GPU i might perform (forward or backward) computation on microbatch b while GPU i+1 performs computation on microbatch b+1, thereby keeping both GPUs active at the same time. During a single forward or backward pass, execution flow for a single microbatch might visit the same device multiple times, depending on the partitioning decision. For instance, an operation that is at the beginning of the model might be placed on the same device as an operation at the end of the model, while the operations in between are on different devices, which means this device is visited twice.
The library offers two different pipeline schedules, *simple* and *interleaved*, which can be configured using the `pipeline` parameter in the SageMaker Python SDK. In most cases, interleaved pipeline can achieve better performance by utilizing the GPUs more efficiently.

**Interleaved Pipeline**

In an interleaved pipeline, backward execution of the microbatches is prioritized whenever possible. This allows quicker release of the memory used for activations, using memory more efficiently. It also allows for scaling the number of microbatches higher, reducing the idle time of the GPUs. At steady-state, each device alternates between running forward and backward passes. This means that the backward pass of one microbatch may run before the forward pass of another microbatch finishes.

The preceding figure illustrates an example execution schedule for the interleaved pipeline over 2 GPUs. In the figure, F0 represents the forward pass for microbatch 0, and B1 represents the backward pass for microbatch 1. *Update* represents the optimizer update of the parameters. GPU0 always prioritizes backward passes whenever possible (for instance, executes B0 before F2), which allows for clearing of the memory used for activations earlier.

**Simple Pipeline**

A simple pipeline, by contrast, finishes running the forward pass for each microbatch before starting the backward pass. This means that it only pipelines the forward pass and backward pass stages within themselves. The following figure illustrates an example of how this works, over 2 GPUs.

**Pipelining Execution in Specific Frameworks**

Use the following sections to learn about the framework-specific pipeline scheduling decisions SageMaker's distributed model parallel library makes for Tensorflow and PyTorch.

**Pipeline Execution with TensorFlow**

The following image is an example of a TensorFlow graph partitioned by the model parallel library, using automated model splitting. When a graph is split, each resulting subgraph is replicated B times (except for the variables), where B is the number of microbatches. In this figure, each subgraph is replicated 2 times (B=2). An `SMPInput` operation is inserted at each input of a subgraph, and an `SMPOutput` operation is inserted at each output. These operations communicate with the library backend to transfer tensors to and from each other.

The following image is an example of 2 subgraphs split with B=2 with gradient operations added. The gradient of a `SMPInput` op is a `SMPOutput` op, and vice versa. This enables the gradients to flow backwards during back-propagation.
This GIF demonstrates an example interleaved pipeline execution schedule with $B=2$ microbatches and 2 subgraphs. Each device sequentially executes one of the subgraph replicas to improve GPU utilization. As $B$ grows larger, the fraction of idle time slots goes to zero. Whenever it is time to do (forward or backward) computation on a specific subgraph replica, the pipeline layer signals to the corresponding blue SMPInput operations to start executing.

Once the gradients from all microbatches in a single mini-batch are computed, the library combines the gradients across microbatches, which can then be applied to the parameters.

**Pipeline Execution with PyTorch**

Conceptually, pipelining follows a similar idea in PyTorch. However, since PyTorch does not involve static graphs and so the model parallel library's PyTorch feature uses a more dynamic pipelining paradigm.

As in TensorFlow, each batch is split into a number of microbatches, which are executed one at a time on each device. However, the execution schedule is handled via execution servers launched on each device. Whenever the output of a submodule that is placed on another device is needed on the current device, an execution request is sent to the execution server of the remote device along with the input tensors to the submodule. The server then executes this module with the given inputs and returns the response to the current device.

Since the current device is idle during the remote submodule execution, the local execution for the current microbatch pauses, and the library runtime switches execution to another microbatch which the current device can actively work on. The prioritization of microbatches is determined by the chosen...
pipeline schedule. For an interleaved pipeline schedule, microbatches that are in the backward stage of the computation are prioritized whenever possible.

**Use the SageMaker Distributed Model Parallel API**

To use Amazon SageMaker's distributed model parallel library, you must create a training script for one of the supported frameworks and launch the training job using the SageMaker Python SDK. To learn how you can incorporate the library into a training script, see [Modify Your Training Script Using SageMaker's Distributed Model Parallel Library](p. 1770). The library's API documentation is located in the SageMaker Python SDK. Refer to the [SageMaker's distributed model parallel API documentation](p. 1767).

SageMaker supports the following training environment configurations.

1. You can use a prebuilt TensorFlow or PyTorch container. This option is recommended for new users of the model parallel library, and is demonstrated in the example [MNIST with PyTorch 1.6 and Amazon SageMaker's distributed model parallel library](p. 1767).
2. You can extend SageMaker prebuilt containers to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. To see an example of how you can extend a pre-built container, see [Extend a Prebuilt Container](p. 1769).
3. You can adapt your own Docker container to work with SageMaker using the [SageMaker Training toolkit](p. 1767). For an example, see [Adapting Your Own Training Container](p. 1769).

For options 2 and 3 in the preceding list, refer to [Extend or Adapt A Docker Container that Contains SageMaker's Distributed Model Parallel Library](p. 1767) to learn how to install the model parallel library in an extended or customized Docker container.

In all cases, you launch your job using a SageMaker Python SDK TensorFlow or PyTorch Estimator to initialize the library and launch a training job. See the following section, [Launch a Training Job with the SageMaker Python SDK](p. 1767), to learn more.

**Important**

If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), for best performance set the following flags in the `mpirun` command. If you use one of these flags, you must use the other.

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa
```

Additionally, if you are using PyTorch, you must set the data loader variable `num_workers=0`. To learn more about the data loader requirement, see [Important Considerations](p. 1767).

**Launch a Training Job with the SageMaker Python SDK**

The SageMaker Python SDK supports managed training of TensorFlow and PyTorch models. To launch a training job using one of these frameworks, you can define a TensorFlow Estimator or a PyTorch Estimator.

The TensorFlow and PyTorch Estimator object contains a distribution parameter, which is used to enable and specify parameters for the initialization of SageMaker's distributed model parallel library. The library internally uses MPI, so in order to use model parallelism, MPI must be enabled using the distribution parameter.

The following is an example of how you can launch a new PyTorch training job with the library.

```python
sagemaker_session = sagemaker.session.Session(boto_session=session)

mpi_options = {
    "enabled" : True,
```
To enable the library, a dictionary with the keys "mpi" and "smdistributed" needs to be passed as the distribution argument of the TensorFlow and PyTorch Estimator constructors in Python SDK. For the "mpi" key, a dict must be passed which contains:

- "enabled": True to launch the training job with MPI.
- "processes_per_host": Specify the number of processes MPI should launch on each host. In SageMaker a host is a single Amazon EC2 ml instance. The SageMaker Python SDK maintains a one-to-one mapping between processes and GPUs across model and data parallelism. This means that SageMaker schedules each process on a single, separate GPU and no GPU contains more than one process. If you are using PyTorch, you must restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`. To learn more, see PyTorch (p. 1779).

**Important**

`processes_per_host` must be less than the number of GPUs per instance and typically will be equal to the number of GPUs per instance.

For example, if you use one instance with 4-way model parallelism and 2-way data parallelism, then `processes_per_host` should be `2 x 4 = 8`. Therefore, you must choose an instance that has at least 8 GPUs, such as an `ml.p3.16xlarge`.

The following image illustrates how 2-way data parallelism and 4-way model parallelism is distributed across 8 GPUs: the models is partitioned across 4 GPUs, and each partition is added to 2 GPUs.

- "custom_mpi_options": Use this key to pass any custom MPI options you might need. To avoid Docker warnings from contaminating your training logs, we recommend the following flag.

```
#--mca btl_vader_single_copy_mechanism none
```
If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), for best performance use the following flags in the `mpirun` command:

```
-x FI_EFA_USE_DEVICE_RDMA=1 -x FI_PROVIDER=efa
```

For the "smdistributed" key, a dictionary must be passed which has the only key "modelparallel". Using "modelparallel" and "dataparallel" in the same training job is not supported.

For the "modelparallel" dictionary, an inner dictionary must be passed, which enables the modelparallel library by setting "enabled": True, as well as a dict of "parameters" to customize the library. Among the parameters, the "partitions" key is required, which specifies how many model partitions are requested. To learn more about values you can use in parameters, see the SageMaker distributed data parallel API documentation.

To launch the training job using SageMaker model parallel configured training script, you use the `Estimator.fit()` function. You can launch a SageMaker training job using a SageMaker notebook instance, or locally.

- Using a SageMaker notebook instance is recommended for new users. To see an example of how you can launch a training job using a SageMaker notebook instance, see Distributed Training Jupyter Notebook Examples (p. 1783).
- You can launch locally if you have set up your AWS credentials and Region for development.

Use the following resources to learn more about using the SageMaker Python SDK with these frameworks:

- Use TensorFlow with the SageMaker Python SDK
- Use PyTorch with the SageMaker Python SDK

Extend or Adapt A Docker Container that Contains SageMaker's Distributed Model Parallel Library

To extend a pre-built container, or adapt your own container to use SageMaker's distributed model parallel library, you must use one of the PyTorch or TensorFlow GPU general framework base-images. The distributed model parallel library is included in all CUDA 11 (cu11x) TensorFlow 2.3.x and PyTorch 1.6.x versioned images and later. See Available Deep Learning Containers Images for a list of available images.

**Tip**
It is recommended that you use the image that contains the latest version of TensorFlow or PyTorch to access the most up to date version of the SageMaker distributed model parallel library.

For example, if you are using PyTorch 1.8.1, your Dockerfile should contain a `FROM` statement similar to the following:

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.8.1-gpu-py36-cu111-ubuntu18.04

# Add your dependencies here
RUN ...

ENV PATH="/opt/ml/code:${PATH}"
```
This environment variable is used by the SageMaker PyTorch container to determine our user code directory.

```
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code
```

This is because /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.

```
COPY cifar10.py /opt/ml/code/cifar10.py
```

Additionally, when you define a PyTorch or TensorFlow estimator, you must specify that the `entry_point` for your training script. This should be the same path identified with `ENV SAGEMAKER_SUBMIT_DIRECTORY` in your Dockerfile.

You must push this docker container to Amazon Elastic Container Registry (Amazon ECR) and use the image URI (`image_uri`) to define an estimator. See Extend a Prebuilt Container for more information.

For example, if your Dockerfile was defined using the preceding code block and used `name` and `tag` to push it to Amazon ECR, you would define a PyTorch estimator as follows. This example assumes you have already defined `smp_options` and `mpi_options`.

```python
smd_mp_estimator = PyTorch(
    entry_point='/opt/ml/code/pt_mnist.py',  # Identify source_dir='utils',
    role=role,
    instance_type='ml.p3.16xlarge',
    sagemaker_session=sagemaker_session,
    image_uri='aws_account_id.dkr.ecr.region.amazonaws.com/name:tag',
    instance_count=1,
    distribution={
        "smdistributed": smp_options,
        "mpi": mpi_options
    },
    base_job_name="SMD-MP-demo",
)
```

Modify Your Training Script Using SageMaker's Distributed Model Parallel Library

Use this section to learn how to customize your training script with Amazon SageMaker's distributed model parallel library-specific API functions and parameters. We recommend you use this documentation alongside the model parallel library API documentation.

The training script examples provided in these sections are simplified and designed to highlight the required changes you must make to use the library. For end to end, runnable notebook examples that demonstrate how to use a TensorFlow or PyTorch training script with the SageMaker distributed model parallel library, see Distributed Training Jupyter Notebook Examples (p. 1783).

**Topics**

- Modify a TensorFlow Training Script (p. 1770)
- Modify a PyTorch Training Script (p. 1776)

**Modify a TensorFlow Training Script**

The following are examples of training scripts that you can use to configure the SageMaker distributed model parallel library with TensorFlow versions 2.3.1 and 2.4.1 with auto-partitioning and manual
partitioning. This selection of examples also includes an example integrated with Horovod for hybrid model and data parallelism. We recommend that you review Unsupported Framework Features (p. 1771) before creating a training script.

The required modifications you must make to your training script to use the library are listed in TensorFlow (p. 1771).

To learn how to modify your training script to use hybrid model and data parallelism with Horovod, see TensorFlow with Horovod (p. 1773).

If you want to use manual partitioning, also review Manual partitioning with TensorFlow (p. 1775).

Tip
For end to end, runnable notebook examples that demonstrate how to use a TensorFlow training script with the SageMaker distributed model parallel library, see TensorFlow Examples (p. 1783).

Note that auto-partitioning is enabled by default. Unless otherwise specified, the following example scripts use auto-partitioning.

Topics
- Unsupported Framework Features (p. 1771)
- TensorFlow (p. 1771)
- TensorFlow with Horovod (p. 1773)
- Manual partitioning with TensorFlow (p. 1775)

Unsupported Framework Features

The following TensorFlow features are unsupported by the library:

- `tf.GradientTape()` is currently not supported. You can use `Optimizer.get_gradients()` or `Optimizer.compute_gradients()` instead to compute gradients.
- The `tf.train.Checkpoint.restore()` API is currently not supported. For checkpointing, use `smp.CheckpointManager` instead, which provides the same API and functionality. Note that checkpoint restores with `smp.CheckpointManager` should take place after the first step.

TensorFlow

The following training script changes are required to run a TensorFlow model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Define Keras model by inheriting from `smp.DistributedModel` instead of Keras Model class. Return the model outputs from the call method of the `smp.DistributedModel` object. Be mindful that any tensors returned from the call method will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Set `drop_remainder=True` in `tf.Dataset.batch()` method. This is to ensure that the batch size is always divisible by the number of microbatches.
4. Seed the random operations in the data pipeline using `smp.dp_rank()`, e.g., `shuffle(ds, seed=smp.dp_rank())` to ensure consistency of data samples across GPUs that hold different model partitions.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`. 1771
6. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`. The `smp.step` function must have a return value that depends on the output of `smp.DistributedModel`.

7. If there is an evaluation step, similarly place the forward logic inside an `smp.step-decorated function` and post-process the outputs using `StepOutput API`.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf
# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp
# smdistributed: Initialize
smp.init()
# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0
# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]
# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train)).shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)
# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers
    def call(self, x, training=None):
        # define forward pass and return the model output
model = MyModel()
loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")
# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)

    return grads, loss, predictions
@tf.function
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)
```
# smdistributed: Accumulate the gradients across microbatches
gradients = [g.accumulate() for g in gradients]
optimizer.apply_gradients(zip(gradients, model.trainable_variables))

# smdistributed: Merge predictions and average losses across microbatches
train_accuracy(labels, predictions.merge())
return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()

# TensorFlow with Horovod

The SageMaker distributed model parallel library can be used with Horovod for hybrid model and data parallelism. In this case, the total number of GPUs must be divisible by the number of partitions. The quotient is inferred to be the number of model replicas or data parallelism degree. For instance, if a training job is launched with 8 processes (which corresponds to 8 GPUs), and partitions is 2, then the library applies 2-way model parallelism and 4-way data parallelism over the 8 GPUs.

To access the data parallel rank and model parallel rank of a process, you can use `smp.dp_rank()` and `smp.mp_rank()`, respectively. To see all MPI primitives the library exposes, see [MPI Basics](#) in the API documentation.

If you are using Horovod, you should not directly call `hvd.init`. Instead, set "horovod" to True in the SageMaker Python SDK `modelparallel` parameters, and the library internally initializes Horovod. This is because Horovod must be initialized based on the device assignments of model partitions, and calling `hvd.init()` directly results in problems.

Furthermore, using `hvd.DistributedOptimizer` directly results in poor performance or hangs, since this implicitly places the AllReduce operation inside `smp.step`. The recommended way to use the model parallel library with Horovod is by directly calling `hvd.allreduce` after calling `accumulate()` or `reduce_mean()` on the gradients returned from `smp.step`, as seen in the following example.

The four main changes needed in the script are:

- Adding `hvd.allreduce`
- Broadcasting variables after the first batch, as required by Horovod
- Setting the "horovod" parameter to True in the `modelparallel` dict in the Python SDK
- Seeding shuffling and/or sharding operations in the data pipeline with `smp.dp_rank()`.

To learn more about the SageMaker's distributed model parallel library API, refer to the [API documentation](#).

```python
import tensorflow as tf
import horovod.tensorflow as hvd

# smdistributed: Import TF2.x API
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
```
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data(
    "MNIST-data-%d" % smp.rank()
)
x_train, x_test = x_train / 255.0, x_test / 255.0
# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: Seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True)
)

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API
class MyModel(smp.DistributedModel):
    def __init__(self):
        super(MyModel, self).__init__()
        # define layers

    def call(self, x, training=None):
        # define forward pass and return model outputs

model = MyModel()
loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@tf.function
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)
    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
def train_step(images, labels, first_batch):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    # Horovod: Allreduce the accumulated gradients
    gradients = [hvd.allreduce(g.accumulate()) for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # Horovod: Broadcast the variables after first batch
    if first_batch:
        hvd.broadcast_variables(model.variables, root_rank=0)
        hvd.broadcast_variables(optimizer.variables(), root_rank=0)

    # smdistributed: Merge predictions across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
for batch, (images, labels) in enumerate(train_ds):
    loss = train_step(images, labels, tf.constant(batch == 0))

Manual partitioning with TensorFlow

Use `smp.partition` context managers to place operations in specific partition. Any operation not placed in any `smp.partition` contexts is placed in the `default_partition`. To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import tensorflow as tf
# smdistributed: Import TF2.x API.
import smdistributed.modelparallel.tensorflow as smp

# smdistributed: Initialize
smp.init()

# Download and load MNIST dataset.
(x_train, y_train), (x_test, y_test) = tf.keras.datasets.mnist.load_data("MNIST-data-\%d" % smp.rank())
x_train, x_test = x_train / 255.0, x_test / 255.0

# Add a channels dimension
x_train = x_train[..., tf.newaxis]
x_test = x_test[..., tf.newaxis]

# smdistributed: If needed, seed the shuffle with smp.dp_rank(), and drop_remainder
# in batching to make sure batch size is always divisible by number of microbatches.
train_ds = (tf.data.Dataset.from_tensor_slices((x_train, y_train))
    .shuffle(10000, seed=smp.dp_rank())
    .batch(256, drop_remainder=True))

# smdistributed: Define smp.DistributedModel the same way as Keras sub-classing API.
class MyModel(smp.DistributedModel):
    def __init__(self):
        # define layers
        def call(self, x):
            with smp.partition(0):
                x = self.layer0(x)
            with smp.partition(1):
                return self.layer1(x)

    model = MyModel()

loss_object = tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True)
optimizer = tf.keras.optimizers.Adam()
train_accuracy = tf.keras.metrics.SparseCategoricalAccuracy(name="train_accuracy")

# smdistributed: Define smp.step. Return any tensors needed outside
@smp.step
def get_grads(images, labels):
    predictions = model(images, training=True)
    loss = loss_object(labels, predictions)

    grads = optimizer.get_gradients(loss, model.trainable_variables)
    return grads, loss, predictions

@tf.function
```
def train_step(images, labels):
    gradients, loss, predictions = get_grads(images, labels)

    # smdistributed: Accumulate the gradients across microbatches
    gradients = [g.accumulate() for g in gradients]
    optimizer.apply_gradients(zip(gradients, model.trainable_variables))

    # smdistributed: Merge predictions and average losses across microbatches
    train_accuracy(labels, predictions.merge())
    return loss.reduce_mean()

for epoch in range(5):
    # Reset the metrics at the start of the next epoch
    train_accuracy.reset_states()
    for images, labels in train_ds:
        loss = train_step(images, labels)
        accuracy = train_accuracy.result()
not used in the computation of the tensor that is fed into the `smp.DistributedModel.backward` call.

- If there are `torch.cuda synchronize()` calls in your code, you might need to call `torch.cuda.set_device(smp.local_rank())` immediately before the synchronize call. Otherwise unnecessary CUDA contexts might be created in device 0, which will needlessly consume memory.

- Since the library places `nn.Modules` on different devices, the modules in the model must not depend on any global state that is modified inside `smp.step`. Any state that remains fixed throughout training, or that is modified outside `smp.step` in a way that is visible to all processes, is allowed.

- You don't need to move the model to GPU (for example, using `model.to(device)`) when using the library. If you try to move the model to GPU before the model is partitioned (before the first `smp.step` call), the move call is ignored. The library automatically moves the part of the model assigned to a rank to its GPU. Once training with the library starts, don't move the model to CPU and use it, as it won't have correct parameters for modules not assigned to the partition held by the process. If you want to retrain a model or use it for inference without the library after it was trained using the model parallel library, the recommended way is to save the full model using our checkpointing API and load it back to a regular PyTorch Module.

- If you have a list of modules such that output of one feeds into another, replacing that list with `nn.Sequential` can significantly improve performance.

- The weight update (`optimizer.step()`) needs to happen outside of `smp.step` because that is when the entire backward pass is done and gradients are ready. When using a hybrid model with model and data parallelism, at this point, Allreduce of gradients is also guaranteed to finish.

- When using the library in combination with data parallelism, make sure that the number of batches on all data parallel ranks is the same so that Allreduce does not hang waiting for a rank which is not participating in the step.

- If you launch a training job using an ml.p4d instance type (such as ml.p4d.24xlarge), you must set the data loader variable `num_workers=0`. For example, you may define your `DataLoader` as follows:

```python
dataloader = torch.utils.data.DataLoader(
    data,
    batch_size=batch_size,
    num_workers=0,
    pin_memory=True,
    drop_last=True,
    shuffle=True,
)
```

- The inputs to `smp.step` must be the model inputs generated by `DataLoader`. This is because `smp.step` internally splits the input tensors along the batch dimension and pipelines them. This means that passing `DataLoader` itself to the `smp.step` function to generate the model inputs inside does not work.

For example, if you define a `DataLoader` as follows:

```python
train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)
```

You should access the model inputs generated by `train_loader` and pass those to an `smp.step` decorated function. Do not pass `train_loader` directly to the `smp.step` function.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        ...
        _, loss_mb = train_step(model, data, target)
        ...
```
```python
@sm.distribute
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss
```

- The input tensors to `sm.distribute` must be moved to the current device using `.to()` API, which must take place after the `torch.cuda.set_device(local_rank())` call.

For example, you may define the `train` function as follows. This function adds data and target to the current device using `.to()` API before using those input tensors to call `train_step`.

```python
def train(model, device, train_loader, optimizer):
    model.train()
    for batch_idx, (data, target) in enumerate(train_loader):
        # smdistributed: Move input tensors to the GPU ID used by the current process,
        # based on the set_device call.
        data, target = data.to(device), target.to(device)
        optimizer.zero_grad()
        # Return value, loss_mb is a StepOutput object
        _, loss_mb = train_step(model, data, target)

        # smdistributed: Average the loss across microbatches.
        loss = loss_mb.reduce_mean()
        optimizer.step()
```

The input tensors to this `sm.distribute` decorated function have been moved to the current device in the `train` function above. The model does not need to be moved to the current device. The library automatically moves the part of the model assigned to a rank to its GPU.

```python
@sm.distribute
def train_step(model, data, target):
    return output, loss
```

### Unsupported Framework Features

The following PyTorch features are unsupported by SageMaker's distributed model parallel library:

- When using data parallelism with DDP, the `DistributedDataParallel` wrapper is not supported. The library internally manages integrating with DDP, including parameter broadcast and gradient Allreduce. When using the library, module buffers are only broadcast once at the start of training. If your model has module buffers and you require module buffers to be synchronized across data parallel groups at each step, you can do so through the `torch.distributed` API, using the process group that can be obtained via `sm.distributed.get_dp_process_group()`.

- For mixed precision training, the `apex.amp` module is not supported. The recommended way to use the library with automatic mixed-precision is to use `torch.cuda.amp`, with the exception of using `sm.amp.GradScaler` instead of the implementation in torch.

- `torch.jit.ScriptModules` or `ScriptFunctions` are not supported by `sm.distributed.DistributedModel`.

- `apex.FusedLayerNorm`, `FusedAdam`, `FusedLAMB`, and `FusedNovoGrad` from apex are not supported. You can use the library implementations of these through `sm.optimizers` and `sm.nn` APIs instead.
PyTorch

The following training script changes are required to run a PyTorch model with SageMaker's distributed model parallel library:

1. Import and initialize the library with `smp.init()`.
2. Wrap the model with `smp.DistributedModel`. Be mindful that any tensors returned from the `forward` method of the underlying `nn.Module` object will be broadcast across model-parallel devices, incurring communication overhead, so any tensors that are not needed outside the call method (such as intermediate activations) should not be returned.
3. Wrap the optimizer with `smp.DistributedOptimizer`.
4. Use the returned `DistributedModel` object instead of a user model.
5. Put the forward and backward logic in a step function and decorate it with `smp.step`.
6. Restrict each process to its own device through `torch.cuda.set_device(smp.local_rank())`.
7. Move the input tensors to the GPU using the `.to()` API before the `smp.step` call (see example below).
9. Perform post-processing on the outputs across microbatches using `StepOutput` methods such as `reduce_mean`.
10. If there is an evaluation step, similarly place the forward logic inside an `smp.step`-decorated function and post-process the outputs using `StepOutput` API.
11. Set `drop_last=True` in `DataLoader`. Alternatively, manually skip a batch in the training loop if the batch size is not divisible by the number of microbatches.

To learn more about the SageMaker's distributed model parallel library API, refer to the API documentation.

```python
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchnet.dataset import SplitDataset
from torchvision import datasets
import smdistributed.modelparallel.torch as smp

class GroupedNet(nn.Module):
    def __init__(self):
        super(GroupedNet, self).__init__()
        # define layers

    def forward(self, x):
        # define forward pass and return model outputs

# smdistributed: Define smp.step. Return any tensors needed outside. @smp.step
def train_step(model, data, target):
    output = model(data)
    loss = F.nll_loss(output, target, reduction="mean")
    model.backward(loss)
    return output, loss

def train(model, device, train_loader, optimizer):
    model.train()
```
for batch_idx, (data, target) in enumerate(train_loader):
    # smdistributed: Move input tensors to the GPU ID used by the current process,
    # based on the set_device call.
    data, target = data.to(device), target.to(device)
    optimizer.zero_grad()
    # Return value, loss_mb is a StepOutput object
    _, loss_mb = train_step(model, data, target)
    # smdistributed: Average the loss across microbatches.
    loss = loss_mb.reduce_mean()
    optimizer.step()

    # smdistributed: initialize the backend
    smp.init()

    # smdistributed: Set the device to the GPU ID used by the current process.
    torch.cuda.set_device(smp.local_rank())
    device = torch.device("cuda")

    # smdistributed: Download only on a single process per instance.
    # When this is not present, the file is corrupted by multiple processes trying
    # to download and extract at the same time
    dataset = datasets.MNIST("../data", train=True, download=False)

    # smdistributed: Shard the dataset based on data-parallel ranks
    if smp.dp_size() > 1:
        partitions_dict = {f"{i}": 1 / smp.dp_size() for i in range(smp.dp_size())}
        dataset = SplitDataset(dataset, partitions=partitions_dict)
        dataset.select(f"{smp.dp_rank()}")

    # smdistributed: Set drop_last=True to ensure that batch size is always divisible
    # by the number of microbatches
    train_loader = torch.utils.data.DataLoader(dataset, batch_size=64, drop_last=True)

model = GroupedNet()
optimizer = optim.Adadelta(model.parameters(), lr=4.0)

    # smdistributed: Use the DistributedModel container to provide the model
    # to be partitioned across different ranks. For the rest of the script,
    # the returned DistributedModel object should be used in place of
    # the model provided for DistributedModel class instantiation.
    model = smp.DistributedModel(model)
    optimizer = smp.DistributedOptimizer(optimizer)

    train(model, device, train_loader, optimizer)

Manual Partitioning with PyTorch

Use smp.partition context managers to place modules in specific devices. Any module not placed
in any smp.partition contexts is placed in the default_partition. The default_partition
needs to be provided if auto_partition is set to False. The modules that are created within a specific
smp.partition context are placed on the corresponding partition.

To learn more about the SageMaker’s distributed model parallel library API, refer to the API
documentation.

### SageMaker distributed model parallel Configuration Tips and Pitfalls

Review the following tips and pitfalls before using Amazon SageMaker’s distributed model parallel library. This list includes tips that are applicable across frameworks. For TensorFlow and PyTorch specific tips, see Modify a TensorFlow Training Script (p. 1770) and Modify a PyTorch Training Script (p. 1776), respectively.

#### Batch Size and Number of Microbatches

- The library is most efficient when the batch size is increased. For use cases where the model fits within a single device, but can only be trained with a small batch size, batch size can and should be increased after the library is integrated. Model parallelism saves memory for large models, enabling you to train using batch sizes that previously did not fit in memory.
- Choosing a number of microbatches that is too small or too large can hurt performance. The library executes each microbatch sequentially in each device, so microbatch size (batch size divided by number of microbatches) must be large enough to fully utilize each GPU. At the same time, pipeline efficiency increases with the number of microbatches, so striking the right balance is important. Typically, a good starting point is to try 2 or 4 microbatches, increasing the batch size to the memory limit, and then experiment with larger batch sizes and numbers of microbatches. As the number of microbatches is increased, larger batch sizes might become feasible if an interleaved pipeline is used.
- Your batch size must be always divisible by the number of microbatches. Note that depending on the size of the dataset, sometimes the last batch of every epoch can be of a smaller size than the rest, and this smaller batch needs to be divisible by the number of microbatches as well. If it is not, you can set drop_remainder=True in the tf.Dataset.batch() call (in TensorFlow), or set drop_last=True in DataLoader (in PyTorch), so that this last, small batch is not used. If you are using a different API for the data pipeline, you might need to manually skip the last batch whenever it is not divisible by the number of microbatches.

#### Manual Partitioning

- If you use manual partitioning, be mindful of the parameters that are consumed by multiple operations and modules in your model, such as the embedding table in transformer architectures. Modules that share the same parameter must be placed in the same device for correctness. When auto-partitioning is used, the library automatically enforces this constraint.

#### Data Preparation

- If the model takes multiple inputs, make sure you seed the random operations in your data pipeline (e.g., shuffling) with smp.dp_rank(). If the dataset is being deterministically sharded across data parallel devices, make sure that the shard is indexed by smp.dp_rank(). This is to make sure that the order of the data seen on all ranks that form a model partition is consistent.

#### Returning Tensors from smp.DistributedModel

- Any tensor that is returned from the smp.DistributedModel.call (for TensorFlow) or smp.DistributedModel.forward (for PyTorch) function is broadcast to all other ranks, from the
rank that computed that particular tensor. As a result, any tensor that is not needed outside the call and forward methods (intermediate activations, for example) should not be returned, as this causes needless communication and memory overhead and hurts performance.

The @smp.step Decorator

- If an smp.step-decorated function has a tensor argument that does not have a batch dimension, the argument name must be provided in the non_split_inputs list when calling smp.step. This prevents the library from attempting to split the tensor into microbatches. For more information see smp.step in the API documentation.

Distributed Training Jupyter Notebook Examples

The following notebooks provide example Amazon SageMaker distributed implementations for popular deep learning frameworks and models. For vision (image) models, try MNIST or MaskRCNN. For language (text) models, try BERT.

These notebooks are provided in the SageMaker examples repository. You can also browse them on the SageMaker examples website.

The examples are set up to use p3.16xlarge instances for the worker nodes, but you may choose other p3 instance types if you wish. You can test a notebook using a cluster with only 1 node, but to see any performance benefit, you should use a cluster of multiple nodes (2 or more). The examples call out the section in which you modify this configuration.

PyTorch Examples

SageMaker Distributed Data Parallel

- MNIST with PyTorch 1.6 and SageMaker Data Parallel
- MaskRCNN with PyTorch 1.6 and SageMaker Data Parallel
- BERT with PyTorch 1.6 and SageMaker Data Parallel

SageMaker Distributed Model Parallel

- MNIST with PyTorch 1.6 and SageMaker Model Parallel
- BERT with PyTorch 1.6 and SageMaker Model Parallel

TensorFlow Examples

SageMaker Distributed Data Parallel

- MNIST with TensorFlow 2.3.1 and SageMaker Data Parallel
- MaskRCNN with TensorFlow 2.3.1 and SageMaker Data Parallel
- BERT with TensorFlow 2.3.1 and SageMaker Data Parallel

SageMaker Distributed Model Parallel

- MNIST with TensorFlow 2.3.1 and SageMaker Model Parallel
Use a SageMaker Notebook Instance

To use the provided examples, we recommend that you use an Amazon SageMaker notebook instance. A notebook instance is a machine learning (ML)–optimized Amazon EC2 instance running the Jupyter Notebook and JupyterServer apps. If you do not have an active notebook instance, follow the instructions in Create a Notebook Instance (p. 119) in the SageMaker developer guide to create one.

After you have created an instance, in the Notebook instances area of the SageMaker console, do the following:

1. Open JupyterLab.
2. Select the examples icon ( ) in the left tray.
3. Browse the examples for Training and look for notebooks titled Distributed Data Parallel or Distributed Model Parallel.

Use SageMaker Studio

You can run these example Jupyter Notebooks in SageMaker Studio. To download and use an example notebook, do the following in Studio:

1. Open a terminal.
2. In the command line, navigate to the SageMaker folder.
   
   $ cd SageMaker

3. Clone the SageMaker examples repo.

   git clone https://github.com/aws/amazon-sagemaker-examples.git

4. In the JupyterLab interface, navigate into the amazon-sagemaker-examples folder.
5. In the training/distributed_training folder, there are folders for frameworks, and in each of these, there are folders for data_parallel and model_parallel. Choose the example of your choice and follow the instructions to launch distributed training with an SageMaker distributed training library.

Troubleshooting

If you run into an error, you can use the following list to try to troubleshoot your training job. If the problem persists, contact AWS Support.

Topics
- Using Debugger with SageMaker distributed (p. 1784)
- Saving Checkpoints (p. 1785)
- Convergence Using Model Parallel and TensorFlow (p. 1786)

Using Debugger with SageMaker distributed

When Debugger is enabled (which is enabled by default for all SageMaker TensorFlow and PyTorch jobs) you might see an error that looks like the following:
FileNotFoundError: [Errno 2] No such file or directory: '/opt/ml/checkpoints/metadata.json.sagemaker-uploading

To fix this issue, disable Debugger by passing `debugger_hook_config=False` when creating the framework estimator in the SageMaker Python SDK as seen in the following example.

```python
estimator = TensorFlow(
    role=role,
    instance_count=1,
    instance_type=instance_type,
    debugger_hook_config=False
)
```

**Saving Checkpoints**

You might run into the following error when saving checkpoints of a large model on SageMaker:

```
InternalServerError: We encountered an internal error. Please try again
```

This could be caused by a SageMaker limitation while uploading the local checkpoint to Amazon S3 during training. To disable checkpointing in SageMaker and follow the following example to explicitly upload the checkpoints.

If you run into above error, do not use `checkpoint_s3_uri` with the SageMaker estimator call. While saving checkpoints for larger models, we recommend saving checkpoints to a custom directory and passing the same to the helper function (as a `local_path` argument).

```python
import os
def aws_s3_sync(source, destination):
    """aws s3 sync in quiet mode and time profile""
    import time, subprocess
    cmd = ['aws', 's3', 'sync', '--quiet', source, destination]
    start_time = time.time()
    p = subprocess.Popen(cmd, stdout=subprocess.PIPE, stderr=subprocess.PIPE)
    p.wait()
    end_time = time.time()
    print("Time Taken to Sync: ", (end_time-start_time))
    return

def sync_local_checkpoints_to_s3(local_path="/opt/ml/checkpoints",
                                s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints'):
    """sample function to sync checkpoints from local path to s3"

    import boto3
    #check if local path exists
    if not os.path.exists(local_path):
        raise RuntimeError("Provided local path {local_path} does not exist. Please check")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3.s3_uri.startswith("s3://"):
        raise ValueError("Provided s3 uri {s3_uri} is not valid.")

    s3_bucket = s3.s3_uri.replace("s3://", '').split('/')[0]
    print(f"S3 Bucket: {s3.bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
```
aws_s3_sync(local_path, s3_uri)
return

def sync_s3_checkpoints_to_local(local_path="/opt/ml/checkpoints",
    s3_uri=os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))+'/checkpoints/):
    """ sample function to sync checkpoints from s3 to local path """
    import boto3
    #try to create local path if it does not exist
    if not os.path.exists(local_path):
        print(f"Provided local path {local_path} does not exist. Creating...")
        try:
            os.makedirs(local_path)
        except Exception as e:
            raise RuntimeError(f"Failed to create {local_path}")

    #check if s3 bucket exists
    s3 = boto3.resource('s3')
    if not s3_uri.startswith("s3://"):
        raise ValueError(f"Provided s3 uri {s3_uri} is not valid.")
    s3_bucket = s3_uri.replace('s3://','').split('/')[0]
    print(f"S3 Bucket: {s3_bucket}")
    try:
        s3.meta.client.head_bucket(Bucket=s3_bucket)
    except Exception as e:
        raise e
    aws_s3_sync(s3_uri, local_path)
return

Usage of helper functions:

#base_s3_uri - user input s3 uri or save to model directory (default)
#curr_host - to save checkpoints of current host
#iteration - current step/epoch during which checkpoint is saved

# save checkpoints on every node using local_rank
if smp.local_rank() == 0:
    base_s3_uri = os.path.dirname(os.path.dirname(os.getenv('SM_MODULE_DIR', '')))
    curr_host = os.environ['SM_CURRENT_HOST']
    full_s3_uri = f'(base_s3_uri)/checkpoints/{curr_host}/{iteration}'
    sync_local_checkpoints_to_s3(local_path=checkpoint_dir, s3_uri=full_s3_uri)

Convergence Using Model Parallel and TensorFlow

When you use SageMaker multi-node training with TensorFlow and distributed model parallel, the loss may not converge as expected because the order of training input files may be different on each node. This may cause different ranks in the same model parallel group to work on different input files, causing inconsistencies. To prevent this, ensure the input files are ordered the same way in all the ranks before they get converted to TensorFlow datasets. One way to achieve this is to sort the input file names in the training script.

Detect Posttraining Data and Model Bias

Posttraining bias analysis can help reveal biases that might have emanated from biases in the data, or from biases introduced by the classification and prediction algorithms. These analyses take into consideration the data, including the labels, and the predictions of a model. You assess performance by analyzing predicted labels or by comparing the predictions with the observed target values in the data with respect to groups with different attributes. There are different notions of fairness, each requiring different bias metrics to measure.
There are legal concepts of fairness that might not be easy to capture because they are hard to detect. For example, the US concept of disparate impact that occurs when a group, referred to as a less favored facet $d$, experiences an adverse effect even when the approach taken appears to be fair. This type of bias might not be due to a machine learning model, but might still be detectable by posttraining bias analysis.

Amazon SageMaker Clarify tries to ensure a consistent use of terminology. For a list of terms and their definitions, see Amazon SageMaker Clarify Terms for Bias and Fairness (p. 562).

For additional information about posttraining bias metrics, see Fairness Measures for Machine Learning in Finance.

Sample Notebooks

Amazon SageMaker Clarify provides the following sample notebook for posttraining bias detection:

- Explainability and bias detection with Amazon SageMaker Clarify – Use SageMaker Clarify to create a processing job for the detecting bias and explaining model predictions with feature attributions.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81). If you're prompted to choose a kernel, choose Python 3 (Data Science).

Topics

- Measure Posttraining Data and Model Bias (p. 1787)
- Configure an Amazon SageMaker Clarify Processing Jobs for Fairness and Explainability (p. 1806)
- Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability (p. 1813)

Measure Posttraining Data and Model Bias

Amazon SageMaker Clarify provides eleven posttraining data and model bias metrics to help quantify various conceptions of fairness. These concepts cannot all be satisfied simultaneously and the selection depends on specifics of the cases involving potential bias being analyzed. Most of these metrics are a combination of the numbers taken from the binary classification confusion matrices for the different demographic groups. Because fairness and bias can be defined by a wide range of metrics, human judgment is required to understand and choose which metrics are relevant to the individual use case, and customers should consult with appropriate stakeholders to determine the appropriate measure of fairness for their application.

We use the following notation to discuss the bias metrics. The conceptual model described here is for binary classification, where events are labeled as having only two possible outcomes in their sample space, referred to as positive (with value 1) and negative (with value 0). This framework is usually extensible to multicategory classification in a straightforward way or to cases involving continuous valued outcomes when needed. In the binary classification case, positive and negative labels are assigned to outcomes recorded in a raw dataset for a favored facet $a$ and for a disfavored facet $d$. These labels $y$ are referred to as observed labels to distinguish them from the predicted labels $y'$ that are assigned by a machine learning model during the training or inferences stages of the ML lifecycle. These labels are used to define probability distributions $P_a(y)$ and $P_d(y)$ for their respective facet outcomes.

- labels:
  - $y$ represents the $n$ observed labels for event outcomes in a training dataset.
  - $y'$ represents the predicted labels for the $n$ observed labels in the dataset by a trained model.
- outcomes:
• A positive outcome (with value 1) for a sample, such as an application acceptance.
• $n^{(1)}$ is the number of observed labels for positive outcomes (acceptances).
• $n'^{(1)}$ is the number of predicted labels for positive outcomes (acceptances).
• A negative outcome (with value 0) for a sample, such as an application rejection.
• $n^{(0)}$ is the number of observed labels for negative outcomes (rejections).
• $n'^{(0)}$ is the number of predicted labels for negative outcomes (rejections).

• facet values:
  • facet $a$ – The feature value that defines a demographic that bias favors.
    • $n_a$ is the number of observed labels for the favored facet value: $n_a = n_a^{(1)} + n_a^{(0)}$ the sum of the positive and negative observed labels for the value facet $a$.
    • $n'_a$ is the number of predicted labels for the favored facet value: $n'_a = n'_a^{(1)} + n'_a^{(0)}$ the sum of the positive and negative predicted outcome labels for the facet value $a$. Note that $n'_a = n_a$.
  • facet $d$ – The feature value that defines a demographic that bias disfavors.
    • $n_d$ is the number of observed labels for the disfavored facet value: $n_d = n_d^{(1)} + n_d^{(0)}$ the sum of the positive and negative observed labels for the facet value $d$.
    • $n'_d$ is the number of predicted labels for the disfavored facet value: $n'_d = n'_d^{(1)} + n'_d^{(0)}$ the sum of the positive and negative predicted labels for the facet value $d$. Note that $n'_d = n_d$.

• probability distributions for outcomes of the labeled facet data outcomes:
  • $P_a(y)$ is the probability distribution of the observed labels for facet $a$. For binary labeled data, this distribution is given by the ratio of the number of samples in facet $a$ labeled with positive outcomes to the total number, $P_a(y^1) = n_a^{(1)}/n_a$, and the ratio of the number of samples with negative outcomes to the total number, $P_a(y^0) = n_a^{(0)}/n_a$.
  • $P_d(y)$ is the probability distribution of the observed labels for facet $d$. For binary labeled data, this distribution is given by the number of samples in facet $d$ labeled with positive outcomes to the total number, $P_d(y^1) = n_d^{(1)}/n_d$, and the ratio of the number of samples with negative outcomes to the total number, $P_d(y^0) = n_d^{(0)}/n_d$.

The following table contains a cheat sheet for quick guidance and links to the posttraining bias metrics.

### Posttraining Bias Metrics

<table>
<thead>
<tr>
<th>posttraining bias metric</th>
<th>Description</th>
<th>Example question</th>
<th>Interpreting metric values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1796)</td>
<td>Measures the difference in the proportion of positive predictions between the favored facet $a$ and the disfavored facet $d$.</td>
<td>Has there been an imbalance across demographic groups in the predicted positive outcomes that might indicate bias?</td>
<td>Range for normalized binary &amp; multicategory facet labels: [-1, +1] Range for continuous labels: (-∞, +∞) Interpretation: • Positive values indicate that the favored facet $a$ has a higher proportion of predicted positive outcomes. • Values near zero indicate a more equal proportion of predicted positive</td>

### Difference in Positive Proportions in Predicted Labels (DPPL)

The difference in positive proportions in predicted labels (DPPL) metric determines whether the model predicts outcomes differently for each facet. It is defined as the difference between the proportion of positive predictions \( y' = 1 \) for facet \( a \) and the proportion of positive predictions \( y' = 1 \) for facet \( d \). For example, if the model predictions grant loans to 60% of a middle-aged group (facet \( a \)) and 50% other age groups (facet \( d \)), it might be biased against facet \( d \). In this example, you need to determine whether the 10% difference is material to a case for bias. A comparison of DPL with DPPL assesses whether bias initially present in the dataset increases or decreases in the model predictions after training.

The formula for the difference in proportions of predicted labels:

\[
DPPL = q'_a - q'_d
\]

Where:

- \( q'_a = \frac{n'_a(1)}{n_a} \) is the predicted proportion of facet \( a \) who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a(1) \) represents the number of members of facet \( a \) who get a predicted outcome of value 1 and \( n_a \) the is number of members of facet \( a \).
- \( q'_d = \frac{n'_d(1)}{n_d} \) is the predicted proportion of facet \( d \) who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d(1) \) represents the number of members of facet \( d \) who get a positive predicted outcome and \( n_d \) the is number of members of facet \( d \).

If DPPL is close enough to 0, it means that posttraining demographic parity has been achieved.

For binary and multicategory facet labels, the normalized DPL values range over the interval \([-1, 1]\). For continuous labels, the values vary over the interval \((-\infty, +\infty)\).

- Positive DPPL values indicate that facet \( a \) has a higher proportion of predicted positive outcomes when compared with facet \( d \).

This is referred to as positive bias.

- Values of DPPL near zero indicate a more equal proportion of predicted positive outcomes between facets \( a \) and \( d \) and a value of zero indicates perfect demographic parity.

- Negative DPPL values indicate that facet \( d \) has a higher proportion of predicted positive outcomes when compared with facet \( a \). This is referred to as negative bias.
Disparate Impact (DI)

The difference in positive proportions in the predicted labels metric can be assessed in the form of a ratio.

The comparison of positive proportions in predicted labels metric can be assessed in the form of a ratio instead of as a difference, as it is with the Difference in Positive Proportions in Predicted Labels (DPPL) (p. 1796). The disparate impact (DI) metric is defined as the ratio of the proportion of positive predictions (y' = 1) for facet a over the proportion of positive predictions (y' = 1) for facet d. For example, if the model predictions grant loans to 60% of a middle-aged group (facet a) and 50% other age groups (facet d), then DI = .5/.6 = 0.8, which indicates a positive bias and an adverse impact on facet d.

The formula for the ratio of proportions of the predicted labels:

\[ DI = \frac{q'_d}{q'_a} \]

Where:

- \( q'_a = \frac{n'_a}{n_a} \) is the predicted proportion of facet a who get a positive outcome of value 1. In our example, the proportion of a middle-aged facet predicted to get granted a loan. Here \( n'_a \) represents the number of members of facet a who get a positive predicted outcome and \( n_a \) is the number of members of facet a.
- \( q'_d = \frac{n'_d}{n_d} \) is the predicted proportion of facet d who get a positive outcome of value 1. In our example, a facet of older and younger people predicted to get granted a loan. Here \( n'_d \) represents the number of members of facet d who get a positive predicted outcome and \( n_d \) is the number of members of facet d.

For binary, multicategory facet, and continuous labels, the DI values range over the interval [0, ∞).

- Values less than 1 indicate that facet a has a higher proportion of predicted positive outcomes than facet d. This is referred to as positive bias.
- A value of 1 indicates demographic parity.
- Values greater than 1 indicate that facet d has a higher proportion of predicted positive outcomes than facet a. This is referred to as negative bias.

Difference in Conditional Acceptance (DCAcc)

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for predicted positive outcomes. This metric comes close to mimicking human bias in that it quantifies how many more positive outcomes a model predicted (labels y') for a certain facet as compared to what was observed in the training dataset (labels y). For example, if there were more acceptances (a positive outcome) for loan applications for a middle-aged group (facet a) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet d), this might indicate potential bias in the way loans were approved.

The formula for the difference in conditional acceptance:

\[ DC\text{Acc} = c_a - c_d \]

Where:

- \( c_a = n'_a / n'_a \) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet a to the predicted number of positive outcome (acceptances) for facet a.
- \( c_d = n'_d / n'_d \) is the ratio of the observed number of positive outcomes of value 1 (acceptances) of facet d to the predicted number of predicted positive outcomes (acceptances) for facet d.
Measure Posttraining Data and Model Bias

The DCAcc metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan acceptances.

**Example 1: Positive bias**

Suppose we have a dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 70 from facet $a$ and 20 from facet $d$ were granted loans. In other words, the model granted loans to 17% more from the middle-aged facet than the observed labels in the training data suggested (70/60 = 1.17) and granted loans to 33% less from other age groups than the observed labels suggested (20/30 = 0.67). The calculation of the DCAcc value quantifies this difference between +17% and -33%. The calculation of the DCAcc value gives the following:

$$DCAcc = \frac{70}{60} - \frac{20}{30} = \frac{1}{2}$$

**Example 2: Negative bias**

Suppose we have a dataset of 100 middle-aged people (facet $a$) and 50 people from other age groups (facet $d$) who applied for loans, where the model recommended that 60 from facet $a$ and 30 from facet $d$ be given loans. So the predicted proportions are unbiased with respect to the DPPL metric, but the observed labels show that 50 from facet $a$ and 40 from facet $d$ were granted loans. In other words, the model granted loans to 17% fewer from the middle-aged facet than the observed labels in the training data suggested (50/60 = 0.83), and granted loans to 33% more from other age groups than the observed labels suggested (40/30 = 1.33). The calculation of the DCAcc value quantifies this difference between -17% and +33%. The calculation of the DCAcc value gives the following:

$$DCAcc = \frac{50}{60} - \frac{40}{30} = -\frac{1}{2}$$

Note that you can use DCAcc to help you detect potential (unintentional) biases by humans overseeing the model predictions in a human-in-the-loop setting. Assume, for example, that the predictions $y'$ by the model were unbiased, but the eventual decision is made by a human (possibly with access to additional features) who can alter the model predictions to generate a new and final version of $y'$. The additional processing by the human may unintentionally deny loans to a disproportionate number from one facet. DCAcc can help detect such potential biases.

The range of values for differences in conditional acceptance for binary, multiclass facet, and continuous labels is $(-\infty, +\infty)$.

- **Positive values** occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is higher than the same ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $d$. The larger the difference of the ratios, the more extreme the apparent bias.
- **Values near zero** occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is similar to the ratio for facet $d$. These values indicate that predicted acceptance rates are consistent with the observed values in the labeled data and that qualified applicants from both facets are being accepted in a similar way.
- **Negative values** occur when the ratio of the observed number of acceptances compared to predicted acceptances for facet $a$ is less than that ratio for facet $d$. These values indicate a possible bias against the qualified applicants from facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Conditional Rejection (DCR)**

This metric compares the observed labels to the labels predicted by the model and assesses whether this is the same across facets for negative outcomes (rejections). This metric comes close to mimicking human bias, in that it quantifies how many more negative outcomes a model granted (predicted labels $y'$) to a certain facet as compared to what was suggested by the labels in the training dataset (observed...
labels y). For example, if there were more rejections (a negative outcome) for loan applications for a middle-aged group (facet a) than predicted by the model based on qualifications as compared to the facet containing other age groups (facet d), this might indicate potential bias in the way loans were rejected.

The formula for the difference in conditional acceptance:

\[ DCR = r_d - r_a \]

Where:

\[ r_d = \frac{n_d(0)}{n'_d(0)} \] is the ratio of the observed number of negative outcomes of value 1 (rejections) of facet d to the predicted number of negative outcome (rejections) for facet d.

\[ r_a = \frac{n_a(0)}{n'_a(0)} \] is the ratio of the observed number of negative outcomes of value 0 (rejections) of facet a to the predicted number of negative outcome of value 0 (rejections) for facet a.

The DCR metric can capture both positive and negative biases that reveal preferential treatment based on qualifications. Consider the following instances of age-based bias on loan rejections.

**Example 1: Positive bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 50 from facet a and 40 from facet d were rejected. In other words, the model rejected loans for 17% fewer from the middle aged facet than the observed labels in the training data suggested (50/60 = 0.83), and rejected loans for 33% more from other age groups than the observed labels suggested (40/30 = 1.33). The calculation of the DCR value quantifies this difference between -17% and +33%.

\[ DCR = \frac{40}{30} - \frac{50}{60} = \frac{1}{2} \]

**Example 2: Negative bias**

Suppose we have dataset of 100 middle-aged people (facet a) and 50 people from other age groups (facet d) who applied for loans, where the model recommended that 60 from facet a and 30 from facet d be rejected for loans. So the predicted proportions are unbiased by the DPPL metric, but the observed labels show that 70 from facet a and 20 from facet d were rejected. In other words, the model rejected loans for 17% more from the middle aged facet than the observed labels in the training data suggested (70/60 = 1.17), and rejected loans for 33% fewer from other age groups than the observed labels suggested (20/30 = 0.67). The calculation of the DCR value quantifies this difference between 17% and -33%.

\[ DCR = \frac{20}{30} - \frac{70}{60} = -\frac{1}{2} \]

The range of values for differences in conditional rejection for binary, multicategory facet, and continuous labels is \((-\infty, +\infty)\).

- Positive values occur when the ratio of the observed number of rejections compared to predicted rejections for facet d is greater than that ratio for facet a. These values indicate a possible bias against the qualified applicants from facet d. The larger the value of DCR metric, the more extreme the apparent bias.

- Values near zero occur when the ratio of the observed number of rejections compared to predicted acceptances for facet a is the similar to the ratio for facet d. These values indicate that predicted rejections rates are consistent with the observed values in the labeled data and that the qualified applicants from both facets are being rejected in a similar way.

- Negative values occur when the ratio of the observed number of rejections compared to predicted rejections for facet d is less than that ratio facet a. These values indicate a possible bias against the
qualified applicants from facet \( a \). The larger magnitude of the negative DCR metric, the more extreme the apparent bias.

**Recall Difference (RD)**

The recall difference (RD) metric is the difference in recall of the model between the favored facet \( a \) and disfavored facet \( d \). Any difference in these recalls is a potential form of bias. Recall is the true positive rate (TPR), which measures how often the model correctly predicts the cases that should receive a positive outcome. Recall is perfect for a facet if all of the \( y=1 \) cases are correctly predicted as \( y'=1 \) for that facet. Recall is greater when the model minimizes false negatives known as the Type II error. For example, how many of the people in two different groups (facets \( a \) and \( d \)) that should qualify for loans are detected correctly by the model? If the recall rate is high for lending to facet \( a \), but low for lending to facet \( d \), the difference provides a measure of this bias against the group belonging to facet \( d \).

The formula for difference in the recall rates for facets \( a \) and \( d \):

\[
RD = \frac{TP_a}{TP_a + FN_a} - \frac{TP_d}{TP_d + FN_d} = TPR_a - TPR_d
\]

Where:

- \( TP_a \) are the true positives predicted for facet \( a \).
- \( FN_a \) are the false negatives predicted for facet \( a \).
- \( TP_d \) are the true positives predicted for facet \( d \).
- \( FN_d \) are the false negatives predicted for facet \( d \).
- \( TPR_a = \frac{TP_a}{TP_a + FN_a} \) is the recall for facet \( a \) or its true positive rate.
- \( TPR_d = \frac{TP_d}{TP_d + FN_d} \) is the recall for facet \( d \) or its true positive rate.

For example, consider the following confusion matrices for facets \( a \) and \( d \).

**Confusion Matrix for the Favored Facet \( a \)**

<table>
<thead>
<tr>
<th>Class ( a ) predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
<td>5</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>65</td>
<td>75</td>
</tr>
<tr>
<td>Total</td>
<td>30</td>
<td>70</td>
<td>100</td>
</tr>
</tbody>
</table>

**Confusion Matrix for the Disfavored Facet \( d \)**

<table>
<thead>
<tr>
<th>Class ( d ) predictions</th>
<th>Actual outcome 0</th>
<th>Actual outcome 1</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>18</td>
<td>7</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>Total</td>
<td>23</td>
<td>27</td>
<td>50</td>
</tr>
</tbody>
</table>

The value of the recall difference is \( RD = \frac{65}{70} - \frac{20}{27} = 0.93 - 0.74 = 0.19 \) which indicates a bias against facet \( d \).

The range of values for the recall difference between facets \( a \) and \( d \) for binary and multiclass classification is \([-1, +1]\). This metric is not available for the case of continuous labels.
• Positive values are obtained when there is higher recall for facet $a$ than for facet $d$. This suggests that the model finds more of the true positives for facet $a$ than for facet $d$, which is a form of bias.

• Values near zero indicate that the recall for facets being compared is similar. This suggests that the model finds about the same number of true positives in both of these facets and is not biased.

• Negative values are obtained when there is higher recall for facet $d$ than for facet $a$. This suggests that the model finds more of the true positives for facet $d$ than for facet $a$, which is a form of bias.

**Difference in Acceptance Rates (DAR)**

The difference in acceptance rates (DAR) metric is the difference in the ratios of the true positive (TP) predictions to the observed positives (TP + FP) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting acceptances from these two facets. Precision measures the fraction of qualified candidates from the pool of qualified candidates that are identified as such by the model. If the model precision for predicting qualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DAR.

The formula for difference in acceptance rates between facets $a$ and $d$:

$$\text{DAR} = \frac{TP_a}{TP_a + FP_a} - \frac{TP_d}{TP_d + FP_d}$$

Where:

- $TP_a$ are the true positives predicted for facet $a$.
- $FP_a$ are the false positives predicted for facet $a$.
- $TP_d$ are the true positives predicted for facet $d$.
- $FP_d$ are the false positives predicted for facet $d$.

For example, suppose the model accepts 70 middle-aged applicants (facet $a$) for a loan (predicted positive labels) of whom only 35 are actually accepted (observed positive labels). Also suppose the model accepts 100 applicants from other age demographics (facet $d$) for a loan (predicted positive labels) of whom only 40 are actually accepted (observed positive labels). Then DAR = $35/70 - 40/100 = 0.10$, which indicates a potential bias against qualified people from the second age group (facet $d$).

The range of values for DAR for binary, multicategory facet, and continuous labels is $[-1, +1]$.

• Positive values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $a$ is larger than the same ratio for facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The larger the difference in the ratios, the more extreme the apparent bias.

• Values near zero occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facets $a$ and $d$ have similar values indicating the observed labels for positive outcomes are being predicted with equal precision by the model.

• Negative values occur when the ratio of the predicted positives (acceptances) to the observed positive outcomes (qualified applicants) for facet $d$ is larger than the ratio facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false positives in facet $a$. The more negative the difference in the ratios, the more extreme the apparent bias.

**Difference in Rejection Rates (DRR)**

The difference in rejection rates (DRR) metric is the difference in the ratios of the true negative (TN) predictions to the observed negatives (TN + FN) for facets $a$ and $d$. This metric measures the difference in the precision of the model for predicting rejections from these two facets. Precision measures the fraction of unqualified candidates from the pool of unqualified candidates that are identified as such by
the model. If the model precision for predicting unqualified applicants diverges between the facets, this is a bias and its magnitude is measured by the DRR.

The formula for difference in rejection rates between facets $a$ and $d$:

$$\text{DRR} = \frac{\text{TN}_a}{\text{TN}_a + \text{FN}_a} - \frac{\text{TN}_d}{\text{TN}_d + \text{FN}_d}$$

Where:

- $\text{TN}_d$ are the true negatives predicted for facet $d$.
- $\text{FN}_d$ are the false negatives predicted for facet $d$.
- $\text{TP}_a$ are the true negatives predicted for facet $a$.
- $\text{FN}_a$ are the false negatives predicted for facet $a$.

For example, suppose the model rejects 100 middle-aged applicants (facet $a$) for a loan (predicted negative labels) of whom 80 are actually unqualified (observed negative labels). Also suppose the model accepts 50 applicants from other age demographics (facet $d$) for a loan (predicted negative labels) of whom only 40 are actually unqualified (observed negative labels). Then $\text{DRR} = 40/50 - 80/100 = 0$, so no bias is indicated. When both DAR and DRR are zero, it satisfies a condition known as equalized odds.

The range of values for DRR for binary, multicategory facet, and continuous labels is $[-1, +1]$.

- Positive values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $d$ is larger than the same ratio for facet $a$. These values indicate a possible bias against the favored facet $a$ caused by the occurrence of relatively more false negatives in facet $a$. The larger the difference in the ratios, the more extreme the apparent bias.
- Values near zero occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facets $a$ and $d$ have similar values, indicating the observed labels for negative outcomes are being predicted with equal precision by the model.
- Negative values occur when the ratio of the predicted negatives (rejections) to the observed negative outcomes (unqualified applicants) for facet $a$ is larger than the ratio facet $d$. These values indicate a possible bias against the disfavored facet $d$ caused by the occurrence of relatively more false positives in facet $d$. The more negative the difference in the ratios, the more extreme the apparent bias.

Accuracy Difference (AD)

Accuracy difference (AD) metric is the difference between the prediction accuracy for different facets. This metric determines whether the classification by the model is more accurate for one facet than the other. AD indicates whether one facet incurs a greater proportion of Type I and Type II errors. But it cannot differentiate between Type I and Type II errors. For example, the model may have equal accuracy for different age demographics, but the errors may be mostly false positives (Type I errors) for one age-based group and mostly false negatives (Type II errors) for the other.

Also, if loan approvals are made with much higher accuracy for a middle-aged demographic (facet $a$) than for another age-based demographic (facet $d$), either a greater proportion of qualified applicants in the second group are denied a loan (FN) or a greater proportion of unqualified applicants from that group get a loan (FP) or both. This can lead to within group unfairness for the second group, even if the proportion of loans granted is nearly the same for both age-based groups, which is indicated by a DPPL value that is close to zero.

The formula for AD metric is the difference between the prediction accuracy for facet $a$, $\text{ACC}_a$, minus that for facet $d$, $\text{ACC}_d$:

$$\text{AD} = \text{ACC}_a - \text{ACC}_d$$

Where:
Measure Posttraining Data and Model Bias

ACC_{a} = \frac{TP_{a} + TN_{a}}{TP_{a} + TN_{a} + FP_{a} + FN_{a}}

TP_{a} are the true positives predicted for facet a

TN_{a} are the true negatives predicted for facet a

FP_{a} are the false positives predicted for facet a

FN_{a} are the false negatives predicted for facet a

ACC_{d} = \frac{TP_{d} + TN_{d}}{TP_{d} + TN_{d} + FP_{d} + FN_{d}}

TP_{d} are the true positives predicted for facet d

TN_{d} are the true negatives predicted for facet d

FP_{d} are the false positives predicted for facet d

FN_{d} are the false negatives predicted for facet d

For example, suppose a model approves loans to 70 applicants from facet a of 100 and rejected the other 30. 10 should not have been offered the loan (FP_{a}) and 60 were approved that should have been (TP_{a}). 20 of the rejections should have been approved (FN_{a}) and 10 were correctly rejected (TN_{a}). The accuracy for facet a is as follows:

ACC_{a} = \frac{60 + 10}{60 + 10 + 20 + 10} = 0.7

Next, suppose a model approves loans to 50 applicants from facet d of 100 and rejected the other 50. 10 should not have been offered the loan (FP_{a}) and 40 were approved that should have been (TP_{a}). 40 of the rejections should have been approved (FN_{a}) and 10 were correctly rejected (TN_{a}). The accuracy for facet a is determined as follows:

ACC_{a} = \frac{40 + 10}{40 + 10 + 40 + 10} = 0.5

The accuracy difference is thus AD = ACC_{a} - ACC_{d} = 0.7 - 0.5 = 0.2. This indicates there is a bias against facet d as the metric is positive.

The range of values for AD for binary and multicategory facet labels is [-1, +1].

• Positive values occur when the prediction accuracy for facet a is greater than that for facet d. It means that facet d suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a potential bias against the disfavored facet d.

• Values near zero occur when the prediction accuracy for facet a is similar to that for facet d.

• Negative values occur when the prediction accuracy for facet d is greater than that for facet a. It means that facet a suffers more from some combination of false positives (Type I errors) or false negatives (Type II errors). This means there is a bias against the favored facet a.

Treatment Equality (TE)

The treatment equality (TE) is the difference in the ratio of false positives to false negatives between facets a and d. The main idea of this metric is to assess whether, even if the accuracy across groups is the same, is it the case that errors are more harmful to one group than another? Error rate comes from the total of false positives and false negatives, but the breakdown of these two may be very different across facets. TE measures whether errors are compensating in the similar or different ways across facets.

The formula for the treatment equality:

TE = \frac{FP_{a}/FN_{a}}{FP_{d}/FN_{d}}

Where:

• FP_{a} are the false positives predicted for facet a.

• FN_{a} are the false negatives predicted for facet a.
• FP\textsubscript{d} are the false positives predicted for facet \textit{d}.
• FN\textsubscript{d} are the false negatives predicted for facet \textit{d}.

Note the metric becomes unbounded if FN\textsubscript{a} or FN\textsubscript{d} is zero.

For example, suppose that there are 100 loan applicants from facet \textit{a} and 50 from facet \textit{d}. For facet \textit{a}, 8 were wrongly denied a loan (FN\textsubscript{a}) and another 6 were wrongly approved (FP\textsubscript{a}). The remaining predictions were true, so TP\textsubscript{a} + TN\textsubscript{a} = 86. For facet \textit{d}, 5 were wrongly denied (FN\textsubscript{d}) and 2 were wrongly approved (FP\textsubscript{d}). The remaining predictions were true, so TP\textsubscript{d} + TN\textsubscript{d} = 43. The ratio of false positives to false negatives equals 6/8 = 0.75 for facet \textit{a} and 2/5 = 0.40 for facet \textit{d}. Hence TE = 0.75 - 0.40 = 0.35, even though both facets have the same accuracy:

\[
\text{ACC}_a = \frac{86}{68 + 8 + 6} = 0.86
\]

\[
\text{ACC}_d = \frac{43}{43 + 5 + 2} = 0.86
\]

The range of values for differences in conditional rejection for binary and multicategory facet labels is (-\infty, +\infty). The TE metric is not defined for continuous labels. The interpretation of this metric depends on the relative important of false positives (Type I error) and false negatives (Type II error).

• Positive values occur when the ratio of false positives to false negatives for facet \textit{a} is greater than that for facet \textit{d}.
• Values near zero occur when the ratio of false positives to false negatives for facet \textit{a} is similar to that for facet \textit{d}.
• Negative values occur when the ratio of false positives to false negatives for facet \textit{a} is less than that for facet \textit{d}.

**Conditional Demographic Disparity in Predicted Labels (CDDPL)**

The demographic disparity metric (DDPL) determines whether facet \textit{d} has a larger proportion of the predicted rejected labels than of the predicted accepted labels. It enables a comparison of difference in predicted rejection proportion and predicted acceptance proportion across facets. This metric is exactly the same as the pretraining CDD metric except that it is computed off the predicted labels instead of the observed ones. This metric lies in the range (-1,+1).

The formula for the demographic disparity predictions for labels of facet \textit{d} is as follows:

\[
\text{DDPL}_d = \frac{n_d^{(0)}}{n_0^{(0)}} - \frac{n_d^{(1)}}{n_1^{(1)}} = \text{P}_d(y^{0}) - \text{P}_d(y^{1})
\]

Where:

• \(n_0^{(0)} = n_a^{(0)} + n_d^{(0)}\) is the number of predicted rejected labels for facets \textit{a} and \textit{d}.
• \(n_1^{(1)} = n_a^{(1)} + n_d^{(1)}\) is the number of predicted accepted labels for facets \textit{a} and \textit{d}.
• \(\text{P}_d(y^{0})\) is the proportion of predicted rejected labels (value 0) in facet \textit{d}.
• \(\text{P}_d(y^{1})\) is the proportion of predicted accepted labels (value 1) in facet \textit{d}.

A conditional demographic disparity in predicted labels (CDDPL) metric that conditions DDPL on attributes that define a strata of subgroups on the dataset is needed to rule out Simpson’s paradox. The regrouping can provide insights into the cause of apparent demographic disparities for less favored facets. The classic case arose in the case of Berkeley admissions where men were accepted at a higher rate overall than women. But when departmental subgroups were examined, women were shown to have higher admission rates than men by department. The explanation was that women had applied to departments with lower acceptance rates than men had. Examining the subgroup acceptance rates revealed that women were actually accepted at a higher rate than men for the departments with lower acceptance rates.
The CDDPL metric gives a single measure for all of the disparities found in the subgroups defined by an attribute of a dataset by averaging them. It is defined as the weighted average of demographic disparities in predicted labels (DDPL_i) for each of the subgroups, with each subgroup disparity weighted in proportion to the number of observations in contains. The formula for the conditional demographic disparity in predicted labels is as follows:

$$\text{CDDPL} = \frac{1}{n} \sum n_i \cdot \text{DDPL}_i$$

Where:

- $\sum n_i = n$ is the total number of observations and $n_i$ is the number of observations for each subgroup.
- $\text{DDPL}_i = \frac{n_i^{(0)}}{n^{(0)}} - \frac{n_i^{(1)}}{n^{(1)}} = P_i^{(0)} - P_i^{(1)}$ is the demographic disparity in predicted labels for the subgroup.

So the demographic disparity for a subgroup in predicted labels (DDPL_i) are the difference between the proportion of predicted rejected labels and the proportion of predicted accepted labels for each subgroup.

The range of DDPL values for binary, multicategory, and continuous outcomes is [-1, +1].

- +1: when there are no predicted rejection labels for facet $a$ or subgroup and no predicted acceptances for facet $d$ or subgroup.
- Positive values indicate there is a demographic disparity in predicted labels as facet $d$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The higher the value the greater the disparity.
- Values near zero indicate there is no demographic disparity on average.
- Negative values indicate there is a demographic disparity in predicted labels as facet $a$ or subgroup has a larger proportion of the predicted rejected labels than of the predicted accepted labels. The lower the value the greater the disparity.
- -1: when there are no predicted rejection labels for facet $d$ or subgroup and no predicted acceptances for facet $a$ or subgroup.

### Counterfactual Flittest (FT)

The flittest is an approach that looks at each member of facet $d$ and assesses whether similar members of facet $a$ have different model predictions. The members of facet $a$ are chosen to be k-nearest neighbors of the observation from facet $d$. We assess how many nearest neighbors of the opposite group receive a different prediction, where the flipped prediction can go from positive to negative and vice versa.

The formula for the counterfactual flittest is the difference in the cardinality of two sets divided by the number of members of facet $d$:

$$\text{FT} = \frac{F^+ - F^-}{n_d}$$

Where:

- $F^+$ is the number of disfavored facet $d$ members with an unfavorable outcome whose nearest neighbors in favored facet $a$ received a favorable outcome.
- $F^-$ is the number of disfavored facet $d$ members with a favorable outcome whose nearest neighbors in favored facet $a$ received an unfavorable outcome.
- $n_d$ is the sample size of facet $d$.

The range of values for the counterfactual flittest for binary and multicategory facet labels is [-1, +1]. For continuous labels, we set a threshold to collapse the labels to binary.
Configure SageMaker Clarify processing jobs

Positive values occur when the number of unfavorable counterfactual flitest decisions for the disfavored facet $d$ exceeds the favorable ones.

Values near zero occur when the number of unfavorable and favorable counterfactual flitest decisions balance out.

Negative values occur when the number of unfavorable counterfactual flitest decisions for the disfavored facet $d$ is less than the favorable ones.

Configure an Amazon SageMaker Clarify Processing Jobs for Fairness and Explainability

This topic describes how to configure an Amazon SageMaker Clarify processing job capable of computing bias metrics and feature attributions for explainability. It is implemented using a specialized SageMaker Clarify container image. Instructions are provided for how to locate and download one of these container images. A brief overview of how SageMaker Clarify works is sketched. The parameters needed to configure the processing job and type of analysis are described. Prerequisites are outlined and some advice about compute resources consumed by SageMaker Clarify processing job is provided.

Topics
- Prerequisites (p. 1806)
- Getting Started with a SageMaker Clarify Container (p. 1806)
- How It Works (p. 1808)
- Configure a Processing Job Container's Input and Output Parameters (p. 1808)
- Configure the Analysis (p. 1809)

Prerequisites

Before you begin, you need to meet the following prerequisites:

- You need to provide an input dataset as tabular files in CSV or JSONLines format. The input dataset must include a label column for bias analysis. The dataset should be prepared for machine learning with any pre-processing needed, such as data cleaning or feature engineering, already completed.
- You need to provide a model artifact that supports either the CSV or JSONLines file format as one of its content type inputs. For posttraining bias metrics and explainability, we use the dataset to make inferences with the model artifact. Each row minus the label column must be ready to be used as payload for inferences.
- When creating processing jobs with the SageMaker container image, you need the following:
  - Network isolation must be disabled for the processing job.
  - If the model is in a VPC, the processing job must be in the same VPC as the model.
  - The IAM user/role of the caller must have permissions for SageMaker APIs. We recommend that you use the “arn:aws:iam::aws:policy/AmazonSageMakerFullAccess” managed policy.

Getting Started with a SageMaker Clarify Container

Amazon SageMaker provides prebuilt SageMaker Clarify container images that include the libraries and other dependencies needed to compute bias metrics and feature attributions for explainability. This image has been enabled to run SageMaker Process Data (p. 638) in your account.

The image URIs for the containers are in the following form:

<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-clarify-processing:1.0
For example:

```
205585389593.dkr.ecr.us-east-1.amazonaws.com/sagemaker-clarify-processing:1.0
```

The following table lists the addresses by AWS Region.

### Docker Images for Pretraining Bias Detection

**How It Works**

A SageMaker processing job used the SageMaker Clarify container at several stages in the lifecycle of the machine learning workflow. You can use the SageMaker Clarify container with your datasets and models to compute the following types of analysis:

- pretraining bias metrics
- posttraining bias metrics
- SHAP values for explainability

You can control which of these analyses are computed when you configure the processing job. For pretraining bias metrics, you need to provide the dataset. You can compute posttraining bias metrics and explainability after your model has been trained by providing the dataset and model name. You must configure the necessary parameters in the form of a JSON configuration file and provide this as an input to the processing job.

After the processing job completes, the result of the analyses is saved in the output location specified in the `ProcessingOutputs` parameters of the processing job. You can then download it from there and view the outputs or you can view the results in Studio if you have run a notebook there.

In order to compute posttraining bias metrics and SHAP values, the computation needs to get inferences for the model name provided. To accomplish this, the processing job creates an ephemeral endpoint with the model name, known as a shadow endpoint. The processing job deletes the shadow endpoint after the computations are completed.

At a high level, the processing job completes the following steps:

1. Validate inputs and parameters.
2. Create the shadow endpoint.
3. Compute pretraining bias metrics.
5. Compute local and global feature attributions.
6. Delete shadow endpoint.
7. Generate output files.

**Configure a Processing Job Container's Input and Output Parameters**

The Processing Job requires that you specify the following input parameters: a dataset files with input name "dataset" as S3 object or prefix, and an analysis configuration file with input name "analysis_config" as an S3 object. The job also requires an output parameter: the output location as an S3 prefix.
You can create and run a processing job with SageMaker `CreateProcessingJob` API using the AWS SDK or CLI or SageMaker Python SDK.

Using SageMaker Python SDK, create a `Processor` using the SageMaker Clarify container image URI:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
instance_count=1,
instance_type='ml.c5.xlarge',
max_runtime_in_seconds=1200,
volume_size_in_gb=100)
```

Then, you must also provide the input and output parameters for the `SageMakerClarifyProcessor`. If you provide the "dataset_uri", the dataset input is optional.

```python
dataset_path = "s3://my_bucket/my_folder/train.csv"
analysis_config_path = "s3://my_bucket/my_folder/analysis_config.json"
analysis_result_path = "s3://my_bucket/my_folder/output"

analysis_config_input = ProcessingInput(
    input_name="analysis_config",
    source=analysis_config_path,
    destination="/opt/ml/processing/input/config",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")
dataset_input = ProcessingInput(
    input_name="dataset",
    source=dataset_path,
    destination="/opt/ml/processing/input/data",
    s3_data_type="S3Prefix",
    s3_input_mode="File",
    s3_compression_type="None")
analysis_result_output = ProcessingOutput(
    source="/opt/ml/processing/output",
    destination=analysis_result_path,
    output_name="analysis_result",
    s3_upload_mode="EndOfJob")
```

### Configure the Analysis

Parameters for the analysis configuration must be provided in a JSON file named "analysis_config.json". The path must be provided in the `ProcessingInput` parameter named "analysis_config". Examples of analysis configuration files are provided below. In this JSON configuration file, you specify the following parameters:

- "version" – (Optional) Schema version of the configuration file. The latest supported version is used if not provided.
- "dataset_type" – Format of the dataset. Valid values are "text/csv" for CSV and "application/jsonlines" for JSON Lines.
- "dataset_uri" – (Optional) Dataset S3 prefix/object URI (if not given as `ProcessingInput`). If it is a prefix, then processing job recursively collects all S3 files under the prefix.
- "headers" – (Optional) A list of column names in the dataset. If the `dataset_type` is "application/jsonlines" and "label" is specified, then the last header shall be the header of label column.
- "label" – (Optional) Target attribute for the model to be used for `bias metrics` specified as a column name or index if the dataset format is CSV or as JSONPath if the dataset format is JSONLines.
- "probability_threshold" – (Optional) A float value to indicate the threshold to select the binary label in the case of binary classification. The default value is 0.5.
• "features" – (Optional) JSONPath for locating the feature columns for bias metrics if the dataset format is JSONLines.

• "label_values_or_threshold" – (Optional) List of label values or threshold to indicate positive outcome used for bias metrics.

• "facet" – (Optional) A list of features that are sensitive attributes, referred to as facets, to be used for bias metrics in the form of pairs to include the following:
  • "name_or_index" – Facet column name or index.
  • "value_or_threshold" – (Optional) List of values or threshold that the facet column can take which indicates the sensitive group, i.e. the group that is used to measure bias against. If not provided, bias metrics are computed as one group versus all for every unique value. If the facet column is numeric this threshold value is applied as the lower bound to select the sensitive group.

• "group_variable" – (Optional) A column name or index to indicate group variable to be used for the bias metric Conditional Demographic Disparity.

• "methods" – A list of methods and their parameters for the analyses and reports. If any section is omitted then it is not computed.
  • "pre_training_bias" – (Optional) Section on pretraining bias metrics.
    • "methods" – A list of pretraining metrics to be computed.
  • "post_training_bias" – (Optional) Section on posttraining bias metrics.
    • "methods" – A list of posttraining metrics to be computed.

• "shap" – (Optional) Section on SHAP value computation.
  • "baseline" – A list of rows (at least one) or S3 object URI to be used as the baseline dataset (also known as a background dataset) in the Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should contain only the feature columns/values and omit the label column/values
  • "num_samples" – Number of samples to be used in the Kernel SHAP algorithm. This number determines the size of the generated synthetic dataset to compute the SHAP values.
  • "agg_method" – Aggregation method for global SHAP values. Valid values are as follows:
    • "mean_abs" – Mean of absolute SHAP values for all instances.
    • "median" – Median of SHAP values for all instances.
    • "mean_sq" – Mean of squared SHAP values for all instances.
  • "use_logit" – (Optional) Boolean value to indicate if logit function is to be applied to the model predictions. The default value is "false". If "use_logit" is "true" then the SHAP values have log-odds units.
  • "save_local_shap_values" – (Optional) Boolean value to indicate if local SHAP values are to be saved in the output location. Default is "true".

• "predictor" – (Optional) Section on model parameters, required if "shap" and "post_training_bias" sections are present.
  • "model_name" – Model name (as created by CreateModel API with container mode as SingleModel).
  • "instance_type" – Instance type for the shadow endpoint.
  • "initial_instance_count" – Instance count for the shadow endpoint.
  • "content_type" – (Optional) The model input format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as dataset format.
  • "accept_type" – (Optional) The model output format to be used for getting inferences with the shadow endpoint. Valid values are "text/csv" for CSV and "application/jsonlines". The default value is the same as content_type.
  • "label" – (Optional) Index or JSONPath location in the model output for the target attribute to be used bias metrics. In CSV accept_type case, if it is not provided then assume that the model output is a single numeric value corresponding to score or probability.
• "probability" – (Optional) Index or JSONPath location in the model output for probabilities or scores to be used for explainability. For example, if the model output is JSONLines with a list of labels and probabilities, then for bias methods, the label that corresponds to the maximum probability is selected for bias computations. For explainability method, currently all probabilities are explained.

• "label_headers" – (Optional) A list of values that the "label" takes in the dataset that describe which label value each of the scores returned by the model endpoint correspond to. It is used to extract the label value with the highest score as predicted label for bias computations.

• "content_template" – (Optional) A template string to be used to construct the model input from dataset instances. It is only used when "content_type" is "application/jsonlines". The template should have one and only one placeholder, $features, which is replaced by features list at runtime. For example, given "content_template": "{"myfeatures":$features}" if an instance (no label) is 1,2,3 then model input becomes JSONline '{"myfeatures":[1,2,3]}'.

• "report" – (Optional) Section on report parameters. A report is generated if this section is present.

• "name" – (Optional) Filename prefix for the report notebook and PDF file. The default name is "report".

• "title" – (Optional) Title string for the report notebook and PDF file. The default title is "SageMaker Analysis Report".

Example Analysis Configuration JSON File for a CSV Dataset

```json
{
  "dataset_type": "text/csv",
  "headers": [
    "feature_0",
    "feature_1",
    "feature_2",
    "feature_3",
    "target"
  ],
  "label": "target",
  "label_values_or_threshold": [1],
  "probability_threshold": 0.7,
  "facet": [
    {
      "name_or_index": "feature_1",
      "value_or_threshold": [1]
    },
    {
      "name_or_index": "feature_2",
      "value_or_threshold": [0.7]
    }
  ],
  "group_variable": "feature_3",
  "methods": {
    "shap": {
      "baseline": [
        "yes",
        3,
        0.9,
        1
      ],
      "num_samples": 1000,
      "agg_method": "mean",
      "use_logit": true,
      "save_local_shap_values": true
    }
  }
}```
"pre_training_bias": {
    "methods": "all"
},
"post_training_bias": {
    "methods": "all"
},
"report": {
    "name": "report",
    "title": "Analysis Report"
},
"predictor": {
    "model_name": "my_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1,
    "content_type": "text/csv",
    "accept_type": "text/csv",
    "label": 0,
    "probability": 1
}

Model output as CSV is as follows:

Current,"[0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]"

Corresponding predictor configuration is as follows:

"predictor": {
    ...
    "accept_type": "text/csv",
    "label": 0,
    "probability": 1,
    ...
}

Example Analysis Configuration JSON File for a JSONLines Dataset

{
    "dataset_type": "application/jsonlines",
    "dataset_uri": "s3://my_bucket/my_folder/dataset.jsonl",
    "headers": ["Label", "Feature1", "Feature2"],
    "label": "data.label",
    "features": "data.features.values",
    "facet": [
        {
            "name_or_index": "Feature1",
            "value_or_threshold": [1,5]
        },
        {
            "name_or_index": "Feature2",
            "value_or_threshold": [2,6]
        }
    ],
    "methods": {
        "shap": {
            "baseline": [
                {
                    "data": {"features": [9,10], "label": 0}
                },
                {
                    "data": {"features": [11,12], "label": 1}
                }
            ]
        }
    }
}
Dataset as S3 prefix is as follows:

```json
"dataset_uri": "s3://my_bucket/my_folder"
```

Dataset as S3 object is as follows:

```json
"dataset_uri": "s3://my_bucket/my_folder/train.csv"
```

Baseline as S3 object is as follows:

```json
"baseline": "s3://my_bucket/my_folder/baseline.csv"
```

Model output as JSONLines is as follows:

```json
{"predicted_label": "Current", "score": [0.028986845165491104, 0.8253824710845947, 0.028993206098675728, 0.02898673340678215, 0.02898673340678215, 0.029557107016444206, 0.0290389321744442, 0.02905467338860035]}
```

Corresponding predictor configuration is as follows:

```json

    "model_name": "my_jsonl_model",
    "instance_type": "ml.m5.xlarge",
    "initial_instance_count": 1
}
```

**Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability**

You use SageMaker Clarify processing jobs to analyze potential sources of bias in your training data and to check your trained model for bias. For the procedure to analyze the data in SageMaker Studio, see Generate Reports for Bias in Pretraining Data in SageMaker Studio (p. 573). The focus here is on posttraining bias metric and SHAP values for explainability. Model predictions can be a source of bias (for example, if they make predictions that more frequently produce a negative result for one group than another). SageMaker Clarify is integrated with SageMaker Experiments so that after a model has been trained, you can identify attributes you would like to check for bias (for example, income). SageMaker runs a set of algorithms to check the trained model and provides you with a visual report on the different types of bias for each attribute, such as whether high-income earners receive more positive predictions compared to low-income earners.

**Compute Resources Required for SageMaker Clarify Processing Jobs**

Take the following into consideration when determining the compute resources you need to run SageMaker Clarify processing jobs:
• Processing jobs can take several minutes or more to complete.
• Computing explanations can be more time intensive than the actual inference. This includes the time to launch compute resources.
• Computing explanations can be more compute intensive than the actual inference. Review and monitor the charges you may incur from using SageMaker resources. For more information, see Amazon SageMaker Pricing.

Running the Processing Job

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio to detect posttraining model bias, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81). The following code samples are taken from the example notebook listed previously.

After you have trained your model, instantiate the SageMaker Clarify processor using the following command:

```python
from sagemaker import clarify
clarify_processor = clarify.SageMakerClarifyProcessor(role=role,
                                                      instance_count=1,
                                                      instance_type='ml.c4.xlarge',
                                                      sagemaker_session=session)
```

Next, configure the input dataset, where to store the output, the label column targeted with a `DataConfig` object, specify information about your trained model with `ModelConfig`, and provide information about the formats of your predictions with `ModelPredictedLabelConfig`.

```python
bias_report_output_path = 's3://{}/{}/clarify-bias'.format(bucket, prefix)
bias_data_config = clarify.DataConfig(s3_data_input_path=train_uri,
                                        s3_output_path=bias_report_output_path,
                                        label='Target',
                                        headers=training_data.columns.to_list(),
                                        dataset_type='text/csv')

model_config = clarify.ModelConfig(model_name=model_name,
                                   instance_type='ml.c5.xlarge',
                                   instance_count=1,
                                   accept_type='text/csv')

predictions_config = clarify.ModelPredictedLabelConfig(probability_threshold=0.8)

bias_config = clarify.BiasConfig(label_values_or_threshold=[1],
                                 facet_name='Sex',
                                 facet_values_or_threshold=[0])
```

You can run both the pretraining and posttraining analysis in the processing job at the same time with `run_bias()`.

```python
clarifyProcessor.run_bias(data_config=bias_data_config,
                          bias_config=bias_config,
                          prediction_config=predictions_config)```
model_config=model_config,
model_predicted_label_config=predictions_config,
pre_training_methods='all',
post_training_methods='all')

View the results in Studio or download them from the bias_report_output_path S3 bucket.

**Get the Analysis Results**

After the processing job is finished, you can download the output files to inspect or visualize the results in Studio. The output directory contains the following files:

- analysis.json – Bias metrics and SHAP values in JSON format.
- report.ipynb – Static notebook to visualize the bias metrics and SHAP values.
- explanations_shap/out.csv – Local (per-instance) SHAP values for each row in the dataset in the same format as input dataset. On each row, the output file contains SHAP values for each feature and the predicted label.

In the analysis JSON file, the bias metrics and SHAP values are organized into three separate sections.

```
{
    "explanations": { . . .
    "pre_training_bias_metrics": { . . .
    "post_training_bias_metrics": { . . .
```

SHAP values are in the “explanations” section. Values correspond to the global SHAP value for each feature column.

```
"explanations": {
    "kernel_shap": {
        "label0": {
            "global_shap_values": {
                "feature_0": 0.022486410860333206,
                "feature_1": 0.007381025261958729,
                "feature_2": 0.006843906804137847
            },
            "expected_value": 0.508233428001
        }
    }
}
```

The bias metrics are in the pretraining and posttraining bias metrics sections.

```
{
    "post_training_bias_metrics": {
        "label": "target",
        "label_value_or_threshold": "1",
        "facets": {
            "feature_2": [
                { "value_or_threshold": "1",
                  "metrics": [
                      { "name": "DI",
                        "description": "Disparate Impact (DI)",
                        "value": 0.711340206185567
```
Model Explainability

Amazon SageMaker Clarify provides tools to help explain how machine learning (ML) models make predictions. These tools can help ML modelers and developers and other internal stakeholders understand model characteristics as a whole prior to deployment and to debug predictions provided by the model after it's deployed. Transparency about how ML models arrive at their predictions is also critical to consumers and regulators who need to trust the model predictions if they are going to accept the decisions based on them. SageMaker Clarify uses a model-agnostic feature attribution approach, which you can used to understand why a model made a prediction after training and to provide per-instance explanation during inference. The implementation includes a scalable and efficient implementation of SHAP, based on the concept of a Shapley value from the field of cooperative game theory that assigns each feature an importance value for a particular prediction.

Troubleshooting

If the processing job fails to finish, you can try the following:

- Inspect the job logs directly in the notebook where you ran the job in. The job logs are located in the output of the notebook cell where you initiated the run.
- Inspect the job logs in CloudWatch.
- Add the following line in your notebook to describe the last processing job and look for the failure reason and exit message:
  ```python
clarify_processor.jobs[-1].describe()
  ```
- Execute the following AWS CLI command to describe the processing job and look for the failure reason and exit message:
  ```bash
aws sagemaker describe-processing-job --processing-job-name <processing-job-id>
  ```

If the processing job finishes but no results are found and a warning message is found in the CloudWatch logs that says “Signal 15 received, cleaning up”, this is an indication that the job was stopped either due to customer request using StopProcessingJob API call or the job ran out of allotted time. In this case, check the maximum runtime in the job configuration (max_runtime_in_seconds) and increase as needed.

The failure reason and exit message are intended to contain descriptive messages and exceptions, if encountered, during the run. One common reason is invalid or missing parameters. If you encounter unclear, confusing, or misleading messages or are unable to find a solution, submit feedback.

Model Explainability

[DCR](#)

**Difference in Conditional Rejections (DCR)**

-6.34782608695652184
What is the function of an explanation in the machine learning context? An explanation can be thought of as the answer to a Why question that helps humans understand the cause of a prediction. In the context of an ML model, you might be interested in answering questions such as:

- “Why did the model predict a negative outcome such as a loan rejection for a given applicant?”
- “How does the model make predictions?”
- “Why did the model make an incorrect prediction?”
- “Which features have the largest influence on the behavior of the model?”

You can use explanations for auditing and meeting regulatory requirements, building trust in the model and supporting human decision-making, and debugging and improving model performance.

The need to satisfy the demands for human understanding about the nature and outcomes of ML inference is key to the sort of explanation needed. Research from philosophy and cognitive science disciplines has shown that people care especially about contrastive explanations, or explanations of why an event X happened instead of some other event Y that did not occur. Here, X could be an unexpected or surprising event that happened and Y corresponds to an expectation based on their existing mental model referred to as a baseline. Note that for the same event X, different people might seek different explanations depending on their point of view or mental model Y. In the context of explainable AI, you can think of X as the example being explained and Y as a baseline that is typically chosen to represent an uninformative or average example in the dataset. Sometimes, the baseline might be implicit as with an image with all pixels of the same color in the case of ML models for images.

**Topics**

- Feature Attributions that Use Shapley Values (p. 1817)
- SHAP Baselines for Explainability (p. 1818)
- Create Feature Attribute Baselines and Explainability Reports (p. 1818)

**Feature Attributions that Use Shapley Values**

SageMaker Clarify provides feature attributions based on the concept of Shapley value. You can use Shapley values to determine the contribution that each feature made to model predictions. These attributions can be provided for specific predictions and at a global level for the model as a whole. For example, if you used an ML model for college admissions, the explanations could help determine whether the GPA or the SAT score was the feature most responsible for the model's predictions, and then you can determine how responsible each feature was for determining an admission decision about a particular student.

SageMaker Clarify has taken the concept of Shapley values from game theory and deployed it in a machine learning context. The Shapley value provides a way to quantify the contribution of each player to a game, and hence the means to distribute the total gain generated by a game to its players based on their contributions. In this machine learning context, SageMaker Clarify treats the prediction of the model on a given instance as the game and the features included in the model as the players. For a first approximation, you might be tempted to determine the marginal contribution or effect of each feature by quantifying the result of either dropping that feature from the model or dropping all other features from the model. However, this approach does not take into account that features included in a model are often not independent from each other. For example, if two features are highly correlated, dropping either one of the features might not alter the model prediction significantly.

To address these potential dependencies, the Shapley value requires that the outcome of each possible combination (or coalition) of features must be considered to determine the importance of each feature. Given d features, there are 2^d possible feature combinations, each corresponding to a potential model. To determine the attribution for a given feature f, consider the marginal contribution of including f in all feature combinations (and associated models) that do not contain f, and take the average. It
can be shown that Shapley value is the unique way of assigning the contribution or importance of each feature that satisfies certain desirable properties. In particular, the sum of Shapley values of each feature corresponds to the difference between the predictions of the model and a dummy model with no features. However, even for reasonable values of $d$, say 50 features, it is computationally prohibitive and impractical to train $2^d$ possible models. As a result, SageMaker Clarify needs to make use of various approximation techniques. For this purpose, SageMaker Clarify uses SHapley Additive exPlanations (SHAP), which incorporates such approximations and devised a scalable and efficient implementation of the Kernel SHAP algorithm through additional optimizations.

For additional information on Shapley values, see A Unified Approach to Interpreting Model Predictions.

**SHAP Baselines for Explainability**

As noted earlier, explanations are typically contrastive (that is, they account for deviations from a baseline). As a result, for the same model prediction, you can expect to get different explanations with respect to different baselines so your choice of a baseline is crucial. In an ML context, the baseline corresponds to a hypothetical instance that can be either *uninformative* or *informative*. During the computation of Shapley values, SageMaker Clarify generates several new instances between the baseline and the given instance, in which the absence of a feature is modeled by setting the feature value to that of the baseline and the presence of a feature is modeled by setting the feature value to that of the given instance. Thus, the absence of all features corresponds to the baseline and the presence of all features corresponds to the given instance.

How can you choose good baselines? Often it is desirable to select a baseline with very low information content. For example, you can construct an average instance from the training dataset by taking either the median or average for numerical features and the mode for categorical features. For the college admissions example, you might be interested in explaining why a particular applicant was accepted as compared to a baseline acceptance based on an average applicant.

Alternatively, you can choose to generate explanations with respect to informative baselines. For the college admissions scenario, you might want to explain why a particular applicant was rejected when compared with other applicants from similar demographic backgrounds. In this case, you can choose a baseline that represents the applicants of interest, namely those from a similar demographic background. Thus, you can use informative baselines to concentrate the analysis on the specific aspects of a particular model prediction. You can isolate the features for assessment by setting demographic attributes and other features that you can’t act on to the same value as in the given instance.

**Create Feature Attribute Baselines and Explainability Reports**

For an example notebook with instructions on how to run a SageMaker Clarify processing job in Studio that creates explanations for its predictions relative to a baseline, see Explainability and bias detection with Amazon SageMaker Clarify.

If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81). The following code examples are taken from the example notebook listed previously. This section discusses the code related to the use of Shapley values to provide reports that compare the relative contributions each feature made the predictions.

Use `SHAPConfig` to create the baseline. In this example, the `mean_abs` is the mean of absolute SHAP values for all instances, specified as the baseline. You use `DataConfig` to configure the target variable, data input and output paths, and their formats.

```python
shap_config = clarify.SHAPConfig(baseline=test_features.iloc[0].values.tolist(),
                                  num_samples=15,
                                  mean_abs=True)
```
Incremental Training in Amazon SageMaker

Over time, you might find that a model generates inference that are not as good as they were in the past. With incremental training, you can use the artifacts from an existing model and use an expanded dataset to train a new model. Incremental training saves both time and resources.

Use incremental training to:

- Train a new model using an expanded dataset that contains an underlying pattern that was not accounted for in the previous training and which resulted in poor model performance.
- Use the model artifacts or a portion of the model artifacts from a popular publicly available model in a training job. You don't need to train a new model from scratch.
- Resume a training job that was stopped.
- Train several variants of a model, either with different hyperparameter settings or using different datasets.

For more information about training jobs, see Train a Model with Amazon SageMaker (p. 8).

You can train incrementally using the SageMaker console or the Amazon SageMaker Python SDK.

**Important**

Only three built-in algorithms currently support incremental training: Object Detection Algorithm (p. 1436), Image Classification Algorithm (p. 1356), and Semantic Segmentation Algorithm (p. 1459).

**Topics**

- Perform Incremental Training (Console) (p. 1819)
- Perform Incremental Training (API) (p. 1821)

**Perform Incremental Training (Console)**

To complete this procedure, you need:

- The Amazon Simple Storage Service (Amazon S3) bucket URI where you've stored the training data.
- The S3 bucket URI where you want to store the output of the job.
To perform incremental training (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. The training job name must have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and : + = @ _ % - (hyphen).
5. Choose the algorithm that you want to use. For information about algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 691).
6. (Optional) For Resource configuration, either leave the default values or increase the resource consumption to reduce computation time.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either leave the default (train) or enter a more meaningful name for the training dataset, such as expanded-training-dataset.
   b. For InputMode, choose File. For incremental training, you need to use file input mode.
   c. For S3 data distribution type, choose FullyReplicated. This causes each ML compute instance to use a full replicate of the expanded dataset when training incrementally.
   d. If the expanded dataset is uncompressed, set the Compression type to None. If the expanded dataset is compressed using Gzip, set it to Gzip.
   e. (Optional) If you are using File input mode, leave Content type empty. For Pipe input mode, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.
   f. For Record wrapper, if the dataset is saved in RecordIO format, choose RecordIO. If your dataset is not saved as a RecordIO formatted file, choose None.
   g. For S3 data type, if the dataset is stored as a single file, choose S3Prefix. If the dataset is stored as several files in a folder, choose Manifest.
   h. For S3 location, provide the URL to the path where you stored the expanded dataset.
   i. Choose Done.
8. To use model artifacts in a training job, you need to add a new channel and provide the needed information about the model artifacts.
   a. For Input data configuration, choose Add channel.
   b. For Channel name, enter model to identify this channel as the source of the model artifacts.
Perform Incremental Training (API)

This example shows how to use SageMaker APIs to train a model using the SageMaker image classification algorithm and the Caltech 256 Image Dataset, then train a new model using the first one. It uses Amazon S3 for input and output sources. Please see the incremental training sample notebook for more details on using incremental training.

**Note**

In this example we used the original datasets in the incremental training, however you can use different datasets, such as ones that contain newly added samples. Upload the new datasets to S3 and make adjustments to the `data_channels` variable used to train the new model.

Get an AWS Identity and Access Management (IAM) role that grants required permissions and initialize environment variables:

```python
import sagemaker
from sagemaker import get_execution_role

role = get_execution_role()
print(role)

sess = sagemaker.Session()
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in the `Output data configuration` field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 65).
bucket = sess.default_bucket()
print(bucket)
prefix = 'ic-incr-training'

Get the training image for the image classification algorithm:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri

training_image = get_image_uri(sess.boto_region_name, 'image-classification', repo_version="latest")
# Display the training image
print (training_image)
```

Download the training and validation datasets, then upload them to Amazon Simple Storage Service (Amazon S3):

```python
import os
import urllib.request
import boto3

# Define a download function
def download(url):
    filename = url.split('/')[-1]
    if not os.path.exists(filename):
        urllib.request.urlretrieve(url, filename)

# Download the caltech-256 training and validation datasets
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-train.rec')
download('http://data.mxnet.io/data/caltech-256/caltech-256-60-val.rec')

# Create four channels: train, validation, train_lst, and validation_lst
s3train = 's3://{}/train/'.format(bucket, prefix)
s3validation = 's3://{}/validation/'.format(bucket, prefix)

# Upload the first files to the train and validation channels
!aws s3 cp caltech-256-60-train.rec $s3train --quiet
!aws s3 cp caltech-256-60-val.rec $s3validation --quiet
```

Define the training hyperparameters:

```python
# Define hyperparameters for the estimator
hyperparams = {
    "num_layers": "18",
    "resize": "32",
    "num_training_samples": "50000",
    "num_classes": "10",
    "image_shape": "3,28,28",
    "mini_batch_size": "128",
    "epochs": "3",
    "learning_rate": "0.1",
    "lr_scheduler_step": "2,3",
    "lr_scheduler_factor": "0.1",
    "augmentation_type": "crop_color",
    "optimizer": "sgd",
    "momentum": "0.9",
    "weight_decay": "0.0001",
    "beta_1": "0.9",
    "beta_2": "0.999",
    "gamma": "0.9",
    "eps": "1e-8",
    "top_k": "5",
    "checkpoint_frequency": "1",
}
```
Create an estimator object and train the first model using the training and validation datasets:

```
# Fit the base estimator
s3_output_location = 's3://{}/{}//output'.format(bucket, prefix)
ic = sagemaker.estimator.Estimator(training_image,
   role,
   instance_count=1,
   instance_type='ml.p2.xlarge',
   volume_size=50,
   max_run=360000,
   input_mode='File',
   output_path=s3_output_location,
   sagemaker_session=sess,
   hyperparameters=hyperparams)
train_data = sagemaker.inputs.TrainingInput(s3train, distribution='FullyReplicated',
   content_type='application/x-recordio',
   s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3validation,
   distribution='FullyReplicated',
   content_type='application/x-recordio',
   s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}
ic.fit(inputs=data_channels, logs=True)
```

To use the model to incrementally train another model, create a new estimator object and use the model artifacts (`ic.model_data`, in this example) for the `model_uri` input argument:

```
# Given the base estimator, create a new one for incremental training
incr_ic = sagemaker.estimator.Estimator(training_image,
   role,
   instance_count=1,
   instance_type='ml.p2.xlarge',
   volume_size=50,
   max_run=360000,
   input_mode='File',
   output_path=s3_output_location,
   sagemaker_session=sess,
   hyperparameters=hyperparams,
   model_uri=ic.model_data) # This parameter will
ingest the previous job’s model as a new channel
incr_ic.fit(inputs=data_channels, logs=True)
```

After the training job has completed, the newly trained model artifacts are stored under the S3 output path that you provided in `Output_path`. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 65).

### Managed Spot Training in Amazon SageMaker

Amazon SageMaker makes it easy to train machine learning models using managed Amazon EC2 Spot instances. Managed spot training can optimize the cost of training models up to 90% over on-demand instances. SageMaker manages the Spot interruptions on your behalf.

Managed Spot Training uses Amazon EC2 Spot instance to run training jobs instead of on-demand instances. You can specify which training jobs use spot instances and a stopping condition that specifies
how long SageMaker waits for a job to run using Amazon EC2 Spot instances. Metrics and logs generated during training runs are available in CloudWatch.

Amazon SageMaker automatic model tuning, also known as hyperparameter tuning, can use managed spot training. For more information on automatic model training, see Perform Automatic Model Tuning with SageMaker (p. 1715).

Spot instances can be interrupted, causing jobs to take longer to start or finish. You can configure your managed spot training job to use checkpoints. SageMaker copies checkpoint data from a local path to Amazon S3. When the job is restarted, SageMaker copies the data from Amazon S3 back into the local path. The training job can then resume from the last checkpoint instead of restarting. For more information about checkpointing, see Use Checkpoints in Amazon SageMaker (p. 1825).

Note
Unless your training job will complete quickly, we recommend you use checkpointing with managed spot training. SageMaker built-in algorithms and marketplace algorithms that do not checkpoint are currently limited to a MaxWaitTimeInSeconds of 3600 seconds (60 minutes).

Topics
- Using Managed Spot Training (p. 1824)
- Managed Spot Training Lifecycle (p. 1824)

Using Managed Spot Training

To use managed spot training, create a training job. Set EnableManagedSpotTraining to True and specify the MaxWaitTimeInSeconds. MaxWaitTimeInSeconds must be larger than MaxRuntimeInSeconds. For more information about creating a training job, see DescribeTrainingJob.

You can calculate the savings from using managed spot training using the formula

\[
(1 - \frac{BillableTimeInSeconds}{TrainingTimeInSeconds}) \times 100
\]

For example, if BillableTimeInSeconds is 100 and TrainingTimeInSeconds is 500, the savings is 80%.

Managed Spot Training Lifecycle

You can monitor a training job using TrainingJobStatus and SecondaryStatus returned by DescribeTrainingJob. The list below shows how TrainingJobStatus and SecondaryStatus values change depending on the training scenario:

- **Spot instances acquired with no interruption during training**
  1. InProgress: Starting → Downloading → Training → Uploading

- **Spot instances interrupted once. Later, enough spot instances were acquired to finish the training job.**
  1. InProgress: Starting → Downloading → Training → Interrupted → Starting → Downloading → Training → Uploading

- **Spot instances interrupted twice and MaxWaitTimeInSeconds exceeded.**

Use Checkpoints in Amazon SageMaker

Use checkpoints in Amazon SageMaker to save the state of machine learning (ML) models during training. Checkpoints are snapshots of the model and can be configured by callback functions of ML frameworks. You can use the saved checkpoints to restart a training job from the last saved checkpoint.

The SageMaker training mechanism uses training containers on Amazon EC2 instances, and the checkpoint files are saved under a local directory of the containers. SageMaker provides functionality to copy the checkpoints from the local path to Amazon S3. Using checkpoints, you can do the following:

- Save your model snapshots under training due to an unexpected interruption to the training job or instance.
- Resume training the model in the future from a checkpoint.
- Analyze the model at intermediate stages of training.
- Use checkpoints with SageMaker managed spot training to save on training costs.

If you are using checkpoints with the SageMaker managed spot training, SageMaker manages checkpointing your model training on a spot instance and resuming the training job on the next spot instance. With SageMaker managed spot training, you can significantly reduce the billable time for training ML models. For more information, see Managed Spot Training in Amazon SageMaker (p. 1823).

Topics

- Checkpoints for Frameworks and Algorithms in SageMaker (p. 1825)
- Enable Checkpointing (p. 1826)
- Browse Checkpoint Files (p. 1827)
- Resume Training From a Checkpoint (p. 1827)

Checkpoints for Frameworks and Algorithms in SageMaker

Use checkpoints to save snapshots of ML models built on your preferred frameworks within SageMaker.

SageMaker frameworks and algorithms that support checkpointing

SageMaker supports checkpointing for Deep Learning Containers and a subset of built-in algorithms without requiring training script changes. SageMaker saves the checkpoints to the default local path '/opt/ml/checkpoints' and copies them to Amazon S3.

- Deep Learning Containers: TensorFlow, PyTorch, and MXNet
- Built-in algorithms: Image Classification, Object Detection, Semantic Segmentation, and XGBoost (0.90-1 or later)

Note

If you are using the XGBoost algorithm in framework mode (script mode), you need to bring an XGBoost training script with checkpointing that's manually configured. For more information about the XGBoost training methods to save model snapshots, see Training XGBoost in the XGBoost Python SDK documentation.

If a pre-built algorithm that does not support checkpointing is used in a managed spot training job, SageMaker does not allow a maximum wait time greater than an hour for the job in order to limit wasted training time from interrupts.
For custom training containers and other frameworks

If you are using your own training containers, training scripts, or other frameworks not listed in the previous section, you must properly set up your training script using callbacks or training APIs to save checkpoints to the local path (`/opt/ml/checkpoints`) and load from the local path in your training script. SageMaker estimators can sync up with the local path and save the checkpoints to Amazon S3.

Enable Checkpointing

After you enable checkpointing, SageMaker saves checkpoints to Amazon S3 and syncs your training job with the checkpoint S3 bucket.

The following example shows how to configure checkpoint paths when you construct a SageMaker estimator. To enable checkpointing, add the `checkpoint_s3_uri` and `checkpoint_local_path` parameters to your estimator.

The following example template shows how to create a generic SageMaker estimator and enable checkpointing. You can use this template for the supported algorithms by specifying the `image_uri` parameter. To find Docker image URIs for algorithms with checkpointing supported by SageMaker, see Docker Registry Paths and Example Code (p. 698). You can also replace `estimator` and `Estimator` with other SageMaker frameworks’ estimator parent classes and estimator classes, such as TensorFlow, PyTorch, MXNet, and XGBoost.

```python
import sagemaker
from sagemaker.estimator import Estimator

bucket=sagemaker.Session().default_bucket()
base_job_name="sagemaker-checkpoint-test"
checkpoint_in_bucket="checkpoints"

# The S3 URI to store the checkpoints
checkpoint_s3_bucket="s3://{}/{}/{}".format(bucket, base_job_name, checkpoint_in_bucket)

# The local path where the model will save its checkpoints in the training container
checkpoint_local_path="/opt/ml/checkpoints"

estimator = Estimator(
    ...  # Specify to use built-in algorithms
    output_path=bucket,
    base_job_name=base_job_name,

    # Parameters required to enable checkpointing
    checkpoint_s3_uri=checkpoint_s3_bucket,
    checkpoint_local_path=checkpoint_local_path
)"
The following two parameters specify paths for checkpointing:

- **checkpoint_local_path** – Specify the local path where the model saves the checkpoints periodically in a training container. The default path is set to '/opt/ml/checkpoints'. If you are using other frameworks or bringing your own training container, ensure that your training script's checkpoint configuration specifies the path to '/opt/ml/checkpoints'.

  **Note**
  We recommend specifying the local paths as '/opt/ml/checkpoints' to be consistent with the default SageMaker checkpoint settings. If you prefer to specify your own local path, make sure you match the checkpoint saving path in your training script and the `checkpoint_local_path` parameter of the SageMaker estimators.

- **checkpoint_s3_uri** – The URI to an S3 bucket where the checkpoints are stored in real time.

To find a complete list of SageMaker estimator parameters, see the [Estimator API in the Amazon SageMaker Python SDK documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/estimator-parameters.html).

## Browse Checkpoint Files

Locate checkpoint files using the SageMaker Python SDK and the Amazon S3 console.

### To find the checkpoint files programmatically

To retrieve the S3 bucket URI where the checkpoints are saved, check the following estimator attribute:

```
estimator.checkpoint_s3_uri
```

This returns the Amazon S3 output path for checkpoints configured while requesting the `CreateTrainingJob` request. To find the saved checkpoint files using the Amazon S3 console, use the following procedure.

### To find the checkpoint files from the Amazon S3 console

2. In the left navigation pane, choose **Training jobs**.
3. Choose the link to the training job with checkpointing enabled to open **Job settings**.
4. In the **Job settings** page of the training job, locate the **Checkpoint configuration** section.

   ![Checkpoint configuration](image)

   - **S3 output path**: `s3://path-to-your-checkpoint`
   - **Local path**: `/opt/ml/checkpoints/`

5. Use the link to the S3 bucket to access the checkpoint files.

## Resume Training From a Checkpoint

To resume a training job from a checkpoint, run a new estimator with the same `checkpoint_s3_uri` that you created in the Enable Checkpointing (p. 1826) section. Once the training has resumed, the
Considerations for Checkpointing

Consider the following when using checkpoints in SageMaker.

- To avoid overwrites in distributed training with multiple instances, you must manually configure the checkpoint file names and paths in your training script. The high-level SageMaker checkpoint configuration specifies a single Amazon S3 location without additional suffixes or prefixes to tag checkpoints from multiple instances.
- The SageMaker Python SDK does not support high-level configuration for checkpointing frequency. To control the checkpointing frequency, modify your training script using frameworks’ model save functions or checkpoint callbacks.

Provide Dataset Metadata to Training Jobs with an Augmented Manifest File

To include metadata with your dataset in a training job, use an augmented manifest file. When using an augmented manifest file, your dataset must be stored in Amazon Simple Storage Service (Amazon S3) and you must configure your training job to use dataset stored there. You specify the location and format of this dataset for one or more Channel. Augmented manifests can only support Pipe input mode. See the section, InputMode in Channel to learn more about pipe input mode.

When specifying a channel's parameters, you specify a path to the file, called a S3Uri. Amazon SageMaker interprets this URI based on the specified S3DataType in S3DataSource. The AugmentedManifestFile option defines a manifest format that includes metadata with the input data. Using an augmented manifest file is an alternative to preprocessing when you have labeled data. For training jobs using labeled data, you typically need to preprocess the dataset to combine input data with metadata before training. If your training dataset is large, preprocessing can be time consuming and expensive.

Augmented Manifest File Format

An augmented manifest file must be formatted in JSON Lines format. In JSON Lines format, each line in the file is a complete JSON object followed by a newline separator.

During training, SageMaker parses each JSON line and sends some or all of its attributes on to the training algorithm. You specify which attribute contents to pass and the order in which to pass them.
Stream Augmented Manifest File Data

with the AttributeNames parameter of the CreateTrainingJob API. The AttributeNames parameter is an ordered list of attribute names that SageMaker looks for in the JSON object to use as training input.

For example, if you list ["line", "book"] for AttributeNames, the input data must include the attribute names of line and book in the specified order. For this example, the following augmented manifest file content is valid:

```json
{"author": "Herman Melville", "line": "Call me Ishmael", "book": "Moby Dick"}
{"line": "It was love at first sight.", "author": "Joseph Heller", "book": "Catch-22"}
```

SageMaker ignores unlisted attribute names even if they precede, follow, or are in between listed attributes.

When using augmented manifest files, observe the following guidelines:

- The order of the attributes listed in the AttributeNames parameter determines the order of the attributes passed to the algorithm in the training job.
- The listed AttributeNames can be a subset of all of the attributes in the JSON line. SageMaker ignores unlisted attributes in the file.
- You can specify any type of data allowed by the JSON format in AttributeNames, including text, numerical, data arrays, or objects.
- To include an S3 URI as an attribute name, add the suffix -ref to it.

If an attribute name contains the suffix -ref, the attribute's value must be an S3 URI to a data file that is accessible to the training job. For example, if AttributeNames contains ["image-ref", "is-a-cat"], a valid augmented manifest file might contain these lines:

```json
{"image-ref": "s3://mybucket/sample01/image1.jpg", "is-a-cat": 1}
{"image-ref": "s3://mybucket/sample02/image2.jpg", "is-a-cat": 0}
```

For the first line of this manifest, SageMaker retrieves the contents of the S3 object s3://mybucket/ foo/image1.jpg and streams it to the algorithm for training. The second line is the string representation of the is-a-cat attribute "1", which is followed by the contents of the second line.

To create an augmented manifest file, use Amazon SageMaker Ground Truth to create a labeling job. For more information, see Output Data (p. 405).

### Stream Augmented Manifest File Data

Augmented manifest format enables you to do training in Pipe mode using files without needing to create RecordIO files. You need to specify both train and validation channels as values for the InputDataConfig parameter of the CreateTrainingJob request. Augmented manifest files are supported only for channels using Pipe input mode. For each channel, the data is extracted from its augmented manifest file and streamed (in order) to the algorithm through the channel's named pipe. Pipe mode uses the first in first out (FIFO) method, so records are processed in the order in which they are queued. For information about Pipe input mode, see Input Mode.

Attribute names with a "-ref" suffix point to preformatted binary data. In some cases, the algorithm knows how to parse the data. In other cases, you might need to wrap the data so that records are delimited for the algorithm. If the algorithm is compatible with RecordIO-formatted data, specifying RecordIO for RecordWrapperType solves this issue. If the algorithm is not compatible with RecordIO format, specify None for RecordWrapperType and make sure that your data is parsed correctly for your algorithm.
Using the \[\text{"image-ref"}, \text{"is-a-cat"}\] example, if you use RecordIO wrapping, the following stream of data is sent to the queue:

```
recordio_formatted(s3://mybucket/foo/image1.jpg)recordio_formatted("1")recordio_formatted(s3://mybucket/bar/image2.jpg)recordio_formatted("0")
```

Images that are not wrapped with RecordIO format, are streamed with the corresponding \text{is-a-cat} attribute value as one record. This can cause a problem because the algorithm might not delimit the images and attributes correctly. For more information about using augmented manifest files for image classification, see Train with Augmented Manifest Image Format.

With augmented manifest files and Pipe mode in general, size limits of the EBS volume do not apply. This includes settings that otherwise must be within the EBS volume size limit such as \text{S3DataDistributionType}. For more information about Pipe mode and how to use it, see Using Your Own Training Algorithms - Input Data Configuration.

**Use an Augmented Manifest File (Console)**

To complete this procedure, you need:

- The URL of the S3 bucket where you've stored the augmented manifest file.
- To store the data that is listed in the augmented manifest file in an S3 bucket.
- The URL of the S3 bucket where you want to store the output of the job.

**To use an augmented manifest file in a training job (console)**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Training, then choose Training jobs.
3. Choose Create training job.
4. Provide a name for the training job. The name must be unique within an AWS Region in an AWS account. It can have 1 to 63 characters. Valid characters: a-z, A-Z, 0-9, and \( . : + = @ \_ % - \) (hyphen).
5. Choose the algorithm that you want to use. For information about supported built-in algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 691). If you want to use a custom algorithm, make sure that it is compatible with Pipe mode.
6. (Optional) For Resource configuration, either accept the default values or, to reduce computation time, increase the resource consumption.
   a. (Optional) For Instance type, choose the ML compute instance type that you want to use. In most cases, ml.m4.xlarge is sufficient.
   b. For Instance count, use the default, 1.
   c. (Optional) For Additional volume per instance (GB), choose the size of the ML storage volume that you want to provision. In most cases, you can use the default, 1. If you are using a large dataset, use a larger size.
7. Provide information about the input data for the training dataset.
   a. For Channel name, either accept the default (\text{train}) or enter a more meaningful name, such as \text{training-augmented-manifest-file}.
   b. For InputMode, choose Pipe.
   c. For S3 data distribution type, choose FullyReplicated. When training incrementally, fully replicating causes each ML compute instance to use a complete copy of the expanded dataset. For neural-based algorithms, such as Neural Topic Model (NTM) Algorithm (p. 1414), choose ShardedByS3Key.
d. If the data specified in the augmented manifest file is uncompressed, set the **Compression type** to **None**. If the data is compressed using gzip, set it to **Gzip**.

e. (Optional) For **Content type**, specify the appropriate MIME type. Content type is the multipurpose internet mail extension (MIME) type of the data.

f. For **Record wrapper**, if the dataset specified in the augmented manifest file is saved in RecordIO format, choose **RecordIO**. If your dataset is not saved as a RecordIO-formatted file, choose **None**.

g. For **S3 data type**, choose **AugmentedManifestFile**.

h. For **S3 location**, provide the path to the bucket where you stored the augmented manifest file.

i. For **AugmentedManifestFile attribute names**, specify the name of an attribute that you want to use. The attribute name must be present within the augmented manifest file, and is case-sensitive.

j. (Optional) To add more attribute names, choose **Add row** and specify another attribute name for each attribute.

k. (Optional) To adjust the order of attribute names, choose the up or down buttons next to the names. When using an augmented manifest file, the order of the specified attribute names is important.

l. Choose **Done**.

8. For **Output data configuration**, provide the following information:

a. For **S3 location**, type the path to the S3 bucket where you want to store the output data.

b. (Optional) You can use your AWS Key Management Service (AWS KMS) encryption key to encrypt the output data at rest. For **Encryption key**, provide the key ID or its Amazon Resource Number (ARN). For more information, see **KMS-Managed Encryption Keys**.

9. (Optional) For **Tags**, add one or more tags to the training job. A tag is metadata that you can define and assign to AWS resources. In this case, you can use tags to help you manage your training jobs. A tag consists of a key and a value, which you define. For example, you might want to create a tag with **Project** as a key and a value that refers to a project that is related to the training job, such as **Home value forecasts**.

10. Choose **Create training job**. SageMaker creates and runs the training job.

After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for **S3 output path** in the **Output data configuration** field. To deploy the model to get predictions, see **Step 5: Deploy the Model to Amazon EC2 (p. 65)**.

### Use an Augmented Manifest File (API)

The following shows how to train a model with an augmented manifest file using the SageMaker high-level Python library:

```python
# Create a model object set to using "Pipe" mode.
model = sagemaker.estimator.Estimator(training_image,
    role,
    instance_count=1,
    instance_type='ml.p3.2xlarge',
    volume_size = 50,
    max_run = 360000,
    input_mode = 'Pipe',
    output_path=s3_output_location,
    sagemaker_session=session)

# Create a train data channel with S3_data_type as 'AugmentedManifestFile' and attribute names.
train_data = sagemaker.session.s3_input(your_augmented_manifest_file,
    distribution='FullyReplicated',
    s3_input_mode='Pipe',
    s3_data_type='AugmentedManifestFile',
    s3_key=your_augmented_manifest_file,
    s3DataType='AugmentedManifestFile',
    s3_key=your_augmented_manifest_file)
```

1831
After the training job has finished, SageMaker stores the model artifacts in the bucket whose path you provided for S3 output path in the Output data configuration field. To deploy the model to get predictions, see Step 5: Deploy the Model to Amazon EC2 (p. 65).

Monitor and Analyze Training Jobs Using Metrics

An Amazon SageMaker training job is an iterative process that teaches a model to make predictions by presenting examples from a training dataset. Typically, a training algorithm computes several metrics, such as training error and prediction accuracy. These metrics help diagnose whether the model is learning well and will generalize well for making predictions on unseen data. The training algorithm writes the values of these metrics to logs, which SageMaker monitors and sends to Amazon CloudWatch in real time. To analyze the performance of your training job, you can view graphs of these metrics in CloudWatch. When a training job has completed, you can also get a list of the metric values that it computes in its final iteration by calling the DescribeTrainingJob operation.

Topics
- Training Metrics Sample Notebooks (p. 1832)
- Defining Training Metrics (p. 1832)
- Monitoring Training Job Metrics (Console) (p. 1835)
- Monitoring Training Job Metrics (SageMaker Console) (p. 1835)
- Example: Viewing a Training and Validation Curve (p. 1837)

Training Metrics Sample Notebooks

The following sample notebooks show how to view and plot training metrics:
- An Introduction to the Amazon SageMaker ObjectToVec Model for Sequence-to-sequence Embedding (object2vec_sentence_similarity.ipynb)
- Regression with the Amazon SageMaker XGBoost Algorithm (xgboost_abalone.ipynb)

For instructions how to create and access Jupyter notebook instances that you can use to run the examples in SageMaker, see Example Notebooks (p. 130). To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. To access the example notebooks that show how to use training metrics, object2vec_sentence_similarity.ipynb and xgboost_abalone.ipynb, from the Introduction to Amazon algorithms section. To open a notebook, choose its Use tab, then choose Create copy.

Defining Training Metrics

SageMaker automatically parses the logs for metrics that built-in algorithms emit and sends those metrics to CloudWatch. If you want SageMaker to parse logs from a custom algorithm and send metrics that the algorithm emits to CloudWatch, you have to specify the metrics that you want SageMaker to
send to CloudWatch when you configure the training job. You specify the name of the metrics that you want to send and the regular expressions that SageMaker uses to parse the logs that your algorithm emits to find those metrics.

You can specify the metrics that you want to track with the SageMaker console, the SageMaker Python SDK (https://github.com/aws/sagemaker-python-sdk), or the low-level SageMaker API.

Topics
- Defining Regular Expressions for Metrics (p. 1833)
- Defining Training Metrics (Low-level SageMaker API) (p. 1833)
- Defining Training Metrics (SageMaker Python SDK) (p. 1834)
- Define Training Metrics (Console) (p. 1834)

Defining Regular Expressions for Metrics

To find a metric, SageMaker searches the logs that your algorithm emits and finds logs that match the regular expression that you specify for that metric. If you are using your own algorithm, do the following:

- Make sure that the algorithm writes the metrics that you want to capture to logs
- Define a regular expression that accurately searches the logs to capture the values of the metrics that you want to send to CloudWatch metrics.

For example, suppose your algorithm emits metrics for training error and validation error by writing logs similar to the following to stdout or stderr:

```plaintext
Train_error=0.138318; Valid_error = 0.324557;
```

If you want to monitor both of those metrics in CloudWatch, your `AlgorithmSpecification` would look like the following:

```json
"AlgorithmSpecification": {
  "TrainingImage": ContainerName,
  "TrainingInputMode": "File",
  "MetricDefinitions" : [
    {
      "Name": "train:error",
      "Regex": "Train_error=(.*?);"
    },
    {
      "Name": "validation:error",
      "Regex": "Valid_error=(.*?);"
    }
  ]
}
```

In the regex for the `train:error` metric defined above, the first part of the regex finds the exact text “Train_error=”, and the expression `(.*?);` captures zero or more of any character until the first semicolon character. In this expression, the parenthesis tell the regex to capture what is inside them, `. means any character, * means zero or more, and ? means capture only until the first instance of the ; character.

Defining Training Metrics (Low-level SageMaker API)

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions in the `MetricDefinitions` field of the `AlgorithmSpecification` input parameter.
that you pass to the `CreateTrainingJob` operation. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `AlgorithmSpecification` would look like the following:

```
"AlgorithmSpecification": {
    "TrainingImage": "ContainerName",
    "TrainingInputMode": "File",
    "MetricDefinitions": [
        {
            "Name": "train:error",
            "Regex": "Train_error=(.*?);"
        },
        {
            "Name": "validation:error",
            "Regex": "Valid_error=(.*?);"
        }
    ]
}
```

For more information about defining and running a training job by using the low-level SageMaker API, see `CreateTrainingJob`.

**Defining Training Metrics (SageMaker Python SDK)**

Define the metrics that you want to send to CloudWatch by specifying a list of metric names and regular expressions as the `metric_definitions` argument when you initialize an `Estimator` object. For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your `Estimator` initialization would look like the following:

```
estimator = Estimator(image_name=ImageName,
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    k=10,
    sagemaker_session=sagemaker_session,
    metric_definitions=[
        {'Name': 'train:error', 'Regex': 'Train_error=(.*?);'},
        {'Name': 'validation:error', 'Regex': 'Valid_error=(.*?);'}
    ]
)
```

For more information about training by using Amazon SageMaker Python SDK estimators, see [https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview](https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview).

**Define Training Metrics (Console)**

You can define metrics for a custom algorithm in the console when you create a training job by providing the name and regular expression (regex) for `Metrics`.

For example, if you want to monitor both the `train:error` and `validation:error` metrics in CloudWatch, your metric definitions would look like the following:

```
[
    {
        "Name": "train:error",
        "Regex": "Train_error=(.*?);"
    },
    {
        "Name": "validation:error",
        "Regex": "Valid_error=(.*?);"
    }
]
```
Monitoring Training Job Metrics (Console)

You can monitor the metrics that a training job emits in real time in the CloudWatch console.

To monitor training job metrics (CloudWatch console)
2. Choose **Metrics**, then choose */aws/sagemaker/TrainingJobs*.
3. Choose **TrainingJobName**.
4. On the **All metrics** tab, choose the names of the training metrics that you want to monitor.
5. On the **Graphed metrics** tab, configure the graph options. For more information about using CloudWatch graphs, see Graph Metrics in the Amazon CloudWatch User Guide.

Monitoring Training Job Metrics (SageMaker Console)

You can monitor the metrics that a training job emits in real time by using the SageMaker console.

To monitor training job metrics (SageMaker console)
2. Choose **Training jobs**, then choose the training job whose metrics you want to see.
3. Choose **TrainingJobName**.
4. In the **Monitor** section, you can review the graphs of instance utilization and algorithm metrics.
Example: Viewing a Training and Validation Curve

Typically, you split the data that you train your model on into training and validation datasets. You use the training set to train the model parameters that are used to make predictions on the training dataset. Then you test how well the model makes predictions by calculating predictions for the validation set. To analyze the performance of a training job, you commonly plot a training curve against a validation curve.

Viewing a graph that shows the accuracy for both the training and validation sets over time can help you to improve the performance of your model. For example, if training accuracy continues to increase over time, but, at some point, validation accuracy starts to decrease, you are likely overfitting your model. To address this, you can make adjustments to your model, such as increasing regularization.

For this example, you can use the Image-classification-full-training example that is in the Example notebooks section of your SageMaker notebook instance. If you don't have a SageMaker notebook instance, create one by following the instructions at Step 1: Create an Amazon SageMaker Notebook Instance (p. 55). If you prefer, you can follow along with the End-to-End Multiclass Image Classification Example in the example notebook on GitHub. You also need an Amazon S3 bucket to store the training data and for the model output.

To view training and validation error curves

2. Choose Notebooks, and then choose Notebook instances.
3. Choose the notebook instance that you want to use, and then choose Open.
4. On the dashboard for your notebook instance, choose SageMaker Examples.
5. Expand the Introduction to Amazon Algorithms section, and then choose Use next to Image-classification-fulltraining.ipynb.
7. Run all of the cells in the notebook up to the Inference section. You don't need to deploy an endpoint or get inference for this example.
8. After the training job starts, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
9. Choose Metrics, then choose /aws/sagemaker/TrainingJobs.
10. Choose TrainingJobName.
11. On the All metrics tab, choose the train:accuracy and validation:accuracy metrics for the training job that you created in the notebook.
12. On the graph, choose an area that the metric's values to zoom in. You should see something like the following:
Example: Viewing a Training and Validation Curve

![Untitled graph](image)

In the image, we see a graph with a title "Untitled graph" and a legend indicating graphed metrics (2). The graph shows a trend over time, with data points at different timestamps:

- 00:09: 0.059
- 00:10: 0.24
- 00:11: 0.42
- 00:12: Data point
- 00:13: Data point
- 00:14: Data point
- 00:15: Data point
- 00:16: Data point
- 00:17: Data point

The graph includes options for viewing all metrics, graphed metrics (2), and graph options.

The selection shows the following training job names:

- DEMO-imageclassification-2018-10-27-00-05-40
- DEMO-imageclassification-2018-10-27-00-05-40

The "All" filter is also selected, indicating that all metrics and data points are being displayed.
Deploy Models for Inference

After you build and train your models, you can deploy them to get predictions in one of two ways:

• To set up a persistent endpoint to get predictions from your models, use Amazon SageMaker hosting services. For an overview on deploying a single model or multiple models with SageMaker hosting services, see Deploy a Model on SageMaker Hosting Services (p. 10).

For an example of how to deploy a model to the SageMaker hosting service, see Deploy the Model to SageMaker Hosting Services (p. 65).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

• To get predictions for an entire dataset, use SageMaker batch transform. For an overview on deploying a model with SageMaker batch transform, see Get Inferences for an Entire Dataset with Batch Transform (p. 13).

For an example of how to deploy a model with batch transform, see (Optional) Make Prediction with Batch Transform (p. 66).

Or, if you prefer, watch the following video tutorial:

Deploy Your ML Models to Production at Scale with Amazon SageMaker

Prerequisites

These topics assume that you have built and trained one or more machine learning models and are ready to deploy them. If you are new to SageMaker and have not completed these prerequisite tasks, work through the steps in the Get Started with Amazon SageMaker (p. 34) tutorial to familiarize yourself with an example of how SageMaker manages the data science process and how it handles model deployment. For more information about training a model, see Train Models (p. 686).

What do you want to do?

SageMaker provides features to manage resources and optimize inference performance when deploying machine learning models. For guidance on using inference pipelines, compiling and deploying models with Neo, Elastic Inference, and automatic model scaling, see the following topics.

• To manage data processing and real-time predictions or to process batch transforms in a pipeline, see Deploy an Inference Pipeline (p. 1886).

• If you want to deploy a model on inf1 instances, see Compile and Deploy Models with Neo (p. 1946).

• To train TensorFlow, Apache MXNet, PyTorch, ONNX, and XGBoost models once and optimize them to deploy on ARM, Intel, and Nvidia processors, see Compile and Deploy Models with Neo (p. 1946).

• To preprocess entire datasets quickly or to get inferences from a trained model for large datasets when you don’t need a persistent endpoint, see Use Batch Transform (p. 2058).

• To speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as SageMaker hosted models using a GPU instance for your endpoint, see Use Amazon SageMaker Elastic Inference (EI) (p. 2046).

• To dynamically adjust the number of instances provisioned in response to changes in your workload, see Automatically Scale Amazon SageMaker Models (p. 2065).
• To create an endpoint that can host multiple models using a shared serving container, see Host Multiple Models with Multi-Model Endpoints (p. 1864).
• To test multiple models in production, see Test models in production (p. 2080).

Manage Model Deployments

For guidance on managing model deployments, including monitoring, troubleshooting, and best practices, and for information on storage associated with inference hosting instances:

• For tools that can be used to monitor model deployments, see Monitor Amazon SageMaker (p. 2459).
• For troubleshooting model deployments, see Troubleshoot Amazon SageMaker Model Deployments (p. 2088).
• For model deployment best practices, see Deployment Best Practices (p. 2089).
• For information about the size of storage volumes provided for different sizes of hosting instances, see Host Instance Storage Volumes (p. 2089).

Deploy Your Own Inference Code

For developers that need more advanced guidance on how to run your own inference code:

• To run your own inference code hosting services, see Use Your Own Inference Code with Hosting Services (p. 2123).
• To run your own inference code for batch transforms, see Use Your Own Inference Code with Batch Transform (p. 2129).

Guide to SageMaker

What Is Amazon SageMaker? (p. 1)

Register and Deploy Models with Model Registry

With the SageMaker model registry you can do the following:

• Catalog models for production.
• Manage model versions.
• Associate metadata, such as training metrics, with a model.
• Manage the approval status of a model.
• Deploy models to production.
• Automate model deployment with CI/CD.

Catalog models by creating model package groups that contain different versions of a model. You can create a model group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the model registry adds it to the model group as a new model version. A typical workflow might look like the following:

• Create a model group.
• Create an ML pipeline that trains a model. For information about SageMaker pipelines, see Create and Manage SageMaker Pipelines (p. 2153).
For each run of the ML pipeline, create a model version that you register in the model group you created in the first step.

The following topics show how to use the model registry.

Topics
- Create a Model Group (p. 1841)
- Register a Model Version (p. 1844)
- View Model Groups and Versions (p. 1845)
- View the Details of a Model Version (p. 1847)
- Update the Approval Status of a Model (p. 1852)
- Deploy a Model in the Registry (p. 1857)
- Deploy a Model Version from a Different Account (p. 1858)
- View the Deployment History of a Model (p. 1860)

Create a Model Group

A model group contains a group of versioned models. Create a model group by using either the AWS SDK for Python (Boto3) or in SageMaker Studio.

Create a Model Package Group (Boto3)

To create a model group by using Boto3, call the create_model_package_group method, and specify a name and description as parameters. The following example shows how to create a model group. The response from the create_model_package_group call is the Amazon Resource Name (ARN) of the new model package group.

First, import the required packages and set up the SageMaker Boto3 client.

```python
import time
import os
from sagemaker import get_execution_role, session
import boto3

region = boto3.Session().region_name
role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)

model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
    "ModelPackageName" : model_package_group_name,
    "ModelPackageGroupDescription" : "Sample model package group"
}

create_model_package_group_response = sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn : {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
```
Create a Model Package Group (SageMaker Studio)

To create a model group in SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the **Components and registries** icon ( ).
3. Choose **Model registry**.
4. Choose **Create model group**.
5. In the **Create new model group** dialog box, enter the following information:

   - For **Name**, enter the name of the new model group.
   - (Optional) For **Description**, enter a description for the model group.
   - (Optional) For **Tags**, enter any key-value pairs you want to associate with the model group. For information about using tags, see Tagging AWS resources in the *AWS General Reference*.
   - (Optional) For **Project**, choose a project with which to associate the model group. For information about projects, see Automate MLOps with SageMaker Projects (p. 2182).

6. Choose **Create model group**.
Register a Model Version

You register a model by creating a model version that specifies the model group to which it belongs. A model version must include both the model artifacts (the trained weights of a model), and the inference code for the model. Create a model version by using either the AWS SDK for Python (Boto3) or by creating a step in a SageMaker mode building pipeline.

Register a Model Version (SageMaker Pipelines)

To register a model version by using a SageMaker model building pipeline, create a RegisterModel step in your pipeline. For information about creating RegisterModel step as part of a pipeline, see Define a Pipeline (p. 2153).

Register a Model Version (Boto3)

To register a model version by using Boto3, call the create_model_package method.

First, you set up the parameter dictionary to pass to the create_model_package method.
### View Model Groups and Versions

Model groups and versions help you organize your models. You can view a list of the model versions in a model group.

#### View a List of Model Versions in a Group

You can view all of the model versions that are associated with a model group. If a model group represents all models that you train to address a specific ML problem, you can view all of those related models.

#### View a List of Model Versions in a Group (Boto3)

To view model versions associated with a model group by using Boto3, call the `list_model_packages` method, and pass the name of the model group as the value of the `ModelPackageGroupName` parameter. The following code lists the model versions associated with the model group you created in Create a Model Package Group (Boto3) (p. 1841).

```python
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

#### View a List of Model Versions in a Group (SageMaker Studio)

To view a list of the model versions in a model group, complete the following steps.
1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the Components and registries icon.
3. Choose Model registry.

4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group, as shown following.
View the Details of a Model Version

You can view details of a specific model version by using either the AWS SDK for Python (Boto3) or by using SageMaker Studio.

View the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` method to view the model versions in a model group.

```python
sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
```

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.
2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

```python
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

```json
{
    "ModelPackageName": "ModelGroup1",
    "ModelPackageVersion": 1,
    "ModelPackageDescription": "Test Model",
    "CreationTime": "2020-10-29T01:27:46.000000Z",
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": "257758044811.dkr.ecr.us-east-2.amazonaws.com/sagemaker-xgboost:1.0-1-cpu-py3",
                "ImageDigest": "sha256:99fa602c0ff19aee33297a5926fb497ca7bced2a391b7d600300204ee803bca66",
                "ModelDataUrl": "s3://sagemaker-us-east-2/2020-11-23-04:56:50/GDOnCCEK709-AbaloneTrain-stmiylhtIR/output/model.tar.gz"
            }
        ],
        "SupportedTransformInstanceTypes": ["ml.m5.xlarge"],
        "SupportedRealtimeInferenceInstanceTypes": ["ml.t2.medium", "ml.m5.xlarge"],
        "SupportedContentTypes": ["text/csv"],
        "SupportedResponseMIMETypes": ["text/csv"],
        "ModelPackageStatus": "Completed",
        "ModelPackageStatusDetails": {
            "ValidationStatuses": [],
            "ImageScanStatuses": [],
            "CertifyForMarketplace": false,
            "ModelApprovalStatus": "PendingManualApproval",
            "LastModifiedTime": "2020-10-29T01:28:00.000000Z"
        },
        "ModelPackageStatus": "Completed",
        "ModelPackageStatusDetails": {
            "ValidationStatuses": [],
            "ImageScanStatuses": [],
            "CertifyForMarketplace": false,
            "ModelApprovalStatus": "PendingManualApproval",
            "LastModifiedTime": "2020-10-29T01:28:00.000000Z"
        },
        "ModelPackageStatus": "Completed",
        "ModelPackageStatusDetails": {
            "ValidationStatuses": [],
            "ImageScanStatuses": [],
            "CertifyForMarketplace": false,
            "ModelApprovalStatus": "PendingManualApproval",
            "LastModifiedTime": "2020-10-29T01:28:00.000000Z"
        },
        "ModelPackageStatus": "Completed",
        "ModelPackageStatusDetails": {
            "ValidationStatuses": [],
            "ImageScanStatuses": [],
            "CertifyForMarketplace": false,
            "ModelApprovalStatus": "PendingManualApproval",
            "LastModifiedTime": "2020-10-29T01:28:00.000000Z"
        },
        "ModelPackageStatus": "Completed",
        "ModelPackageStatusDetails": {
            "ValidationStatuses": [],
            "ImageScanStatuses": [],
            "CertifyForMarketplace": false,
            "ModelApprovalStatus": "PendingManualApproval",
            "LastModifiedTime": "2020-10-29T01:28:00.000000Z"
        }
    }
```

View the Details of a Model Version (SageMaker Studio)

To view the details of a model version in SageMaker Studio, complete the following steps.
1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the Components and registries icon (🔗).
3. Choose Model registry.

4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.
6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose one of the following to see details about the model version:

- **Activity** - Shows events for the model version, such as approval status updates.
- **Metrics** - Shows quality metrics for the model. For metrics to appear, you must enable data capture for your model by using &SM; Model Monitor. For information about capturing data, see Capture Data (p. 1921).
- **Settings** - Shows information such as the project that the model version is associated with, the pipeline that generated the model, the model group, and the model's location in Amazon S3.
Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to Approved. If it does not perform to your requirements, you update the approval status to Rejected.

Setting the approval status of a model version to Approved can trigger CI/CD deployment for the model. Similarly, you can block promotion of a model by setting its approval status to Rejected. You can manually set the status approval of a model version after you register it, or you can create a conditional step to evaluate the model when you create a SageMaker pipeline. For information about creating a conditional step in a SageMaker pipeline, see Create and Manage SageMaker Pipelines (p. 2153).

**Note**
SageMaker does not support changing the approval status from Approved to Rejected.

You can update the approval status of a model version by using the AWS SDK for Python (Boto3) or by using SageMaker Studio. You can also update the approval status of a model version as part of a conditional step in a SageMaker pipeline. For information about using a model approval step in a SageMaker pipeline, see SageMaker Pipelines Overview (p. 2136).

Update the Approval Status of a Model (Boto3)

When you created the model version in Register a Model Version (p. 1844), you set the `ModelApprovalStatus` to PendingManualApproval. You must update the approval status for the model to Approved by calling `update_model_package`. Note that you can also automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that
automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to Approved.

```python
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response = 
sm_client.update_model_package(**model_package_update_input_dict)
```

### Update the Approval Status of a Model (SageMaker Studio)

To update the approval status of a model version in SageMaker Studio, complete the following steps.

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the **Components and registries** icon (🔍).
3. Choose **Model registry**.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.
6. In the list of model versions, double-click the model version for which you want to update the approval status.
7. On the model version tab that opens, choose **Update status**.
8. In the **Update model version status** dialog box, for **Status** choose either **Approved** or **Rejected**, and then choose **Update status**.
Deploy a Model in the Registry

After you register a model version and approve it for deployment, deploy it to a SageMaker endpoint for real-time inference.

When you create an MLOps project and choose an MLOps project template that includes model deployment, approved model versions in the model registry are automatically deployed to production. For information about using SageMaker MLOps projects, see Automate MLOps with SageMaker Projects (p. 2182).

**Deploy a Model in the Registry (Boto3)**

To deploy a model version, complete the following steps:

1. Create a model object from the model version by calling `create_model`, passing the Amazon Resource Name (ARN) of the model version as the primary container for the model object. The following code snippet assumes you have already created the SageMaker Boto3 client `sm_client`,
and that you have already created a model version with an ARN that you have stored in a variable named `model_version_arn`.

```python
model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("Model name : ".format(model_name))
primary_container = {
    'ModelPackageName': model_version_arn,
}
create_model_response = sm_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = role,
    PrimaryContainer = primary_container
)
print("Model arn : ".format(create_model_response['ModelArn']))
```

2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.

```python
endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sm_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType':'ml.m4.xlarge',
        'InitialVariantWeight':1,
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName':'AllTraffic'}])
```

3. Create the endpoint by calling `create_endpoint`.

```python
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))
create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

### Deploy a Model Version from a Different Account

Enable an AWS account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create resource policies, you apply the policy to the resource to which you want to grant access. For more information about cross-account resource policies in AWS, see [Cross-account policy evaluation logic](https://docs.aws.amazon.com/IdentityAndAccessManagement/latest/UserGuide/cross-account-policy-evaluation.html) in the *AWS Identity and Access Management User Guide*.

To enable cross-account model deployment in SageMaker, you have to provide a cross-account resource policy for the model group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the model group resides, and the Amazon S3 bucket where the model versions are stored. The following example creates cross-account policies for all three of these resources, and applies the policies to the resources.

```python
import json
```
# cross account id to grant access to
cross_account_id = "123456789012"

# 1. Create policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['ecr:*']
    }]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# 2. Create policy for access to the S3 bucket
bucket_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': 's3:*',
        'Resource': f'arn:aws:s3:::{bucket}/*'
    }]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy
)

# 3. Create policy for access to the ModelPackageGroup
model_package_group_policy = {
    'Version': '2012-10-17',
    'Statement': [{
        'Sid': 'AddPermModelPackageGroup',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['sagemaker:DescribeModelPackageGroup'],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package-group/{model_package_group_name}'
    },
    { 'Sid': 'AddPermModelPackageVersion',
      'Effect': 'Allow',
      'Principal': {...}}
}
'AWS': f'arn:aws:iam::{cross_account_id}:root'
},
'Action': ['sagemaker:DescribeModelPackage',
          'sagemaker:ListModelPackages',
          'sagemaker:UpdateModelPackage',
          'sagemaker:CreateModel'],
'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package/
          {model_package_group_name}/*'
]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(
    ModelPackageName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)

print('ModelPackageGroupArn : {}', format(create_model_package_group_response['ModelPackageGroupArn']))
print("First Versioned ModelPackageArn: " + model_package_arn)
print("Second Versioned ModelPackageArn: " + model_package_arn2)
print("Success! You are all set to proceed for cross account deployment.")

The example assumes that you previously defined the following variables:

- `account` - The account of the authenticated caller.
- `bucket` - The S3 bucket where the model versions are stored.
- `model_package_group_name` - The model group to which you want to grant access.

To be able to deploy a model that was created in a different account, the user must have a role that has
access to SageMaker actions, such as a role with the `AmazonSageMakerFullAccess` managed policy.
For information about SageMaker managed policies, see AWS Managed (Predefined) Policies for Amazon
SageMaker (p. 2415).

**View the Deployment History of a Model**

View the deployments for a model version SageMaker Studio by opening the tab for that model version.

**View the deployment history for a model version**

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the Components and registries icon (.wrap).
3. Choose Model registry.
4. From the model groups list, choose the model group you want to view.
5. A new tab appears with a list of the model versions in the model group.
6. In the list of model versions, double-click the model version for which you want to view details.
7. On the model version tab that opens, choose Activity. Deployments for the model version appear as events in the activity list with an Event type of ModelDeployment.
Host Multiple Models with Multi-Model Endpoints

To create an endpoint that can host multiple models, use multi-model endpoints. Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use a shared serving container that is enabled to host multiple models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker manages loading models in memory and scaling them based on the traffic patterns to them.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints. Multi-model endpoints are also well suited to scenarios that can tolerate occasional cold-start-related latency penalties that occur when invoking infrequently used models.
Multi-model endpoints support A/B testing. They work with Auto Scaling and AWS PrivateLink. You can use multi-model-enabled containers with serial inference pipelines, but only one multi-model-enabled container can be included in an inference pipeline. You can’t use multi-model-enabled containers with Amazon Elastic Inference.

You can use the AWS SDK for Python (Boto) or the SageMaker console to create a multi-model endpoint. You can use multi-model endpoints with custom-built containers by integrating the Multi Model Server library.

**Topics**

- Supported Algorithms and Frameworks (p. 1865)

**Supported Algorithms and Frameworks**

The inference containers for the following algorithms and frameworks support multi-model endpoints:

- XGBoost Algorithm (p. 1481)
- K-Nearest Neighbors (k-NN) Algorithm (p. 1385)
- Linear Learner Algorithm (p. 1399)
- Random Cut Forest (RCF) Algorithm (p. 1451)
- Use TensorFlow with Amazon SageMaker (p. 31)
- Use Scikit-learn with Amazon SageMaker (p. 30)
- Use Apache MXNet with Amazon SageMaker (p. 16)
- Use PyTorch with Amazon SageMaker (p. 27)

To use any other framework or algorithm, use the SageMaker inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container with Multi Model Server (p. 1873).

**Sample Notebooks for Multi-Model Endpoints**

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see the Multi-Model Endpoint XGBoost Sample Notebook. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook. For instructions how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After you’ve created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. The Multi-Model Endpoint notebook is located
How Amazon SageMaker multi-model endpoints work

How Multi-Model Endpoints Work

SageMaker manages the lifecycle of models hosted on multi-model endpoints in the container's memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker dynamically loads them when you invoke them. When SageMaker receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory on that instance. If the model is already loaded in the container's memory, invocation is faster because SageMaker doesn't need to download and load it.

SageMaker continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don't need code changes to use it.

When you update a multi-model endpoint, invocation requests on the endpoint might experience higher latencies as traffic is directed to the instances in the updated endpoint.

Setting SageMaker Multi-Model Endpoint Model Caching Behavior

By default, multi-model endpoints cache frequently used models in memory and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call `create_model`.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
Instance Recommendations for Multi-Model Endpoint Deployments

There are several items to consider when selecting a SageMaker ML instance type for a multi-model endpoint. Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served. Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker attaches for each instance type for an endpoint and for a multi-model endpoint, see Host Instance Storage Volumes (p. 2089). For a container configured to run in MultiModel mode, the storage volume provisioned for its instances has more memory. This allows more models to be cached on the instance storage volume.

When choosing a SageMaker ML instance type, consider the following:

- Multi-model endpoints are not supported on GPU instance types.
- The traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance):
  - Think of the amount of memory on an instance as the cache space for models to be loaded. Think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
  - A higher amount of instance memory enables you to have more models loaded and ready to serve inference requests. You don't need to waste time loading the model.
  - A higher amount of vCPUs enables you to invoke more unique models concurrently (again assuming that inference is bound to CPU).
  - Have some “slack” memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d instance types come with an NVMe SSD storage, SageMaker does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker dynamically unloads models when it runs out of memory to make room for a newly targeted model. For infrequently requested models, you are going to pay a price with the dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for proper performance testing and analysis will pay great dividends in successful production deployments.

You can use the Average statistic of the ModelCacheHit metric to monitor the ratio of requests where the model is already loaded. You can use the SampleCount statistic for the ModelUnloadingTime metric to monitor the number of unload requests sent to the container during a time period. If models
are unloaded too frequently (an indicator of thrashing, where models are being unloaded and loaded
again because there is insufficient cache space for the working set of models), consider using a larger
instance type with more memory or increasing the number of instances behind the multi-model
endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on
more than 1 instance.

SageMaker multi-model endpoints fully supports Auto Scaling, which manages replicas of models to
ensure models scale based on traffic patterns. We recommend that you configure your multi-model
endpoint and the size of your instances by considering all of the above and also set up auto scaling for
your endpoint. The invocation rates used to trigger an auto-scale event is based on the aggregate set of
predictions across the full set of models served by the endpoint.

Create a Multi-Model Endpoint

You can use AWS SDK for Python (Boto) or Amazon SageMaker to create a multi-model endpoint.

Topics

• Create a Multi-Model Endpoint (Console) (p. 1868)
• Create a Multi-Model Endpoint (AWS SDK for Python (Boto)) (p. 1870)

Create a Multi-Model Endpoint (Console)

To create a multi-model endpoint (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Model, and then from the Inference group, choose Create model.
3. For Model name, enter a name.
4. For IAM role, choose or create an IAM role that has the AmazonSageMakerFullAccess IAM policy
attached.
5. In the Container definition section, for Provide model artifacts and inference image options
choose Use multiple models.
Create model

To deploy a model to Amazon SageMaker, first create the model by providing the location and inference code. See Deploying a Model on Amazon SageMaker Hosting Services Learn more.

Model settings

Model name
mml-test-model

Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique for your account in an AWS Region.

IAM role
Amazon SageMaker requires permissions to call other services on your behalf. Choose a role or let us create a role that has the AmazonSageMakerFullAccess IAM policy attached.

AmazonSageMaker-ExecutionRole- XX...X

Container definition 1

Container input options
Provide model artifacts and inference image location

Provide model artifacts and inference image options

- Use a single model
  Use this to host a single model in this container.

- Use multiple models
  Use this to host multiple models in this container.

Location of inference code image
Type the registry path where the inference code image is stored in Amazon ECR.

123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag

Location of model artifacts
Type the URL where model artifacts are stored in S3.
s3://my-bucket/path/to/artifacts/
Choose Create model.

Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see Deploy the Model to SageMaker Hosting Services (p. 65).

Create a Multi-Model Endpoint (AWS SDK for Python (Boto))

You create a multi-model endpoint using the Amazon SageMaker create_model, create_endpoint_config, and create_endpoint APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new Mode parameter value, MultiModel. You also need to pass the ModelDataUrl field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker to deploy multiple XGBoost models to an endpoint, see Multi-Model Endpoint XGBoost Sample Notebook.

The following procedure outlines the key steps used in that sample to create a multi-model endpoint.

To deploy the model (AWS SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see Supported Algorithms and Frameworks (p. 1865). For this example, we use the K-Nearest Neighbors (k-NN) Algorithm (p. 1385) built-in algorithm. We call the SageMaker Python SDK utility function image_uris.retrieve() to get the address for the K-Nearest Neighbors built-in algorithm image.

   ```python
   import sagemaker
   region = sagemaker_session.boto_region_name
   image = sagemaker.image_uris.retrieve("knn", region=region)
   container = { 'Image': image,
                 'ModelDataUrl': 's3://my-bucket/path/to/artifacts/',
                 'Mode': 'MultiModel'
   }
   ```

2. Get a Boto 3 SageMaker client and create the model that uses this container.

   ```python
   import boto3
   sm_client = boto3.client('sagemaker')
   response = sm_client.create_model(
       ModelName = 'my-multi-model-name',
       ExecutionRoleArn = role,
       Containers = [container])
   ```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the Containers argument of CreateModel:

   ```python
   preprocessor_container = { 'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/mypreprocessorimage:mytag' }
   
   multi_model_container = { 'Image': '763104351884.dkr.ecr.us-east-1.amazonaws.com/myimage:mytag',
                            'ModelDataUrl': 's3://my-bucket/path/to/artifacts/',
                            'Mode': 'MultiModel'
   }
   
   response = sm_client.create_model(
       ModelName = 'my-multi-model-name',
       ExecutionRoleArn = role,
       Containers = [container, preprocessor_container, multi_model_container])
   ```
Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker Runtime `InvokeEndpoint` request supports X-Amzn-SageMaker-Target-Model as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

The following example prediction request uses the AWS SDK for Python (Boto 3) in the sample notebook.
The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. (This is called a cold start.) Subsequent calls finish faster because there's no additional overhead after the model has loaded.

**Retry Requests on ModelNotReadyException Errors**

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code for an `invoke_endpoint` request, retry the request. By default, the AWS SDKs for Python (Boto 3) (using **Legacy retry mode**) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for Boto 3, see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```python
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for up to 180 seconds: 1 original request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2  # This value can be adjusted to 5 to go up to the 360s max timeout
    }
)
runtime_sm_client = boto3.client('sagemaker-runtime', config=config)
```

**Add or Remove Models**

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model.

SageMaker unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint.
With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location where you store your models.

```bash
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://my-bucket/path/to/artifacts/
```

**Important**
To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```python
response = runtime_sm_client.invoke_endpoint(
    EndpointName='endpoint_name',
    ContentType='text/csv',
    TargetModel='AdditionalModel.tar.gz',
    Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

---

**Build Your Own Container with Multi Model Server**

Custom Elastic Container Registry (ECR) images deployed in Amazon SageMaker are expected to adhere to the basic contract described in Use Your Own Inference Code with Hosting Services (p. 2123) that govern how SageMaker interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```bash
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker also injects an environment variable into the container:

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipeline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline (p. 1890).

To help you implement these requirements for a custom container, two libraries are available:

- **Multi Model Server** is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.

- **SageMaker Inference Toolkit** is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.
Use the SageMaker Inference Toolkit

Currently, the only pre-built containers that support multi-model endpoints are the MXNet inference container and the PyTorch inference container. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the SageMaker Inference Toolkit to extend an existing pre-built container. The SageMaker inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker, see the Multi-Model Endpoint BYOC Sample Notebook.

**Note**
The SageMaker inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see Contract for Custom Containers to Serve Multiple Models (p. 1875).

To extend a container by using the SageMaker inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get predictions from the model, and process the output in a model handler. For an example of a model handler, see `model_handler.py` from the sample notebook.

2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```python
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it through the
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

    # prevent docker exit
    subprocess.call(['tail', '-f', '/dev/null'])

main()
```

3. In your Dockerfile, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following lines are from the Dockerfile used in the sample notebook:
Amazon SageMaker Developer Guide
Bring Your Own Container

# Copy the default custom service file to handle incoming data and inference requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your AWS account:

```
#!/bin/bash

# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

You can now use this container to deploy multi-model endpoints in SageMaker.

Topics
- Contract for Custom Containers to Serve Multiple Models (p. 1875)

Contract for Custom Containers to Serve Multiple Models

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker to communicate with the container for loading, listing, getting, and unloading models as required. The **model_name** is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using **model_name** as the mapping key. Also, the **model_name** is an opaque identifier and is not necessarily the value of the **TargetModel** parameter passed into the **InvokeEndpoint** API. The original **TargetModel** value in the **InvokeEndpoint**
request is passed to container in the APIs as a X-Amzn-SageMaker-Target-Model header that can be used for logging purposes.

Topics
- Load Model API (p. 1876)
- List Model API (p. 1876)
- Get Model API (p. 1877)
- Unload Model API (p. 1877)
- Invoke Model API (p. 1877)

Load Model API
Instructs the container to load a particular model present in the url field of the body into the memory of the customer container and to keep track of it with the assigned model_name. After a model is loaded, the container should be ready to serve inference requests using this model_name.

```json
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json
{
  "model_name": "{model_name}",
  "url": "/opt/ml/models/{model_name}/model",
}
```

**Note**
If model_name is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker, which then initiates unloading unused models to reclaim.

List Model API
Returns the list of models loaded into the memory of the customer container.

```json
GET /models HTTP/1.1
Accept: application/json
Response =
{
  "models": [
  
  }
```

This API also supports pagination.

```json
GET /models HTTP/1.1
Accept: application/json
Response =
```
SageMaker can initially call the List Models API without providing a value for `next_page_token`. If a `nextPageToken` field is returned as part of the response, it will be provided as the value for `next_page_token` in a subsequent List Models call. If a `nextPageToken` is not returned, it means that there are no more models to return.

### Get Model API

This is a simple read API on the `model_name` entity.

**GET /models/{model_name} HTTP/1.1**

```json
{
   "modelName" : "{model_name}",
   "modelUrl" : "/opt/ml/models/{model_name}/model",
}
```

**Note**

If `model_name` is not loaded, this API should return 404.

### Unload Model API

Instructs the SageMaker platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

**DELETE /models/{model_name}**

**Note**

If `model_name` is not loaded, this API should return 404.

### Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

**POST /models/{model_name}/invoke HTTP/1.1**

```plaintext
Content-Type: Content-Type
Accept: Accept
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```
Note
If `model_name` is not loaded, this API should return 404.

Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It’s your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the `CreateModel` operation, provided that the IAM Execution Role defined in the operation has permissions to download the model. If you need to restrict `InvokeEndpoint` access to a limited set of models in S3, you can do one of the following:

- **Restrict `InvokeEndpoint` calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key.** For example, the following policy allows `InvokeEndpoint` requests only when the value of the `TargetModel` field matches one of the specified regular expressions:

  ```json
  {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Action": [
          "sagemaker:InvokeEndpoint"
        ],
        "Effect": "Allow",
        "Condition": {
          // TargetModel provided must be from this set of values
          "StringLike": {
            "sagemaker:TargetModel": ["company_a/\*", "common/\*"
          }
        }
      },
    ]
  }
  ```

  For information about SageMaker condition keys, see Condition Keys for Amazon SageMaker in the AWS Identity and Access Management User Guide.

- **Create multi-model endpoints with more restrictive S3 prefixes.**

  For more information about how SageMaker uses roles to manage access to endpoints and perform operations on your behalf, see SageMaker Roles (p. 2399). Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded, and the model wait times for loading, downloading, and uploading at a multi-
Deploy multi-container endpoints

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Deploy an Inference Pipeline (p. 1886).

For information about invoking a specific container in a multi-container endpoint, see Use a multi-container endpoint with direct invocation (p. 1880)

Topics
- Create a multi-container endpoint (Boto 3) (p. 1879)
- Update a multi-container endpoint (p. 1880)
- Delete a multi-container endpoint (p. 1880)
- Use a multi-container endpoint with direct invocation (p. 1880)
- Deploy an Inference Pipeline (p. 1886)

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling create_model, create_endpoint_config, and create_endpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call create_model:

- Use the Containers parameter instead of PrimaryContainer, and include more than one container in the Containers parameter.
- The ContainerHostname parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the Mode parameter of the InferenceExecutionConfig field to Direct for direct invocation of each container, or Serial to use containers as an inference pipeline. The default mode is Serial.

Note
Currently there is a limit of up to 5 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and InferenceExecutionConfig with direct invocation.

```python
container1 = {'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage1:mytag',
              'ContainerHostname': 'firstContainer'}

container2 = {'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/myimage2:mytag',
              'ContainerHostname': 'secondContainer'}

inferenceExecutionConfig = {'Mode': 'Direct'}
```
Update a multi-container endpoint

To update a multi-container endpoint, complete the following steps.

1. Call **create_model** to create a new model with a new value for the `Mode` parameter in the `InferenceExecutionConfig` field.

2. Call **create_endpoint_config** to create a new endpoint config with a different name by using the new model you created in the previous step.

3. Call **update_endpoint** to update the endpoint with the new endpoint config you created in the previous step.

Delete a multi-container endpoint

To delete an endpoint, call **delete_endpoint**, and provide the name of the endpoint you want to delete as the `EndpointName` parameter.

Use a multi-container endpoint with direct invocation

SageMaker multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker endpoint. You can host up to 5 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

**Topics**

- **Invoke a multi-container endpoint with direct invocation** (p. 1880)
- **Security with multi-container endpoints with direct invocation** (p. 1881)
- **Metrics for multi-container endpoints with direct invocation** (p. 1882)
- **Autoscale multi-container endpoints** (p. 1885)
- **Troubleshoot multi-container endpoints** (p. 1885)

**Invoke a multi-container endpoint with direct invocation**

To invoke a multi-container endpoint with direct invocation, call `invoke_endpoint` as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.
The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```python
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')
response = runtime_sm_client.invoke_endpoint(
    EndpointName='my-endpoint',
    ContentType='text/csv',
    TargetContainerHostname='secondContainer',
    Body=body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

### Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with the correct access to target containers. SageMaker uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the AWS Identity and Access Management User Guide. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["customIps*", "common*"]
                }
            }
        }
    ]
}
```
The following policy denies `invoke_endpoint` requests when the value of the
`TargetContainerHostname` field matches one of the specified regular expressions in the Deny statement.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["*"]
                }
            }
        },
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Deny",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetContainerHostname": ["special*"]
                }
            }
        }
    ]
}
```

For information about SageMaker condition keys, see Condition Keys for SageMaker in the AWS Identity and Access Management User Guide.

**Metrics for multi-container endpoints with direct invocation**

In addition to the endpoint metrics that are listed in Monitor Amazon SageMaker with Amazon CloudWatch (p. 2459), SageMaker also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: AWS/SageMaker and aws/sagemaker/Endpoints. The AWS/SageMaker namespace includes invocation-related metrics, and the aws/sagemaker/Endpoints namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the `[EndpointName, VariantName, ContainerName]` dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level `[EndpointName, VariantName, ContainerName].`

<table>
<thead>
<tr>
<th>Metric Name</th>
<th>Description</th>
<th>Dimension</th>
<th>NameSpace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocations</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a container inside an endpoint</td>
<td><code>EndpointName, VariantName, ContainerName</code></td>
<td>AWS/SageMaker</td>
</tr>
</tbody>
</table>
Use a multi-container endpoint with direct invocation

To get the total number of requests sent to that container, use the Sum statistic. Units: None
Valid statistics: Sum, Sample Count

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Example</th>
<th>Unit</th>
<th>Valid Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XX Errors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 4xx HTTP response code for on a specific container. For each 4xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Invocation5XX Errors</td>
<td>The number of <code>InvokeEndpoint</code> requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker sends a 1. Units: None Valid statistics: Average, Sum</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for the target container to respond as viewed from SageMaker. ContainerLatency includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
<td>Unit</td>
<td>AWS Component</td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------</td>
<td>------------------------</td>
<td></td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by SageMaker for overhead. OverheadLatency is measured from the time that SageMaker receives the request until it returns a response to the client, minus theModelLatency. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
<td>Microseconds</td>
<td>AWS/SageMaker</td>
<td></td>
</tr>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent</td>
<td>Percent</td>
<td>aws/sagemaker/Endpoints</td>
<td></td>
</tr>
</tbody>
</table>
MemoryUtilization | The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocation, the number of MemoryUtilization metrics equals the number of containers in that endpoint. Units: Percent

| EndpointName, VariantName, ContainerName | aws/sagemaker/Endpoints |

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension [EndpointName, VariantName] for all the metrics in the table except ContainerLatency.

**Autoscale multi-container endpoints**

If you want to configure automatic scaling for a multi-container endpoint using the InvocationsPerInstance metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a high CPU utilization model to a low CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see Automatically Scale Amazon SageMaker Models (p. 2065).

**Troubleshoot multi-container endpoints**

The following sections can help you troubleshoot errors with multi-container endpoints.

**Ping Health Check Errors**

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the MemoryUtilization and CPUUtilization metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as XXX did not pass the ping health check.

**Missing accept-bind-to-port=true Docker label**

The containers in a multi-container endpoints listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker automatically provides this environment variable to the container. If this environment variable isn’t present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```
Otherwise, you will see an error message such as Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format XXXX-YYYY, where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multi-container endpoint.

Deploy an Inference Pipeline

An inference pipeline is a Amazon SageMaker model that is composed of a linear sequence of two to five containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker returns the final response to the client.

When you deploy the pipeline model, SageMaker installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the CreateModel operation or from the console. Instead of setting one PrimaryContainer, you use the Containers parameter, to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the UpdateEndpoint operation. This modularity supports greater flexibility during experimentation.

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

Topics

- Sample Notebooks for Inference Pipelines (p. 1886)
- Feature Processing with Spark ML and Scikit-learn (p. 1887)
- Create a Pipeline Model (p. 1888)
- Run Real-time Predictions with an Inference Pipeline (p. 1890)
- Run Batch Transforms with Inference Pipelines (p. 1892)
- Inference Pipeline Logs and Metrics (p. 1893)
- Troubleshoot Inference Pipelines (p. 1898)

Sample Notebooks for Inference Pipelines

For a sample notebook that uploads and processes a dataset, trains a model, and builds a pipeline model, see the Inference Pipelines with Spark ML and XGBoost on Abalone notebook. This notebook
shows how you can build your machine learning pipeline by using Spark feature Transformers and the SageMaker XGBoost algorithm. After training the model, the sample shows how to deploy the pipeline (feature Transformer and XGBoost) for real-time predictions and also performs a batch transform job using the same pipeline.

For an example that shows how to do both pre-processing and post-processing by using an inference pipeline, see Deploy Apache Spark pre-processing and post-processing with XGBoost for real-time prediction requests in Amazon SageMaker using Inference Pipelines

For more examples that show how to create and deploy inference pipelines, see the Inference Pipelines with SparkML and BlazingText on DBPedia and Training using SparkML on EMR and hosting on SageMaker sample notebooks. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119).

To see a list of all the SageMaker samples, after creating and opening a notebook instance, choose the SageMaker Examples tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the advanced_functionality folder and the third notebook is in the sagemaker-python-sdk folder. To open a notebook, choose its Use tab, then choose Create copy.

Feature Processing with Spark ML and Scikit-learn

Before training a model with either Amazon SageMaker built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

Feature Processing with Spark ML

You can run Spark ML jobs with AWS Glue, a serverless ETL (extract, transform, load) service, from your SageMaker notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an AWS Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker notebook to AWS Glue.

Note

To see which Python and Spark versions AWS Glue supports, refer to AWS Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on AWS Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker Inference Pipeline. MLeap is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

Feature Processing with Sci-kit Learn

You can run and package scikit-learn jobs into containers directly in Amazon SageMaker. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher’s Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.
Create a Pipeline Model

To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker console or the CreateModel operation.

To create an inference pipeline (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Models, and then choose Create models from the Inference group.
3. On the Create model page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.
4. To add information about the containers in the inference pipeline, choose Add container, then choose Next.
5. Complete the fields for each container in the order that you want to execute them, up to the maximum of five. Complete the Container input options, Location of inference code image, and, optionally, Location of model artifacts, Container host name, and Environmental variables fields.
The MyInferencePipelineModel page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker shows them in the Environment variables field.

Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.

MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the SAGEMAKER_BIND_TO_PORT environment variable (instead of 8080). When running in an inference pipeline, SageMaker automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using
Inference Pipelines

port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the SAGEMAKER_SAFE_PORT_RANGE environment variable. Specify the value as an inclusive range in the format "XXXX-YYYY", where XXXX and YYYY are multi-digit integers. SageMaker provides this value automatically when you run the container in a multicontainer pipeline.

**Note**
To use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 1898).

### Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker SDK.

```python
from sagemaker.model import Model
from sagemaker.pipeline_model import PipelineModel
from sagemaker.sparkml.model import SparkMLModel

sparkml_data = 's3://{}/{}{}'.format(s3_model_bucket, s3_model_key_prefix, 'model.tar.gz')
sparkml_model = SparkMLModel(model_data=sparkml_data)
xgb_model = Model(model_data=xgb_model.model_data, image=training_image)

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix
sm_model = PipelineModel(name=model_name, role=role, models=[sparkml_model, xgb_model])
sm_model.deploy(initial_instance_count=1, instance_type='ml.c4.xlarge',
    endpoint_name=endpoint_name)
```

### Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```python
import sagemaker
from sagemaker.predictor import json_serializer, json_deserializer, RealTimePredictor
from sagemaker.content_types import CONTENT_TYPE_CSV, CONTENT_TYPE_JSON

payload = {
    "input": [
    {
        "name": "Pclass",
        "type": "float",
        "val": "1.0"
    },
    {
        "name": "Embarked",
        "type": "string",
        "val": "Q"
    },
    {
        "name": "Age",
        "type": "double",
        "val": "48.0"
    }]
}
```

predictor = RealTimePredictor(endpoint=endpoint_name,
sagemaker_session=sagemaker.Session(), serializer=json_serializer,
content_type=CONTENT_TYPE_JSON, accept=CONTENT_TYPE_CSV)

print(predictor.predict(payload))

The response you get from `predictor.predict(payload)` is the model's inference result.

**Realtime inference pipeline example**

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

**Run Batch Transforms with Inference Pipelines**

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see the "Preparing Data for Batch Transform" section of the ML Pipeline with SparkML and XGBoost - Training and Inference sample notebook. For information about Amazon SageMaker batch transforms, see Get Inferences for an Entire Dataset with Batch Transform (p. 13).

**Note**

To use custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 1898).

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models (created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```python
import sagemaker
input_data_path = 's3://{}//{}//{}'.format(default_bucket, 'key', 'file_name')
```
Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker provides, see Monitor Amazon SageMaker (p. 2459).

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker training jobs and endpoints write CloudWatch metrics and logs in the AWS/SageMaker namespace.

The following tables list the metrics and dimensions for the following:

- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A *dimension* is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 2459).

**Endpoint Invocation Metrics**

The AWS/SageMaker namespace includes the following request metrics from calls to InvokeEndpoint.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invocation4XXErrors</td>
<td>The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Invocation5XXErrors</td>
<td>The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker sends a 1.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Invocations</td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the <code>Sum</code> statistic.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: <code>Sum</code>, <code>Sample Count</code></td>
</tr>
<tr>
<td>InvocationsPerInstance</td>
<td>The number of endpoint invocations sent to a model, normalized by <code>InstanceCount</code> in each <code>ProductionVariant</code>. <code>SageMaker</code> sends <code>1/numberOfInstances</code> as the value for each request, where <code>numberOfInstances</code> is the number of active instances for the <code>ProductionVariant</code> at the endpoint at the time of the request.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: <code>Sum</code></td>
</tr>
<tr>
<td>ModelLatency</td>
<td>The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model container, and to complete the inference in the container. <code>ModelLatency</code> is the total time taken by all containers in an inference pipeline.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></td>
</tr>
<tr>
<td>OverheadLatency</td>
<td>The time added to the time taken to respond to a client request by <code>SageMaker</code> for overhead. <code>OverheadLatency</code> is measured from the time that <code>SageMaker</code> receives the request until it returns a response to the client, minus the <code>ModelLatency</code>. Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></td>
</tr>
<tr>
<td>ContainerLatency</td>
<td>The time it took for an Inference Pipelines container to respond as viewed from <code>SageMaker</code>. <code>ContainerLatency</code> includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container.</td>
</tr>
<tr>
<td></td>
<td>Units: Microseconds</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: <code>Average</code>, <code>Sum</code>, <code>Min</code>, <code>Max</code>, <code>Sample Count</code></td>
</tr>
</tbody>
</table>

**Dimensions for Endpoint Invocation Metrics**

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName, ContainerName</td>
<td>Filters endpoint invocation metrics for a <code>ProductionVariant</code> at the specified endpoint and for the specified variant.</td>
</tr>
</tbody>
</table>
For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker** namespace, as follows.

The **ContainerLatency** metric appears only for inferences pipelines.

### Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For training jobs, CPUUtilization is the CPU utilization of the algorithm container running on the instance. For batch transform jobs, CPUUtilization is the CPU utilization of the transform container running on the instance. For multi-container models, CPUUtilization is the sum of CPU utilization by all containers running on the instance. For endpoint variants, CPUUtilization is the sum of CPU utilization by all of the containers running on the instance. Units: Percent</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%. For training jobs, MemoryUtilization is the memory used by the algorithm container running on the instance. For batch transform jobs, MemoryUtilization is the memory used by the transform container running on the instance.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>For multi-container models, MemoryUtilization is the sum of memory used by all containers running on the instance. For endpoint variants, MemoryUtilization is the sum of memory used by all of the containers running on the instance. Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%. For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance. For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance. For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance. For endpoint variants, GPUUtilization is the sum of the GPU used by all of the containers running on the instance. Units: Percent</td>
</tr>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%. For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance. For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance. For multi-container models, GPUMemoryUtilization is sum of GPU used by all containers running on the instance. For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance. Units: Percent</td>
</tr>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs. For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance. For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance. Units: Percent</td>
</tr>
</tbody>
</table>
Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace. For batch transform jobs, Host has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace. For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id]. Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace.</td>
</tr>
</tbody>
</table>

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to stdout or stderr to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

Use Logs to Monitor an Inference Pipeline

The following table lists the log groups and log streams SageMaker sends to Amazon CloudWatch Logs.

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

Logs

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/TrainingJobs</td>
<td>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</td>
</tr>
<tr>
<td>/aws/sagemaker/Endpoints/[EndpointName]</td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td></td>
<td>[production-variant-name]/[instance-id]</td>
</tr>
<tr>
<td></td>
<td>[production-variant-name]/[instance-id]/[container-name provided in the SageMaker model] (For Inference Pipelines)</td>
</tr>
<tr>
<td></td>
<td>For Inference Pipelines, if you don't provide container names, CloudWatch uses <strong>container-1, container-2</strong>, and so on, in the order that containers are provided in the model.</td>
</tr>
<tr>
<td>/aws/sagemaker/NotebookInstances</td>
<td>[notebook-instance-name]/[LifecycleConfigHook]</td>
</tr>
<tr>
<td>/aws/sagemaker/TransformJobs</td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]</td>
</tr>
<tr>
<td></td>
<td>[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log</td>
</tr>
</tbody>
</table>
Log Group Name | Log Stream Name
|----------------|-----------------------------------------------------|
| [transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker model] (For Inference Pipelines) For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.

**Note**
SageMaker creates the /aws/sagemaker/NotebookInstances log group when you create a notebook instance with a lifecycle configuration. For more information, see Customize a Notebook Instance Using a Lifecycle Configuration Script (p. 123).

For more information about SageMaker logging, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 2470).

**Troubleshoot Inference Pipelines**

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

**Topics**
- Troubleshoot Amazon ECR Permissions for Inference Pipelines (p. 1898)
- Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines (p. 1898)
- Use Error Messages to Troubleshoot Inference Pipelines (p. 1899)

**Troubleshoot Amazon ECR Permissions for Inference Pipelines**

When you use custom Docker images in a pipeline that includes SageMaker built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker to pull the image. The policy must add the following permissions:

```json
{
"Version": "2008-10-17",
"Statement": [
{
"Sid": "allowSageMakerToPull",
"Effect": "Allow",
"Principal": {
"Service": "sagemaker.amazonaws.com"
},
"Action": [
"ecr:GetDownloadUrlForLayer",
"ecr:BatchGetImage",
"ecr:BatchCheckLayerAvailability"
]
}
}
```

**Use CloudWatch Logs to Troubleshoot SageMaker Inference Pipelines**

SageMaker publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.
For example, logs for this endpoint are published to the following log groups and streams:

<table>
<thead>
<tr>
<th>logGroup</th>
<th>logStream</th>
</tr>
</thead>
<tbody>
<tr>
<td>/aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint</td>
<td>MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1</td>
</tr>
<tr>
<td>/aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint</td>
<td>MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2</td>
</tr>
</tbody>
</table>

A log stream is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A log group is a group of log streams that share the same retention, monitoring, and access control settings.

**To see the log groups and streams**

2. In the navigation page, choose **Logs**.
3. In **Log Groups**, filter on **MyInferencePipelinesEndpoint**.
4. To see the log streams, on the CloudWatch **Log Groups** page, choose **MyInferencePipelinesEndpoint**, and then **Search Log Group**.

For a list of the logs that SageMaker publishes, see Inference Pipeline Logs and Metrics (p. 1893).

**Use Error Messages to Troubleshoot Inference Pipelines**

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker is invoking an endpoint, the service returns a **ModelError** (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker provides a detailed error message, such as:

Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum...
If a container fails the ping health check while SageMaker is creating an endpoint, it returns a `ClientError` and indicates all of the containers that failed the ping check in the last health check.

Amazon SageMaker Model Monitor

Amazon SageMaker Model Monitor continuously monitors the quality of Amazon SageMaker machine learning models in production. With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations enables you to take corrective actions, such as retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

- **Monitor Data Quality (p. 1902)** - Monitor drift in data quality.
- **Monitor Model Quality (p. 1907)** - Monitor drift in model quality metrics, such as accuracy.
- **Monitor Bias Drift for Models in Production (p. 1913)** - Monitor bias in you model's predictions.
- **Monitor Feature Attribution Drift for Models in Production (p. 1917)** - Monitor drift in feature attribution.

### Topics

- How Model Monitor Works (p. 1900)
- Monitor Data Quality (p. 1902)
- Monitor Model Quality (p. 1907)
- Monitor Bias Drift for Models in Production (p. 1913)
- Monitor Feature Attribution Drift for Models in Production (p. 1917)
- Capture Data (p. 1921)
- Schedule Monitoring Jobs (p. 1922)
- Amazon SageMaker Model Monitor Prebuilt Container (p. 1924)
- Interpret Results (p. 1925)
- Visualize Results in Amazon SageMaker Studio (p. 1927)
- Advanced Topics (p. 1933)

### How Model Monitor Works

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues arise. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works.
To enable model monitoring, you take the following steps, which follow the path of the data through the various data collection, monitoring, and analysis processes:

- Enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time predictions from your model are compared to the constraints, and are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline, and watch for any violations reported and for metrics and notifications from Amazon CloudWatch.

**Notes**

- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see [Host Multiple Models with Multi-Model Endpoints](p. 1864).
- Model Monitor supports monitoring inference pipelines, but capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- If you launch SageMaker Studio in a custom Amazon VPC, you need to create VPC endpoints to enable Model Monitor to communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see [VPC endpoints](the Amazon Virtual Private Cloud User Guide). For information about launching SageMaker Studio in a custom VPC, see [Connect SageMaker Studio Notebooks to Resources in a VPC](p. 2432).

**Model Monitor Sample Notebooks**

For a sample notebook that takes you through the full end-to-end workflow for Model Monitor, see the [Introduction to Amazon SageMaker Model Monitor](p. 1).

For a sample notebook that enables the model monitoring experience for an existing endpoint, see the [Enable Model Monitoring](p. 1).
For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the Model Monitor Visualization.

For instructions that show you how to create and access Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After you have created a notebook instance and opened it, choose the SageMaker Examples tab to see a list of all the SageMaker samples. To open a notebook, choose the notebook’s Use tab and choose Create copy.

Monitor Data Quality

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

• Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture Data (p. 1921).
• Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see Create a Baseline (p. 1902).
• Define and schedule data quality monitoring jobs. For more information, see Schedule Monitoring Jobs (p. 1922).
• View data quality metrics. For more information, see Schema for Statistics (statistics.json file) (p. 1904).
• Integrate data quality monitoring with Amazon CloudWatch. For more information, see CloudWatch Metrics (p. 1905).
• Interpret the results of a monitoring job. For more information, see Interpret Results (p. 1925).
• Use SageMaker Studio to enable data quality monitoring and visualize results. For more information, see Visualize Results in Amazon SageMaker Studio (p. 1927).

Topics

• Create a Baseline (p. 1902)
• Schema for Statistics (statistics.json file) (p. 1904)
• CloudWatch Metrics (p. 1905)
• Schema for Violations (constraint_violations.json file) (p. 1905)

Create a Baseline

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This sagemaker-model-monitor-analyzer container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with Deequ. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to trained the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker to suggest a set of baseline
constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

**To Create a baseline from a training dataset**

When you have your training data ready and stored in Amazon S3, start a baseline processing job with DefaultModelMonitor.suggest_baseline(..) using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor Prebuilt Container (p. 1924) that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the output_s3_uri location that you specify.

```python
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)
```

**Note**

If you provide the feature/column names in the training dataset as the first row and set the header=True option as shown in the previous code sample, SageMaker uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the statistics.json file and the suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri.

**Output Files for Tabular Dataset Statistics and Constraints**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. For more information about the schema for this file, see Schema for Statistics (statistics.json file) (p. 1938).</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. For more information about the schema for this file, see Schema for Constraints (constraints.json file) (p. 1940).</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the Environment map as shown in the following example:

```
"Environment": {
    "dataset_format": "\"csv\": { \"header\": true},
    "dataset_source": "/opt/ml/processing/sm_input",
```
Schema for Statistics (statistics.json file)

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```json
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
    "features": [
        {
            "name": "feature-name",
            "inferred_type": "Fractional" | "Integral",
            "numerical_statistics": {
                "common": {
                    "num_present": number,
                    "num_missing": number
                },
                "mean": number,
                "sum": number,
                "std_dev": number,
                "min": number,
                "max": number,
                "distribution": {
                    "kll": {
                        "buckets": [
                            {
                                "lower_bound": number,
                                "upper_bound": number,
                                "count": number
                            }
                        ],
                        "sketch": {
                            "parameters": {
                                "c": number,
                                "k": number
                            },
                            "data": [
                                [num, num, num, num],
                                [num, num]
                            ][num, num]
                        }
                    }
                }
            }
        }
    ]
}
```

"output_path": "/opt/ml/processing/sm_output",
"publish_cloudwatch_metrics": "Disabled",
}
Monitor Data Quality

```json
{
  "name": "feature-name",
  "inferred_type": "String",
  "string_statistics": {
    "common": {
      "num_present": number,
      "num_missing": number
    },
    "distinct_count": number,
    "distribution": {
      "categorical": {
        "buckets": [
          {
            "value": "string",
            "count": number
          }
        ]
      }
    }
  },
  #provision for custom stats
}
```

Note the following:

- The prebuilt containers compute **KLL sketch**, which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

## CloudWatch Metrics

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the `emit_metrics` option is `Enabled` in the baseline constraints file, SageMaker emits these metrics for each feature/column observed in the dataset in the `/aws/sagemaker/Endpoints/data-metric` namespace with `EndpointName` and `ScheduleName` dimensions.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for `MetricName: feature_data_{feature_name}, Stat: Max`
- Metric: Min → query for `MetricName: feature_data_{feature_name}, Stat: Min`
- Metric: Sum → query for `MetricName: feature_data_{feature_name}, Stat: Sum`
- Metric: SampleCount → query for `MetricName: feature_data_{feature_name}, Stat: SampleCount`
- Metric: Average → query for `MetricName: feature_data_{feature_name}, Stat: Average`

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for `MetricName: feature_non_null_{feature_name}, Stat: Sum`
- Metric: Baseline Drift → query for `MetricName: feature_baseline_drift_{feature_name}, Stat: Sum`

## Schema for Violations (constraint_violations.json file)

The violations file is generated as the output of a `MonitoringExecution`, which lists the results of evaluating the constraints (specified in the `constraints.json` file) against the current dataset that was
analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```json
{
    "violations": [
        {
            "feature_name": "string",
            "constraint_check_type": "data_type_check",
            "completeness_check",
            "baseline_drift_check",
            "missing_column_check",
            "extra_column_check",
            "categorical_values_check"
        }
    
    "description": "string"
}
}
```

### Types of Violations Monitored

<table>
<thead>
<tr>
<th>Violation Check Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>data_type_check</strong></td>
<td>If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged. During the baseline step, the generated constraints suggest the inferred data type for each column. The <code>monitoring_config.datatype_check_threshold</code> parameter can be tuned to adjust the threshold on when it is flagged as a violation.</td>
</tr>
<tr>
<td><strong>completeness_check</strong></td>
<td>If the completeness (% of non-null items) observed in the current execution exceeds the threshold specified in completeness threshold specified per feature, this violation is flagged. During the baseline step, the generated constraints suggest a completeness value.</td>
</tr>
<tr>
<td><strong>baseline_drift_check</strong></td>
<td>If the calculated distribution distance between the current and the baseline datasets is more than the threshold specified in <code>monitoring_config.comparison_threshold</code>, this violation is flagged.</td>
</tr>
<tr>
<td><strong>missing_column_check</strong></td>
<td>If the number of columns in the current dataset is less than the number in the baseline dataset, this violation is flagged.</td>
</tr>
<tr>
<td><strong>extra_column_check</strong></td>
<td>If the number of columns in the current dataset is more than the number in the baseline, this violation is flagged.</td>
</tr>
<tr>
<td><strong>categorical_values_check</strong></td>
<td>If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged. This value is dictated by the threshold in <code>monitoring_config.domain_content_threshold</code>.</td>
</tr>
</tbody>
</table>
Monitor Model Quality

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual ground truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time inference with actual labels that you store in an Amazon S3 bucket, and compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model Quality Metrics (p. 1910).

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint. To monitor model quality, follow these steps:

1. Enable data capture. This captures inference input and output from a real-time inference endpoint and stores the data in Amazon S3. For more information, see Capture Data (p. 1921).
2. Create a baseline. In this step, you run a baseline job that compares predictions from the model with ground truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see Create a Model Quality Baseline (p. 1907).
3. Define and schedule model quality monitoring jobs. For more information, see Schedule Model Quality Monitoring Jobs (p. 1909).
4. Ingest ground truth labels that model monitor merges with captured prediction data from real-time inference endpoint. For more information, see Ingest Ground Truth Labels and Merge Them With Predictions (p. 1909).
5. Integrate model quality monitoring with Amazon CloudWatch. For more information, see Model Quality CloudWatch Metrics (p. 1913).
6. Interpret the results of a monitoring job. For more information, see Interpret Results (p. 1925).
7. Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see Visualize Results in Amazon SageMaker Studio (p. 1927).

Topics
- Create a Model Quality Baseline (p. 1907)
- Schedule Model Quality Monitoring Jobs (p. 1909)
- Ingest Ground Truth Labels and Merge Them With Predictions (p. 1909)
- Model Quality Metrics (p. 1910)
- Model Quality CloudWatch Metrics (p. 1913)

Create a Model Quality Baseline

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the ground truth for your data.

To create a baseline job use the ModelQualityMonitor class provided by the SageMaker Python SDK, and complete the following steps.
To create a model quality baseline job

1. First, create an instance of the ModelQualityMonitor class. The following code snippet shows how to do this.

```python
from sagemaker import get_execution_role, session, Session
from sagemaker.model_monitor import ModelQualityMonitor

role = get_execution_role()
session = Session()

model_quality_monitor = ModelQualityMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=1800,
    sagemaker_session=session
)
```

2. Now call the `suggest_baseline` method of the ModelQualityMonitor object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

```python
baseline_job_name = "MyBaseLineJob"
job = model_quality_monitor.suggest_baseline(
    job_name=baseline_job_name,
    baseline_dataset=baseline_dataset_uri, # The S3 location of the validation dataset.
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri = baseline_results_uri, # The S3 location to store the results.
    problem_type='BinaryClassification',
    inference_attribute= "prediction", # The column in the dataset that contains predictions.
    probability_attribute= "probability", # The column in the dataset that contains probabilities.
    ground_truth_attribute= "label" # The column in the dataset that contains ground truth labels.
)
job.wait(logs=False)
```

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the latest_baselining_job method of the ModelQualityMonitor object.

```python
baseline_job = model_quality_monitor.latest_baselining_job
```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the suggested_constraints method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```python
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constraints"]).T
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.
5. When you are satisfied with the constraints, pass them as the constraints parameter when you create a monitoring schedule. For more information, see Schedule Model Quality Monitoring Jobs (p. 1909).

The suggested baseline constraints are contained in the constraints.json file in the location you specify with output_s3_uri. For information about the schema for this file in the Schema for Constraints (constraints.json file) (p. 1940).

**Schedule Model Quality Monitoring Jobs**

For general information about scheduling monitoring jobs, see the section called “Schedule Monitoring Jobs” (p. 1922). For model quality monitoring, you also have to consider the fact that the availability of ground truth labels might be delayed.

To address this, use offsets. Model quality jobs include StartOffset and EndOffset, which are fields of the ModelQualityJobInput parameter of the create_model_quality_job_definition method that work as follows:

- StartOffset - If specified, jobs subtract this time from the start time.
- EndOffset - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, -P7H, where 7H is 7 hours. You can use -P#H or -P#D, where H=hours, D=days, and M=minutes, and # is the number.

For example, if your ground truth starts coming in after 1 day, but is not complete for a week, set StartOffset to -P8D and EndOffset to -P1D. Then, if you schedule a job to run at 2020-01-09T13:00, it analyzes data from between 2020-01-01T13:00 and 2020-01-08T13:00.

**Important**

The schedule cadence should be such that one execution finishes before the next execution starts, which allows the ground truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of MaxRuntimeInSeconds specified as part of StoppingCondition should be no more than 1800.

**Ingest Ground Truth Labels and Merge Them With Predictions**

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint and upload it to Amazon S3.

To match ground truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```json
{
   "groundTruthData": {
      "data": "1",
      "encoding": "CSV" # only CSV supported at launch, we assume "data" only consists of label
   },
   "eventMetadata": {
      "eventId": "aaaa-bbbb-ccccc"
   },
   "eventVersion": "0"
}
```

In the groundTruthData structure, eventId can be one of the following:
Monitor Model Quality

- **eventId** – This ID is automatically generated when a user invokes the endpoint.
- **inferenceId** – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with ground truth records. You are responsible for making sure that the `inferenceId` in the ground truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a ground truth record.

You must upload ground truth data to an Amazon S3 bucket that has the same path format as captured data, which is of the following form:

`s3://bucket/prefixyyyy/mm/dd/hh`

The date in this path is the date when the ground truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the ground truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using AWS SDK for Python (Boto3), do this by specifying the location of ground truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the ground truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.

**Model Quality Metrics**

Model quality monitoring jobs compute different metrics depending on the ML problem type. The following sections list the metrics analyzed for each ML problem type.

**Note**

Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data 5 times, computing the metric, and taking the standard deviation for those results.

**Regression Metrics**

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```json
"regression_metrics" : {
   "mae" : {
      "value" : 0.3711832061068702,
      "standard_deviation" : 0.0037566388129940394
   },
   "mse" : {
      "value" : 0.3711832061068702,
      "standard_deviation" : 0.0037566388129940524
   },
   "rmse" : {
      "value" : 0.609248066149471,
      "standard_deviation" : 0.003079253267651125
   },
   "r2" : {
      "value" : -1.3766111872212665,
      "standard_deviation" : 0.022653980022771227
   }
}
```
Binary Classification Metrics

The following shows an example of the metrics that model quality monitor computes for a binary classification problem.

```
"binary_classification_metrics" : {
    "confusion_matrix" : {
        "0" : {
            "0" : 1,

  }
}
```
Model Quality CloudWatch Metrics

If you set the value of the `enable_cloudwatch_metrics` to `True` when you create the monitoring schedule, model quality monitoring jobs send all metrics to Amazon CloudWatch.

Model quality metrics appear in the `aws/sagemaker/Endpoints/model-metrics` namespace. For a list of the metrics that are emitted, see Model Quality Metrics (p. 1910).

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see Create a CloudWatch Alarm Based on a Static Threshold in the Amazon CloudWatch User Guide.

Monitor Bias Drift for Models in Production

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates.

With bias detection capabilities in Model Monitor, when SageMaker detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that
Monitor Bias Drift

is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=\left(a_{\min}, a_{\max}\right)$, for instance an interval of $(-0.1, 0.1)$, that DPPL should belong to during deployment. Any deviation from this range should raise a bias detected alert. With SageMaker Clarify, you can perform these checks at regular intervals.

For example, you can set the frequency of the checks to 2 days. This means that SageMaker Clarify computes the DPPL metric on data collected during a 2-day window. In this example, $D_{\text{win}}$ is the data that the model processed during last 2-day window. An alert is issued if the DPPL value $b_{\text{win}}$ computed on $D_{\text{win}}$ falls outside of an allowed range $A$. This approach to checking if $b_{\text{win}}$ is outside of $A$ can be somewhat noisy. $D_{\text{win}}$ might consist of very few samples and might not be representative of the live data distribution. The small sample size means that the value of bias $b_{\text{win}}$ computed over $D_{\text{win}}$ might not be a very robust estimate. In fact, very high (or low) values of $b_{\text{win}}$ may be observed purely due to chance. To ensure that the conclusions drawn from the observed data $D_{\text{win}}$ are statistically significant, SageMaker Clarify makes use of confidence intervals. Specifically, it uses the Normal Bootstrap Interval method to construct an interval $C=\left(c_{\min}, c_{\max}\right)$ such that SageMaker Clarify is confident that the true bias value computed over the full live data is contained in $C$ with high probability. Now, if the confidence interval $C$ overlaps with the allowed range $A$, SageMaker Clarify interprets it as “it is likely that the bias metric value of the live data distribution falls within the allowed range”. If $C$ and $A$ are disjoint, SageMaker Clarify is confident that the bias metric does not lie in $A$ and raises an alert.

Model Monitor Sample Notebook

Amazon SageMaker Clarify provides the following sample notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in Amazon SageMaker Studio only. If you need instructions on how to open a notebook in Amazon SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81). If you’re prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

Topics

- Create a Bias Drift Baseline (p. 1914)
- Schedule Bias Drift Monitoring Jobs (p. 1916)
- Inspect Reports for Data Bias Drift (p. 1916)

Create a Bias Drift Baseline

After you have configured your application to capture real-time inference data, the first task to monitor for bias drift is to create a baseline. This involves configuring the data inputs, which groups are sensitive, how the predictions are captured, and the model and its posttraining bias metrics. Then you need to start the baselining job.

Model bias monitor can detect bias drift of ML models on a regular basis. Similar to the other monitoring types, the standard procedure of creating a model bias monitor is first baselining and then establishing a monitoring schedule.
model_bias_monitor = ModelBiasMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)

DataConfig stores information about the dataset to be analyzed (for example, the dataset file), its format (that is, CSV or JSONLines), headers (if any) and label.

model_bias_baselining_job_result_uri = f"{baseline_results_uri}/model_bias"
model_bias_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_bias_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)

BiasConfig is the configuration of the sensitive groups in the dataset. Typically, bias is measured by computing a metric and comparing it across groups. The group of interest is called the facet. For posttraining bias, you should also take the positive label into account.

model_bias_config = BiasConfig(
    label_values_or_threshold=[1],
    facet_name="Account Length",
    facet_values_or_threshold=[100],
)

ModelPredictedLabelConfig specifies how to extract a predicted label from the model output. In this example, the 0.8 cutoff has been chosen in anticipation that customers will turn over frequently. For more complicated outputs, there are a few more options, like "label" is the index, name, or JSONPath to locate predicted label in endpoint response payload.

modelpredicted_label_config = ModelPredictedLabelConfig(
    probability_threshold=0.8,
)

ModelConfig is the configuration related to the model to be used for inferencing. In order to compute posttraining bias metrics, the computation needs to get inferences for the model name provided. To accomplish this, the processing job uses the model to create an ephemeral endpoint (also known as shadow endpoint). The processing job deletes the shadow endpoint after the computations are completed. This configuration is also used by the explainability monitor.

model_config = ModelConfig(
    model_name=model_name,
    instance_count=endpoint_instance_count,
    instance_type=endpoint_instance_type,
    content_type=dataset_type,
    accept_type=dataset_type,
)

Now you can start the baselining job.

model_bias_monitor.suggest_baseline(
    model_config=model_config,
data_config=model_bias_data_config,
bias_config=model_bias_config,
model_predicted_label_config=model_predicted_label_config,
)
print(f"ModelBiasMonitor baselining job: {model_bias_monitor.latest_baselining_job_name}"

The scheduled monitor automatically picks up baselining job name and waits for it before monitoring begins.

**Schedule Bias Drift Monitoring Jobs**

Now that you have a baseline, you can call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If you have submitted a baselining job, the monitor automatically picks up analysis configuration from the baselining job. If you skip the baselining step or the capture dataset has a different nature from the training dataset, you must provide the analysis configuration.

```python
model_bias_analysis_config = None
if not model_bias_monitor.latest_baselining_job:
    model_bias_analysis_config = BiasAnalysisConfig(
        model_bias_config,
        headers=all_headers,
        label=label_header,
    )
model_bias_monitor.create_monitoring_schedule(
    analysis_config=model_bias_analysis_config,
    output_s3_uri=s3_report_path,
    endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT1H",
        end_time_offset="-PT0H",
        probability_threshold_attribute=0.8,
    ),
    ground_truth_input=ground_truth_upload_path,
    schedule_cron_expression=schedule_expression,
)
print(f"Model bias monitoring schedule: {model_bias_monitor.monitoring_schedule_name}""
```

**Inspect Reports for Data Bias Drift**

If you are not able to inspect the results of the monitoring in the generated reports in SageMaker Studio, you can print them out as follows:

```python
schedule_desc = model_bias_monitor.describe_schedule()
if schedule_desc['LastMonitoringExecutionSummary'] in ['Completed', "CompletedWithViolations"]:
    last_model_bias_monitor_execution = model_bias_monitor.list_executions()[-1]
    last_model_bias_monitor_execution.output.destination
    print(f'\nReport URI: {last_model_bias_monitor_execution.output.destination}')
else:
    print("****STOP****\nNo completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
```

1916
If there are violations compared to the baseline, they are listed here:

```python
if last_model_bias_monitor_execution:
    model_bias_violations = last_model_bias_monitor_execution.constraint_violations()
    if model_bias_violations:
        print(model_bias_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.

## Monitor Feature Attribution Drift for Models in Production

A drift in the distribution of live data for models in production can result in a corresponding drift in the feature attribution values, just as it could cause a drift in bias when monitoring bias metrics. Amazon SageMaker Clarify feature attribution monitoring helps data scientists and ML engineers monitor predictions for feature attribution drift on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing feature attributions in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if it is detected that the attribution values drift beyond a certain threshold.

To illustrate this with a specific situation, consider a hypothetical scenario for college admissions. Assume that we observe the following (aggregated) feature attribution values in the training data and in the live data:

### College Admission Hypothetical Scenario

<table>
<thead>
<tr>
<th>Feature</th>
<th>Attribution in training data</th>
<th>Attribution in live data</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAT score</td>
<td>0.70</td>
<td>0.10</td>
</tr>
<tr>
<td>GPA</td>
<td>0.50</td>
<td>0.20</td>
</tr>
<tr>
<td>Class rank</td>
<td>0.05</td>
<td>0.70</td>
</tr>
</tbody>
</table>

The change from training data to live data appears significant. The feature ranking has completely reversed. Similar to the bias drift, the feature attribution drifts might be caused by a change in the live data distribution and warrant a closer look into the model behavior on the live data. Again, the first step in these scenarios is to raise an alarm that a drift has happened.

We can detect the drift by comparing how the ranking of the individual features changed from training data to live data. In addition to being sensitive to changes in ranking order, we also want to be sensitive to the raw attribution score of the features. For instance, given two features that fall in the ranking by the same number of positions going from training to live data, we want to be more sensitive to the feature that had a higher attribution score in the training data. With these properties in mind, we use the Normalized Discounted Cumulative Gain (NDCG) score for comparing the feature attributions rankings of training and live data.

Specifically, assume we have the following:

- $F=[f_1,...,f_m]$ is the list of features sorted with respect to their attribution scores in the training data where $m$ is the total number of features. For instance, in our case, $F=[\text{SAT Score, GPA, Class Rank}]$.
- $a(f)$ is a function that returns the feature attribution score on the training data given a feature $f$. For example, $a(\text{SAT Score}) = 0.70$.
- $F'= [f'_1, ..., f'_m]$ is the list of features sorted with respect to their attribution scores in the live data. For example, $F'= [\text{Class Rank, GPA, SAT Score}]$. 

1917
Then, we can compute the NDCG as:

\[ \text{NDCG} = \frac{\text{DCG}}{\text{iDCG}} \]

with

- \( \text{DCG} = \sum_{i=1}^{m} a(f_i)/\log_2(i+1) \)
- \( \text{iDCG} = \sum_{i=1}^{m} a(f_i)/\log_2(i+1) \)

The quantity DCG measures whether features with high attribution in the training data are also ranked higher in the feature attribution computed on the live data. The quantity iDCG measures the \( \text{ideal score} \) and it's just a normalizing factor to ensure that the final quantity resides in the range \([0, 1]\), with 1 being the best possible value. A NDCG value of 1 means that the feature attribution ranking in the live data is the same as the one in the training data. In this particular example, because the ranking changed by quite a bit, the NDCG value is 0.69.

In SageMaker Clarify, if the NDCG value is below 0.90, we automatically raise an alert.

**Model Monitor Example Notebook**

SageMaker Clarify provides the following example notebook that shows how to capture real-time inference data, create a baseline to monitor evolving bias against, and inspect the results:

- Monitoring bias drift and feature attribution drift Amazon SageMaker Clarify – Use Amazon SageMaker Model Monitor to monitor bias drift and feature attribution drift over time.

This notebook has been verified to run in SageMaker Studio only. If you need instructions on how to open a notebook in SageMaker Studio, see Create or Open an Amazon SageMaker Studio Notebook (p. 81). If you're prompted to choose a kernel, choose Python 3 (Data Science). The following topics contain the highlights from the last two steps, and they contain code examples from the example notebook.

**Topics**

- Create a SHAP Baseline for Models in Production (p. 1918)
- Schedule Feature Attribute Drift Monitoring Jobs (p. 1920)
- Inspect Reports for Feature Attribute Drift in Production Models (p. 1920)

**Create a SHAP Baseline for Models in Production**

Explanations are typically contrastive, that is, they account for deviations from a baseline. For information on explainability baselines, see SHAP Baselines for Explainability (p. 1818).

In addition to providing explanations for per-instance inferences, SageMaker Clarify also supports global explanation for ML models that helps you understand the behavior of a model as a whole in terms of its features. SageMaker Clarify generates a global explanation of an ML model by aggregating the Shapley values over multiple instances. SageMaker Clarify supports the following different ways of aggregation, which you can use to define baselines:

- \( \text{mean}_\text{abs} \) – Mean of absolute SHAP values for all instances.
- \( \text{median} \) – Median of SHAP values for all instances.
- \( \text{mean}_\text{sq} \) – Mean of squared SHAP values for all instances.

After you have configured your application to capture real-time inference data, the first task to monitor for drift in feature attribution is to create a baseline to compare against. This involves configuring
the data inputs, which groups are sensitive, how the predictions are captured, and the model and its 
posttraining bias metrics. Then you need to start the baselining job. Model explainability monitor can 
explain the predictions of a deployed model that’s producing inferences and detect feature attribution 
drift on a regular basis.

```python
model_explainability_monitor = ModelExplainabilityMonitor(
    role=role,
    sagemaker_session=sagemaker_session,
    max_runtime_in_seconds=1800,
)
```

In this example, the explainability baselining job shares the test dataset with the bias baselining job, so it 
uses the same `DataConfig`, and the only difference is the job output URI.

```python
model_explainability_baselining_job_result_uri = f"{baseline_results_uri}/
model_explainability"
model_explainability_data_config = DataConfig(
    s3_data_input_path=validation_dataset,
    s3_output_path=model_explainability_baselining_job_result_uri,
    label=label_header,
    headers=all_headers,
    dataset_type=dataset_type,
)
```

Currently the SageMaker Clarify explainer offers a scalable and efficient implementation of SHAP, so the 
explainability config is `SHAPConfig`, including the following:

- **baseline** – A list of rows (at least one) or S3 object URI to be used as the baseline dataset in the 
  Kernel SHAP algorithm. The format should be the same as the dataset format. Each row should 
  contain only the feature columns/values and omit the label column/values.
- **num_samples** – Number of samples to be used in the Kernel SHAP algorithm. This number determines 
  the size of the generated synthetic dataset to compute the SHAP values.
- **agg_method** – Aggregation method for global SHAP values. Following are valid values:
  - **mean_abs** – Mean of absolute SHAP values for all instances.
  - **median** – Median of SHAP values for all instances.
  - **mean_sq** – Mean of squared SHAP values for all instances.
- **use_logit** – Indicator of whether the logit function is to be applied to the model predictions. Default 
  is False. If use_logit is True, the SHAP values will have log-odds units.
- **save_local_shap_values** (bool) – Indicator of whether to save the local SHAP values in the output 
  location. Default is True.

```python
# Here use the mean value of test dataset as SHAP baseline
test_dataframe = pd.read_csv(test_dataset, header=None)
shap_baseline = [list(test_dataframe.mean())]
shap_config = SHAPConfig(
    baseline=shap_baseline,
    num_samples=100,
    agg_method="mean_abs",
    save_local_shap_values=False,
)
```

Start a baselining job. The same `model_config` is required because the explainability baselining job 
needs to create a shadow endpoint to get predictions for the generated synthetic dataset.
Schedule Feature Attribute Drift Monitoring Jobs

Model explainability monitoring helps you understand and interpret the predictions made by your ML models. When Model Monitor is configured to monitor model explainability, SageMaker automatically detects any drift in relative importance of features and creates reports explaining feature attributions.

Call the `create_monitoring_schedule()` method to schedule an hourly monitor to analyze the data with a monitoring schedule. If a baselining job has been submitted, the monitor automatically picks up analysis configuration from the baselining job. However, if you skip the baselining step or the capture dataset has a different nature from the training dataset, you have to provide the analysis configuration. `ModelConfig` is required by `ExplainabilityAnalysisConfig` for the same reason that it's required for the baselining job. Note that only features are required for computing feature attribution, so you should exclude ground truth labeling.

Inspect Reports for Feature Attribute Drift in Production Models

After the schedule that you set up is started by default, you need to wait for its first execution to start, and then stop the schedule to avoid incurring charges.

To inspect the reports, use the following code:

```python
schedule_desc = model_explainability_monitor.describe_schedule() 
execution_summary = schedule_desc.get("LastMonitoringExecutionSummary") 
if execution_summary and execution_summary["MonitoringExecutionStatus"] in ["Completed", "CompletedWithViolations"]:
    last_model_explainability_monitor_execution =
    model_explainability_monitor.list_executions()[[-1]
    last_model_explainability_monitor_execution_report_uri =
    last_model_explainability_monitor_execution.output.destination
    print(f"Report URI: {last_model_explainability_monitor_execution_report_uri}")
    last_model_explainability_monitor_execution_report_files =
    sorted(S3Downloader.list(last_model_explainability_monitor_execution_report_uri))
    print("Found Report Files:")
    print(" \
    ".join(last_model_explainability_monitor_execution_report_files))
else:
    last_model_explainability_monitor_execution = None
    print("****STOP**** 
    
    No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
```

If there are any violations compared to the baseline, they are listed here:

```python
if last_model_explainability_monitor_execution:
    model_explainability_violations =
    last_model_explainability_monitor_execution.constraint_violations()
    if model_explainability_violations:
        print(model_explainability_violations.body_dict)
```

In SageMaker Studio, you can see visualizations of the analysis results and CloudWatch metrics by choosing the **Endpoints** tab, and then double-clicking the endpoint.
Capture Data

To use Model Monitor, configure your real-time inference endpoint to capture data from requests and responses and store the captured data in Amazon S3. Model monitor compares metrics from this data with a baseline that you create for the model. For information about creating a baseline, see Create a Baseline (p. 1902).

To set up data capture

1. First, configure the Amazon S3 buckets Model Monitor uses to store the captured data.

```python
import boto3
import re
import json
from sagemaker import get_execution_role, session

region= boto3.Session().region_name
role = get_execution_role()
print("RoleArn: {}".format(role))

# You can use a different bucket, but make sure the role you chose for this notebook # has s3:PutObject permissions. This is the bucket into which the data is captured bucket = session.Session(boto3.Session()).default_bucket()
print("Demo Bucket: {}".format(bucket))
prefix = 'sagemaker/DEMO-ModelMonitor'
data_capture_prefix = '{}/datacapture'.format(prefix)
s3_capture_upload_path = 's3://{}/{}'.format(bucket, data_capture_prefix)
reports_prefix = '{}/reports'.format(prefix)
s3_report_path = 's3:///{}/'.format(bucket,reports_prefix)

# You can use a different bucket, but make sure the role you chose for this notebook # has s3:PutObject permissions. This is the bucket into which the data is captured bucket = session.Session(boto3.Session()).default_bucket()
print("Demo Bucket: {}".format(bucket))
prefix = 'sagemaker/DEMO-ModelMonitor'
data_capture_prefix = '{}/datacapture'.format(prefix)
s3_capture_upload_path = 's3://{}/{}'.format(bucket, data_capture_prefix)
reports_prefix = '{}/reports'.format(prefix)
s3_report_path = 's3:///{}/'.format(bucket,reports_prefix)

print("Capture path: {}".format(s3_capture_upload_path))
print("Report path: {}".format(s3_report_path))
print("Preproc Code path: {}".format(s3_code_preprocessor_uri))
print("Postproc Code path: {}".format(s3_code_postprocessor_uri))
```

2. Next, upload the pre-trained model to Amazon S3.

```python
model_file = open("model/your-prediction-model.tar.gz", 'rb')
s3_key = os.path.join(prefix, 'your-prediction-model.tar.gz')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(model_file)
```

3. Configure the data you want to capture by configuring the data you want to capture in a DataCaptureConfig structure. You can capture the request payload, the response payload, or both with this configuration.

```python
from sagemaker.model_monitor import DataCaptureConfig

endpoint_name = 'your-pred-model-monitor-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
print("EndpointName={}".format(endpoint_name))

data_capture_config=DataCaptureConfig(
    enable_capture = True,
    sampling_percentage=100,
    destination_s3_uri=s3_capture_upload_path
)"
4. Enable data capture by passing the configuration you created in the previous step when you deploy the model.

```python
predictor = model.deploy(initial_instance_count=1,
                        instance_type='ml.m4.xlarge',
                        endpoint_name=endpoint_name,
                        data_capture_config=data_capture_config)
```

5. Invoke the endpoint to send data to the endpoint to get inferences in real time. Because you enabled the data capture in the previous steps, the request and response payload, along with some additional metadata, is saved in the Amazon S3 location that you specified in `DataCaptureConfig`.

```python
from sagemaker.predictor import RealTimePredictor
import time

predictor = RealTimePredictor(endpoint=endpoint_name, content_type='text/csv')

# get a subset of test data for a quick test
!head -120 test_data/test-dataset-input-cols.csv > test_data/test_sample.csv
print("Sending test traffic to the endpoint {}. Please wait...").format(endpoint_name))

with open('test_data/test_sample.csv', 'r') as f:
    for row in f:
        payload = row.rstrip('
')
        response = predictor.predict(data=payload)
        time.sleep(0.5)

print("Done!")
```

6. View captured data by listing the data capture files stored in Amazon S3. Expect to see different files from different time periods, organized based on the hour when the invocation occurred.

```python
s3_client = boto3.Session().client('s3')
current_endpoint_capture_prefix = '{}/{}'.format(data_capture_prefix, endpoint_name)
result = s3_client.list_objects(Bucket=bucket, Prefix=current_endpoint_capture_prefix)
capture_files = [capture_file.get("Key") for capture_file in result.get('Contents')]
print("Found Capture Files:")
print(" 
 
\n").join(capture_files))
```

The format of the Amazon S3 path is as follows:

```
s3://{destination-bucket-prefix}/{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/\nfilename.jsonl
```

## Schedule Monitoring Jobs

Amazon SageMaker Model Monitor provides you the ability to continuously monitor the data collected from the endpoints on a schedule. You can create a monitoring schedule with the `CreateMonitoringSchedule` API with a predefined periodic interval. For example, every \( x \) hours (\( x \) can range from 1 to 23).

With a monitoring schedule, SageMaker can kick off processing jobs at a specified frequency to analyze the data collected during a given period. SageMaker provides a prebuilt container for performing analysis on tabular datasets. In the processing job, SageMaker compares the dataset for the current analysis with the baseline statistics, constraints provided and generate a violations report. In addition,
CloudWatch metrics are emitted for each feature under analysis. Alternatively, you could choose to bring your own container as outlined in the Bring Your Own Containers (p. 1936) topic.

You can create a model monitoring schedule for the endpoint created earlier. Use the baseline resources (constraints and statistics) to compare against the real-time traffic. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already have it in Amazon S3, you can point to it directly.

```python
# copy over the training dataset to Amazon S3 (if you already have it in Amazon S3, you could reuse it)
baseline_prefix = prefix + '/baselining'
baseline_data_prefix = baseline_prefix + '/data'
baseline_results_prefix = baseline_prefix + '/results'

baseline_data_uri = 's3://{}/{}'.format(bucket,baseline_data_prefix)
baseline_results_uri = 's3://{}/{}'.format(bucket, baseline_results_prefix)
print('Baseline data uri: {}'.format(baseline_data_uri))
print('Baseline results uri: {}'.format(baseline_results_uri))

training_data_file = open("test_data/training-dataset-with-header.csv", 'rb')
s3_key = os.path.join(baseline_prefix, 'data', 'training-dataset-with-header.csv')
boto3.Session().resource('s3').Bucket(bucket).Object(s3_key).upload_fileobj(training_data_file)
```

Create a model monitoring schedule for the endpoint using the baseline constraints and statistics to compare against real-time traffic.

```python
from sagemaker.model_monitor import CronExpressionGenerator
from time import gmtime, strftime

mon_schedule_name = 'DEMO-xgb-churn-pred-model-monitor-schedule-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
my_default_monitor.create_monitoring_schedule(
    schedule_name=mon_schedule_name,
    endpoint_input=predictor.endpoint,
    post_analytics_processor_script=s3_code_postprocessor_uri,
    output_s3_uri=s3_report_path,
    statistics=my_default_monitor.baseline_statistics(),
    constraints=my_default_monitor.suggested_constraints(),
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Describe and inspect the schedule: After you describe it, observe that the MonitoringScheduleStatus in MonitoringScheduleSummary returned by the ListMonitoringSchedules API changes to Scheduled.

```python
desc_schedule_result = my_default_monitor.describe_schedule()
print('Schedule status: {}'.format(desc_schedule_result['MonitoringScheduleStatus']))
```

### The cron Expression for Monitoring Schedule

To provide details for the monitoring schedule, use ScheduleConfig, which is a cron expression that describes details about the monitoring schedule.

Amazon SageMaker Model Monitor supports the following cron expressions:

- To set the job to start every hour, use the following:
  
  Hourly: 
  
  ```
  cron(0 * ? * *)
  ```

1923
• To run the job daily, use the following:

  `cron(0 [00-23] ? * *)`

For example, the following are valid `cron` expressions:

• Daily at 12 PM UTC: `cron(0 12 ? * *)`
• Daily at 12 AM UTC: `cron(0 0 ? * *)`

To support running every 6, 12 hours, Model Monitor supports the following expression:

`cron(0 [00-23]/[01-24] ? * *)`

For example, the following are valid `cron` expressions:

• Every 12 hours, starting at 5 PM UTC: `cron(0 17/12 ? * *)`
• Every two hours, starting at 12 AM UTC: `cron(0 0/2 ? * *)`

**Notes**

• Although the `cron` expression is set to start at 5 PM UTC, note that there could be a delay of 0-20 minutes from the actual requested time to run the execution.
• If you want to run on a daily schedule, don’t provide this parameter. SageMaker picks a time to run every day.
• Currently, SageMaker only supports hourly integer rates between 1 hour and 24 hours.

**Amazon SageMaker Model Monitor Prebuilt Container**

SageMaker provides a built-in container sagemaker-model-monitor-analyzer that provides you with a range of model monitoring capabilities, including constraint suggestion, statistics generation, constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark and is built with Deequ. The prebuilt container for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-model-monitor-analyzer`

For example: `159807026194.dkr.ecr.us-west-2.amazonaws.com/sagemaker-model-monitor-analyzer`

If you are in an AWS region in China, the prebuilt container for SageMaker Model Monitor can be accessed as follows:

`<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com.cn/sagemaker-model-monitor-analyzer`

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>156813124566</td>
<td>us-east-1</td>
</tr>
<tr>
<td>777275614652</td>
<td>us-east-2</td>
</tr>
</tbody>
</table>
To write your own analysis container, see the container contract described in Customize Monitoring (p. 1933).

Interpret Results

After you run a baseline processing job and obtained statistics and constraint for your dataset, you can execute monitoring jobs that calculate statistics and list any violations encountered relative to the baseline constraints. Amazon CloudWatch metrics are also reported in your account by default. For information on viewing the results of monitoring in Amazon SageMaker Studio, see Visualize Results in Amazon SageMaker Studio (p. 1927).

List Executions

The schedule starts monitoring jobs at the specified intervals. The following code lists the latest five executions. If you are running this code after creating the hourly schedule, the executions might be
empty, and you might have to wait until you cross the hour boundary (in UTC) to see the executions start. The following code includes the logic for waiting.

```python
mon_executions = my_default_monitor.list_executions()
print("We created a hourly schedule above and it will kick off executions ON the hour (plus 0 - 20 min buffer.\nWe will have to wait till we hit the hour..."")
while len(mon_executions) == 0:
    print("Waiting for the 1st execution to happen...")
    time.sleep(60)
    mon_executions = my_default_monitor.list_executions()
```

## Inspect a Specific Execution

In the previous step, you picked up the latest completed or failed scheduled execution. You can explore what went right or wrong. The terminal states are:

- **Completed** – The monitoring execution completed and no issues were found in the violations report.
- **CompletedWithViolations** – The execution completed, but constraint violations were detected.
- **Failed** – The monitoring execution failed, possibly due to client error (for example, a role issues) or infrastructure issues. To identify the cause, see the `FailureReason` and `ExitMessage`.

```python
latest_execution = mon_executions[-1] # latest execution's index is -1, previous is -2 and so on..
time.sleep(60)
latest_execution.wait(logs=False)
print("Latest execution status: {}".format(latest_execution.describe()['ProcessingJobStatus']))
print("Latest execution result: {}".format(latest_execution.describe()['ExitMessage']))
```

```python
latest_job = latest_execution.describe()
if (latest_job['ProcessingJobStatus'] != 'Completed'):
    print("====STOP==== 
 No completed executions to inspect further. Please wait till an execution completes or investigate previously reported failures.")
```

```python
report_uri=latest_execution.output.destination
print('Report Uri: {}'.format(report_uri))
```

## List Generated Reports

List the generated reports

```python
from urllib.parse import urlparse
s3uri = urlparse(report_uri)
report_bucket = s3uri.netloc
report_key = s3uri.path.lstrip('/
')
print('Report bucket: {}'\n'.format(report_bucket))
print('Report key: {}'\n'.format(report_key))
s3_client = boto3.Session().client('s3')
result = s3_client.list_objects(Bucket=report_bucket, Prefix=report_key)
report_files = [report_file.get("Key") for report_file in result.get('Contents')]
print("Found Report Files:")
print("\n ",join(report_files))
```

---

1926
Violations Report

If there are violations compared to the baseline, they are generated in the violations report. Use the following code to list the violations.

```python
violations = my_default_monitor.latest_monitoring_constraint_violations()
pd.set_option('display.max_colwidth', -1)
constraints_df = pd.io.json.json_normalize(violations.body_dict["violations"])
constraints_df.head(10)
```

This applies only to datasets that contain tabular data. The following schema files specify the statistics calculated and the violations monitored for.

Output Files for Tabular Datasets

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>Contains columnar statistics for each feature in the dataset that is analyzed. See the schema of this file in the next topic. Note This file is created only for data quality monitoring.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>Contains a list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the baseline_constraints and baseline_statistics paths.</td>
</tr>
</tbody>
</table>

The Amazon SageMaker Model Monitor Prebuilt Container (p. 1924) saves a set of Amazon CloudWatch metrics for each feature by default.

The container code can emit CloudWatch metrics in this location: /opt/ml/output/metrics/cloudwatch.

Visualize Results in Amazon SageMaker Studio

You can also visualize the results of monitoring in Amazon SageMaker Studio. You can view the details of any monitoring job run, and you can create charts that show the baseline and captured values for any metric that the monitoring job calculates.

To view the detailed results of a monitoring job

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the Components and registries icon.
3. Choose Endpoints in the drop-down menu.
4. On the endpoint tab, choose the monitoring type for which you want to see job details.

5. Choose the name of the monitoring job run for which you want to view details from the list of monitoring jobs.
6. The **MONITORING JOB DETAILS** tab opens with a detailed report of the monitoring job.

You can create a chart that displays the baseline and captured metrics for a time period.
To create a chart in SageMaker Studio to visualize monitoring results

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. In the left navigation pane, choose the Components and registries icon ((figsize:445x663)).
3. Choose Endpoints in the drop-down menu.

4. On the Endpoint tab, choose the monitoring type you want to create a chart for. This example shows a chart for the Model quality monitoring type.
5. Choose **Add chart**.

6. On the **CHART PROPERTIES** tab, choose the time period, statistic, and metric that you want to chart. This example shows a chart for a **Timeline of 1 week**, the **Average Statistic** of, and the **F1 Metric**.
7. The chart that shows the baseline and current metric statistic you chose in the previous step shows up in the **Endpoint** tab.
Advanced Topics

The following sections contain more advanced tasks that explain how to customize monitoring using preprocessing and postprocessing scripts, how to build your own container, and how to use AWS CloudFormation to create a monitoring schedule.

Topics
- Customize Monitoring (p. 1933)
- Create a Monitoring Schedule with an AWS CloudFormation Custom Resource (p. 1943)

Customize Monitoring

In addition to using the built-in monitoring mechanisms, you can create your own custom monitoring schedules and procedures using preprocessing and postprocessing scripts or by using or building your own container.

Topics
- Preprocessing and Postprocessing (p. 1933)
- Bring Your Own Containers (p. 1936)

Preprocessing and Postprocessing

In addition to using the built-in mechanisms, you can extend the code with the preprocessing and postprocessing scripts.

Topics
- Postprocessing Script (p. 1933)
- Preprocessing Script (p. 1934)

Postprocessing Script

You can extend the code with the postprocessing script by following this contract:
def postprocess_handler():
    print("Hello from post-proc script!")

Specify it as a path in Amazon Simple Storage Service (Amazon S3) in the CreateMonitoringSchedule request, as shown following:

### Preprocessing Script

The Amazon SageMaker Model Monitor container works only with tabular or flattened JSON structures. We provide a per-record preprocessor for some small changes required to transform the dataset. For example, if your output is an array \([1.0, 2.1]\), you need to convert this into a flattened JSON, like \{"prediction0": 1.0, "prediction1": 2.1\}. A sample implementation might look like the following:

```python
def preprocess_handler(inference_record):
    input_data = inference_record.endpoint_input.data
    output_data = inference_record.endpoint_output.data

    input_data['feature0'] = random.randint(1, 3)
    input_data['feature1'] = random.uniform(0, 1.6)
    input_data['feature2'] = random.uniform(0, 1.6)

    output_data['prediction0'] = random.uniform(1, 30)

    return {**input_data, **output_data}
```

Specify it as a path in Amazon S3 in the CreateMonitoringSchedule request:

The structure of the inference_record is defined as follows:

```python
KEY_EVENT_METADATA = "eventMetadata"
KEY_EVENT_METADATA_EVENT_ID = "eventId"
KEY_EVENT_METADATA_EVENT_TIME = "inferenceTime"
KEY_EVENT_METADATA_CUSTOM_ATTR = "customAttributes"

KEY_EVENTDATA = "captureData"
KEY_EVENTDATA_INPUT = "endpointInput"
KEY_EVENTDATA_OUTPUT = "endpointOutput"
KEY_EVENTDATA_ENCODING = "encoding"
KEY_EVENTDATA_DATA = "data"
KEY_EVENTDATA_OBSERVED_CONTENT_TYPE = "observedContentType"
KEY_EVENTDATA_MODE = "mode"

KEY_EVENT_VERSION = "eventVersion"

"""
    {
        "captureData": {
            "endpointInput": {  
                "observedContentType": "text/csv",
                "mode": "INPUT",
                "data": "132,25,113.2,96,269.9,107,,0,0,0,0,0,1,0,1,0,0,1",
                "encoding": "CSV"
            },
            "endpointOutput": {  
                "observedContentType": "text/csv; charset=utf-8",
```
"mode": "OUTPUT",
"data": "0.01076381653547287",
"encoding": "CSV"
}
},
"eventMetadata": {
"eventId": "feca1ab1-8025-47e3-8f6a-99e3fdd7b8d9",
"inferenceTime": "2019-11-20T23:33:12Z"
},
"eventVersion": "0"
}"

```python
class EventConfig:
    def __init__(self, endpoint, variant, start_time, end_time):
        self.endpoint = endpoint
        self.variant = variant
        self.start_time = start_time
        self.end_time = end_time

class EventMetadata:
    def __init__(self, event_metadata_dict):
        self.event_id = event_metadata_dict.get('event_id', None)
        self.event_time = event_metadata_dict.get('event_time', None)
        self.custom_attribute = event_metadata_dict.get('custom_attribute', None)

class EventData:
    def __init__(self, data_dict):

Bring Your Own Containers

Amazon SageMaker Model Monitor provides a prebuilt container with ability to analyze the data captured from endpoints for tabular datasets. If you would like to bring your own container, Model Monitor provides extension points which you can leverage.

Under the hood, when you create a MonitoringSchedule, Model Monitor ultimately kicks off processing jobs. Hence the container needs to be aware of the processing job contract documented in the Build Your Own Processing Container (Advanced Scenario) (p. 642) topic. Note that Model Monitor kicks off the processing job on your behalf per the schedule. While invoking, Model Monitor sets up additional environment variables for you so that your container has enough context to process the data for that particular execution of the scheduled monitoring. For additional information on container inputs, see the Container Contract Inputs (p. 1936).

In the container, using the above environment variables/context, you can now analyze the dataset for the current period in your custom code. After this analysis is complete, you can choose to emit your reports to be uploaded to an S3 bucket. The reports that the prebuilt container generates are documented in Container Contract Outputs (p. 1938). If you would like the visualization of the reports to work in SageMaker Studio, you should follow the same format. You can also choose to emit completely custom reports.

You also emit CloudWatch metrics from the container by following the instructions in CloudWatch Metrics for Bring Your Own Containers (p. 1942).

Topics
- Container Contract Inputs (p. 1936)
- Container Contract Outputs (p. 1938)
- CloudWatch Metrics for Bring Your Own Containers (p. 1942)

Container Contract Inputs

The Amazon SageMaker Model Monitor platform invokes your container code according to a specified schedule. If you chose to write your own container code, the following environment variables are available for your container code. In this context, you can analyze the current dataset or evaluate the constraints if you chose to and emit metrics, if applicable.

"Environment": {
  "dataset_format": "{"sagemakerCaptureJson": "{"captureIndexNames": ["endpointInput", "endpointOutput"]}}",
  "dataset_source": "/opt/ml/processing/endpointdata",
  "end_time": "2019-12-01T16: 20: 00Z",
  "output_path": "/opt/ml/processing/resultdata",
  "publish_cloudwatch_metrics": "Disabled",
  "sagemaker_endpoint_name": "endpoint-name",
  "sagemaker_monitoring_schedule_name": "schedule-name",
  "start_time": "2019-12-01T15: 20: 00Z"
}
### Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>dataset_format</strong></td>
<td>For a job started from a MonitoringSchedule backed by an Endpoint, this is sageMakerCaptureJson with the capture indices endpointInput, or endpointOutput, or both.</td>
</tr>
<tr>
<td><strong>dataset_source</strong></td>
<td>The local path in which the data corresponding to the monitoring period, as specified by start_time and end_time, are available. At this path, the data is available in /{endpoint-name}/{variant-name}/yyyy/mm/dd/hh. We sometimes download more than what is specified by the start and end times. It is up to the container code to parse the data as required.</td>
</tr>
<tr>
<td><strong>output_path</strong></td>
<td>The local path to write output reports and other files. You specify this parameter in the CreateMonitoringSchedule request as MonitoringOutputConfig.MonitoringOutput[0].LocalPath. It is uploaded to the S3Uri path specified in MonitoringOutputConfig.MonitoringOutput[0].S3Uri.</td>
</tr>
<tr>
<td><strong>publish_cloudwatch_metrics</strong></td>
<td>For a job launched by CreateMonitoringSchedule, this parameter is set to Enabled. The container can choose to write the Amazon CloudWatch output file at [filepath].</td>
</tr>
<tr>
<td><strong>sagemaker_endpoint_name</strong></td>
<td>The name of the Endpoint that this scheduled job was launched for.</td>
</tr>
<tr>
<td><strong>sagemaker_monitoring_schedule_name</strong></td>
<td>The name of the MonitoringSchedule that launched this job.</td>
</tr>
<tr>
<td><em>sagemaker_endpoint_datacapture_prefix</em></td>
<td>The prefix specified in the DataCaptureConfig parameter of the Endpoint. The container can use this if it needs to directly access more data than already downloaded by SageMaker at the dataset_source path.</td>
</tr>
<tr>
<td><strong>start_time, end_time</strong></td>
<td>The time window for this analysis run. For example, for a job scheduled to run at 05:00 UTC and a job that runs on 20/02/2020, start_time: is 2020-02-19T06:00:00Z and end_time: is 2020-02-20T05:00:00Z</td>
</tr>
<tr>
<td><strong>baseline_constraints</strong></td>
<td>The local path of the baseline constraint file specified in BaselineConfig.ConstraintResource.S3Uri. This is available only if this parameter was specified in the CreateMonitoringSchedule request.</td>
</tr>
</tbody>
</table>
### Parameter Name | Description
--- | ---
**baseline_statistics** | The local path to the baseline statistics file specified in `BaselineConfig.StatisticsResource.S3Uri`. This is available only if this parameter was specified in the `CreateMonitoringSchedule` request.:

---

**Container Contract Outputs**

The container can analyze the data available in the `*dataset_source*` path and write reports to the path in `*output_path*`. The container code can write any reports that suit your needs.

If you use the following structure and contract, certain output files are treated specially by SageMaker in the visualization and API. This applies only to tabular datasets.

**Output Files for Tabular Datasets**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics.json</td>
<td>This file is expected to have columnar statistics for each feature in the dataset that is analyzed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints.json</td>
<td>This file is expected to have the constraints on the features observed. The schema for this file is available in the next section.</td>
</tr>
<tr>
<td>constraints_violations.json</td>
<td>This file is expected to have the list of violations found in this current set of data as compared to the baseline statistics and constraints file specified in the <code>baseline_constraints</code> and <code>baseline_statistics</code> path.</td>
</tr>
</tbody>
</table>

In addition, if the `publish_cloudwatch_metrics` value is "Enabled" container code can emit Amazon CloudWatch metrics in this location: `/opt/ml/output/metrics/cloudwatch`. The schema for these files is described in the following sections.

**Topics**
- Schema for Statistics (statistics.json file) (p. 1938)
- Schema for Constraints (constraints.json file) (p. 1940)

**Schema for Statistics (statistics.json file)**

The schema defined in the `statistics.json` file specifies the statistical parameters to be calculated for the baseline and data that is captured. It also configures the bucket to be used by KLL, a very compact quantiles sketch with lazy compaction scheme.

```json
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },
    # feature level stats
}```
"features": [
{
"name": "feature-name",
"inferred_type": "Fractional" | "Integral",
"numerical_statistics": {
"common": {
"num_present": number,
"num_missing": number
},
"mean": number,
"sum": number,
"std_dev": number,
"min": number,
"max": number,
"distribution": {
"kll": {
"buckets": [
{
"lower_bound": number,
"upper_bound": number,
"count": number
}
],
"sketch": {
"parameters": {
"c": number,
"k": number
},
"data": [
[ num,
  num,
  num,
  num
],
[ num,
  num
][ num,
  num
]
}
#sketch
#KLL
#distribution
#num_stats
},
"string_statistics": {
"common": {
"num_present": number,
"num_missing": number
},
"distinct_count": number,
"distribution": {
"categorical": {
"buckets": [
{
"value": "string",
"count": number
}
]
}
}
Notes

- The specified metrics are recognized by SageMaker in later visualization changes. The container can emit more metrics if required.
- KLL sketch is the recognized sketch. Custom containers can write their own representation, but it won’t be recognized by SageMaker in visualizations.
- By default, the distribution is materialized in 10 buckets. You can’t change this.

Schema for Constraints (constraints.json file)

A constraints.json file is used to express the constraints that a dataset must satisfy. Amazon SageMaker Model Monitor containers can use the constraints.json file to evaluate datasets against. Prebuilt containers provide the ability to generate the constraints.json file automatically for a baseline dataset. If you bring your own container, you can provide it with similar abilities or you can create the constraints.json file in some other way. Here is the schema for the constraint file that the prebuilt container uses. Bring your own containers can adopt the same format or enhance it as required.

```json
{
  "version": 0,
  "features": [
    {
      "name": "string",
      "inferred_type": "Integral" | "Fractional" | "String" | "Unknown",
      "completeness": number, # denotes observed non-null value percentage
      "num_constraints": {
        "is_non_negative": boolean,
      },
      "string_constraints": {
        "domains": [
          "list of",
          "observed values",
          "for small cardinality"
        ],
      },
      "monitoringConfigOverrides": {
      },
    }#feature
  ]#features

  # options to control monitoring for this feature with monitoring jobs
  # See the following table for notes on what each constraint is doing.
  "monitoring_config": {
    "evaluate_constraints": "Enabled",
    "emit_metrics": "Enabled",
    "datatype_check_threshold": 0.1,
    "domain_content_threshold": 0.1,
    "distribution_constraints": {
      "perform_comparison": "Enabled",
      "comparison_threshold": 0.1,
      "comparison_method": "Simple"||"Robust"
    }
  }
}
### Monitoring Constraints

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluate_constraints</td>
<td>When Enabled, evaluates whether the current dataset being analyzed satisfies the constraints specified in the constraints.json file taken as a baseline. Valid values: Enabled or Disabled Default: Enabled</td>
</tr>
<tr>
<td>emit_metrics</td>
<td>When Enabled, emits CloudWatch metrics for the data contained in the file. Valid values: Enabled or Disabled Default: Enabled</td>
</tr>
<tr>
<td>datatype_check_threshold</td>
<td>If the threshold is above the value of the specified datatype_check_threshold, this causes a failure that is treated as a violation in the violation report. If the data types in the current execution are not the same as in the baseline dataset, this threshold is used to evaluate if it needs to be flagged as a violation.  Valid values: float Default: 0.1</td>
</tr>
<tr>
<td>domain_content_threshold</td>
<td>If there are more unknown values for a String field in the current dataset than in the baseline dataset, this threshold can be used to dictate if it needs to be flagged as a violation. Valid values: float Default: 0.1</td>
</tr>
<tr>
<td>distribution_constraints</td>
<td>perform comparison</td>
</tr>
<tr>
<td></td>
<td>When Enabled, this flag instructs the code to perform a distribution comparison between the baseline distribution and the distribution observed for the current dataset. Valid values: Enabled or Disabled Default: Enabled</td>
</tr>
<tr>
<td>Constraint</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| comparison_threshold | If the threshold is above the value set for the comparison_threshold, this causes a failure that is treated as a violation in the violation report. The distance is calculated by getting the maximum absolute difference between the cumulative distribution functions of two distributions.  
Valid values: float  
Default: 0.1 |
| comparison_method   | Whether to calculate linf_simple or linf_robust. The linf_simple is based on the maximum absolute difference between the cumulative distribution functions of two distributions. Calculating linf_robust is based on linf_simple, but is used when there are not enough samples. The linf_robust formula is based on the Two-sample Kolmogorov–Smirnov test.  
Valid values: linf_simple or linf_robust. |

CloudWatch Metrics for Bring Your Own Containers

If the publish_cloudwatch_metrics value is Enabled in the Environment map in the /opt/ml/processing/processingjobconfig.json file, the container code emits Amazon CloudWatch metrics in this location: /opt/ml/output/metrics/cloudwatch.

The schema for this file is closely based on the CloudWatch PutMetrics API. The namespace is not specified here. It defaults to /aws/sagemaker/Endpoint/data-metrics. However, you can specify dimensions. We recommend that you add the Endpoint and MonitoringSchedule dimensions at a minimum.

```json
{
  "MetricName": "", # Required
  "Timestamp": "2019-11-26T03:00:00Z", # Required
  "Dimensions": [{"Name":"Endpoint","Value":"endpoint_0"},
                  {"Name":"MonitoringSchedule","Value":"schedule_0"}],
  "Value": Float,
  # Either the Value or the StatisticValues field can be populated and not both.
  "StatisticValues": {
    "SampleCount": Float,
    "Sum": Float,
    "Minimum": Float,
    "Maximum": Float
  },
  "Unit": "Count", # Optional
}
```
Create a Monitoring Schedule with an AWS CloudFormation Custom Resource

To use AWS CloudFormation to create a monitoring schedule, use an AWS CloudFormation custom resource. The custom resource is in Python. To deploy it, see Python Lambda deployment.

Custom Resource

Start by adding a custom resource to your AWS CloudFormation template. This points to a AWS Lambda function that you create in the next step.

This resource enables you to customize the parameters for the monitoring schedule. You can add or remove more parameters by modifying the AWS CloudFormation resource and the Lambda function in the following example resource.

```json
{
   "AWSTemplateFormatVersion": "2010-09-09",
   "Resources": {
      "MonitoringSchedule": {
         "Type": "Custom::MonitoringSchedule",
         "Version": "1.0",
         "Properties": {
            "ScheduleName": "YourScheduleName",
            "EndpointName": "YourEndpointName",
            "BaselineConstraintsUri": "s3://your-baseline-constraints/constraints.json",
            "BaselineStatisticsUri": "s3://your-baseline-stats/statistics.json",
            "PostAnalyticsProcessorSourceUri": "s3://your-post-processor/postprocessor.py",
            "RecordPreprocessorSourceUri": "s3://your-preprocessor/preprocessor.py",
            "InputLocalPath": "/opt/ml/processing/input",
            "OutputLocalPath": "/opt/ml/processing/output",
            "OutputS3URI": "s3://your-output-uri",
            "ImageURI": "111111111111.dkr.ecr.us-west-2.amazonaws.com/your-image",
            "ScheduleExpression": "cron(0 * * * *)",
            "PassRoleArn": "arn:aws:iam::111111111111:role/AmazonSageMaker-ExecutionRole"
         }
      }
   }
}
```

Lambda Custom Resource Code

This AWS CloudFormation custom resource uses the Custom Resource Helper AWS library, which you can install with pip using `pip install crhelper`.

This Lambda function is invoked by AWS CloudFormation during the creation and deletion of the stack. This Lambda function is responsible for creating and deleting the monitoring schedule and using the parameters defined in the custom resource described in the preceding section.

```python
import boto3
import botocore
import logging

from crhelper import CfnResource
from botocore.exceptions import ClientError
```
logger = logging.getLogger(__name__)
sm = boto3.client('sagemaker')

# cfnhelper makes it easier to implement a CloudFormation custom resource
helper = CfnResource()

# CFN Handlers
def handler(event, context):
    helper(event, context)

@helper.create
def create_handler(event, context):
    ""
    Called when CloudFormation custom resource sends the create event
    ""

    }
Compile and Deploy Models with Neo

Neo is a capability of Amazon SageMaker that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.

Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks (p. 1961) for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures (p. 1988) for edge devices.

How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.
You can create a Neo compilation job from either the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the SageMaker SDK. For information on how to compile a model, see Use Neo to Compile a Model (p. 1948). With a few CLI commands, an API invocation, or a few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker endpoint or on an AWS IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

**Neo Sample Notebooks**

For sample notebooks that use SageMaker Neo to train, compile, optimize, and deploy machine learning models to make inferences, see:

- MNIST Training, Compilation and Deployment with MXNet Module
- MNIST Training, Compilation and Deployment with Tensorflow Module
- Deploying pre-trained PyTorch vision models with SageMaker Neo
- Model Optimization with an Image Classification Example
- Model Optimization with XGBoost Example

For instructions on how to run these example notebooks in SageMaker, see Example Notebooks (p. 130). If you need instructions on how to create a notebook instance to run these examples, see Use Amazon SageMaker Notebook Instances (p. 119). To navigate to the relevant example in your notebook instance, choose the Amazon SageMaker Examples tab to see a list of all of the SageMaker samples. To open a notebook, choose its Use tab, then choose Create copy.
Use Neo to Compile a Model

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning models: the Neo CLI, the Amazon SageMaker console, or the Amazon SageMaker SDK.

**Topics**
- Prepare Model for Compilation (p. 1948)
- Compile a Model (AWS Command Line Interface) (p. 1953)
- Compile a Model (Amazon SageMaker Console) (p. 1956)
- Compile a Model (Amazon SageMaker SDK) (p. 1960)

Prepare Model for Compilation

SageMaker Neo requires machine learning models satisfy specific input data shape. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

**Topics**
- What input data shapes does SageMaker Neo expect? (p. 1948)
- Saving Models for SageMaker Neo (p. 1949)

What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:

**Keras**

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{'input_1': [1, 3, 224, 224]}`
- For two inputs: `{'input_1': [1, 3, 224, 224], 'input_2': [1, 3, 224, 224]}`

**MXNet/ONNX**

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'data': [1, 3, 1024, 1024]}`
- For two inputs: `{'var1': [1, 1, 28, 28], 'var2': [1, 1, 28, 28]}`
PyTorch

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: {'input0':[1,3,224,224]}
- For one input in list format: [[1,3,224,224]]
- For two inputs in dictionary format: {'input0':[1,3,224,224], 'input1':[1,3,224,224]}
- For two inputs in list format: [[[1,3,224,224], [1,3,224,224]]

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: {'input':[1,1024,1024,3]}
- For two inputs: {'data1': [1,28,28,1], 'data2':[1,28,28,1]}

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: {'input':[1,224,224,3]}

XGBoost

An input data name and shape are not needed.

Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (*.tar.gz).

Keras

Keras models require one model definition file (.h5).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to .h5 format with `model.save("<model-name>", save_format="h5").`
2. Freeze the SavedModel after exporting.

Below is an example of how to export a tf.keras model as a frozen graph (option two):

```python
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
    input_shape=(224, 224, 3), pooling='avg')
model.summary()
```
# Save as a SavedModel

eexport_dir = 'saved_model/
model.save(export_dir, save_format='tf')

# Freeze saved model

input_node_names = [inp.name.split(':')[0] for inp in model.inputs]
output_node_names = [output.name.split(':')[0] for output in model.outputs]

print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=['serve'])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess,
        sess.graph.as_graph_def(),
        output_node_names)

    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".", name="frozen_graph.pb",
        as_text=False)

**Warning**

Do not export your model with the SavedModel class using model.save(<path>,
save_format='tf'). This format is suitable for training, but it is not suitable for inference.

**MXNet**

MXNet models must be saved as a single symbol file *-symbol.json and a single parameter *.params files.

**Gluon Models**

Define the neural network using the `HybridSequential` Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```python
from mxnet import nd, sym
from mxnet.gluon import nn

def get_net():
    net = nn.HybridSequential()  # Here we use the class HybridSequential.
    net.add(nn.Dense(256, activation='relu'),
           nn.Dense(128, activation='relu'),
           nn.Dense(2))
    net.initialize()
    return net

# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()

# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)

# hybridize model
net.hybridize()

# export model
net.export('<model_name>') # this will create model-symbol.json and model-0000.params files

for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
    tar.add(name)
tar.close()
```

For more information about hybridizing models, see the **MXNet hybridize documentation**.
Gluon Model Zoo (GluonCV)

GluonCV model zoo models come pre-hybridized. So you can just export them.

```python
import numpy as np
import mxnet as mx
import gluoncv as gcv

net = gcv.model_zoo.get_model('<model_name>', pretrained=True)
ett.export('<model_name>')</tgz
for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
tar.add(name)
tar.close()
```

Non Gluon Models

All non-Gluon models when saved to disk use *-symbol and *.params files. They are therefore already in the correct format for Neo.

```python
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>', 0, sym, args, aux) # this will create
<model_name>-symbol.json and <model_name>-0000.params files
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ['<model_name>-0000.params', '<model_name>-symbol.json']:
tar.add(name)
tar.close()
```

PyTorch

PyTorch models must be saved as a definition file (.pt or .pth) with input datatype of float32.

To save your model, use torch.jit.trace followed by torch.save. This will save an object to a disk file and by default uses python pickle (pickle_module=pickle) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```python
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()
```

TensorFlow

TensorFlow requires one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file is required.
Pre-Trained Model

The following code example shows how to use the tar Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the `!` magic command at the beginning of the statement):

```python
import os
import tensorflow as tf

# Download SSD_Mobilenet trained model
wget http://download.tensorflow.org/models/object_detection/ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Change into the directory where the model is stored
cd ssd_mobilenet_v2_coco_2018_03_29

# Compress the tar file and save it in a directory called 'saved model'
tar czvf panorama-model.tar.gz saved_model
```

The command flags used in this example accomplish the following:

- `c`: Create an archive
- `z`: Compress the archive with gzip
- `v`: Display archive progress
- `f`: Specify the filename of the archive

Built-In Estimators

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in `.fit` method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```python
from sagemaker.tensorflow import TensorFlow

estimator = TensorFlow(entry_point='mnist.py',
                       role=role,
                       framework_version='1.15.3',
                       py_version='py3',
                       training_steps=1000,
                       evaluation_steps=100,
                       instance_count=2,
                       instance_type='ml.c4.xlarge')

Then train the model with `.fit` built-in method:

```python
estimator.fit(inputs)
```

Before finally compiling model with the build in compile_model method:

```python
# Specify output path of the compiled model
output_path = '/'.join(estimator.output_path.split('/')[::-1])

# Compile model
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
```

1952
You can also use the sagemaker.estimator.Estimator Class to initialize an estimator object for training and compiling a built-in algorithm with the compile_model method from the SageMaker Python SDK:

```python
from sagemaker.image_uris import retrieve
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
training_image = retrieve(framework='image-classification', region=aws_region, image_scope='training')

# Create estimator object for training
estimator = sagemaker.estimator.Estimator(image_uri=training_image,
                                           role=role,
                                           instance_count=1,
                                           instance_type='ml.p3.8xlarge',
                                           volume_size = 50,
                                           max_run = 360000,
                                           input_mode= 'File',
                                           output_path=s3_training_output_location,
                                           base_job_name='image-classification-training')

# Setup the input data_channels to be used later for training.
train_data = sagemaker.inputs.TrainingInput(s3_training_data_location,
                                           content_type='application/x-recordio',
                                           s3_data_type='S3Prefix')
validation_data = sagemaker.inputs.TrainingInput(s3_validation_data_location,
                                                content_type='application/x-recordio',
                                                s3_data_type='S3Prefix')
data_channels = {'train': train_data, 'validation': validation_data}

# Train model
estimator.fit(inputs=data_channels, logs=True)

# Compile model with Neo
optimized_estimator = estimator.compile_model(target_instance_family='ml_c5',
                                              input_shape={'data':[1, 3, 224, 224],
                                                           'softmax_label':[1]},
                                              output_path=s3_compilation_output_location,
                                              framework='mxnet',
                                              framework_version='1.7')
```

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker SDK) (p. 1960).

**Compile a Model (AWS Command Line Interface)**

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using AWS Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.
1. Create a Compilation Job

With the CreateCompilationJob API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

The following table demonstrates how to configure CreateCompilationJob API based on whether your target is a device or a platform.

Device Example

```json
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

You can optionally specify the framework version you used with the FrameworkVersion field if you used the PyTorch framework to train your model and your target device is a ml_* target.

```json
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-ExecutionRole-yyyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/train",
        "DataInputConfig": "{'data': [1,3,1024,1024]}",
        "Framework": "PYTORCH",
        # The FrameworkVersion field is only supported when compiling for PyTorch framework and ml_* targets, excluding ml_inf. Supported values are 1.4 or 1.5 or 1.6. Default is 1.6
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5",
        # When compiling for ml_* instances using PyTorch framework, use the "CompilerOptions" field in
        "CompilerOptions": "{'dtype': 'long'}",
        # OutputConfig to provide the correct data type ("dtype") of the model’s input. Default assumed is "float32"
        "StoppingCondition": {
            "MaxRuntimeInSeconds": 300
        }
    }
}
```
Compile Models

Note
This API field is only supported for PyTorch.

Platform Example

```json
{
  "CompilationJobName": "neo-test-compilation-job",
  "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
              ExecutionRole-yyyyymmddThhmmss",
  "InputConfig": {
    "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/
            train",
    "DataInputConfig": "{\'data\': [1,3,1024,1024]}",
    "Framework": "MXNET"
  },
  "OutputConfig": {
    "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-
                         data/compile",
    # A target platform configuration example for a p3.2xlarge instance
    "TargetPlatform": {
      "Os": "LINUX",
      "Arch": "X86_64",
      "Accelerator": "NVIDIA"
    },
    "CompilerOptions": "{\'cuda-ver\': '10.0', \'trt-ver\': '6.0.1', \'gpu-code\':
                        \'sm_70\'}"
  },
  "StoppingCondition": {
    "MaxRuntimeInSeconds": 300
  }
}
```

Note
For the `OutputConfig` API operation, the `TargetDevice` and `TargetPlatform` API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of `DataInputConfig` depending on frameworks, see What input data shapes Neo expects.

For more information about setting up the configurations, see the `InputConfig`, `OutputConfig`, and `TargetPlatform` API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```sh
aws sagemaker create-compilation-job
  --cli-input-json file://job.json
  --region us-west-2
# You should get CompilationJobArn
```

3. Describe the compilation job by running the following command:

```sh
aws sagemaker describe-compilation-job
  --compilation-job-name $JOB_NM
  --region us-west-2
```

4. Stop the compilation job by running the following command:
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2

# There is no output for compilation-job operation

5. List the compilation job by running the following command:

aws sagemaker list-compilation-jobs \
--region us-west-2

Compile a Model (Amazon SageMaker Console)

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker console.

1. In the Amazon SageMaker console, choose Compilation jobs, and then choose Create compilation job.

2. On the Create compilation job page, under Job name, enter a name. Then select an IAM role.

3. If you don’t have an IAM role, choose Create a new role.
4. On the Create an IAM role page, choose Any S3 bucket, and choose Create role.

5. Non PyTorch Frameworks

Within the Input configuration section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the Location of model artifacts input field. Your model artifacts must be in a compressed tarball file format (.tar.gz).

For the Data input configuration field, enter the JSON string that specifies the shape of the input data. For Machine learning framework, choose the framework of your choice.
To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

PyTorch Framework

Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for ml_* (except ml_inf) target, you can optionally specify the version of PyTorch you used.

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

**Note**

When compiling for ml_* instances using PyTorch framework, use Compiler options field in Output Configuration to provide the correct data type (dtype) of the model’s input. The default is set to "float32".
Warning
If you specify a Amazon S3 bucket URI path that leads to .pth file, you will receive the following error after starting compilation: ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file.

6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.
7. Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

![Compilation Job page screenshot](image)

8. Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.

![Compilation Job page screenshot](image)

**Compile a Model (Amazon SageMaker SDK)**

You can use the `compile_model` API in the Amazon SageMaker SDK for Python to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

**Note**

You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to 500 when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```python
# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred target_instance_family
compiled_model = trained_model_estimator.compile_model(target_instance_family='ml_c5',
            input_shape=expected_trained_model_input,
            output_path='insert s3 output path',
            env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'})
```
The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker model that can be deployed to an endpoint. Sample notebooks of using the SDK for Python are provided in the Neo Model Compilation Sample Notebooks section.

## Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and AWS Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the AWS CLI, the SageMaker Console, or the SageMaker SDK for Python. See Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified during the compilation job. You can deploy your compiled model to cloud instances and AWS Inferentia instances using the SageMaker SDK for Python, AWS SDK for Python (Boto3), AWS CLI, or the AWS console.

If you deploy your model using AWS CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

### Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances, AWS Inferentia instance types, or Amazon Elastic Inference accelerators.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see Deploy a Model with Cloud Instances. For information on how to deploy your compiled model with Elastic Inference accelerators, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2054).

### Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.8.0</td>
<td>Supports 1.8.0 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------</td>
<td>---------------------</td>
<td>------------------------------</td>
<td>--------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>ONNX</td>
<td>1.5.0</td>
<td>Supports 1.5.0 or earlier</td>
<td>Image Classification, SVM</td>
<td>One model file (.onnx)</td>
<td></td>
</tr>
<tr>
<td>Keras</td>
<td>2.2.4</td>
<td>Supports 2.2.4 or earlier</td>

<tr>
<td>XGBoost</td>
<td>0.9</td>
<td>Supports 0.9 or earlier</td>
<td>Decision Trees</td>
<td>One XGBoost model file (.model) where the number of nodes in a tree is less than $2^{31}$</td>
<td></td>
</tr>
<tr>
<td>DARKNET</td>
<td></td>
<td></td>
<td>Image Classification, Object Detection</td>
<td>One config (.cfg) file and one weights (.weights) file</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

"Model Version" is the version of the framework used to train and export the model.

**Instance Types**

You can deploy your SageMaker compiled model to one of the cloud instances listed below:
Cloud Instances

<table>
<thead>
<tr>
<th>Instance</th>
<th>Compute Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml_c4</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_c5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m4</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_m5</td>
<td>Standard</td>
</tr>
<tr>
<td>ml_p2</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_p3</td>
<td>Accelerated computing</td>
</tr>
<tr>
<td>ml_g4dn</td>
<td>Accelerated computing</td>
</tr>
</tbody>
</table>

For information on the available vCPU, memory, and price per hour for each instance type, see Amazon SageMaker Pricing.

**Note**
When compiling for ml_* instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (dtype) of the model's input. The default is set to "float32".

**AWS Inferentia**

SageMaker Neo supports the following deep learning frameworks for Inferentia:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>MXNet</td>
<td>1.5.1</td>
<td>Supports 1.5.1 or earlier</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>One symbol file (.json) and one parameter file (.params)</td>
<td>GluonCV v0.8.0</td>
</tr>
<tr>
<td>PyTorch</td>
<td>1.5.1</td>
<td>Supports 1.5.1 or earlier</td>
<td>Image Classification</td>
<td>One model definition file (.pt or .pth) with input dtype of float32</td>
<td></td>
</tr>
<tr>
<td>TensorFlow</td>
<td>1.15.0</td>
<td>Supports 1.15.0 or earlier</td>
<td>Image Classification</td>
<td>For saved models, one .pb or</td>
<td></td>
</tr>
</tbody>
</table>
You can deploy your SageMaker Neo-compiled model to AWS Inferentia-based Amazon EC2 Inf1 instances. AWS Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the ml_inf1 instance to deploy your compiled models.

**Amazon Elastic Inference**

SageMaker Neo supports the following deep learning frameworks for Elastic Inference:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>2.3.2</td>
<td>Supports 2.3</td>
<td>Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition</td>
<td>For saved models, one .pb or one .pbtxt file and a variables directory that contains variables. For frozen models, only one .pb or .pbtxt file.</td>
</tr>
</tbody>
</table>

You can deploy your SageMaker Neo-compiled model to an Elastic Inference Accelerator. For more information, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2054).

**Deploy a Model**

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.

For Inf1 instances, models need to be compiled specifically for ml.inf1 instances. Models compiled for other instance types are not guaranteed to work with ml.inf1 instances.
For Elastic Inference accelerators, models need to be compiled specifically for ml_eia2 devices. For information on how to deploy your compiled model to an Elastic Inference accelerator, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2054).

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: Amazon SageMaker SDK for Python, SDK for Python (Boto3), AWS Command Line Interface, and SageMaker Console.

**Note**
For deploying a model using AWS CLI, the console, or Boto3, see Neo Inference Container Images to select the inference image URI for your primary container.

**Topics**
- Prerequisites (p. 1965)
- Deploy a Compiled Model Using SageMaker SDK (p. 1971)
- Deploy a Compiled Model Using Boto3 (p. 1974)
- Deploy a Compiled Model Using the AWS CLI (p. 1975)
- Deploy a Compiled Model Using the Console (p. 1977)

**Prerequisites**

**Note**
Follow the instructions in this section if you compiled your model using AWS SDK for Python (Boto3), AWS CLI, or the SageMaker console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from this list.
2. An entry point script file:
   a. For PyTorch and MXNet models:

   *If you trained your model using SageMaker*, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo, the training script (`mnist.py`) implements the required functions.

   *If you did not train your model using SageMaker*, you need to provide an entry point script (`inference.py`) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MxNet or Model Directory Structure for PyTorch.

When using Neo Inference Optimized Container images with PyTorch and MXNet on CPU and GPU instance types, the inference script must implement the following functions:

- `model_fn`: Loads the model.
- `input_fn`: Converts the incoming request payload into a numpy array.
- `predict_fn`: Performs the prediction.
- `output_fn`: Converts the prediction output into the response payload.
- Alternatively, you can define `transform_fn` to combine `input_fn`, `predict_fn`, and `output_fn`.

The following are examples of `inference.py` script within a directory named `code (code/inference.py)` for PyTorch and MXNet (Gluon and Module). The examples first load the model and then serve it on image data on a GPU:
MXNet Module

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
    mod = mx.mod.Module(symbol=sym, context=ctx, label_names=None)
    exe = mod.bind(for_training=False,
                   data_shapes=[('data', (1,3,224,224))],
                   label_shapes=mod._label_shapes)
    mod.set_params(arg_params, aux_params, allow_missing=True)
    # Run warm-up inference on empty data during model load (required for GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    mod.forward(Batch([data]))
    return mod

def transform_fn(mod, image, input_content_type, output_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                           mean=mx.nd.array([0.485, 0.456, 0.406]),
                                           std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)

    # prediction/inference
    mod.forward(Batch([processed_input]))

    # post-processing
    prob = mod.get_outputs()[0].asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type
```

MXNet Gluon

```python
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json',
                                              ['data'], 'compiled-0000.params', ctx=ctx)
```
# Hybridize the model & pass required options for Neo: static_alloc=True &
# static_shape=True
block.hybridize(static_alloc=True, static_shape=True)

# Run warm-up inference on empty data during model load (required for GPU)
data = mx.nd.empty((1,3,224,224), ctx=ctx)
warm_up = block(data)
return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
        mean=mx.nd.array([0.485, 0.456, 0.406]),
        std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype('float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type

PyTorch 1.4 and Older

import os
import torch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.
    Keyword arguments:
    model_dir -- the directory path where the model artifacts are present
    """

    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')
with torch.neo.config(model_dir=model_dir, neo_runtime=True):
    model = torch.jit.load(model_path)
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    model = model.to(device)

# We recommend that you run warm-up inference during model load
sample_input_path = os.path.join(model_dir, 'sample_input.pkl')
with open(sample_input_path, 'rb') as input_file:
    model_input = pickle.load(input_file)
if torch.is_tensor(model_input):
    model_input = model_input.to(device)
else:
    print("Only supports a torch tensor or a tuple of torch tensors")
return model

def transform_fn(model, request_body, request_content_type,
                 response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """
    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([transforms.Resize(256),
                                       transforms.CenterCrop(224),
                                       transforms.ToTensor(),
                                       transforms.Normalize(
                                           mean=[0.485, 0.456, 0.406],
                                           std=[0.229, 0.224, 0.225]),
                                       ])
    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)
    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    batchified = batchified.to(device)
    output = model.forward(batchified)
    return json.dumps(output.cpu().numpy().tolist()), response_content_type

PyTorch 1.5 and Newer

Use neopytorch to specify the file path of the model if you trained with PyTorch version 1.5 and newer.

import os
import torch
import neopytorch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms as transforms
from PIL import Image
import io
import json
import pickle

def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.
    """
    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')
    neopytorch.config(model_dir=model_dir, neo_runtime=True)
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    model = torch.jit.load(model_path, map_location=device)
    model = model.to(device)

    # We recommend that you run warm-up inference during model load
    sample_input_path = os.path.join(model_dir, 'sample_input.pkl')
    with open(sample_input_path, 'rb') as input_file:
        model_input = pickle.load(input_file)
    if torch.is_tensor(model_input):
        model_input = model_input.to(device)
    elif isinstance(model_input, tuple):
        model_input = (inp.to(device)
                        for inp in model_input if torch.is_tensor(inp))
    else:
        print("Only supports a torch tensor or a tuple of torch tensors")
    return model

def transform_fn(model, request_body, request_content_type,
                 response_content_type):
    """Run prediction and return the output.
    The function
    1. Pre-processes the input request
    2. Runs prediction
    3. Post-processes the prediction output.
    """
    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
        transforms.Resize(256),
        transforms.CenterCrop(224),
        transforms.ToTensor(),
        transforms.Normalize(
            mean=[
                0.485, 0.456, 0.406],
            std=[
                0.229, 0.224, 0.225])
    ])
    normalized = preprocess(decoded)
batchified = normalized.unsqueeze(0)

    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
batchified = batchified.to(device)
output = model.forward(batchified)
return json.dumps(output.cpu().numpy().tolist()), response_content_type
b. **For inf1 instances or onnx, xgboost, keras container images**

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- **neo_preprocess**: Converts the incoming request payload into a numpy array.
- **neo_postprocess**: Converts the prediction output from Neo Deep Learning Runtime into the response body.

**Note**
The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see [Neo Model Compilation Sample Notebooks](#).

c. **For TensorFlow models**

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script `inference.py` file that can be used at the time of inference. The script should implement either a either a pair of `input_handler` and `output_handler` functions or a single handler function.

**Note**
Note that if handler function is implemented, `input_handler` and `output_handler` are ignored.

The following is a code example of `inference.py` script that you can put together with the compile model to perform custom pre- and post-processing on an image classification model. The SageMaker client sends the image file as an `application/x-image` content type to the `input_handler` function, where it is converted to JSON. The converted image file is then sent to the TensorFlow Model Server (TFX) using then REST API.

```python
import json
import os as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST API

    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details

    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    """
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512)))
    image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
    body = json.dumps({'signature_name': 'serving_default', 'instances':
                       image.tolist()})
    return body

def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the client.
```
If there is no custom pre- or post-processing, the SageMaker client converts the file image to JSON in a similar way before sending it over to the SageMaker endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

Deploy a Compiled Model Using SageMaker SDK

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

Topics

- If you compiled your model using the SageMaker SDK (p. 1971)
- If you compiled your model using MXNet or PyTorch (p. 1971)
- If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow (p. 1973)

If you compiled your model using the SageMaker SDK

The sagemaker.Model object handle for the compiled model supplies the deploy() function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is ml_c5.

```python
predictor = compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.c5.4xlarge')
```

# Print the name of newly created endpoint
print(predictor.endpoint_name)

If you compiled your model using MXNet or PyTorch

Create the SageMaker model and deploy it using the deploy() API under the framework-specific Model APIs. For MXNet, it is MXNetModel and for PyTorch, it is PyTorchModel. When you are creating and deploying an SageMaker model, you must set MMS_DEFAULT_RESPONSE_TIMEOUT environment variable to 500 and specify the entry_point parameter as the inference script (inference.py) and the source_dir parameter as the directory location (code) of the inference script. To prepare the inference script (inference.py) follow the Prerequisites step.
The following example shows how to use these functions to deploy a compiled model using the SageMaker SDK for Python:

**MXNet**

```python
from sagemaker.mxnet import MXNetModel

# Create SageMaker model and deploy an endpoint
sm_mxnet_compiled_model = MXNetModel(
    model_data='insert S3 path of compiled MXNet model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.8.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for MXNet',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_mxnet_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.4 and Older**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.4.0',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)

# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)
```

**PyTorch 1.5 and Newer**

```python
from sagemaker.pytorch import PyTorchModel

# Create SageMaker model and deploy an endpoint
sm_pytorch_compiled_model = PyTorchModel(
    model_data='insert S3 path of compiled PyTorch model archive',
    role='AmazonSageMaker-ExecutionRole',
    entry_point='inference.py',
    source_dir='code',
    framework_version='1.5',
    py_version='py3',
    image_uri='insert appropriate ECR Image URI for PyTorch',
)
```

1972
# Replace the example instance_type below to your preferred instance_type
predictor = sm_pytorch_compiled_model.deploy(initial_instance_count = 1, instance_type = 'ml.p3.2xlarge')

# Print the name of newly created endpoint
print(predictor.endpoint_name)

Note
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

Construct a TensorFlowModel object, then call deploy:

```python
role='AmazonSageMaker-ExecutionRole'
model_path='S3 path for model file'
framework_image='inference container arn'
tf_model = TensorFlowModel(model_data=model_path,
                           framework_version='1.15.3',
                           role=role,
                           image_uri=framework_image)
instance_type='ml.c5.xlarge'
predictor = tf_model.deploy(instance_type=instance_type,
                           initial_instance_count=1)
```

See Deploying directly from model artifacts for more information.

You can select a Docker image Amazon ECR URI that meets your needs from this list.

For more information on how to construct a TensorFlowModel object, see the SageMaker SDK.

Note
Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as “warming up” the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```python
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
from tensorflow_serving.apis import regression_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data, shape=test_data.shape, dtype=tf.float32))
```
log = prediction_log_pb2.PredictionLog(
predict_log=prediction_log_pb2.PredictLog(request=request))
writer.write(log.SerializeToString())

For more information on how to “warm up” your model, see the TensorFlow TFX page.

**Deploy a Compiled Model Using Boto3**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).

**Topics**
- Deploy the Model (p. 1974)

**Deploy the Model**

After you have satisfied the prerequisites, use the `create_model`, `create_endpoint_config`, and `create_endpoint` APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```python
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
    ModelName='my-sagemaker-model',
    PrimaryContainer={
        'Image': '<insert the ECR Image URI>',
        'ModelDataUrl': 's3://path/to/model/artifact/model.tar.gz',
        'Environment': {}
    },
    ExecutionRoleArn='ARN for AmazonSageMaker-
    ExecutionRole'
)

print("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
    EndpointConfigName='sagemaker-neomxnet-
    endpoint-configuration',
    ProductionVariants=[
        {'VariantName': <provide your variant name>,
         'ModelName': 'my-sagemaker-model',
         'InitialInstanceCount': 1,
         'InstanceType': <provide your instance type here>}
    ],
)

print("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
create_endpoint_api_response = client.create_endpoint(
    EndpointName='<provide your endpoint name>',
    EndpointConfigName='<insert your endpoint config name>',
)
Note
The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

For full syntax of create_model, create_endpoint_config, and create_endpoint APIs, see create_model, create_endpoint_config, and create_endpoint, respectively.

If you did not train your model using SageMaker, specify the following environment variables:

**MXNet and PyTorch**

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region",
  "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

**TensorFlow**

```
"Environment": {
  "SAGEMAKER_PROGRAM": "inference.py",
  "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
  "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
  "SAGEMAKER_REGION": "insert your region"
}
```

If you trained your model using SageMaker, specify the environment variable SAGEMAKER_SUBMIT_DIRECTORY as the full Amazon S3 bucket URI that contains the training script.

**Deploy a Compiled Model Using the AWS CLI**

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the AWS CLI.

**Topics**

- Deploy the Model (p. 1975)

**Deploy the Model**

After you have satisfied the prerequisites, use the create-model, create-endpoint-config, and create-endpoint AWS CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

**Create a Model**

From Neo Inference Container Images, select the inference image URI and then use create-model API to create a SageMaker model. You can do this with two steps:

1. Create a create_model.json file. Within the file, specify the name of the model, the image URI, the path to the model.tar.gz file in your Amazon S3 bucket, and your SageMaker execution role:
If you trained your model using SageMaker, specify the following environment variable:

```
"Environment": {
    "SAGEMAKER_SUBMIT_DIRECTORY": "[Full S3 path for *.tar.gz file containing the training script]"
}
```

If you did not train your model using SageMaker, specify the following environment variables:

**MXNet and PyTorch**

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

**TensorFlow**

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}
```

**Note**

The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

```
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the create-model API, see [create-model](#).

**Create an Endpoint Configuration**

After creating a SageMaker model, create the endpoint configuration using the create-endpoint-config API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as create_config.json:

```
{
    "EndpointConfigName": "<provide your endpoint config name>",
    "ProductionVariants": []
}
```

```json
{
   "VariantName": "<provide your variant name>",
   "ModelName": "my-sagemaker-model",
   "InitialInstanceCount": 1,
   "InstanceType": "<provide your instance type here>",
   "InitialVariantWeight": 1.0
}
}
```

Now run the following AWS CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the `create-endpoint-config` API, see `create-endpoint-config`.

Create an Endpoint

After you have created your endpoint configuration, create an endpoint using the `create-endpoint` API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --endpoint-config-name '<insert your endpoint config name>'
```

For the full syntax of the `create-endpoint` API, see `create-endpoint`.

Deploy a Compiled Model Using the Console

You must satisfy the prerequisites section if the model was compiled using AWS SDK for Python (Boto3), the AWS CLI, or the Amazon SageMaker console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the Amazon SageMaker console.

Topics
- Deploy the Model (p. 1977)

Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

1. Choose Models, and then choose Create models from the Inference group. On the Create model page, complete the Model name, IAM role, and VPC fields (optional), if needed.
2. To add information about the container used to deploy your model, choose **Add container** container, then choose **Next**. Complete the **Container input options**, **Location of inference code image**, and **Location of model artifacts**, and optionally, **Container host name**, and **Environmental variables** fields.
3. To deploy Neo-compiled models, choose the following:

- **Container input options**: Choose **Provide model artifacts and inference image**.
- **Location of inference code image**: Choose the inference image URI from Neo Inference Container Images, depending on the AWS Region and kind of application.
- **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
- **Environment variables**:
  - Leave this field blank for **SageMaker XGBoost**.
  - If you trained your model using SageMaker, specify the environment variable SAGEMAKER_SUBMIT_DIRECTORY as the Amazon S3 bucket URI that contains the training script.
  - If you did not train your model using SageMaker, specify the following environment variables:

<table>
<thead>
<tr>
<th>Key</th>
<th>Values for MXNet and PyTorch</th>
<th>Values TensorFlow</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOGLEVEL</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
<td>&lt;your region&gt;</td>
</tr>
<tr>
<td>MMS_DEFAULT_RESPONSE_TIMEOUT</td>
<td>500</td>
<td>Leave this field blank for TF</td>
</tr>
</tbody>
</table>

4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the **Create model landing page**, choose **Create endpoint**.

5. In **Create and configure endpoint** diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.
6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.
To deploy models to Amazon SageMaker, first create an endpoint configuration. In the configuration, specify which models to deploy, and the relative traffic weighting and hardware requirements for each.

Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.
8. Choose **Save**.
9. On the New endpoint configuration page, choose **Create endpoint configuration**, and then choose **Create endpoint**.

**Request Inferences from a Deployed Service**

If you have followed instructions in Deploy a Model (p. 1964), you should have a SageMaker endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

**Topics**
- Request Inferences from a Deployed Service (Amazon SageMaker SDK) (p. 1982)
- Request Inferences from a Deployed Service (Boto3) (p. 1984)
- Request Inferences from a Deployed Service (AWS CLI) (p. 1985)

**Request Inferences from a Deployed Service (Amazon SageMaker SDK)**

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires `application/json` as the content type.
PyTorch and MXNet

If you are using PyTorch v1.4 or later or MXNet 1.7.0 or later and you have an Amazon SageMaker endpoint InService, you can make inference requests using the `predictor` package of the SageMaker SDK for Python.

**Note**
The API varies based on the SageMaker SDK for Python version:

- For version 1.x, use the `RealTimePredictor` and `Predict` API.
- For version 2.x, use the `Predictor` and the `Predict` API.

The following code example shows how to use these APIs to send an image for inference:

**SageMaker Python SDK v1.x**

```python
from sagemaker.predictor import RealTimePredictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = RealTimePredictor(endpoint=endpoint, content_type='application/x-image')
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**SageMaker Python SDK v2.x**

```python
from sagemaker.predictor import Predictor

endpoint = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=payload)
print (inference_response)
```

**TensorFlow**

The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```python
from sagemaker.predictor import Predictor
from PIL import Image
import numpy as np
import json

endpoint = 'insert the name of your endpoint here'

# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
```
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})

predictor = Predictor(endpoint)
inference_response = predictor.predict(data=body)
print(inference_response)

Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker SDK for Python (Boto3) client and `invoke_endpoint()` API once you have an SageMaker endpoint InService. The following code example shows how to send an image for inference:

**PyTorch and MXNet**

```python
import boto3
import json

endpoint = 'insert name of your endpoint here'

runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()

# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/x-image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode())
```

**TensorFlow**

For TensorFlow submit an input with `application/json` for the content type.

```python
from PIL import Image
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(
    EndpointName=ioc_predictor_endpoint_name,
    Body=body,
    ContentType=content_type
)
```

**XGBoost**

For an XGBoost application, you should submit a CSV text instead:

```python
1984
```
import boto3
import json

endpoint = 'insert your endpoint name here'
runtime = boto3.Session().client('sagemaker-runtime')
csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv',
    Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode())

Note that BYOM allows for a custom content type. For more information, see
runtime_InvokeEndpoint.

Request Inferences from a Deployed Service (AWS CLI)

Inference requests can be made with the sagemaker-runtime invoke-endpoint once you have an
Amazon SageMaker endpoint InService. You can make inference requests with the AWS Command
Line Interface (AWS CLI). The following example shows how to send an image for inference:

aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
    --body fileb://image.jpg --content-type=application/x-image output_file.txt

An output_file.txt with information about your inference requests is made if the inference was
successful.

For TensorFlow submit an input with application/json as the content type.

aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint here'
    --body fileb://input.json --content-type=application/json output_file.txt

Inference Container Images

Based on your use case, replace the highlighted portion in the inference image URI template provided
below with appropriate values.

Amazon SageMaker XGBoost

aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest

Replace aws_account_id from the table at the end of this page based on the aws_region you used.

TensorFlow

CPU or GPU instance types

aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
tensorflow:fx_version-instance_type-py3

Replace aws_account_id from the table at the end of this page based on the aws_region you
used.
Replace `fx_version` with 1.15.3.

Replace `instance_type` with either `cpu` or `gpu`.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
tensorflow:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used. Note that for instance type `inf` only `us-east-1` and `us-west-2` are supported.

Replace `fx_version` with 1.15.0

Replace `instance_type` with `inf`.

**MXNet**

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
mxnet:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.8.0.

Replace `instance_type` with either `cpu` or `gpu`.

Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
mxnet:fx_version-instance_type-py3
```

Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.5.1.

Replace `instance_type` with `inf`.

**PyTorch**

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
pytorch:fx_version-instance_type-py3
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with 1.4, 1.5, or 1.6.

Replace `instance_type` with either `cpu` or `gpu`.
Inferentia instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-pytorch:fx_version-instance_type-py3
```

Replace `aws_region` with either `us-east-1` or `us-west-2`.

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `fx_version` with `1.5.1`.

Replace `instance_type` with `inf`.

Darknet

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-darknet:instance-type
```

Replace `aws_account_id` from the table at the end of this page based on the `aws_region` you used.

Replace `instance-type` with either `cpu` or `gpu`.

The following table maps `aws_account_id` with `aws_region`. Use this table to find the correct inference image URI you need for your application.

<table>
<thead>
<tr>
<th>aws_account_id</th>
<th>aws_region</th>
</tr>

</tbody>
</table>
Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments’ Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use AWS services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 AWS Configuration for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics
- Supported Frameworks, Devices, Systems, and Architectures (p. 1988)
- Deploy Models (p. 1997)
- Getting Started with Neo on Edge Devices (p. 1998)

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models (p. 1992) section.

Topics
- Supported Frameworks (p. 1988)
- Supported Devices, Chip Architectures, and Systems (p. 1990)
- Tested Models (p. 1992)

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>

</table>
## Supported Devices, Chip Architectures, and Systems

Amazon SageMaker Neo supports the following devices, chip architectures, and operating systems.

### Devices

You can select a device using the dropdown list in the Amazon SageMaker console or by specifying the `TargetDevice` in the output configuration of the `CreateCompilationJob` API.

You can choose from one of the following edge devices:

<table>

## Tested Models

The following collapsible sections provide information about machine learning models that were tested by the Amazon SageMaker Neo team. Expand the collapsible section based on your framework to check if a model was tested.

**Note**

This is not a comprehensive list of models that can be compiled with Neo.

See [Supported Frameworks](p. 1988) and [SageMaker Neo Supported Operators](#) to find out if you can compile your model with SageMaker Neo.

Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using DLR, or you can use AWS IoT Greengrass.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See Supported Frameworks, Devices, Systems, and Architectures to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see Use Neo to Compile a Model.

Deploy a Compiled Model (DLR)

DLR is a compact, common runtime for deep learning models and decision tree models. DLR uses the TVM runtime, Treelite runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```
pip install dlr[raspberry]
```
Deploy a Model (AWS IoT Greengrass)

AWS IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With AWS IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all AWS IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with AWS IoT Greengrass, see How to configure optimized machine learning inference using the AWS Management Console.

Getting Started with Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using AWS CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

Note
You can run the following code snippets on your local machine, within a SageMaker notebook, within SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:

- You do not need to install Boto3.
- You do not need to add the ‘AmazonSageMakerFullAccess’ IAM policy

This guide assumes you are running the following instructions on your edge device.

Prerequisites

1. Install Boto3
   
   If you are running these commands on your edge device, you must install the AWS SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device’s terminal or within a Jupyter notebook instance:

   Terminal

   $ pip install boto3

   Jupyter Notebook

   !pip install boto3

2. Set Up AWS Credentials
   
   You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the AWS credentials should be stored in the file ~/.aws/credentials on your edge device. Within the credentials file, you should see two environment variables: aws_access_key_id and aws_secret_access_key.

   In your terminal, run:
The AWS General Reference Guide has instructions on how to get the necessary aws_access_key_id and aws_secret_access_key. For more information on how to set up credentials on your device, see the Boto3 documentation.

3. Set up an IAM Role and attach policies.

Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python (Boto3), the console, or the AWS CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```python
import boto3
AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)
role_name = 'role-name'

policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        },
    ],
    'Version': '2012-10-17'
}

new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/",
    RoleName=role_name
)

role_arn = new_role['Role']['Arn']
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.
Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker and Amazon S3:

```python
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

4. **Create an Amazon S3 bucket to store your model artifacts**

SageMaker Neo will access your model artifacts from Amazon S3

**Boto3**

```python
# Create an S3 client
s3_client = boto3.client('s3', region_name=AWS_REGION)

# Name buckets
bucket='name-of-your-bucket'

# Check if bucket exists
if boto3.resource('s3').Bucket(bucket) not in boto3.resource('s3').buckets.all():
    s3_client.create_bucket(
        Bucket=bucket,
        CreateBucketConfiguration={
            'LocationConstraint': AWS_REGION
        }
    )
else:
    print(f'Bucket {bucket} already exists. No action needed. ')
```

**CLI**

```bash
$ aws s3 mb s3://'name-of-your-bucket' --region specify-your-region

# Check your bucket exists
$ aws s3 ls s3://'name-of-your-bucket'/
```

5. **Train a machine learning model**

See [Train a Model with Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/quickstart-training.html) for more information on how to train a machine learning model using Amazon SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](https://docs.aws.amazon.com/sagemaker/latest/dg/neuro-hp-training.html)

If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd.mobilenet_v1_1.0` model from TensorFlow's website. The model you just copied is an object detection model trained from the [COCO dataset](https://github.com/tensorflow/models/blob/master/research/object_detection/object_detection.pb

```bash
model_zip_filename = './coco_ssd.mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd.mobilenet_v1_1.0_quant_2018_06_29.zip
```
--output {model_zip_filename}

Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tarfile (.tar.gz) before using it in later steps. Type the following into your Jupyter notebook:

```python
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

Once you have trained your machine learning mode, store it in an S3 bucket.

**Boto3**

```python
s3_client.upload_file(filename=model_filename, bucket=bucket, key=model_filename)
```

**CLI**

Replace your-model-filename and your-S3-bucket with the name of your S3 bucket.

```
$ aws s3 cp your-model-filename s3://your-S3-bucket
```

---

**Step 1: Compile the Model**

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker Neo. You can compile your model using the AWS CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. **The Amazon S3 bucket URI where you stored the trained model.**

   If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the AWS CLI:

   ```bash
   $ aws s3 ls
   ```

   For example:

   ```bash
   $ aws s3 ls
   2020-11-02 17:08:50 bucket
   ```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:

   ```bash
   ```

   2001
3. **The machine learning framework you used to train your model.**

Define the framework you used to train your model.

```python
framework = 'framework-name'
```

For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

```python
framework = 'tflite'
```

For a complete list of Neo-supported frameworks, see [Supported Frameworks, Devices, Systems, and Architectures](#).

4. **The shape of your model's input.**

Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. `value` is a list of the integer dimensions of an input tensor and `key` is the exact name of an input tensor in the model.

```json
data_shape = '{"name": [tensor-shape]}'
```

For example:

```json
data_shape = '{"normalized_input_image_tensor": [1, 300, 300, 3]}'
```

**Note**

Make sure the model is correctly formatted depending on the framework you used. See [What input data shapes does SageMaker Neo expect?](#) The key in this dictionary must be changed to the new input tensor's name.

5. **Either the name of the target device to compile for or the general details of the hardware platform**

```python
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```python
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in [Supported Frameworks, Devices, Systems, and Architectures](#).

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```python
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')
```
response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time
while True:
    response = sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
        print('Compiling ...')
        time.sleep(30)
    print('Done!')

If you want additional information for debugging, include the following print statement:

print(response)

If the compilation job is successful, your compiled model is stored in the output Amazon S3 bucket you specified earlier (s3_output_location). Download your compiled model locally:

object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)

**Step 2: Set Up Your Device**

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install AWS IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the coco_ssd_mobilenet object detection algorithm and you will use DLR.

1. **Install additional packages**

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

   For example, for the coco_ssd_mobilenet object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.
### Step 3: Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

   ```bash
   # Download compiled model locally to edge device
   object_path = f'output/{model_name}-{target_device}.tar.gz'
   neo_compiled_model = f'compiled-{model_name}.tar.gz'
   s3_client.download_file(bucket_name, object_path, neo_compiled_model)
   # Extract model from .tar.gz so DLR can use it
   mkdir ./dlr_model # make a directory to store your model (optional)
   !tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model
   ```

2. **Import DLR and an initialized `DLRModel` object.**

   ```python
   import dlr
   device = 'cpu'
   model = dlr.DLRModel('./dlr_model', device)
   ```

3. **Download an image for inferencing and format it based on how your model was trained.**

   For the `coco_ssd_mobilenet` example, you can download an image from the COCO dataset and then reform the image to 300x300:

   ```python
   from PIL import Image
   # Download an image for model to make a prediction
   input_image_filename = './input_image.jpg'
   !curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output
   (input_image_filename)
   # Format image so model can make predictions
   resized_image = image.resize((300, 300))
   ```
# Model is quantized, so convert the image to uint8

```python
x = np.array(resized_image).astype('uint8')
```

4. **Use DLR to make inferences.**

Finally, you can use DLR to make a prediction on the image you just downloaded:

```python
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the [neo-ai-dlr Github repository](https://github.com/neo-ai/dlr).

## Troubleshoot Errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

- **Did you encounter an error before you deployed your model?** If yes, see Troubleshoot Neo Compilation Errors.
- **Did you encounter an error after you compiled your model?** If yes, see Troubleshoot Neo Inference Errors.

### Error Classification Types

This list classifies the *user errors* you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are *system errors*.

#### Client permission error

Neo passes the errors for these straight through from the dependent service.

- **Access Denied** when calling sts:AssumeRole
- **Any 400 error** when calling Amazon S3 to download or upload a client model
- **PassRole error**

#### Load error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (*.pb or *.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (*.pth).
- **MXNET**: Expect only one symbol file (*.json) and one parameter file (*.params).
- **XGBoost**: Expect only one XGBoost model file (*.model). The input model has size limitation.

#### Compilation error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:

- **OperatorNotImplemented**: An operator has not been implemented.
• **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.

• **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.

• **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

## Troubleshoot Neo Compilation Errors

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

### How to Use This Page

Attempt to resolve your error by the going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See What input data shapes does SageMaker Neo expect?
2. Check common framework-specific errors.
3. Check if your error is an infrastructure error.

### Framework-Related Errors

#### TensorFlow

<table>
<thead>

</tbody>
</table>

## Troubleshoot Neo Inference Errors

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to **PyTorch 1.4.0 or later** and **MXNet v1.7.0 or later**.
• Make sure the first inference (warm-up inference) on a valid input data is done in model_fn(), otherwise the following error message may be seen on the terminal when predict API is called:

```plaintext
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
```

• Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

**On the terminal:**

```plaintext
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (503) from <users-sagemaker-endpoint> with message "{ "code": 503, "type": "InternalServerException", "message": "Prediction failed" } ".
```

**In CloudWatch:**

```plaintext
W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError: 'NoneType' object has no attribute 'transform'
```

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER_PROGRAM</td>
<td>inference.py</td>
</tr>
<tr>
<td>SAGEMAKER_SUBMIT_DIRECTORY</td>
<td>/opt/ml/model/code</td>
</tr>
<tr>
<td>SAGEMAKER_CONTAINER_LOG_LEVEL</td>
<td>20</td>
</tr>
<tr>
<td>SAGEMAKER_REGION</td>
<td>&lt;your region&gt;</td>
</tr>
</tbody>
</table>

• Make sure that the MMS_DEFAULT_RESPONSE_TIMEOUT environment variable is set to 500 or a higher value while creating the Amazon SageMaker model; otherwise, the following error message may be seen on the terminal:

```plaintext
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed out while waiting for a response from container model. Review the latency metrics for each container in Amazon CloudWatch, resolve the issue, and try again."
```

---

**SageMaker Edge Manager**

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

**Why Use Edge Manager?**

Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

2008
However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay over time. Monitoring models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

**How Does it Work?**

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker inference engine (Edge Manager agent), and maintaining models on the devices.

SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker Ground Truth and retrain the models in SageMaker.

**How Do I Use SageMaker Edge Manager?**

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. **Read the Getting Started section** - This section walks you through setting up your first edge packaging job and creating your first fleet.
2. **Explore Edge Manager Jupyter notebook examples** - Example notebooks are stored in the amazon-sagemaker-examples GitHub repository in the sagemaker_edge_manager folder.
Getting Started

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker Edge Manager prerequisites.

Topics

• Setting Up (p. 2010)
• Train, Compile, and Package Your Model (p. 2012)
• Create and Register Fleets and Authenticate Devices (p. 2015)
• Download and Set Up Edge Manager (p. 2018)
• Run Agent (p. 2021)

Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker and AWS IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

1. **Set up an AWS account.**

   Create an AWS account and an IAM administrator user. For instructions on how to set up your AWS account, see How do I create and activate a new AWS account? For instructions on how to create an administrator user in your AWS account, see Creating your first IAM admin user and group.

2. **Create an IAM role for Amazon SageMaker.**

   SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker and has permission to access Amazon S3. Using this role, SageMaker can run under your account and access to your Amazon S3 bucket.

   You can create an IAM role by using the IAM console, AWS SDK for Python (Boto3), or AWS CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

   a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/
   b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
   c. For Select type of trusted entity, choose AWS service.
   d. Choose the service that you want to allow to assume this role. In this case, choose SageMaker. Then choose Next: Permissions.
   e. Choose Next: Tags.
   f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
   g. Choose Next: Review.
   h. Type in a Role name.
   i. If possible, type a role name or role name suffix. Role names must be unique within your AWS account. They are not distinguished by case. For example, you cannot create roles named both PRODROLE and prodrole. Because other AWS resources might reference the role, you cannot edit the name of the role after it has been created.
j. (Optional) For Role description, type a description for the new role.
k. Review the role and then choose Create role.

Note the SageMaker Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:

i. Go to the IAM console: https://console.aws.amazon.com/iam/
ii. Select Roles.
iii. Search for the role you just created by typing in the name of the role in the search field.
iv. Select the role.
v. The role ARN is at the top of the Summary page.

3. Create an IAM role for AWS IoT.

The AWS IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker client object.

Configure an IAM role in your AWS account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with AWS IoT services.

Create a role for AWS IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker.

a. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
b. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
c. For Select type of trusted entity, choose AWS service.
d. Choose the service that you want to allow to assume this role. In this case, choose IoT. Select IoT as the Use Case.
e. Choose Next: Permissions.
f. Choose Next: Tags.
g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.
h. Choose Next: Review.
i. Type in a Role name. The role name must start with SageMaker.
j. (Optional) For Role description, type a description for the new role.
k. Review the role and then choose Create role.
l. Once the role is created, choose Roles in the IAM console. Search for the role you created by typing in role name in the Search field.
m. Choose your role.
n. Next, choose Attach Policies.
o. Search for AmazonSageMakerEdgeDeviceFleetPolicy in the Search field. Select AmazonSageMakerEdgeDeviceFleetPolicy.
p. Choose Attach policy.
q. Add the following policy statement to the trust relationship:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "credentials.iot.amazonaws.com"
            }
        }
    ]
}
```
A trust policy is a JSON policy document in which you define the principals that you trust to assume the role. For more information about trust policies, see Roles terms and concepts.

r. Note the AWS IoT role ARN. You use the AWS IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:
   i. Go to the IAM console: https://console.aws.amazon.com/iam/
   ii. Choose Roles.
   iii. Search for the role you created by typing in the name of the role in the Search field.
   iv. Select the role.
   v. The role ARN is on the Summary page.

4. **Create an Amazon S3 bucket.**

   SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

   a. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
   b. Choose Create bucket.
   c. In Bucket name, enter a name for your bucket.
   d. In Region, choose the AWS Region where you want the bucket to reside.
   e. In Bucket settings for Block Public Access, choose the settings that you want to apply to the bucket.
   f. Choose Create bucket.

For more information about creating Amazon S3 buckets, see Getting started with Amazon S3.

Store the name of the bucket in the following variable:

```
bucket=<bucket-name>
```

### Train, Compile, and Package Your Model

In this section you will create SageMaker and AWS IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. **Import libraries and create client objects.**

   This tutorial uses the AWS SDK for Python (Boto3) to create clients to interact with SageMaker, Amazon S3, and AWS IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:
import boto3
import json
import time

AWS_REGION = 'us-west-2'# Specify your Region
bucket = 'edge-manager-demo-bucket'
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)
iot_client = boto3.client('iot', region_name=AWS_REGION)

Define variables and assign them the role ARN you created for SageMaker and AWS IoT as strings:

```
# Replace with the role ARN you created for SageMaker
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace with the role ARN you created for AWS IoT.
# Note: The name must start with 'SageMaker'
# iot_role_arn = "arn:aws:iam::<account>:role/SageMaker*"
```

2. **Train a machine learning model.**

See Train a Model with Amazon SageMaker for more information on how to train a machine learning model using SageMaker. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd_mobilenet` model from TensorFlow's website. The model you just copied is an object detection model trained from the COCO dataset. Type the following into your Jupyter Notebook:

```
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip \ --output {model_zip_filename}
```

This particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed TAR file (.tar.gz) before using it in later steps. Type the following into your Jupyter Notebook:

```
# Extract model from zip file
!unzip -u {model_zip_filename}
model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]

# Compress model into .tar.gz so SageMaker Neo can use it
model_filename = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

3. **Upload your model to Amazon S3.**

Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an AWS CLI command to upload the model to the Amazon S3 bucket you created earlier in a directory called `models`. Type in the following into your Jupyter Notebook:

```
!aws cp detect.tar.gz s3://{bucket}/models/
```

4. **Compile your model with SageMaker Neo.**
Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URI where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

For the Keras MobileNet V2 model, use the following:

```python
framework = 'tflite'
target_device = 'rasp3b'  # Raspberry Pi 3
data_shape = '{"normalized_input_image_tensor":[1, 300, 300, 3]}'
```

SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect? (p. 1948). For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures (p. 1988).

Use the CreateCompilationJob API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker to store your compiled model, and your edge device target.

```python
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{}/{}/{}'.format(bucket, model_directory, model_filename)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{}/{}'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
                                        RoleArn=sagemaker_role_arn,
                                        InputConfig={
                                            'S3Uri': s3_model_uri,
                                            'DataInputConfig': data_shape,
                                            'Framework': framework.upper(),
                                        },
                                        OutputConfig={
                                            'S3OutputLocation': s3_output_location,
                                            'TargetDevice': target_device,
                                        },
                                        StoppingCondition={'MaxRuntimeInSeconds': 900})
```

5. **Package your compiled model.**

Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the create_edge_packaging API or the SageMaker console.

You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up (p. 2010) section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```python
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version=1.1
```
Define the Amazon S3 URI where you want to store the packaged model.

```python
# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)
```

Use `CreateEdgePackagingJob` to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was stored in the variable `compilation_job_name`). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker to store the packaged model.

```python
sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName=edge_packaging_name,
    CompilationJobName=compilation_job_name,
    RoleArn=sagemaker_role_arn,
    ModelName=model_name,
    ModelVersion=model_version,
    OutputConfig={
        "S3OutputLocation": packaging_s3_output
    }
)
```

Create and Register Fleets and Authenticate Devices

In this section you will create your AWS IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to AWS IoT Core, associate the role alias with AWS IoT that was generated when you created your fleet, get your AWS account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.

1. **Create AWS IoT things.**

   SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and endpoints in the AWS cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to AWS IoT, you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure the IAM role for your devices.

   First, create AWS IoT thing objects with the AWS IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

   ```python
   iot_thing_name = 'sample-device'
iot_thing_type = 'getting-started-demo'

   iot_client.create_thing_type(
       thingTypeName=iot_thing_type
   )

   iot_client.create_thing(
       thingName=iot_thing_name,
       thingTypeName=iot_thing_type
   )
   # Create an AWS IoT thing objects
   iot_client.create_thing(
       thingName=iot_thing_name,
       thingTypeName=iot_thing_type
   )
```

2. **Create your device fleet.**
Create a device fleet with the SageMaker client object defined in a previous step. You can also use the SageMaker console to create a device fleet.

```python
device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
```

Specify your IoT role ARN. This lets AWS IoT grant temporary credentials to devices.

```python
device_model_directory='device_output'
s3_device_fleet_output = 's3://{}/{}'.format(bucket, device_model_directory)
sagemaker_client.create_device_fleet(
    DeviceFleetName=device_fleet_name,
    RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
    OutputConfig={
        'S3OutputLocation': s3_device_fleet_output
    }
)
```

An AWS IoT role alias is created when you create a device fleet. This role alias is associated with AWS IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the AWS IoT thing name as shown in the following example:

```python
# Device name should be 36 characters
device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
sagemaker_client.register_devices(
    DeviceFleetName=device_fleet_name,
    Devices=[
        {"DeviceName": device_name,
         "IotThingName": iot_thing_name
        }
    ]
)
```

4. **Create X.509 certificates.**

After creating the AWS IoT thing object, you must create a X.509 device certificate for your thing object. This certificate authenticates your device to AWS IoT Core.

Use the following to create a private key, public key, and a X.509 certificate file using the AWS IoT client defined (`iot_client`) earlier.

```python
# Creates a 2048-bit RSA key pair and issues an X.509 certificate
# using the issued public key.
create_cert = iot_client.create_keys_and_certificate(
    setAsActive=True
)

# Get certificate from dictionary object and save in its own
# with open('/device.pem.crt', 'w') as f:
for line in create_cert['certificatePem'].split('
'):
    f.write(line)
    f.write('
')
```
5. **Associate the role alias with AWS IoT.**

When you create a device fleet with SageMaker (sagemaker_client.create_device_fleet()), a role alias is generated for you. An AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates, and then obtain short-lived AWS credentials from an IAM role that is associated with an AWS IoT role alias. The role alias allows you to change the role of the device without having to update the device. Use `DescribeDeviceFleet` to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
# to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name = sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)["IotRoleAlias"]
start_index = full_role_alias_name.find('SageMaker') # Find beginning of role name
role_alias_name = full_role_alias_name[start_index:]
```

Use the `iot_client` to facilitate associating the role alias generated from creating the device fleet with AWS IoT:

```python
role_alias = iot_client.describe_role_alias(
    roleAlias=role_alias_name)
```

For more information about IAM role alias, see [Role alias allows access to unused services](#).

You created and registered a certificate with AWS IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

```python
alias_policy = {
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "iot:AssumeRoleWithCertificate",
        "Resource": role_alias['roleAliasDescription']['roleAliasArn']
    }
}
```

```python
policy_name = 'aliaspolicy-+' + str(time.time()).split('.')[0]
aliaspolicy = iot_client.create_policy(policyName=policy_name,
    policyDocument=json.dumps(alias_policy))
```

# Attach policy
```python
iot_client.attach_policy(policyName=policy_name,
                        target=create_cert['certificateArn'])
```
6. **Get your AWS account-specific endpoint for the credentials provider.**

   Edge devices need an endpoint in order to assume credentials. Obtain your AWS account-specific endpoint for the credentials provider.

   ```python
   # Get the unique endpoint specific to your AWS account that is making the call.
   iot_endpoint = iot_client.describe_endpoint(
       endpointType='iot:CredentialProvider'
   )
   endpoint="https://{}/role-aliases/{}/credentials".format(iot_endpoint['endpointAddress'],role_alias_name)
   ```

7. **Get the official Amazon root CA file and upload it to the Amazon S3 bucket.**

   Use the following in your Jupyter Notebook or AWS CLI (if you use your terminal, remove the ‘!’ magic function):

   ```bash
   !wget https://www.amazontrust.com/repository/AmazonRootCA1.pem
   ```

   Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses `curl`, but you can use any HTTP client.

   ```bash
   !curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem $endpoint
   ```

   If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

   ```bash
   !aws s3 cp private.pem.key s3://{bucket}/authorization-files/
   !aws s3 cp device.pem.crt s3://{bucket}/authorization-files/
   !aws s3 cp AmazonRootCA1.pem s3://{bucket}/authorization-files/
   ```

---

**Download and Set Up Edge Manager**

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Linux platform (Raspberry Pi OS is based on Debian). Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the us-west-2 Region.

   ```bash
   aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
   ```

   This returns release artifacts sorted by their version.

   ```bash
   2020-12-01 23:33:36 0
   ```
The version has the following format: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. It consists of three components:

- `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.
- `<YYYY-MM-DD>`: The timestamp of the artifact release.
- `<SHA-7>`: The repository commit ID from which the release is built.

Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
```

Once you have the artifact, unzip the zipped TAR file:

```
!mkdir agent_demo
!tar -xvzf 1.20201218.81f481f.tgz -C ./agent_demo
```

You also need the signing root certificates from the release bucket:

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-west-2/us-west-2.pem ./
```

2. **Define a SageMaker Edge Manager agent configuration file.**

First, define the agent configuration file as follows:

```
sagemaker_edge_config = {
    "sagemaker_edge_core_device_uuid": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_root_certs_path": "/agent_demo/certificates",
    "sagemaker_edge_provider_aws_cert_file": "/agent_demo/iot-credentials/AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "/agent_demo/iot-credentials/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "/agent_demo/iot-credentials/private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "endpoint",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "Aws",
    "sagemaker_edge_provider_s3_bucket_name": bucket,
    "sagemaker_edge_core_capture_data_destination": "Cloud"
}
```

Next, save it as a JSON file:

```
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
edge_config_file.close()
```
Replace the following:

- "device_name" with the name of your device (this string was stored in an earlier step in a variable named `device_name`).
- "device_fleet_name" with the name of your device fleet (this string was stored an earlier step in a variable named `device_fleet_name`).
- "endpoint" with your AWS account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named `endpoint`).

3. Copy the release artifacts, configuration file, and credentials to your device.

The following instructions are performed on the edge device itself.

**Note**
You must first install Python, the AWS SDK for Python (Boto3), and the AWS CLI on your edge device.

Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

```bash
mkdir agent_demo
cd agent_demo
```

Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

```bash
# Copy release artifacts
aws s3 cp s3://sagemaker-edge-manager-demo/release_artifacts/ ./ --recursive
```

Go the `/bin` directory and make the binary files executable:

```bash
cd bin
chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example
```

```bash
cd agent_demo
```

Make a directory to store your AWS IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable `bucket`):

```bash
mkdir iot-credentials
cd iot-credentials
aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./
```

```bash
cd ../
```

Make a directory to store your model signing root certificates:

```bash
mkdir certificates
cd certificates
aws s3 cp s3://<bucket-name>/certificates/us-west-2.pem ./
```
cd agent_demo

Copy your configuration file to your device:

```
#Download config file from S3
aws s3 cp s3://<bucket-name>/config_files/sagemaker_edge_config.json ./
```

cd agent_demo

Your `agent_demo` directory on your edge device should look similar to the following:

```
###agent_demo
|    ### bin
|        ### sagemaker_edge_agent_binary
|        ### sagemaker_edge_agent_client_example
|    ### sagemaker_edge_config.json
|    ### certificates
|        ### us-west-2.pem
|    ### iot-credentials
|        ### AmazonRootCA1.pem
|        ### device.pem.crt
|        ### private.pem.key
|    ### docs
|        ### api
|        ### examples
|    ### ATTRIBUTIONS.txt
|    ### LICENSE.txt
|    ### RELEASE_NOTES.md
```

**Run Agent**

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.

1. **Launch the agent.**

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the [gRPC documentation](#).

   To use gRPC, perform the following steps:
   
   b. Generate server and client code using the protocol buffer compiler.
   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.
   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.

   The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the `/bin` directory of your release artifact. The `sagemaker_edge_agent_binary` binary executable is in this directory.
To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

```
./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c sagemaker_edge_config.json
```

2. **Check your device.**

Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

```
sagemaker_client.describe_device(
    DeviceName=device_name,
    DeviceFleetName=device_fleet_name
)
```

For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

```
{
    "DeviceName": "sample-device",
    "DeviceFleetName": "demo-device-fleet",
    "IOTThingName": "sample-thing-name-1",
    "RegistrationTime": 1600977370,
    "LatestHeartbeat": 1600977370,
    "Models": [
        {
            "ModelName": "mobilenet_v2.tar.gz",
            "ModelVersion": "1.1",
            "LatestSampleTime": 1600977370,
            "LatestInference": 1600977370
        }
    ]
}
```

The timestamp provided by `LatestHeartbeat` indicates the last signal that was received from the device. `LatestSampleTime` and `LatestInference` describe the time stamp of the last data sample and inference, respectively.

3. **Check your fleet.**

Check that your fleet is working with `GetDeviceFleetReport`. Provide the name of the fleet the device belongs to.

```
sagemaker_client.get_device_fleet_report(
    DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.

```
# Sample output
{
    "DeviceFleetName": "sample-device-fleet",
    "OutputConfig": {
```
Set Up Devices and Fleets

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the AWS SDK for Python (Boto3) or through the SageMaker console.

Topics
- Create a Fleet (p. 2023)
- Register a Device (p. 2026)
- Check Status (p. 2028)

Create a Fleet

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the Amazon SageMaker console.

Create a Fleet (Boto3)

Use the CreateDeviceFleet API to create a fleet. Specify a name for the fleet, your AWS IoT Role ARN for the RoleArn field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an AWS KMS Key ID.

```python
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-fleet-name",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        S3OutputLocation="s3://bucket/",
        KMSKeyId: "1234abcd-12ab-34cd-56ef-1234567890ab",
    },
    Tags=[
        {
            "Key": "string",
            "Value": "string"
        }
    ]
)
```
An AWS IoT Role Alias is created for you when you create a device fleet. The AWS IoT role alias provides a mechanism for connected devices to authenticate to AWS IoT using X.509 certificates and then obtain short-lived AWS credentials from an IAM role that is associated with the AWS IoT role alias.

Use `DescribeDeviceFleet` to get the role alias name and ARN.

```python
# Print Amazon Resource Name (ARN) and alias that has access
to AWS Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)['IotRoleAlias']
```

Use `DescribeDeviceFleet` API to get a description of fleets you created.

```python
sagemaker_client.describe_device_fleet(
    DeviceFleetName="sample-fleet-name"
)
```

By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in AWS IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.

```json
{ "DeviceFleetName": "sample-fleet-name",
  "IAMRole": "arn:aws:iam::999999999:role/rolename",
  "Description": "this is a sample fleet",
  "OutputConfig": {
    "S3OutputLocation": "s3://bucket/folder",
    "KMSKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
  },
  "CreationTime": "1600977370",
  "LastModifiedTime": "1600977370"
}
```

**Create a Fleet (Console)**

You can create a Edge Manager packaging job using the Amazon SageMaker console.

1. In the SageMaker console, choose **Edge Inference** and then choose **Edge device fleets**.
2. Choose **Create device fleet**.
3. Enter a name for the device fleet in the **Device fleet name** field. Choose **Next**.

### Device fleet properties

Use the fields below to enter the name and the role for AWS IoT to use. You can optionally add a device fleet description.

**Device fleet name**

device-fleet-test

**Device fleet description - optional**

*Enter a description here*

**IAM role - optional**

The role for AWS IoT to use when granting temporary credentials to devices

*Enter the role ARN*

**Device fleet tags - optional**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value - optional</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[Add new tag]

You can add up to 50 tags

4. On the **Output configuration** page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by selecting an existing AWS KMS key from the dropdown list or by entering a key's ARN. Choose **Submit**.
5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the Device fleet tags section.

**Register a Device**

**Important**

Device registration is required to use any part of SageMaker Edge Manager.

You can create a fleet programmatically with the AWS SDK for Python (Boto3) or through the Amazon SageMaker console.

**Register a Device (Boto3)**

To register your device, first create and register an AWS IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the AWS IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing AWS IoT functionality after you set up your devices to work with Edge Manager.

To connect your device to AWS IoT you need to create AWS IoT thing objects, create and register a client certificate with AWS IoT, and create and configure IAM role for your devices.

See the Getting Started Guide for an in-depth example or the Explore AWS IoT Core services in hands-on tutorial.

Use the RegisterDevices API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and AWS IoT thing name associated with the device.

```python
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
    Devices=[
```
Register a Device (Console)

You can register your device using the Amazon SageMaker console.

1. In the SageMaker console, choose **Edge Inference** and then choose **Edge devices**.
2. Choose **Register devices**.

3. In the **Device properties** section, enter the name of the fleet the device belongs to under the **Device fleet name** field. Choose **Next**.

4. In the **Device source** section, add your devices one by one. You must include a **Device Name** for each device in your fleet. You can optionally provide a description (in the **Description** field) and an Internet of Things (IoT) object name (in the **IoT name** field). Choose **Submit** once you have added all your devices.
The **Devices** page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and AWS IoT name, if you provided one.

Choose a device to view the device's details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

**Check Status**

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console to interactively choose a fleet for a status check. You can also use the AWS SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

  To check the status of an individual device, use `DescribeDevice` API. A list containing one or more models is provided if a models have been deployed to the device.

  ```python
  sagemaker_client.describe_device(
      DeviceName="sample-device-1",
      DeviceFleetName="sample-fleet-name"
  )
  ```

  Running `DescribeDevice` returns:

  ```json
  { "DeviceName": "sample-device",  "Description": "this is a sample device",  "DeviceFleetName": "sample-device-fleet",  "IoTThingName": "SampleThing",  "RegistrationTime": 1600977370,  "LatestHeartbeat": 1600977370,  "Models": [ 
```
• Check a fleet of devices.

To check the status of the fleet, use the `GetDeviceFleetReport` API. Provide the name of the device fleet to get a summary of the fleet.

```python
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

• Check for a heartbeat.

Each device within a fleet periodically generates a signal, or "heartbeat". The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

Check the last heartbeat with made by a device with the `DescribeDevice` API. Specify the name of the device and the fleet to which the edge device belongs.

```python
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

**Package Model**

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

**Topics**

- Prerequisites (p. 2029)
- Package a Model (Amazon SageMaker Console) (p. 2031)
- Package a Model (Boto3) (p. 2034)

**Prerequisites**

To package a model, you must do the following:

1. **Compile your machine learning model with SageMaker Neo.**

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see Compile and Deploy Models with Neo. If you are first-time user of SageMaker Neo, go through Getting Started with Neo Edge Devices.

2. **Get the name of your compilation job.**

   Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the Amazon SageMaker console and choose Compilation jobs to find a list of
compilations that have been submitted to your AWS account. The names of submitted compilation jobs are in the Name column.

3. **Get your IAM ARN.**

You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

Use one of the following methods to get your IAM ARN:

- **Programmatically with the SageMaker Python SDK**

```python
import sagemaker

# Initialize SageMaker Session object so you can interact with AWS resources
sess = sagemaker.Session()

# Get the role ARN
role = sagemaker.get_execution_role()

print(role)

>> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
```

For more information about using the SageMaker Python SDK, see the [SageMaker Python SDK API](https://boto3.amazonaws.com/v1/documentation/api/latest/guide/sagemaker.html).

- **Using the AWS Identity and Access Management (IAM) console**

Sign in to the [AWS Management Console](https://console.aws.amazon.com/iam/) and open the IAM console. In the IAM Resources section, choose Roles to view a list of roles in your AWS account. Select or create a role that has AmazonSageMakerFullAccess, AWSIoTFullAccess, and AmazonS3FullAccess.

For more information on IAM, see [What is IAM?](https://docs.aws.amazon.com/IAM/latest/UserGuide/what-is-iam.html)

4. **Have an S3 bucket URI.**

You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

Use one of the following methods to create an Amazon S3 bucket:

- **Programmatically with the SageMaker Python SDK**

You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: sagemaker-{region}-{aws-account-id}. To create a default bucket with the SageMaker Python SDK, use the following:

```python
import sagemaker

session=sagemaker.create_session()

bucket=session.default_bucket()
```

- **Using the Amazon S3 console**

Open the [Amazon S3 console](https://console.aws.amazon.com/s3/) and see [How do I create an S3 Bucket?](https://docs.aws.amazon.com/AmazonS3/latest/userguide/creating-bucket.html) for step-by-step instructions.
Package a Model (Amazon SageMaker Console)

You can create a SageMaker Edge Manager packaging job using the Amazon SageMaker console. Before continuing, make sure you have satisfied the Prerequisites (p. 2029).

1. In the SageMaker console, choose Edge Inference and then choose Edge packaging jobs, as shown in the following image.

2. On the Job properties page, enter a name for your packaging job under Edge packaging job name. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under Model name and Model version, respectively.

3. Next, select an IAM role. You can choose a role or let AWS create a role for you. You can optionally specify a resource key ARN and job tags.

4. Choose Next.
### Job properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge packaging job name</td>
<td>sample-edge-package</td>
<td>63 characters max</td>
</tr>
<tr>
<td>Model name</td>
<td>sample-model</td>
<td>128 characters max</td>
</tr>
<tr>
<td>Model version</td>
<td>1</td>
<td>128 characters max</td>
</tr>
<tr>
<td>IAM role</td>
<td>Admin</td>
<td>Amazon SageMaker Edge requires permissions to create this edge packaging job on your behalf, choose a role or AmazonSageMakerFullAccess IAM policy attached.</td>
</tr>
<tr>
<td>Resource key ARN - optional</td>
<td></td>
<td>Enter the resource key to encrypt the EBS volume the job uses</td>
</tr>
<tr>
<td>Edge packaging job tags - optional</td>
<td></td>
<td>You can add up to 50 tags</td>
</tr>
</tbody>
</table>

5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose Next.
6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

   **Output configuration**
   Use the fields below to specify the S3 bucket URI where you want devices to store sample data. You can also (optional) specify an encryption key.

   **S3 bucket URI**
   Enter your S3 bucket URI where you want devices to store sample data.
   
   ```
s3://bucket-example/sagemaker-edge/device-output
   ```
   To find a path, **go to Amazon S3**

   **Encryption key - optional**
   Encrypt your data. Choose an existing KMS key or enter a key's ARN.
   
   ```
   No Custom Encryption
   ```

   The **Status** column on the **Edge packaging** jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

   Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

   The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.
The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, AWS KMS key ID (if provided), AWS IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

## Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the AWS SDK for Python (Boto3). Before continuing, make sure you have satisfied the [Prerequisites (p. 2029)](#).

To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```python
# Import AWS SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    }
)
```

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```python
response = sagemaker_client.describe_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

This returns a dictionary that can be used to poll the status of the packaging job:

```python
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name"
    )
    if response["EdgePackagingJobStatus"] == 'Completed':
        break
    elif response["EdgePackagingJobStatus"] == 'Failed':
        raise RuntimeError('Packaging job failed')
    time.sleep(30)
print('Done!')
```
For a list of packaging jobs, use ListEdgePackagingJobs. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for NameContains, a partial name for ModelNameContains to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with SortBy, and by which direction to sort for SortOrder (either Ascending or Descending).

```python
sagemaker_client.list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use StopEdgePackagingJob and provide the name of your edge packaging job.

```python
sagemaker_client.stop_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the Boto3 documentation.

**Edge Manager Agent**

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

**How the Agent Works**

The agent runs on the CPU of your devices. The agent will run inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent will support the GPU in the provided Deep Learning Runtime (DLR).

The agent is released in binary format for supported operating systems. Check your operating system is supported and meets the minimum OS requirement in the following table:

### Linux

**Version:** Ubuntu 18.04

**Supported Binary Formats:** x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

### Windows

**Version:** Windows 10 version 1909

**Supported Binary Formats:** x86-32 bit (DLL) and x86-64 bit (DLL)

**Installing Edge Manager agent**

To use Edge Manager agent, you first need to obtain the release artifacts and a Root Certificate. The release artifacts are stored in an Amazon S3 bucket in the us-west-2 Region. To download the artifacts, specify your operating system (<OS>) and the VERSION.

Based on your operating system, replace <OS> with one of the following:
The VERSION is broken into three components: MAJOR_VERSION..YYYY-MM-DD..SHA-7, where:

- MAJOR_VERSION: The release version. The release version is currently set to 1.
- YYYY-MM-DD: The time stamp of the artifacts release.
- SHA-7: The repository commit ID from which the release is built.

You need to provide the MAJOR_VERSION and the time stamp in YYYY-MM-DD format. We suggest you use the latest artifact release time stamp. Use the following to get the latest time stamp.

Run the following in your command line to get the latest time stamp. Replace <OS> with your operating system:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0
PRE 1.20201218.81f481f/
PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version: has a major release version of 1, a time stamp of 20201218 (in YYYY-MM-DD format), and a 81f481f SHA-7 commit ID.

**Note**
The above command assumes you have configured AWS Command Line Interface. For more information, about how to configure the settings that the AWS CLI uses to interact with AWS, see Configuring the AWS CLI.

Based on your operating system, use the following commands to install the artifacts:

**Windows 32-bit**

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/<VERSION>/sha256_hex.shasum .
```

**Windows 64-bit**

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/Releases/<VERSION>/.<VERSION>.zip .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/Releases/<VERSION>/sha256_hex.shasum .
```
You will also need to download a Root Certificate. This certificate validates model artifacts signed by AWS before loading them onto your edge devices.

Replace `<OS>` corresponding to your platform from the list of supported operation systems and replace `<REGION>` with your AWS region.

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-<OS>/Certificates/<REGION>/AWSRootCA1.pem .
```

### Running SageMaker Edge Manager agent

SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux. Running as a shared object (.dll) is supported on Windows.

On Linux, we recommend that you run the binary via a service that’s a part of your initialization (init) system. If you want to run the binary directly, you can do so in a terminal as shown below. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent you will first need to create a JSON configuration file. Specify the following key-value pairs:

- **deviceUUID** (optional): Unique edge device identifier.
- **deviceFleetName**: The name of the fleet the device belongs to.
- **region**: AWS region.
- **rootCertsPath**: Absolute folder path to root certificates.
- **provider**: Use “Aws”.
- **awsCACertFile**: Absolute path to Amazon Root CA certificate (AmazonRootCA1.pem).
- **awsCertFile**: Absolute path to AWS IoT signing root certificate (*.pem.crt).
- **awsCertPKFile**: Absolute path to AWS IoT private key. (*.pem.key).
- **awsIOTCredEndpoint**: AWS IoT credentials endpoint (identifier.iot.region.amazonaws.com). See, [Connecting devices to AWS IoT](#) for more information.
- **captureDataDestination**: The destination for uploading capture data. Select either “Cloud” or “Disk”.
- **S3BucketName**: Name of Amazon S3 bucket (not the Amazon S3 bucket URI). Bucket must have ‘sagemaker’ string within its name.
Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.
SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.

The `proto` file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this `proto` file.

**Note**
There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where `VERSION` is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. See Installing Edge Manager agent (p. 2035) for information on how to obtain the release version (`<MAJOR_VERSION>`), time stamp of the release artifact (`<YYYY-MM-DD>`), and the repository commit ID (`SHA-7`)

**Linux**

The zip archive can be extracted with the command:

```
    tar -xvzf <VERSION>.tgz
```

**Windows**

The zip archive can be extracted with the UI or command:

```
    unzip <VERSION>.tgz
```

The release artifact hierarchy (after extracting the `tar/zip` archive) is shown below. The agent `proto` file is available under `api/`.

**Topics**

- Load Model (p. 2040)
- Unload Model (p. 2041)
List Models (p. 2041)
Describe Model (p. 2042)
Capture Data (p. 2042)
Get Capture Status (p. 2044)
Predict (p. 2044)

Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the EdgePackagingJob operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model's signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```java
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
// rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);
```

Input

```java
// request for LoadModel rpc call
// message LoadModelRequest {
  string url = 1;
  string name = 2; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*" 
}
```

Output

```java
// response for LoadModel rpc call
// message LoadModelResponse {
  Model model = 1;
}
```

Model represents the metadata of a model
url - url representing the path of the model
name - name of model
input_tensor_metadatas - TensorMetadata array for the input tensors
output_tensor_metadatas - TensorMetadata array for the output tensors

Note:
// 1. input and output tensor metadata could empty for dynamic models.
//
message Model {
    string url = 1;
    string name = 2;
    repeated TensorMetadata input_tensor_metadatas = 3;
    repeated TensorMetadata output_tensor_metadatas = 4;
}

Un hot Model

Unloads a previously loaded model. It is identified via the model alias which was provided during loadModel. If the alias is not found or model is not loaded then returns error.

// perform unload for a model
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist
//
rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);

Input

// // request for UnLoadModel rpc call
// //
// message UnLoadModelRequest {
//     string name = 1; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*$"
// }

Output

// // response for UnLoadModel rpc call
// //
// message UnLoadModelResponse {}
// request for ListModels rpc call
//
message ListModelsRequest {}

## Output

//
// response for ListModels rpc call
//
message ListModelsResponse {
  repeated Model models = 1;
}

### Describe Model

Describes a model that is loaded on the agent.

```
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn’t exist at the url
//
rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
```

## Input

```
//
// request for DescribeModel rpc call
//
message DescribeModelRequest {
  string name = 1;
}
```

## Output

```
//
// response for DescribeModel rpc call
//
message DescribeModelResponse {
  Model model = 1;
}
```

### Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

```
// allows users to capture input and output tensors along with auxiliary data.
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
```
// 5. ALREADY_EXISTS - capture initiated for the given capture_id
// 6. RESOURCE_EXHAUSTED - buffer is full cannot accept any more requests.
// 7. OUT_OF_RANGE - timestamp is in the future.
// 8. INVALID_ARGUMENT - capture_id is not of expected format.
//
rpc CaptureData(CaptureDataRequest) returns (CaptureDataResponse);

Input

enum Encoding {
  CSV = 0;
  JSON = 1;
  NONE = 2;
  BASE64 = 3;
}

// AuxiliaryData represents a payload of extra data to be capture along with inputs and outputs of inference
// encoding - supports the encoding of the data
// data - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.

message AuxiliaryData {
  string name = 1;
  Encoding encoding = 2;
  oneof data {
    bytes byte_data = 3;
    SharedMemoryHandle shared_memory_handle = 4;
  }
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id and offset in bytes to location of multi-dimensional tensor array.

message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

// request for CaptureData rpc call
//
message CaptureDataRequest {
  string model_name = 1;
  string capture_id = 2; //uuid string
  Timestamp inference_timestamp = 3;
  repeated Tensor input_tensors = 4;
  repeated Tensor output_tensors = 5;
  repeated AuxiliaryData inputs = 6;
  repeated AuxiliaryData outputs = 7;
}
Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the `CaptureData()` is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

```protobuf
// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
// rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns
//   (GetCaptureDataStatusResponse);
```

Input

```protobuf
// request for GetCaptureDataStatus rpc call
// message GetCaptureDataStatusRequest {
//   string capture_id = 1;
// }
```

Output

```protobuf
enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}

// response for GetCaptureDataStatus rpc call
// message GetCaptureDataStatusResponse {
//   CaptureDataStatus status = 1;
// }
```

Predict

The `predict` API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

```protobuf
//
```
// perform inference on a model.

// Note:
// 1. users can chose to send the tensor data in the protobuf message or
// through a shared memory segment on a per tensor basis, the Predict
// method with handle the decode transparently.
// 2. serializing large tensors into the protobuf message can be quite expensive,
// based on our measurements it is recommended to use shared memory of
// tenors larger than 256KB.
// 3. SMEdge IPC server will not use shared memory for returning output tensors,
// i.e., the output tensor data will always send in byte form encoded
// in the tensors of PredictResponse.
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all
// these call will be serialized under the hood. this shall be addressed
// in a later release.
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch

// rpc Predict(PredictRequest) returns (PredictResponse);

Input

// request for Predict rpc call
//
message PredictRequest {
  string name = 1;
  repeated Tensor tensors = 2;
}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//    tensor_metadata - represents metadata of the shared memory segment
//    data_or_handle - represents the data of shared memory, this could be passed in
// two ways:
//    array
//    memory segment
//    tensor array.
// message Tensor {
//  TensorMetadata tensor_metadata = 1; //optional in the predict request
//  oneof data {
//    bytes byte_data = 4; // will only be used for input tensors
//    SharedMemoryHandle shared_memory_handle = 5;
//  }
//}

// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//    tensor_metadata - represents metadata of the shared memory segment
//    data_or_handle - represents the data of shared memory, this could be passed in
// two ways:
//    array
//    memory segment

Use Amazon SageMaker Elastic Inference (EI)

By using Amazon Elastic Inference (EI), you can speed up the throughput and decrease the latency of getting real-time inferences from your deep learning models that are deployed as Amazon SageMaker hosted models, but at a fraction of the cost of using a GPU instance for your endpoint. EI allows you to add inference acceleration to a hosted endpoint for a fraction of the cost of using a full GPU instance. Add an EI accelerator in one of the available sizes to a deployable model in addition to a CPU instance type, and then add that model as a production variant to an endpoint configuration that you use to deploy a hosted endpoint. You can also add an EI accelerator to a SageMaker notebook instance so that you can test and evaluate inference performance when you are building your models.

Elastic Inference is supported in EI-enabled versions of TensorFlow, Apache MXNet, and PyTorch. To use any other deep learning framework, export your model by using ONNX, and then import your model into
MXNet. You can then use your model with EI as an MXNet model. For information about importing an ONNX model into MXNet, see Importing an ONNX model into MXNet.

Topics
- How EI Works (p. 2047)
- Choose an EI Accelerator Type (p. 2047)
- Use EI in a SageMaker Notebook Instance (p. 2048)
- Use EI on a Hosted Endpoint (p. 2048)
- Frameworks that Support EI (p. 2048)
- Use EI with SageMaker Built-in Algorithms (p. 2049)
- EI Sample Notebooks (p. 2049)
- Set Up to Use EI (p. 2049)
- Attach EI to a Notebook Instance (p. 2052)
- Use EI on Amazon SageMaker Hosted Endpoints (p. 2054)

How EI Works

Amazon Elastic Inference accelerators are network attached devices that work along with SageMaker instances in your endpoint to accelerate your inference calls. Elastic Inference accelerates inference by allowing you to attach fractional GPUs to any SageMaker instance. You can select the client instance to run your application and attach an Elastic Inference accelerator to use the right amount of GPU acceleration for your inference needs. Elastic Inference helps you lower your cost when not fully utilizing your GPU instance for inference. We recommend trying Elastic Inference with your model using different CPU instances and accelerator sizes.

The following EI accelerator types are available. You can configure your endpoints or notebook instances with any EI accelerator type.

In the table, the throughput in teraflops (TFLOPS) is listed for both single-precision floating-point (F32) and half-precision floating-point (F16) operations. The memory in GB is also listed.

<table>
<thead>
<tr>
<th>Accelerator Type</th>

</tbody>
</table>

Choose an EI Accelerator Type

Consider the following factors when choosing an accelerator type for a hosted model:

- Models, input tensors and batch sizes influence the amount of accelerator memory you need. Start with an accelerator type that provides at least as much memory as the file size of your trained model. Factor in that a model might use significantly more memory than the file size at runtime.
Demands on CPU compute resources, main system memory, and GPU-based acceleration and accelerator memory vary significantly between different kinds of deep learning models. The latency and throughput requirements of the application also determine the amount of compute and acceleration you need. Thoroughly test different configurations of instance types and EI accelerator sizes to make sure you choose the configuration that best fits the performance needs of your application.

For more information on selecting an EI accelerator, see:

- Amazon Elastic Inference Overview
- Choosing an Instance and Accelerator Type for Your Model
- Optimizing costs in Amazon Elastic Inference with TensorFlow

Use EI in a SageMaker Notebook Instance

Typically, you build and test machine learning models in a SageMaker notebook before you deploy them for production. You can attach EI to your notebook instance when you create the notebook instance. You can set up an endpoint that is hosted locally on the notebook instance by using the local mode supported by TensorFlow, MXNet, and PyTorch estimators and models in the Amazon SageMaker Python SDK to test inference performance. Elastic Inference enabled PyTorch is not currently supported on notebook instances. For instructions on how to attach EI to a notebook instance and set up a local endpoint for inference, see Attach EI to a Notebook Instance (p. 2052). There are also Elastic Inference-enabled SageMaker Notebook Jupyter kernels for Elastic Inference-enabled versions of TensorFlow and Apache MXNet. For information about using SageMaker notebook instances, see Use Amazon SageMaker Notebook Instances.

Use EI on a Hosted Endpoint

When you are ready to deploy your model for production to provide inferences, you create a SageMaker hosted endpoint. You can attach EI to the instance where your endpoint is hosted to increase its performance at providing inferences. For instructions on how to attach EI to a hosted endpoint instance, see Use EI on Amazon SageMaker Hosted Endpoints (p. 2054).

Frameworks that Support EI

Amazon Elastic Inference is designed to be used with AWS enhanced versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks. These enhanced versions of the frameworks are automatically built into containers when you use the Amazon SageMaker Python SDK, or you can download them as binary files and import them in your own Docker containers.

You can download the EI-enabled TensorFlow binary files from the public amazonei-tensorflow Amazon S3 bucket to the TensorFlow serving containers. For more information about building a container that uses the EI-enabled version of TensorFlow, see Amazon Elastic Inference with TensorFlow in SageMaker.

You can download the EI-enabled MXNet binary files from the public amazonei-apachemxnet Amazon S3 bucket to the MXNet serving containers. For more information about building a container that uses the EI-enabled version of MXNet, see Amazon Elastic Inference with MXNet in SageMaker.

You can download the EI-enabled PyTorch binary files from the public amazonei-pytorch Amazon S3 bucket to the PyTorch serving containers. For more information about building a container that uses the EI-enabled version of PyTorch, see Amazon Elastic Inference with PyTorch in SageMaker.

To use Elastic Inference in a hosted endpoint, you can choose any of the following frameworks depending on your needs.
• SageMaker Python SDK - Deploy TensorFlow models
• SageMaker Python SDK - Deploy MXNet models
• SageMaker Python SDK - Deploy PyTorch models

If you need to create a custom container for deploying your model that is complex and requires extensions to a framework that the SageMaker pre-built containers do not support, use the low-level AWS SDK for Python (Boto 3).

Use EI with SageMaker Built-in Algorithms

Currently, the Image Classification Algorithm (p. 1356) and Object Detection Algorithm (p. 1436) built-in algorithms support EI. For an example that uses the Image Classification algorithm with EI, see End-to-End Multiclass Image Classification Example.

EI Sample Notebooks

The following Sample notebooks provide examples of using EI in SageMaker:

• Using Amazon Elastic Inference with MXNet on Amazon SageMaker
• Using Amazon Elastic Inference with MXNet on an Amazon SageMaker Notebook Instance
• Using Amazon Elastic Inference with Neo-compiled TensorFlow model on SageMaker
• Using Amazon Elastic Inference with a pre-trained TensorFlow Serving model on SageMaker

Set Up to Use EI

Use the instructions in this topic only if one of the following applies to you:

• You want to use a customized role or permission policy.
• You want to use a VPC for your hosted model or notebook instance.

Note
If you already have an execution role that has the AmazonSageMakerFullAccess managed policy attached (this is true for any IAM role that you create when you create a notebook instance, training job, or model in the console) and you are not connecting to an EI model or notebook instance in a VPC, you do not need to make any of these changes to use EI in Amazon SageMaker.

Topics
• Set Up Required Permissions (p. 2049)
• Use a Custom VPC to Connect to EI (p. 2052)

Set Up Required Permissions

To use EI in SageMaker, the role that you use to open a notebook instance or create a deployable model must have a policy with the required permissions attached. You can attach the AmazonSageMakerFullAccess managed policy, which contains the required permissions, to the role, or you can add a custom policy that has the required permissions. For information about creating an IAM role, see Creating a Role for an AWS Service (Console) in the AWS Identity and Access Management User Guide. For information about attaching a policy to a role, see Adding and Removing IAM Policies.
Add these permissions specifically for connecting EI in an IAM policy.

 }
}
}
Use a Custom VPC to Connect to EI

To use EI with SageMaker in a VPC, you need to create and configure two security groups, and set up a PrivateLink VPC interface endpoint. EI uses VPC interface endpoint to communicate with SageMaker endpoints in your VPC. The security groups you create are used to connect to the VPC interface endpoint.

Set up Security Groups to Connect to EI

To use EI within a VPC, you need to create two security groups:

- A security group to control access to the VPC interface endpoint that you will set up for EI.
- A security group that allows SageMaker to call into the first security group.

To configure the two security groups

1. Create a security group with no outbound connections. You will attach this to the VPC endpoint interface you create in the next section.
2. Create a second security group with no inbound connections, but with an outbound connection to the first security group.
3. Edit the first security group to allow inbound connections only to the second security group and all outbound connections.

For more information about VPC security groups, see Security Groups for Your VPC in the Amazon Virtual Private Cloud User Guide.

Set up a VPC Interface Endpoint to Connect to EI

To use EI with SageMaker in a custom VPC, you need to set up a VPC interface endpoint (PrivateLink) for the EI service.

- Set up a VPC interface endpoint (PrivateLink) for the EI. Follow the instructions at Creating an Interface Endpoint. In the list of services, choose com.amazonaws.<region>.elastic-inference.runtime. For Security group, make sure you select the first security group you created in the previous section to the endpoint.
- When you set up the interface endpoint, choose all of the Availability Zones where EI is available. EI fails if you do not set up at least two Availability Zones. For information about VPC subnets, see VPCs and Subnets.

Attach EI to a Notebook Instance

To test and evaluate inference performance using EI, you can attach EI to a notebook instance when you create or update a notebook instance. You can then use EI in local mode to host a model at an endpoint hosted on the notebook instance. You should test various sizes of notebook instances and EI accelerators to evaluate the configuration that works best for your use case.

Set Up to Use EI

To use EI locally in a notebook instance, create a notebook instance with an EI instance.

To create a notebook instance with an EI instance

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose **Notebook instances**.
3. Choose **Create notebook instance**.
4. For **Notebook instance name**, provide a unique name for your notebook instance.
5. For **notebook instance type**, choose a CPU instance such as `ml.t2.medium`.
6. For **Elastic Inference (EI)**, choose an instance from the list, such as `ml.eia2.medium`.
7. For **IAM role**, choose an IAM role that has the required permissions to use SageMaker and EI.
8. (Optional) For **VPC - Optional**, if you want the notebook instance to use a VPC, choose one from the available list. Otherwise, leave it as **No VPC**. If you use a VPC follow the instructions at **Use a Custom VPC to Connect to EI** (p. 2052).
9. (Optional) For **Lifecycle configuration - optional**, either leave it as **No configuration** or choose a lifecycle configuration. For more information, see **Customize a Notebook Instance Using a Lifecycle Configuration Script** (p. 123).
10. (Optional) For **Encryption key - optional**. If you want SageMaker to use an AWS Key Management Service (AWS KMS) key to encrypt data in the ML storage volume attached to the notebook instance, specify the key.
11. (Optional) For **Volume Size In GB - optional**, leave the default value of 5.
12. (Optional) For **Tags**, add tags to the notebook instance. A tag is a label you assign to help manage your notebook instances. A tag consists of a key and a value, both of which you define.
13. Choose **Create Notebook Instance**.

After you create your notebook instance with EI attached, you can create a Jupyter notebook and set up an EI endpoint that is hosted locally on the notebook instance.

**Topics**
- Use EI in Local Mode in SageMaker (p. 2053)

**Use EI in Local Mode in SageMaker**

To use EI locally in an endpoint hosted on a notebook instance, use local mode with the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch estimators or models. For more information about local mode support in the SageMaker Python SDK, see [https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview](https://github.com/aws/sagemaker-python-sdk#sagemaker-python-sdk-overview).

**Topics**
- Use EI in Local Mode with SageMaker TensorFlow Estimators and Models (p. 2053)
- Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models (p. 2054)
- Use EI in Local Mode with SageMaker PyTorch Estimators and Models (p. 2054)

**Use EI in Local Mode with SageMaker TensorFlow Estimators and Models**

The following code shows how to use local mode with an estimator object. To call the `deploy` method, you must have previously either:

- Trained the model by calling the `fit` method of an estimator.
- Pass a model artifact when you initialize the model object.
# Deploys the model to a local endpoint

tf_predictor = tf_model.deploy(initial_instance_count=1,
       instance_type='local',
       accelerator_type='local_sagemaker_notebook')

**Use EI in Local Mode with SageMaker Apache MXNet Estimators and Models**

To use EI with MXNet in local mode, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type` when you call the `deploy` method of an estimator or a model object. For more information about Amazon SageMaker Python SDK MXNet estimators and models, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

# Deploys the model to a local endpoint

mxnet_predictor = mxnet_estimator.deploy(initial_instance_count=1,
       instance_type='local',
       accelerator_type='local_sagemaker_notebook')

For a complete example of using EI in local mode with MXNet, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference_local.html.

**Use EI in Local Mode with SageMaker PyTorch Estimators and Models**

To use EI with PyTorch in local mode, when you call the `deploy` method of an estimator or a model object, specify `local` for `instance_type` and `local_sagemaker_notebook` for `accelerator_type`. For more information about Amazon SageMaker Python SDK PyTorch estimators and models, see SageMaker PyTorch Estimators and Models.

The following code shows how to use local mode with an estimator object. You must have previously called the `fit` method of the estimator to train the model.

# Deploys the model to a local endpoint

pytorch_predictor = pytorch_estimator.deploy(initial_instance_count=1,
       instance_type='local',
       accelerator_type='local_sagemaker_notebook')

**Use EI on Amazon SageMaker Hosted Endpoints**

To use Elastic Inference (EI) in Amazon SageMaker with a hosted endpoint for real-time inference, specify an EI accelerator when you create the deployable model to be hosted at that endpoint. You can do this in one of the following ways:

- Use the Amazon SageMaker Python SDK versions of either the TensorFlow, MXNet, or PyTorch and the SageMaker pre-built containers for TensorFlow, MXNet, and PyTorch
- Build your own container, and use the low-level SageMaker API (Boto 3). You will need to import the EI-enabled version of either TensorFlow, MXNet, or PyTorch from the provided Amazon S3 locations into your container, and use one of those versions to write your training script.
- Use either the Image Classification Algorithm (p. 1356) or Object Detection Algorithm (p. 1436) built-in algorithms, and use the AWS SDK for Python (Boto3) to run your training job and create your deployable model and hosted endpoint.
Use EI with a SageMaker TensorFlow Container

SageMaker provides default model training and inference code for your convenience. For custom file formats, you might need to implement custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
                          instance_type='ml.m4.xlarge',
                          accelerator_type='ml.eia2.medium')
```

Use EI with a SageMaker MXNet Container

To use MXNet with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using MXNet in the Amazon SageMaker Python SDK, see https://sagemaker.readthedocs.io/en/stable/frameworks/mxnet/index.html.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the `deploy` method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its `deploy` method, as shown in the example code.

```python
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
                             instance_type='ml.m4.xlarge',
                             accelerator_type='ml.eia2.medium')
```
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')

Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in the example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

For a complete example of using EI with MXNet in SageMaker, see the sample notebook at https://github.com/awslabs/amazon-sagemaker-examples/blob/master/sagemaker-python-sdk/mxnet_mnist/mxnet_mnist_elastic_inference.ipynb

Use EI with a SageMaker PyTorch Container

To use PyTorch with EI in SageMaker, you need to call the `deploy` method of either the `Estimator` or `Model` objects. You then specify an accelerator type using the `accelerator_type` input argument. For information about using PyTorch in the Amazon SageMaker Python SDK, see SageMaker PyTorch Estimators and Models.

For your convenience, SageMaker provides default model training and inference code. For custom file formats, you might need to write custom model training and inference code.

Use an Estimator Object

To use an estimator object with EI, when you use the deploy method, include the `accelerator_type` input argument. The estimator returns a predictor object, which we call its deploy method, as shown in this example code.

```
# Deploy an estimator using EI (using the accelerator_type input argument)
predictor = estimator.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

Use a Model Object

To use a model object with EI, when you use the deploy method, include the `accelerator_type` input argument. The model returns a predictor object, which we call its deploy method, as shown in this example code.

```
# Deploy a model using EI (using the accelerator_type input argument)
predictor = model.deploy(initial_instance_count=1,
    instance_type='ml.m4.xlarge',
    accelerator_type='ml.eia2.medium')
```

Use EI with Your Own Container

To use EI with a model in a custom container that you build, use the low-level AWS SDK for Python (Boto 3). download and import the AWS EI-enabled versions of TensorFlow, Apache MXNet, or PyTorch machine learning frameworks, and write your training script using those frameworks.
Import the EI Version of TensorFlow, MXNet, or PyTorch into Your Docker Container

To use EI with your own container, you need to import either the Amazon EI TensorFlow Serving library, the Amazon EI Apache MXNet library, or the Elastic Inference enabled PyTorch library into your container. The EI-enabled versions of TensorFlow and MXNet are currently available as binary files stored in Amazon S3 locations. You can download the EI-enabled binary for TensorFlow from the Amazon S3 bucket at https://s3.console.aws.amazon.com/s3/buckets/amazonei-tensorflow. For information about building a container that uses the EI-enabled version of TensorFlow, see https://github.com/aws/sagemaker-tensorflow-container#building-the-sagemaker-elastic-inference-tensorflow-serving-container. You can download the EI-enabled binary for Apache MXNet from the public Amazon S3 bucket at https://s3.console.aws.amazon.com/s3/buckets/amazonei-apachemxnet. For information about building a container that uses the EI-enabled version of MXNet, see https://github.com/aws/sagemaker-mxnet-container#building-the-sagemaker-elastic-inference-mxnet-container. You can download the Elastic Inference enabled binary for PyTorch from the public Amazon S3 bucket at https://s3.console.aws.amazon.com/s3/buckets/amazonei-pytorch. For information about building a container that uses the Elastic Inference enabled version of PyTorch, see Building your image.

Create an EI Endpoint with AWS SDK for Python (Boto 3)

To create an endpoint by using AWS SDK for Python (Boto 3), you first create an endpoint configuration. The endpoint configuration specifies one or more models (called production variants) that you want to host at the endpoint. To attach EI to one or more of the production variants hosted at the endpoint, you specify one of the EI instance types as the `AcceleratorType` field for that `ProductionVariant`. You then pass that endpoint configuration when you create the endpoint.

Create an Endpoint Configuration

To use EI, you need to specify an accelerator type in the endpoint configuration.

```python
# Create Endpoint Configuration
from time import gmtime, strftime
def create_endpoint_config():
    endpoint_config_name = 'ImageClassificationEndpointConfig-' + strftime("%Y-%m-%d-%H-%M-%S",
    gmtime())
    print(endpoint_config_name)
    create_endpoint_config_response = sagemaker.create_endpoint_config(
        EndpointConfigName = endpoint_config_name,
        ProductionVariants=[
            {'InstanceType':'ml.m4.xlarge',
            'InitialInstanceCount':1,
            'ModelName':model_name,
            'VariantName':'AllTraffic',
            'AcceleratorType':ml.eia2.medium}])
    print("Endpoint Config Arn: " + create_endpoint_config_response['EndpointConfigArn'])

Create an Endpoint

After you create an endpoint configuration with an accelerator type, you can create an endpoint.

```python
def create_endpoint():
    endpoint_name = 'ImageClassificationEndpoint-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
    endpoint_response = sagemaker.create_endpoint(
        EndpointName=endpoint_name,
        EndpointConfigName=endpoint_config_name)
```

After creating the endpoint, you can invoke it using the `invoke_endpoint` method in a Boto3 runtime object, as you would any other endpoint.
Use Batch Transform

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to assist the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records (p. 2060). For example, you can filter input data to provide context for creating and interpreting reports about the output data.

For more information about batch transforms, see Get Inferences for an Entire Dataset with Batch Transform (p. 13).

Topics

- Use Batch Transform to Get Inferences from Large Datasets (p. 2058)
- Speed up a Batch Transform Job (p. 2059)
- Use Batch Transform to Test Production Variants (p. 2059)
- Batch Transform Errors (p. 2060)
- Batch Transform Sample Notebooks (p. 2060)
- Associate Prediction Results with Input Records (p. 2060)

Use Batch Transform to Get Inferences from Large Datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, suppose that you have a dataset file, input1.csv, stored in an S3 bucket. The content of the input file might look like the following:

Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
...
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM

When a batch transform job starts, SageMaker initializes compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiples files, one instance might process input1.csv, and another instance might process the file named input2.csv.

To keep large payloads below the MaxPayloadInMB limit, you can split an input file into several mini-batches. For example, you might create a mini-batch from input1.csv by including only two of the records.

Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM
Note
SageMaker processes each input file separately. It doesn't combine mini-batches from different input files to comply with the MaxPayloadInMB limit.

To split input files into mini-batches, when you create a batch transform job, set the SplitType parameter value to Line. If SplitType is set to None or if an input file can't be split into mini-batches, SageMaker uses the entire input file in a single request.

If the batch transform job successfully processes all of the records in an input file, it creates an output file with the same name and the .out file extension. For multiple input files, such as input1.csv and input2.csv, the output files are named input1.csv.out and input2.csv.out. The batch transform job stores the output files in the specified location in Amazon S3, such as s3://awsexamplebucket/output/.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file input1.csv.out, based on the input file shown earlier, would look like the following.

Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-AttributeM

To combine the results of multiple output files into a single output file, set the AssembleWith parameter to Line.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set MaxPayloadInMB to 0. Amazon SageMaker built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the CreateTransformJob API. For more information about the correlation between batch transform input and output objects, see OutputDataConfig. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform (p. 66).

Speed up a Batch Transform Job

If you are using the CreateTransformJob API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as MaxPayloadInMB, MaxConcurrentTransforms, or BatchStrategy. If you are using the SageMaker console, you can specify these optimal parameter values in the Additional configuration section of the Batch transform job configuration page. SageMaker automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Use Batch Transform to Test Production Variants

To test different models or various hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics (p. 1893).
**Batch Transform Errors**

SageMaker uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker marks the job as failed. If an input file contains a bad record, the transform job doesn’t create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

Exceeding the MaxPayloadInMB limit causes an error. This might happen with a large dataset if it can’t be split, the SplitType parameter is set to none, or individual records within the dataset exceed the limit.

If you are using your own algorithms, you can use placeholder text, such as ERROR, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

**Batch Transform Sample Notebooks**

For a sample notebook that uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix, followed by the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies, see Batch Transform with PCA and DBSCAN Movie Clusters. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker, see Use Amazon SageMaker Notebook Instances (p. 119). After creating and opening a notebook instance, choose the SageMaker Examples tab to see a list of all the SageMaker examples. The topic modeling example notebooks that use the NTM algorithms are located in the Advanced functionality section. To open a notebook, choose its Use tab, then choose Create copy.

**Associate Prediction Results with Input Records**

When making predictions on a large dataset, you can exclude attributes that aren’t needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

**Topics**

- Workflow for Associating Inferences with Input Records (p. 2060)
- Use Data Processing in Batch Transform Jobs (p. 2061)
- Supported JSONPath Operators (p. 2062)
- Batch Transform Examples (p. 2062)

**Workflow for Associating Inferences with Input Records**

The following diagram shows the workflow for associating inferences with input records.
To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.
3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

### Use Data Processing in Batch Transform Jobs

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.
2. Join the raw input data with the transformed data with the `JoinSource` parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see [DataProcessing](https://docs.aws.amazon.com/sagemaker/latest/dg/transform.html).
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for both input and output files. For example, with the `TransformOutput` field of the
CreateTransformJob API, you must set both the Content Type and Accept parameters to one of the following values: text/csv, application/json, or application/jsonlines. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples (p. 2062). For more information about input and output file formats for built-in algorithms, see Use Amazon SageMaker Built-in Algorithms (p. 691).

The record delimiters for the input and output must also be consistent with your chosen file input. The SplitType parameter indicates how to split the records in the input dataset. The AssembleWith parameter indicates how to reassemble the records for the output. If you set input and output formats to text/csv, you must also set the SplitType and AssemblyType parameters to line. If you set the input and output formats to application/jsonlines, you can set both SplitType and AssemblyType to line.

For JSON files, the attribute name SageMakerOutput is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

**Supported JSONPath Operators**

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. $[0], $[1:]. CSV data should also follow RFC format.

<table>
<thead>
<tr>
<th>JSONPath Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>The root element to a query. This operator is required at the beginning of all path expressions.</td>
<td>$</td>
</tr>
<tr>
<td>.&lt;name&gt;</td>
<td>A dot-notated child element.</td>
<td>$.id</td>
</tr>
<tr>
<td>*</td>
<td>A wildcard. Use in place of an attribute name or numeric value.</td>
<td>$.id.*</td>
</tr>
<tr>
<td>[ '&lt;name&gt;', '&lt;name&gt;' ]</td>
<td>A bracket-notated element or multiple child elements.</td>
<td>$['id','SageMakerOutput']</td>
</tr>
<tr>
<td>[&lt;number&gt;,&lt;number&gt;]</td>
<td>An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.</td>
<td>$[1],$[1,3,5]</td>
</tr>
<tr>
<td>[&lt;start&gt;:&lt;end&gt;]</td>
<td>An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit &lt;start&gt;, SageMaker uses the first element of the array. If you omit &lt;end&gt;, SageMaker uses the last element of the array.</td>
<td>$[2:5],$[:5],$[2:]</td>
</tr>
</tbody>
</table>

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, $.field1.['child1','child2'] is supported while $.field1.['child1','child2.grandchild'] is not.

For more information about JSONPath operators, see JsonPath on GitHub.

**Batch Transform Examples**

The following examples show some common ways to join input data with prediction results.
Topics

- Example: Output Only Inferences (p. 2063)
- Example: Output Input Data and Inferences (p. 2063)
- Example: Output an ID Column with Results and Exclude the ID Column from the Input (CSV) (p. 2064)
- Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input (JSON) (p. 2064)

Example: Output Only Inferences

By default, the `DataProcessing` parameter doesn't join inference results with input. It outputs only the inference results.

If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK and specify the following settings in a transformer call.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")
```

To output inferences using the AWS SDK for Python, add the following code to your `CreateTransformJob` request. The following code mimics the default behavior.

```json
{
    "DataProcessing": {
        "InputFilter": "$",
        "JoinSource": "None",
        "OutputFilter": "$"
    }
}
```

Example: Output Input Data and Inferences

If you're using the Amazon SageMaker Python SDK, to combine the input data with the inferences in the output file, specify "Input" for the `JoinSource` parameter in a transformer call.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, join_source= "Input")
```

If you're using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the following code to your `CreateTransformJob` request.

```json
{
    "DataProcessing": {
        "JoinSource": "Input"
    }
}
```

For JSON or JSON Lines input files, the results are in the `SageMakerOutput` key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`.

SageMaker stores both in the input file in the `SageMakerInput` key.

```json
{
    "key":1,
    "SageMakerOutput":{"label":1}
}
Note
The joined result for JSON must be a key-value pair object. If the input isn’t a key-value pair object, SageMaker creates a new JSON file. In the new JSON file, the input data is stored in the SageMakerInput key and the results are stored as the SageMakerOutput value.

For a CSV file, for example, if the record is [1, 2, 3], and the label result is [1], then the output file would contain [1, 2, 3, 1].

Example: Output an ID Column with Results and Exclude the ID Column from the Input (CSV)

If you are using the Amazon SageMaker Python SDK, to include results or an ID column in the output, specify indexes of the joined dataset in a transformer call. For example, if your data includes five columns and the first one is the ID column, use the following transformer request.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$[1:]", join_source= "Input", output_filter="$")
```

If you are using the AWS SDK for Python (Boto 3), add the following code to your CreateTransformJob request.

```json
{
  "DataProcessing": {
    "InputFilter": "$[1:]",
    "JoinSource": "Input",
    "OutputFilter": "$
  }
}
```

To specify columns in SageMaker, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set InputFilter to "$[1:]". The colon (:) tells SageMaker to include all of the elements between two values, inclusive. For example, $[1:4] specifies the second through fifth columns.

If you omit the number after the colon, for example, $[5:], the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, $[:5], the subset includes all columns from the first column (index 0) through the sixth column.

Example: Output an ID Attribute with Results and Exclude the ID Attribute from the Input (JSON)

If you are using the Amazon SageMaker Python SDK, include results of an ID attribute in the output by specifying it in a transformer call. For example, if you store data in the features attribute and the record ID in the ID attribute, you would use the following transformer request.

```python
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$.features", join_source= "Input",
output_filter="$[‘id’, ‘SageMakerOutput’]"
```

If you are using the AWS SDK for Python (Boto 3), join all input data with the inference by adding the following code to your CreateTransformJob request.

```json
{
  "DataProcessing": {
```

2064
Warning
If you are using a JSON-formatted input file, the file can’t contain the attribute name SageMakerOutput. This attribute name is reserved for the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

Automatically Scale Amazon SageMaker Models

Amazon SageMaker supports automatic scaling (autoscaling) for your hosted models. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances so that you don’t pay for provisioned instances that you aren’t using.

Topics
- Prerequisites (p. 2065)
- Configure model autoscaling with the console (p. 2068)
- Register a model (p. 2069)
- Define a scaling policy (p. 2070)
- Apply a scaling policy (p. 2072)
- Edit a scaling policy (p. 2073)
- Delete a scaling policy (p. 2074)
- Query Endpoint Autoscaling History (p. 2076)
- Update or delete endpoints that use automatic scaling (p. 2077)
- Load testing your autoscaling configuration (p. 2079)
- Use AWS CloudFormation to update autoscaling policies (p. 2080)

Prerequisites

Before you can use autoscaling, you must have already created an Amazon SageMaker model deployment. Deployed models are referred to as a production variant. This includes information about the model and the resources used to host it.

For more information about deploying a model endpoint, see Deploy the Model to SageMaker Hosting Services (p. 65).

To enable autoscaling for a model, you can use the console, the AWS CLI, or the Application Auto Scaling API. It is recommended to try to Configure model autoscaling with the console (p. 2068) to get familiar with the requirements and to test your first autoscaling configuration. When using the AWS CLI or Application Auto Scaling the flow is to register the model, define the scaling policy, then apply it. The following overview provides further details on the prerequisites and components used with autoscaling.

Autoscaling policy overview

To use automatic scaling, you define and apply a scaling policy that uses Amazon CloudWatch metrics and target values that you assign. Automatic scaling uses the policy to increase or decrease the number of instances in response to actual workloads.
You can use the AWS Management Console to apply a scaling policy based on a predefined metric. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the AWS Management Console. Alternatively, you can use either the AWS Command Line Interface (AWS CLI) or the Application Auto Scaling API to apply a scaling policy based on a predefined or custom metric.

There are two types of supported scaling policies: target-tracking scaling and step scaling. It is recommended to use target-tracking scaling policies for your autoscaling configuration. You configure the target-tracking scaling policy by specifying a predefined or custom metric and a target value for the metric. For more information about using Application Auto Scaling target-tracking scaling policies, see Target Tracking Scaling Policies.

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. Otherwise, using target-tracking scaling is preferred as it will be fully automated. For more information about using Application Auto Scaling step scaling policies, see Step Scaling Policies.

A scaling policy has the following components:

- A target metric—The Amazon CloudWatch metric that SageMaker automatic scaling uses to determine when and how much to scale.
- Minimum and maximum capacity—The minimum and maximum number of instances to use for scaling.
- A cool down period—The amount of time, in seconds, after a scale-in or scale-out activity completes before another scale-out activity can start.
- Required permissions—Permissions that are required to perform automatic scaling actions.
- A service-linked role—An AWS Identity and Access Management (IAM) role that is linked to a specific AWS service. A service-linked role includes all of the permissions that the service requires to call other AWS services on your behalf. SageMaker automatic scaling automatically generates this role, AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint, for you.

Target metric for autoscaling

Amazon CloudWatch alarms trigger the scaling policy, which calculate how to adjust scaling based on the metric and target value that you set. The scaling policy adds or removes endpoint instances as required to keep the metric at, or close to, the specified target value. In addition, a scaling policy also adjusts to fluctuations in the metric when a workload changes. The scaling policy minimizes rapid fluctuations in the number of available instances for your model.

For example, a scaling policy that uses the predefined InvocationsPerInstance metric with a target value of 70 can keep InvocationsPerInstance at, or close to 70.

Minimum and maximum capacity

You may specify the maximum number of endpoint instances for the model. The maximum value must be equal to or greater than the value specified for the minimum number of endpoint instances. SageMaker automatic scaling does not enforce a limit for this value.

You must also specify the minimum number of instances for the model. This value must be at least 1, and equal to or less than the value specified for the maximum number of endpoint instances.

To determine the minimum and maximum number of instances that you need for typical traffic, test your autoscaling configuration with the expected rate of traffic to your model.

Important

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.
Cooldown period

Tune the responsiveness of your scaling policy by adding a cooldown period. A cooldown period controls when your model is scaled-in (by reducing instances) or scaled-out (by increasing instances). It does this by blocking subsequent scale-in or scale-out requests until the period expires. This slows the deletion of instances for scale-in requests, and the creation of instances for scale-out requests. A cooldown period helps to ensure that the scaling policy doesn't launch or terminate additional instances before the previous scaling activity takes effect. After automatic scaling dynamically scales using a scaling policy, it waits for the cooldown period to complete before resuming scaling activities.

You configure the cooldown period in your automatic scaling policy. You can specify the following cooldown periods:

- A scale-in activity reduces the number of instances. A scale-in cooldown period specifies the amount of time, in seconds, after a scale-in activity completes before another scale-in activity can start.
- A scale-out activity increases the number of instances. A scale-out cooldown period specifies the amount of time, in seconds, after a scale-out activity completes before another scale-out activity can start.

If you don't specify a scale-in or a scale-out cooldown period automatic scaling use the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your automatic scaling configuration, consider increasing this value. You can see this behavior if the traffic to your model has a lot of spikes, or if you have multiple automatic scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

Permissions

The SagemakerFullAccessPolicy IAM policy has all of the IAM permissions required to perform autoscaling. For more information about SageMaker IAM permissions, see SageMaker Roles (p. 2399).

If you are using a custom permission policy, you must include the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [  
    "sagemaker:DescribeEndpoint",
    "sagemaker:DescribeEndpointConfig",
    "sagemaker:UpdateEndpointWeightsAndCapacities"
  ],
  "Resource": "*"
}
{
  "Action": [  
    "application-autoscaling:*"
  ],
  "Effect": "Allow",
  "Resource": "*"
}
{
  "Action": "iam:CreateServiceLinkedRole",
  "Effect": "Allow",
  "Resource": "*"
}
```
Service-linked role

Autoscaling uses the AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint service-linked role; it created for you automatically. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles are predefined by the service and include all of the permissions that the service requires to call other AWS services on your behalf. For more information, see Service-Linked Roles.

Configure model autoscaling with the console

To configure autoscaling for a model using the console

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Endpoints.
3. Choose the endpoint that you want to configure.
4. For Endpoint runtime settings, choose the model variant that you want to configure.
5. For Endpoint runtime settings, choose Configure autoscaling.

The Configure variant automatic scaling page appears.

6. For Minimum capacity, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.
7. For Maximum capacity, type the maximum number of instances that you want the scaling policy to maintain.
8. For the target value, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing (p. 2079).

Application Auto Scaling adds or removes instances to keep the metric close to the value that you specify.

9. For Scale-in cool down (seconds) and Scale-out cool down (seconds), type the number seconds for each cool down period. Assuming that the order in the list is based on either most important to less important of first applied to last applied.
10. Select Disable scale in to prevent the scaling policy from deleting variant instances if you want to ensure that your variant scales out to address increased traffic, but are not concerned with removing instances to reduce costs when traffic decreases, disable scale-in activities.

Scale-out activities are always enabled so that the scaling policy can create endpoint instances as needed.
11. Choose Save.
This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

**Note**

SageMaker doesn't support autoscaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see Amazon EC2 Instance Types.

## Register a model

You can add autoscaling for a model with the AWS CLI or the Application Auto Scaling API. You first must register the model, then you must define an autoscaling policy.

### Register a model with the AWS CLI

With the AWS CLI, you can configure autoscaling based on either a predefined or a custom metric.

To register your endpoint, use the `register-scalable-target` AWS CLI command with the following parameters:

- `--service-namespace`—Set this value to `sagemaker`.
- `--resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example, `endpoint/MyEndPoint/variant/MyVariant`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--min-capacity`—The minimum number of instances that this model should manage. Set `min-capacity` to at least 1. It must be equal to or less than the value specified for `max-capacity`.
- `--max-capacity`—The maximum number of instances that Application Auto Scaling should manage. Set `max-capacity` to a minimum of 1, it must be equal to or greater than the value specified for `min-capacity`.

#### Example

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have one to eight instances:

```bash
aws application-autoscaling register-scalable-target
    --service-namespace sagemaker
    --resource-id endpoint/MyEndPoint/variant/MyVariant
    --scalable-dimension sagemaker:variant:DesiredInstanceCount
    --min-capacity 1
    --max-capacity 8
```

### Register a model with the Application Auto Scaling API

To define the scaling limits for the model, register your model with Application Auto Scaling. Application Auto Scaling dynamically scales the number of production variant instances.

To register your model with Application Auto Scaling, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:
Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the AWS CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

The following options are available for defining a target-tracking scaling policy configuration.

Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the SageMakerVariantInvocationsPerInstance predefined metric. SageMakerVariantInvocationsPerInstance is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a PredefinedMetricSpecification for the predefined metric and a TargetValue for the target value of that metric.
Example

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the `SageMakerVariantInvocationsPerInstance` predefined metric to adjust the number of variant instances so that each instance has an `InvocationsPerInstance` metric of 70.

```json
{
  "TargetValue": 70.0,
  "PredefinedMetricSpecification":
  {
    "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
  }
}
```

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

**Important**
Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a variant named `my-variant`, a custom metric adjusts the variant based on an average CPU utilization of 50 percent across all instances.

```json
{
  "TargetValue": 50,
  "CustomizedMetricSpecification":
  {
    "MetricName": "CPUUtilization",
    "Namespace": "/aws/sagemaker/Endpoints",
    "Dimensions": [
      {"Name": "EndpointName", "Value": "my-endpoint" },
      {"Name": "VariantName","Value": "my-variant"}
    ],
    "Statistic": "Average",
    "Unit": "Percent"
  }
}
```

Add a cooldown period

To add a cooldown period for scaling-out your model, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling-in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.
Example

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of 70 across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```json
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    },
    "ScaleInCooldown": 600,
    "ScaleOutCooldown": 300
}
```

Apply a scaling policy

After registering your model and defining a scaling policy, apply the scaling policy to the registered model. To apply a scaling policy, you can use the AWS CLI or the Application Auto Scaling API.

Apply a scaling policy (AWS CLI)

To apply a scaling policy to your model, use the `put-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to `TargetTrackingScaling`.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example uses with Application Auto Scaling to apply a target-tracking scaling policy named `myscalablepolicy` to a model (variant) named `myscalablevariant`. The policy configuration is saved in a file named `config.json`.

```
aws application-autoscaling put-scaling-policy \
    --policy-name myscalablepolicy \
    --policy-type TargetTrackingScaling \
    --resource-id endpoint/MyEndpoint/variant/MyVariant \
    --service-namespace sagemaker \
    --scalable-dimension sagemaker:variant:DesiredInstanceCount \
    --target-tracking-scaling-policy-configuration file://config.json
```

Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:
• PolicyName—The name of the scaling policy.
• ServiceNamespace—Set this value to sagemaker.
• ResourceId—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, endpoint/MyEndpoint/variant/MyVariant.
• ScalableDimension—Set this value to sagemaker:variant:DesiredInstanceCount.
• PolicyType—Set this value to TargetTrackingScaling.
• TargetTrackingScalingPolicyConfiguration—The target-tracking scaling policy configuration to use for the variant.

Example

The following example uses Application Auto Scaling to apply a target-tracking scaling policy named myscalablepolicy to a variant named myscalablevariant. It uses a policy configuration based on the SageMakerVariantInvocationsPerInstance predefined metric.

```json
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
  "PolicyName": "myscalablepolicy",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "PolicyType": "TargetTrackingScaling",
  "TargetTrackingScalingPolicyConfiguration": {
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
      "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
  }
}
```

Edit a scaling policy

You can edit an autoscaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API.

Scale-in

Scaling-in occurs when there is no traffic: if a variant's traffic becomes zero, SageMaker automatically scales in to the minimum number of instances specified. In this case, SageMaker emits metrics with a value of zero. Minimum instance count is required to be 1 or higher.

Disable scale-in activity

You can prevent the target-tracking scaling policy configuration from scaling in your variant by disabling scale-in activity. Disabling scale-in activity prevents the scaling policy from deleting instances, while still allowing it to create them as needed.
To enable or disable scale-in activity for your model, specify a Boolean value for DisableScaleIn. For more information about DisableScaleIn, see TargetTrackingScalingPolicyConfiguration in the Application Auto Scaling API Reference.

**Example**

The following is an example of a target-tracking configuration for a scaling policy where it will scale-out, but not scale-in. In this configuration, the SageMakerVariantInvocationsPerInstance predefined metric will scale-out based on an average of 70 invocations (inference requests) across all instances the model is on. The configuration also disables scale-in activity for the scaling policy.

```json
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification": {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance",
        "DisableScaleIn": true
    }
}
```

**Scale-out**

To manually scale-out, adjust the minimum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the --min-capacity argument, or use the Application Auto Scaling API's MinCapacity parameter.

**Disable scale-out activity**

To prevent scale-out, adjust the maximum capacity. You can use the console to update this value. Alternatively, use the AWS CLI with the --max-capacity argument, or use the Application Auto Scaling API's MaxCapacity parameter.

**Edit a scaling policy (Console)**

To edit a scaling policy with the AWS Management Console, use the same procedure that you used to Configure model autoscaling with the console (p. 2068).

**Edit a scaling policy (AWS CLI or Application Auto Scaling API)**

You can use the AWS CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you apply a scaling policy:

- With the AWS CLI, specify the name of the policy that you want to edit in the --policy-name parameter. Specify new values for the parameters that you want to change.
- With the Application Auto Scaling API, specify the name of the policy that you want to edit in the PolicyName parameter. Specify new values for the parameters that you want to change.

For more information, see Apply a scaling policy (p. 2072).

**Delete a scaling policy**

You can delete a scaling policy with the AWS Management Console, the AWS CLI, or the Application Auto Scaling API. You must delete a scaling policy if you wish to update a model's endpoint.

**Delete a scaling policy (Console)**
To delete an automatic scaling policy (console)

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the navigation pane, choose Endpoints.
3. Choose the endpoint for which you want to delete automatic scaling.
4. For Endpoint runtime settings, choose the variant that you want to configure.
5. Choose Configure auto scaling.
6. Choose Deregister auto scaling.

Delete a scaling policy (AWS CLI or Application Auto Scaling API)

You can use the AWS CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

Delete a scaling policy (AWS CLI)

To delete a scaling policy from a variant, use the `delete-scaling-policy` AWS CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

Example

The following example deletes a target-tracking scaling policy named `myscalablepolicy` from a variant named `myscalablevariant`.

```bash
aws application-autoscaling delete-scaling-policy
   --policy-name myscalablepolicy
   --resource-id endpoint/MyEndpoint/variant/MyVariant
   --service-namespace sagemaker
   --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy from your variant, use the `DeleteScalingPolicy` Application Auto Scaling API action with the following parameters:

- `PolicyName`—The name of the scaling policy.
- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceId`—The resource identifier for the variant. For this parameter, the resource type is endpoint and the unique identifier is the name of the variant. For example, `endpoint/MyEndpoint/variant/MyVariant`.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

Example

The following example uses the Application Auto Scaling API to delete a target-tracking scaling policy named `myscalablepolicy` from a variant named `myscalablevariant`.

```bash
aws application-autoscaling delete-scaling-policy
   PolicyName myscalablepolicy
   ServiceNamespace sagemaker
   ResourceId endpoint/MyEndpoint/variant/MyVariant
   ScalableDimension sagemaker:variant:DesiredInstanceCount
```
Query Endpoint Autoscaling History

You can view the status of scaling activities from your endpoint using `DescribeScalingActivities`. `DescribeScalingActivities` provides descriptive information about the scaling activities in the specified namespace from the previous six weeks.

How To Query Endpoint Autoscaling Actions

Query your autoscaling endpoints with `DescribeScalingActivities`. To do so, specify `ServiceNamespace` parameter. `ServiceNamespace` is the name of the AWS service that provides the resource.

Valid service name values include the following:

- `ecs`
- `elasticmapreduce`
- `ec2`
- `appstream`
- `dynamodb`
- `rds`
- `sagemaker`
- `custom-resource`
- `comprehend`
- `lambda`
- `cassandra`

In this situation you need to set `ServiceNamespace` to `sagemaker`.

Use the following AWS CLI command to view details about all of your `sagemaker` endpoints that have a scaling policy:

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker
```

You can search for a specific endpoint using `ResourceId`:

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

When you run this command, it returns the following output:

```
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "string",
  "StartTime": timestamp,
}
How to Identify Blocked AutoScaling Due to Instance Quotas

When you scale out or add more instances, you might reach your account-level instance quota. You can use `DescribeScalingActivities` to check whether you have reached your instance quota. When you exceed your quota, automatic scaling is blocked.

To check if you have reached your instance quota, use the AWS CLI command as shown in the proceeding example where you specified the `ResourceId`:

```bash
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/<endpoint_name>/variant/<variant_name>
```

Within the return syntax, check the `StatusCode` and `StatusMessage` keys and their associated values. `StatusCode` returns `Failed`. Within `StatusMessage` there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```json
{
  "ActivityId": "activity-id",
  "ServiceNamespace": "sagemaker",
  "ResourceId": "endpoint/<endpoint_name>/variant/<variant_name>",
  "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
  "Description": "string",
  "Cause": "minimum capacity was set to 110",
  "StartTime": timestamp,
  "EndTime": timestamp,
  "StatusCode": "Failed",
  "StatusMessage": "Failed to set desired instance count to 110. Reason: The account-level service limit 'ml.xx.xxxxxx for endpoint usage' is 1000 Instances, with current utilization of 997 Instances and a request delta of 20 Instances. Please contact AWS support to request an increase for this limit. (Service: AmazonSageMaker; Status Code: 400; Error Code: ResourceLimitExceeded; Request ID: request-id)."
}
```

Update or delete endpoints that use automatic scaling

Topics

- Update endpoints that use automatic scaling (p. 2077)
- Delete endpoints configured for automatic scaling (p. 2078)

Update endpoints that use automatic scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If the update would change the instance type for any model that is a target for automatic scaling, the update fails.

In the AWS Management Console, you see a warning that you must deregister the model from automatic scaling before you can update it. If you are trying to update the endpoint by calling the
Update or delete endpoints that use automatic scaling

UpdateEndpoint API, the call fails. Before you update the endpoint, delete any scaling policies configured for it by calling the DeleteScalingPolicy Application Auto Scaling API action, then call DeregisterScalableTarget to deregister the variant as a scalable target. After you update the endpoint, you can register the variant as a scalable target and attach an automatic scaling policy to the updated variant.

There is one exception. If you change the model for a variant that is configured for automatic scaling, Amazon SageMaker automatic scaling allows the update. This is because changing the model doesn’t typically affect performance enough to change automatic scaling behavior. If you do update a model for a variant configured for automatic scaling, ensure that the change to the model doesn’t significantly affect performance and automatic scaling behavior.

When you update SageMaker endpoints that have automatic scaling applied, complete the following steps:

To update an endpoint that has automatic scaling applied

1. Deregister the endpoint as a scalable target by calling DeregisterScalableTarget.
2. Because automatic scaling is blocked while the update operation is in progress (or if you turned off automatic scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling UpdateEndpointWeightsAndCapacities.
3. Call DescribeEndpoint repeatedly until the value of the EndpointStatus field of the response is InService.
4. Call DescribeEndpointConfig to get the values of the current endpoint config.
5. Create a new endpoint config by calling CreateEndpointConfig. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to DescribeEndpointConfig in the previous step. For all other values, use the values that you got as the response when you called DescribeEndpointConfig in the previous step.
6. Update the endpoint by calling UpdateEndpoint. Specify the endpoint config you created in the previous step as the EndpointConfig field. If you want to retain the variant properties like instance count or weight, set the value of the RetainAllVariantProperties parameter to True. This specifies that production variants with the same name will are updated with the most recent DesiredInstanceCount from the response from the call to DescribeEndpoint, regardless of the values of the InitialInstanceCount field in the new EndpointConfig.
7. (Optional) Re-enable automatic scaling by calling RegisterScalableTarget.

Note
Steps 1 and 7 are required only if you are updating an endpoint with the following changes:

- Changing the instance type for a production variant that has automatic scaling configured
- Removing a production variant that has automatic scaling configured.

Delete endpoints configured for automatic scaling

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for automatic scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn’t provide permission for the DeleteScalingPolicy and DeregisterScalableTarget actions, you must delete automatic scaling policies and deregister scalable targets and before deleting the endpoint.
Note
You, as an IAM user, might not have sufficient permission to delete an endpoint if another IAM user configured automatic scaling for a variant on that endpoint.

Load testing your autoscaling configuration

Perform load tests to choose an automatic scaling configuration that works the way you want.

For an example of load testing to optimize automatic scaling for an Amazon SageMaker endpoint, see Load test and optimize an Amazon SageMaker endpoint using automatic scaling.

The following guidelines for load testing assume you are using an automatic scaling policy that uses the predefined target metric `SageMakerVariantInvocationsPerInstance`.

Topics
- Determine the performance characteristics (p. 2079)
- Calculate the target load (p. 2079)

Determine the performance characteristics

Perform load testing to find the peak `InvocationsPerInstance` that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see Deploy the Model to SageMaker Hosting Services (p. 65).
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the output of the load testing tool.

   Note
   You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate `SageMakerVariantInvocationsPerInstance` shown below.

   When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum value. Use the following equation in combination with load testing to determine the correct value for the `SageMakerVariantInvocationsPerInstance` target metric in your automatic scaling configuration.

\[
SageMakerVariantInvocationsPerInstance = (MAX_RPS \ast SAFETY_FACTOR) \ast 60
\]

Where `MAX_RPS` is the maximum RPS that you determined previously, and `SAFETY_FACTOR` is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that
SageMaker uses to implement automatic scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

**Note**
SageMaker recommends that you start testing with a SAFETY_FACTOR of 0.5. Test your automatic scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

## Use AWS CloudFormation to update autoscaling policies

The following is an example for how to enable autoscaling on an endpoint using AWS CloudFormation.

```yaml
Endpoint:
  Type: "AWS::SageMaker::Endpoint"
  Properties:
    EndpointName: yourEndpointName
    EndpointConfigName: yourEndpointConfigName

ScalingTarget:
  Type: "AWS::ApplicationAutoScaling::ScalableTarget"
  Properties:
    MaxCapacity: 10
    MinCapacity: 2
    ResourceId: endpoint/MyEndPoint/variant/MyVariant
    RoleARN: arn
    ScalableDimension: sagemaker:variant:DesiredInstanceCount
    ServiceNamespace: sagemaker

ScalingPolicy:
  Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
  Properties:
    PolicyName: myscalablepolicy
    PolicyType: TargetTrackingScaling
    ScalingTargetId:
      Ref: ScalingTarget
    TargetTrackingScalingPolicyConfiguration:
      TargetValue: 75.0
      ScaleInCooldown: 600
      ScaleOutCooldown: 30
    PredefinedMetricSpecification:
      PredefinedMetricType: SageMakerVariantInvocationsPerInstance
```

For more details, refer to CloudFront's AutoScalingPlans API reference.

## Test models in production

In production ML workflows, data scientists and engineers frequently try to improve their models in various ways, such as by performing Perform Automatic Model Tuning with SageMaker (p. 1715), training on additional or more-recent data, and improving feature selection. Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously-existing version, replace the old version of the model with the new version in production.

Amazon SageMaker enables you to test multiple models or model versions behind the same endpoint using production variants. Each production variant identifies a machine learning (ML) model and the resources deployed for hosting the model. By using production variants, you can test ML models that
Test models by specifying traffic distribution

To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see CreateEndpointConfig. The following diagram shows how this works in more detail.

Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the TargetVariant parameter when you call
InvokeEndpoint. SageMaker ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the TargetVariant parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.

Model A/B test example

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production."

**Step 1: Create and deploy models**

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```python
model_url = f"s3://{path_to_model_1}"
model_url2 = f"s3://{path_to_model_2}"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:

```python
from sagemaker.amazon.amazon_estimator import get_image_uri
```
We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial weight of 1 for both variants. This means that 50% of requests go to Variant1, and the remaining 50% of requests to Variant2. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

Finally we're ready to deploy these production variants on a SageMaker endpoint.

```python
from sagemaker.session import production_variant

variant1 = production_variant(model_name=model_name,
                               instance_type="ml.m5.xlarge",
                               initial_instance_count=1,
                               variant_name='Variant1',
                               initial_weight=1)

variant2 = production_variant(model_name=model_name2,
                               instance_type="ml.m5.xlarge",
                               initial_instance_count=1,
                               variant_name='Variant2',
                               initial_weight=1)
```

**Step 2: Invoke the deployed models**

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.

```bash
# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/test_sample_tail_input_cols.csv
```

2083
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")

with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
                                   ContentType="text/csv",
                                   Body=payload)
        time.sleep(0.5)

print("Done!")

SageMaker emits metrics such as Latency and Invocations for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker emits, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 2459). Let’s query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Variant1</th>
<th>Variant2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-06-05 15:34:00+00:00</td>
<td>44.0</td>
<td>60.0</td>
</tr>
<tr>
<td>2020-06-05 15:35:00+00:00</td>
<td>7.0</td>
<td>9.0</td>
</tr>
</tbody>
</table>

Now let’s invoke a specific version of the model by specifying Variant1 as the TargetVariant in the call to invoke_endpoint.

print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print('.', end='', flush=True)
        payload = rowrstrip('\n')
        sm_runtime.invoke_endpoint(EndpointName=endpoint_name,
                                   ContentType="text/csv",
                                   Body=payload,
                                   *TargetVariant="Variant1"*) # Notice the new parameter
        time.sleep(0.5)

To confirm that all new invocations were processed by Variant1, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by Variant1, as we had specified. There were no invocations made for Variant2.
Step 3: Evaluate model performance

To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating characteristic/Area under the curve for each variant. First, let's look at these metrics for Variant1:

- Accuracy: 0.9583333333333334
- Precision: 0.9411764705882353
- Recall: 0.8
- F1 Score: 0.8648484848484848
- AUC is 0.895

Now let's look at the metrics for Variant2:
For most of our defined metrics, Variant2 is performing better, so this is the one that we want to use in production.

**Step 4: Increase traffic to the best model**

Now that we have determined that Variant2 performs better than Variant1, we shift more traffic to it. We can continue to use TargetVariant to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling `UpdateEndpointWeightsAndCapacities`. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

Now we shift 75% of the traffic to Variant2 by assigning new weights to each variant using `UpdateEndpointWeightsAndCapacities`. SageMaker now sends 75% of the inference requests to Variant2 and remaining 25% of requests to Variant1.

```python
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```
The CloudWatch metrics for total invocations for each variant shows us higher invocations for Variant2 than for Variant1:

![Graph showing invocations for Variant1 and Variant2]

We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `sm.update_endpoint_weights_and_capacities` to update the traffic assignments for the variants. The weight for Variant1 is set to 0 and the weight for Variant2 is set to 1. SageMaker now sends 100% of all inference requests to Variant2.

```python
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 0,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 1,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```

The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by Variant2 and there are no inference requests processed by Variant1.

![Graph showing invocations for Variant1 and Variant2]

You can now safely update your endpoint and delete Variant1 from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.
Troubleshoot Amazon SageMaker Model Deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker, see the following guidance.

Topics

• Detection Errors in the Active CPU Count  (p. 2088)

Detection Errors in the Active CPU Count

If you deploy a SageMaker model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when running a model in a Docker container, and, more generally, within Linux 
taskset commands or control groups (cgroups). SageMaker deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker doesn’t limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the -XX:-UseContainerSupport parameter when starting Java applications. For example, run the java command to start your JVM as follows:

```
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
```
Check whether the JVM used in your container supports the `-XX:-UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker containers. For example, when using a JVM to support SparkML Scala. The `-XX:-UseContainerSupport` parameter also affects the output returned by the Java `Runtime.getRuntime().availableProcessors()` API.

### Deployment Best Practices

This topic provides guidance on best practices for deploying machine learning models in Amazon SageMaker.

#### Deploy Multiple Instances Across Availability Zones

**Create robust endpoints when hosting your model.** SageMaker endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommended that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two Subnets, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.

#### Host Instance Storage Volumes

When you create an endpoint, Amazon SageMaker attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.

For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see Host Instance Storage Volumes Table.
Using Docker containers with SageMaker

Amazon SageMaker makes extensive use of Docker containers for build and runtime tasks. SageMaker provides prebuilt Docker images for its built-in algorithms and the supported deep learning frameworks used for training and inference. Using containers, you can train machine learning algorithms and deploy models quickly and reliably at any scale. The topics in this section show how to deploy these containers for your own use cases.

Topics

• Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker (p. 2090)
• Docker Container Basics (p. 2091)
• Use Prebuilt SageMaker Docker images (p. 2091)
• Adapting Your Own Docker Container to Work with SageMaker (p. 2105)
• Create a container with your own algorithms and models (p. 2117)
• Example Notebooks: Use Your Own Algorithm or Model (p. 2132)
• Troubleshooting your Docker containers (p. 2134)

Scenarios for Running Scripts, Training Algorithms, or Deploying Models with SageMaker

Amazon SageMaker always uses Docker containers when running scripts, training algorithms, and deploying models. However, your level of engagement with containers depends on your use case.

• **Use a built-in SageMaker algorithm or framework.** For most use cases, you can use the built-in algorithms and frameworks without worrying about containers. You can train and deploy these algorithms from the SageMaker console, the AWS Command Line Interface (AWS CLI), a Python notebook, or the Amazon SageMaker Python SDK by specifying the algorithm or framework version when creating your Estimator. The built-in algorithms available are itemized and described in the Use Amazon SageMaker Built-in Algorithms (p. 691) topic. For more information on the available frameworks, see ML Frameworks and Toolkits (p. 16). For an example of how to train and deploy a built-in algorithm using a Jupyter notebook running in a SageMaker notebook instance, see the Get Started with Amazon SageMaker (p. 34) topic.

• **Use prebuilt SageMaker container images.** Alternatively, you can use the built-in algorithms and frameworks using Docker containers. SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker Images, see Available Deep Learning Container Images. It also supports machine learning libraries such as scikit-learn and SparkML. If you use the Amazon SageMaker Python SDK, you can deploy the containers by passing the full container URI to their respective SageMaker SDK Estimator class. For the full list of deep learning frameworks currently supported by SageMaker, see Prebuilt SageMaker Docker Images for TensorFlow, MXNet, Chainer, and PyTorch (p. 2092). For information on the scikit-learn and SparkML prebuilt container images, see Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2092). For more information about using frameworks with the Amazon SageMaker...
Docker Container Basics

Docker is a program that performs operating system-level virtualization for installing, distributing, and managing software. It packages applications and their dependencies into virtual containers that provide isolation, portability, and security. With Docker, you can ship code faster, standardize application operations, seamlessly move code, and economize by improving resource utilization. For more general information about Docker, see Docker overview.

The following information outlines the most significant aspects of using Docker containers with Amazon SageMaker.

SageMaker Functions

SageMaker uses Docker containers in the backend to manage training and inference processes. SageMaker abstracts away from this process, so it happens automatically when an estimator is used. While you don’t need to use Docker containers explicitly with SageMaker for most use cases, you can use Docker containers to extend and customize SageMaker functionality.

Containers with SageMaker Studio

SageMaker Studio runs from a Docker container and uses it to manage functionality. As a result, you cannot create and upload a Docker container from a SageMaker Studio instance. However, you can use a prebuilt SageMaker container as long as that container was created outside of Studio.

Use Prebuilt SageMaker Docker images

Amazon SageMaker provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. It also supports machine learning libraries such as scikit-learn and SparkML.

You can use these images from your SageMaker notebook instance or SageMaker Studio. You can also extend the prebuilt SageMaker images to include libraries and needed functionality. The following topics give information about the available images and how to use them.

Note
For information on Docker images for developing reinforcement learning (RL) solutions in SageMaker, see SageMaker RL Containers.

Topics
- Prebuilt SageMaker Docker Images for TensorFlow, MXNet, Chainer, and PyTorch (p. 2092)
- Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML (p. 2092)
- Train a Deep Graph Network (p. 2094)
- Extend a Prebuilt Container (p. 2097)
Prebuilt SageMaker Docker Images for TensorFlow, MXNet, Chainer, and PyTorch

SageMaker provides prebuilt Docker images that include deep learning framework libraries and other dependencies needed for training and inference. For a complete list of the available pre-built Docker images, see Deep Learning Containers Images.

If you are not using the Amazon SageMaker Python SDK and one of its estimators to retrieve the pre-built images, you have to retrieve them yourself.

Using the SageMaker Python SDK

With the SageMaker Python SDK, you can train and deploy models using these popular deep learning frameworks. For instructions on installing and using the SDK, see Amazon SageMaker Python SDK. The following table lists the available frameworks and instructions on how to use them with the SageMaker Python SDK:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>TensorFlow</td>
<td>Using TensorFlow with the SageMaker Python SDK</td>
</tr>
<tr>
<td>MXNet</td>
<td>Using MXNet with the SageMaker Python SDK</td>
</tr>
<tr>
<td>PyTorch</td>
<td>Using PyTorch with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Chainer</td>
<td>Using Chainer with the SageMaker Python SDK</td>
</tr>
<tr>
<td>Hugging Face</td>
<td>Using Hugging Face with the SageMaker Python SDK</td>
</tr>
</tbody>
</table>

Extending Prebuilt SageMaker Docker Images

You can customize these prebuilt containers or extend them to handle any additional functional requirements for your algorithm or model that the prebuilt SageMaker Docker image doesn't support. For an example, see Extending Our PyTorch Containers.

You can also use prebuilt containers to deploy your custom models or models that have been trained in a framework other than SageMaker. For an overview of the process of bringing the trained model artifacts into SageMaker and hosting them at an endpoint, see Bring Your Own Pretrained MXNet or TensorFlow Models into Amazon SageMaker.

Prebuilt Amazon SageMaker Docker Images for Scikit-learn and Spark ML

SageMaker provides prebuilt Docker images that install the scikit-learn and Spark ML libraries. These libraries also include the dependencies needed to build Docker images that are compatible with SageMaker using the Amazon SageMaker Python SDK. With the SDK, you can use scikit-learn for machine learning tasks and use Spark ML to create and tune machine learning pipelines. For instructions on installing and using the SDK, see SageMaker Python SDK.

Using the SageMaker Python SDK

The following table contains links to the GitHub repositories with the source code for the scikit-learn and Spark ML containers. The table also contains links to instructions that show how use these containers with Python SDK estimators to run your own training algorithms and hosting your own models.
### Prebuilt Scikit-learn and Spark ML Images

<table>
<thead>
<tr>
<th>Library</th>
<th>Prebuilt Docker Image Source Code</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>scikit-learn</td>
<td>SageMaker Scikit-learn Containers</td>
<td>Using Scikit-learn with the Amazon SageMaker Python SDK</td>
</tr>
<tr>
<td>Spark ML</td>
<td>SageMaker Spark ML Serving Containers</td>
<td>SparkML Python SDK Documentation</td>
</tr>
</tbody>
</table>

### Specifying the Prebuilt Images Manually

If you are not using the SageMaker Python SDK and one of its estimators to manage the container, you have to retrieve the relevant prebuilt container manually. The SageMaker prebuilt Docker images are stored in Amazon Elastic Container Registry (Amazon ECR). You can push or pull them using their fullname registry addresses. SageMaker uses the following Docker Image URL patterns for scikit-learn and Spark M:

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-scikit-learn:<SCIKIT-LEARN_VERSION>-cpu-py<PYTHON_VERSION>

  For example, 746614075791.dkr.ecr.us-west-1.amazonaws.com/sagemaker-scikit-learn:0.23-1-cpu-py3

- `<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-sparkml-serving:<SPARK-ML_VERSION>

  For example, 341280168497.dkr.ecr.ca-central-1.amazonaws.com/sagemaker-sparkml-serving:2.4

The following table lists the supported values for account IDs and corresponding AWS Region names.

<table>
<thead>
<tr>
<th>ACCOUNT_ID</th>
<th>REGION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>746614075791</td>
<td>us-west-1</td>
</tr>
<tr>
<td>246618743249</td>
<td>us-west-2</td>
</tr>
<tr>
<td>683313688378</td>
<td>us-east-1</td>
</tr>
<tr>
<td>257758044811</td>
<td>us-east-2</td>
</tr>
<tr>
<td>354813040037</td>
<td>ap-northeast-1</td>
</tr>
<tr>
<td>366743142698</td>
<td>ap-northeast-2</td>
</tr>
<tr>
<td>121021644041</td>
<td>ap-southeast-1</td>
</tr>
<tr>
<td>783357654285</td>
<td>ap-southeast-2</td>
</tr>
<tr>
<td>720646828776</td>
<td>ap-south-1</td>
</tr>
<tr>
<td>141502667606</td>
<td>eu-west-1</td>
</tr>
<tr>
<td>764974769150</td>
<td>eu-west-2</td>
</tr>
<tr>
<td>492215442770</td>
<td>eu-central-1</td>
</tr>
<tr>
<td>341280168497</td>
<td>ca-central-1</td>
</tr>
</tbody>
</table>
Finding Available Images

Use the following commands to find out which versions of the images are available. For example, use the following to find the available sagemaker-sparkml-serving image in the ca-central-1 Region:

```bash
aws ecr describe-images
  --region ca-central-1
  --registry-id 341280168497
  --repository-name sagemaker-sparkml-serving
```

Train a Deep Graph Network

In this overview, you learn how to get started with a deep graph network by using one of the DGL containers in Amazon Elastic Container Registry (Amazon ECR). You can also see links to practical examples for deep graph networks.

What Is a Deep Graph Network?

Deep graph networks refer to a type of neural network that is trained to solve graph problems. A deep graph network uses an underlying deep learning framework like PyTorch or MXNet. The potential for graph networks in practical AI applications is highlighted in the Amazon SageMaker tutorials for Deep Graph Library (DGL). Examples for training models on graph datasets include social networks, knowledge bases, biology, and chemistry.
Deep Graph Networks

Several examples are provided using Amazon SageMaker’s deep learning containers that are preconfigured with DGL. If you have special modules you want to use with DGL, you can also build your own container. The examples involve heterographs, which are graphs that have multiple types of nodes and edges, and draw on a variety of applications across disparate scientific fields, such as bioinformatics and social network analysis. DGL provides a wide array of graph neural network implementations for different types models. Some of the highlights include:

- Graph convolutional network (GCN)
- Relational graph convolutional network (R-GCN)
- Graph attention network (GAT)
- Deep generative models of graphs (DGMG)
- Junction tree neural network (JTNN)

Get Started

DGL is available as a deep learning container in Amazon ECR. You can select deep learning containers when you write your estimator function in an Amazon SageMaker notebook. You can also craft your own custom container with DGL by following the Bring Your Own Container guide. The easiest way to get started with a deep graph network uses one of the DGL containers in Amazon ECR.

Note

Backend framework support is limited to PyTorch and MXNet.

Setup

Figure 1. The DGL ecosystem
If you are using Amazon SageMaker Studio, you need to clone the examples repository first. If you are using a notebook instance, you can find the examples by choosing the SageMaker icon at bottom of the left toolbar.

**To clone the Amazon SageMaker SDK and notebook examples repository**

1. From the JupyterLab view in Amazon SageMaker, go to the File Browser at the top of the left toolbar. From the File Browser panel, you can see a new navigation at the top of the panel.
2. Choose the icon on the far right to clone a Git repository.
3. Add the repository URL: https://github.com/awslabs/amazon-sagemaker-examples.git
4. Browse the newly added folder and its contents. The DGL examples are stored in the sagemaker-python-sdk folder.

**Run a Graph Network Training Example**

**To train a deep graph network**

1. From the JupyterLab view in Amazon SageMaker, browse the example notebooks and look for DGL folders. Several files may be included to support an example. Examine the README for any prerequisites.
2. Run the .ipynb notebook example.
3. Find the estimator function, and note the line where it is using an Amazon ECR container for DGL and a specific instance type. You may want to update this to use a container in your preferred Region.
4. Run the function to launch the instance and use the DGL container for training a graph network. Charges are incurred for launching this instance. The instance self-terminates when the training is complete.

**Examples**

An example of knowledge graph embedding (KGE) is provided. It uses the Freebase dataset, a knowledge base of general facts. An example use case would be to graph the relationships of persons and predict their nationality.

An example implementation of a graph convolutional network (GCN) shows how you can train a graph network to predict toxicity. A physiology dataset, Tox21, provides toxicity measurements for how substances affect biological responses.

Another GCN example shows you how to train a graph network on a scientific publications bibliography dataset, known as Cora. You can use it to find relationships between authors, topics, and conferences.

The last example is a recommender system for movie reviews. It uses a graph convolutional matrix completion (GCMC) network trained on the MovieLens datasets. These datasets consist of movie titles, genres, and ratings by users.

**Use a Deep Learning Container with DGL**

The following examples use preconfigured deep learning containers. These are the easiest to try since they work out of the box on Amazon SageMaker.

- Semi-supervised classification of a knowledge base using a GCN
- Learning embeddings of large-scale knowledge graphs using a dataset of scientific publications
Bring Your Own Container with DGL

The following examples enable you to bring your own container (BYOC). Read the BYOC guide and familiarize yourself with that process before trying these. Configuration is required.

- Molecular property prediction of toxicity using a GCN
- Recommender system for movies using a GCMC implementation

Extend a Prebuilt Container

If a prebuilt SageMaker container doesn't fulfill all of your requirements, you can extend the existing image to accommodate your needs. Even if there is direct support for your environment or framework, you may want to add additional functionality or configure your container environment differently. By extending a prebuilt image, you can leverage the included deep learning libraries and settings without having to create an image from scratch. You can extend the container to add libraries, modify settings, and install additional dependencies.

The following tutorial shows how to extend a prebuilt SageMaker image and publish it to Amazon ECR.

Topics

- Requirements to Extend a Prebuilt Container (p. 2097)
- Extend SageMaker Containers to Run a Python Script (p. 2097)

Requirements to Extend a Prebuilt Container

To extend a pre-built SageMaker image, you need to set the following environment variables within your Dockerfile. For more information on environment variables with SageMaker containers, see the SageMaker Training Toolkit GitHub repo.

- SAGEMAKER_SUBMIT_DIRECTORY: The directory within the container in which the Python script for training is located.
- SAGEMAKER_PROGRAM: The Python script that should be invoked and used as the entry point for training.

You can also install additional libraries by including the following in your Dockerfile:

```bash
RUN pip install <library>
```

The following tutorial shows how to use these environment variables.

Extend SageMaker Containers to Run a Python Script

In this tutorial, you learn how to extend the SageMaker PyTorch container with a Python file that uses the CIFAR-10 dataset. By extending the SageMaker PyTorch container, you utilize the existing training solution made to work with SageMaker. This tutorial extends a training image, but the same steps can be taken to extend an inference image. For a full list of the available images, see Available Deep Learning Containers Images.

To run your own training model using the SageMaker containers, build a Docker container through a SageMaker Notebook instance.

Step 1: Create an SageMaker Notebook Instance

1. Open the SageMaker console.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.

SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmSS, such as AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time when the role was created, separated by a T.

d. For Root Access, choose Enable.

e. Choose Create notebook instance.

4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon SageMaker to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

Step 2: Create and Upload the Dockerfile and Python Training Scripts

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.

2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
# SageMaker PyTorch image
FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04

ENV PATH="/opt/ml/code:${PATH}"

# this environment variable is used by the SageMaker PyTorch container to determine our user code directory.
ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code

# /opt/ml and all subdirectories are utilized by SageMaker, use the /code subdirectory to store your user code.
COPY cifar10.py /opt/ml/code/cifar10.py

# Defines cifar10.py as script entrypoint
```

2098
The Dockerfile script performs the following tasks:

- **FROM 763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-training:1.5.1-cpu-py36-ubuntu16.04** – Downloads the SageMaker PyTorch base image. You can replace this with any SageMaker base image you want to bring to build containers.
- **ENV SAGEMAKER_SUBMIT_DIRECTORY /opt/ml/code** – Sets /opt/ml/code as the training script directory.
- **COPY cifar10.py /opt/ml/code/cifar10.py** – Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.
- **ENV SAGEMAKER_PROGRAM cifar10.py** – Sets your cifar10.py training script as the entrypoint script.

3. Create or upload a training script `cifar10.py` in the `docker_test_folder`. You can use the following example script for this exercise.

```python
import ast
import argparse
import logging
import os
import torch
import torch.distributed as dist
import torch.nn as nn
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision
import torchvision.models
import torchvision.transforms as transforms
import torch.nn.functional as F

logger = logging.getLogger(__name__)
logger.setLevel(logging.DEBUG)

classes = ('plane', 'car', 'bird', 'cat', 'deer', 'dog', 'frog', 'horse', 'ship', 'truck')

# https://github.com/pytorch/tutorials/blob/master/beginner_source/blitz/cifar10_tutorial.py#L118

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(3, 6, 5)
        self.pool = nn.MaxPool2d(2, 2)
        self.conv2 = nn.Conv2d(6, 16, 5)
        self.fc1 = nn.Linear(16 * 5 * 5, 120)
        self.fc2 = nn.Linear(120, 84)
        self.fc3 = nn.Linear(84, 10)

    def forward(self, x):
        x = self.pool(F.relu(self.conv1(x)))
```
x = self.pool(F.relu(self.conv2(x)))
x = x.view(-1, 16 * 5 * 5)
x = F.relu(self.fc1(x))
x = F.relu(self.fc2(x))
x = self.fc3(x)
return x

def _train(args):
    is_distributed = len(args.hosts) > 1 and args.dist_backend is not None
    logger.debug("Distributed training - {}".format(is_distributed))
    if is_distributed:

    parser.add_argument('--momentum', type=float, default=0.9, metavar='M',
                        help='momentum (default: 0.9)')
    parser.add_argument('--dist-backend', type=str, default='gloo', help='distributed
                        backend (default: gloo)')
```

# The parameters below retrieve their default values from SageMaker environment
# variables, which are
# instantiated by the SageMaker containers framework.
# https://github.com/aws/sagemaker-containers
# how-a-script-is-executed-inside-the-container
```python
parser.add_argument('--hosts', type=str, default=ast.literal_eval(os.environ['SM_HOSTS']))
parser.add_argument('--current-host', type=str, default=os.environ['SM_CURRENT_HOST'])
parser.add_argument('--model-dir', type=str, default=os.environ['SM_MODEL_DIR'])
parser.add_argument('--data-dir', type=str, default=os.environ['SM_CHANNEL_TRAINING'])
parser.add_argument('--num-gpus', type=int, default=os.environ['SM_NUM_GPUS'])
```
Step 3: Build the Container

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the New Launch icon and then choose conda_pytorch_p36 in the Notebook section.

2. Run the following command in the first notebook cell to change to the docker_test_folder directory:

   ```
   % cd ~/SageMaker/docker_test_folder
   ```

   This returns your current directory as follows:

   ```
   ! pwd
   ```

   output: /home/ec2-user/SageMaker/docker_test_folder

3. Log in to Docker to access the base container:

   ```
   ! aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin 763104351884.dkr.ecr.us-east-1.amazonaws.com
   ```

4. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

   ```
   ! docker build -t pytorch-extended-container-test .
   ```

   The Docker build command must be run from the Docker directory you created, in this case docker_test_folder.

   **Note**

   If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

   ```
   unable to prepare context: unable to evaluate symlinks in Dockerfile path: lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
   ```

   Remember that docker looks for a file specifically called Dockerfile without any extension within the current directory. If you named it something else, you can pass in the file name manually with the -f flag. For example, if you named your Dockerfile Dockerfile-text.txt, run the following command:

   ```
   ! docker build -t tf-custom-container-test -f Dockerfile-text.txt .
   ```

Step 4: Test the Container

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose Notebook in conda_pytorch_p36 framework. The rest of the code snippets must run from the Jupyter notebook instance.

2. Download the CIFAR-10 dataset.

   ```
   import torch
   ```
import torchvision
import torchvision.transforms as transforms

def _get_transform():
    return transforms.Compose([transforms.ToTensor(),
                                transforms.Normalize((0.5, 0.5, 0.5), (0.5, 0.5, 0.5))])

def get_train_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    trainset=torchvision.datasets.CIFAR10(root=data_dir, train=True, download=True, transform=transform)
    return torch.utils.data.DataLoader(trainset, batch_size=4, shuffle=True, num_workers=2)

def get_test_data_loader(data_dir='/tmp/pytorch/cifar-10-data'):
    transform=_get_transform()
    testset=torchvision.datasets.CIFAR10(root=data_dir, train=False, download=True, transform=transform)
    return torch.utils.data.DataLoader(testset, batch_size=4, shuffle=False, num_workers=2)

trainloader=get_train_data_loader('/tmp/pytorch-example/cifar-10-data')
testloader=get_test_data_loader('/tmp/pytorch-example/cifar-10-data')

3. Set role to the role used to create your Jupyter notebook. This is used to configure your SageMaker Estimator.

    from sagemaker import get_execution_role
    role=get_execution_role()

4. Paste the following example script into the notebook code cell to configure a SageMaker Estimator using your extended container.

    from sagemaker.estimator import Estimator
    hyperparameters={'epochs': 1}
    estimator=Estimator(
        image_uri='pytorch-extended-container-test',
        role=role,  
        instance_count=1,  
        instance_type='local',  
        hyperparameters=hyperparameters
    )
    estimator.fit('file:///tmp/pytorch-example/cifar-10-data')

5. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

Step 5: Push the Container to Amazon Elastic Container Registry (Amazon ECR)

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.

    Run the following command lines in a notebook cell.
%%sh
# Specify an algorithm name
algorithm_name=pytorch-extended-container-test

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Build the docker image locally with the image name and then push it to ECR
# with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}

2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3

client=boto3.client('sts')
account=client.get_caller_identity()['Account']

my_session=boto3.session.Session()
region=my_session.region_name

algorithm_name="pytorch-extended-container-test"
ecr_image='{}.dkr.ecr.{}.amazonaws.com/{}:latest'.format(account, region, algorithm_name)

ecr_image
# This should return something like
# 12-digits-of-your-account.dkr.ecr.us-east-2.amazonaws.com/tf-2.2-test:latest
```

3. Use the `ecr_image` retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker PyTorch estimator.

```python
import sagemaker

from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator=Estimator(
    image_uri=ecr_image,
```
Adapting Your Own Docker Container to Work with SageMaker

You can adapt an existing Docker image to work with SageMaker. You may need to use an existing, external Docker image with SageMaker when you have a container that satisfies feature or safety requirements that are not currently supported by a prebuilt SageMaker image. There are two toolkits that allow you to bring your own container and adapt it to work with SageMaker:

- SageMaker Training Toolkit
- SageMaker Inference Toolkit

The following topics show how to adapt your existing image using the SageMaker Training and Inference toolkits:

**Topics**
- Individual Framework Libraries (p. 2106)
- Using the SageMaker Training and Inference Toolkits (p. 2106)
- Adapting Your Own Training Container (p. 2107)
- Adapting Your Own Inference Container (p. 2113)
Individual Framework Libraries

In addition to the SageMaker Training Toolkit and SageMaker Inference Toolkit, SageMaker also provides toolkits specialized for TensorFlow, MXNet, PyTorch, and Chainer. The following table provides links to the GitHub repositories that contain the source code for each framework and their respective serving toolkits. The instructions linked are for using the Python SDK to run training algorithms and host models on SageMaker. The functionality for these individual libraries is included in the SageMaker Training Toolkit and SageMaker Inference Toolkit.

<table>
<thead>
<tr>
<th>Framework</th>
<th>Toolkit Source Code</th>
</tr>
</thead>
</table>
| TensorFlow | SageMaker TensorFlow Training  
|           | SageMaker TensorFlow Serving |
| MXNet     | SageMaker MXNet Training  
|           | SageMaker MXNet Inference |
| PyTorch   | SageMaker PyTorch Training  
|           | SageMaker PyTorch Inference |
| Chainer   | SageMaker Chainer SageMaker Containers |

Using the SageMaker Training and Inference Toolkits

The SageMaker Training and SageMaker Inference toolkits implement the functionality that you need to adapt your containers to run scripts, train algorithms, and deploy models on SageMaker. When installed, the library defines the following for users:

- The locations for storing code and other resources.
- The entry point that contains the code to run when the container is started. Your Dockerfile must copy the code that needs to be run into the location expected by a container that is compatible with SageMaker.
- Other information that a container needs to manage deployments for training and inference.

SageMaker Toolkits Containers Structure

When SageMaker trains a model, it creates the following file folder structure in the container's /opt/ml directory.

```
/opt/ml
    ### input
    #     ### config
    #     #     ### hyperparameters.json
    #     #     ### resourceConfig.json
    #     ### data
    #     #     ### <channel_name>
    #     #     #     ### <input data>
    ### model
    #     ### code
    #     ### output
```
When you run a model training job, the SageMaker container uses the `/opt/ml/input/` directory, which contains the JSON files that configure the hyperparameters for the algorithm and the network layout used for distributed training. The `/opt/ml/input/` directory also contains files that specify the channels through which SageMaker accesses the data, which is stored in Amazon Simple Storage Service (Amazon S3). The SageMaker containers library places the scripts that the container will run in the `/opt/ml/code/` directory. Your script should write the model generated by your algorithm to the `/opt/ml/model/` directory. For more information, see Use Your Own Training Algorithms (p. 2117).

When you host a trained model on SageMaker to make inferences, you deploy the model to an HTTP endpoint. The model makes real-time predictions in response to inference requests. The container must contain a serving stack to process these requests.

In a hosting or batch transform container, the model files are located in the same folder to which they were written during training.

```
/opt/ml/model
```

For more information, see Use Your Own Inference Code (p. 2123).

### Single Versus Multiple Containers

You can either provide separate Docker images for the training algorithm and inference code or you can use a single Docker image for both. When creating Docker images for use with SageMaker, consider the following:

- Providing two Docker images can increase storage requirements and cost because common libraries might be duplicated.
- In general, smaller containers start faster for both training and hosting. Models train faster and the hosting service can react to increases in traffic by automatically scaling more quickly.
- You might be able to write an inference container that is significantly smaller than the training container. This is especially common when you use GPUs for training, but your inference code is optimized for CPUs.
- SageMaker requires that Docker containers run without privileged access.
- Both Docker containers that you build and those provided by SageMaker can send messages to the `Stdout` and `Stderr` files. SageMaker sends these messages to Amazon CloudWatch logs in your AWS account.

For more information about how to create SageMaker containers and how scripts are executed inside them, see the SageMaker Training Toolkit and SageMaker Inference Toolkit repositories on GitHub. They also provide lists of important environmental variables and the environmental variables provided by SageMaker containers.

### Adapting Your Own Training Container

To run your own training model, build a Docker container using the Amazon SageMaker Training Toolkit through an Amazon SageMaker notebook instance.

**Step 1: Create a SageMaker notebook instance**

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. In the left navigation pane, choose Notebook, choose Notebook instances, and then choose Create notebook instance.

3. On the Create notebook instance page, provide the following information:
   a. For Notebook instance name, enter RunScriptNotebookInstance.
   b. For Notebook Instance type, choose ml.t2.medium.
   c. In the Permissions and encryption section, do the following:
      i. For IAM role, choose Create a new role.
      ii. On the Create an IAM role page, choose Specific S3 buckets, specify an Amazon S3 bucket named sagemaker-run-script, and then choose Create role.
      SageMaker creates an IAM role named AmazonSageMaker-ExecutionRole-YYYYMMDDTHHmmSS. For example, AmazonSageMaker-ExecutionRole-20190429T110788. Note that the execution role naming convention uses the date and time at which the role was created, separated by a T.
   d. For Root Access, choose Enable.
   e. Choose Create notebook instance.

4. On the Notebook instances page, the Status is Pending. It can take a few minutes for Amazon SageMaker to launch a machine learning compute instance—in this case, it launches a notebook instance—and attach an ML storage volume to it. The notebook instance has a preconfigured Jupyter notebook server and a set of Anaconda libraries. For more information, see CreateNotebookInstance.

5. In the Permissions and encryption section, copy the IAM role ARN number, and paste it into a notepad file to save it temporarily. You use this IAM role ARN number later to configure a local training estimator in the notebook instance. The IAM role ARN number looks like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'

6. After the status of the notebook instance changes to InService, choose Open JupyterLab.

**Step 2: Create and upload the Dockerfile and Python training scripts**

1. After JupyterLab opens, create a new folder in the home directory of your JupyterLab. In the upper-left corner, choose the New Folder icon, and then enter the folder name docker_test_folder.
2. Create a Dockerfile text file in the docker_test_folder directory.
   a. Choose the New Launcher icon (+) in the upper-left corner.
   b. In the right pane under the Other section, choose Text File.
   c. Paste the following Dockerfile sample code into your text file.

```
FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3-jupyter

# Install sagemaker-training toolkit that contains the common functionality necessary to create a container compatible with SageMaker and the Python SDK.
RUN pip3 install sagemaker-training

# Copies the training code inside the container
COPY train.py /opt/ml/code/train.py

# Defines train.py as script entrypoint
ENV SAGEMAKER_PROGRAM train.py
```

2108
The Dockerfile script performs the following tasks:

- `FROM tensorflow/tensorflow:2.2.0rc2-gpu-py3-jupyter` - Downloads the TensorFlow Docker base image. You can replace this with any Docker base image you want to bring to build containers, as well as with AWS pre-built container base images.

- `RUN pip install sagemaker-training` - Installs SageMaker Training Toolkit that contains the common functionality necessary to create a container compatible with SageMaker.

- `COPY train.py /opt/ml/code/train.py` - Copies the script to the location inside the container that is expected by SageMaker. The script must be located in this folder.

- `ENV SAGEMAKER_PROGRAM train.py` - Takes your training script `train.py` as the entrypoint script copied in the `/opt/ml/code` folder of the container. This is the only environmental variable that you must specify when you build your own container.

d. On the left directory navigation pane, the text file name might automatically be named `untitled.txt`. To rename the file, right-click the file, choose **Rename**, rename the file as `Dockerfile` without the `.txt` extension, and then press Ctrl+s or Command+s to save the file.

3. Create or upload a training script `train.py` in the `docker_test_folder`. You can use the following example script for this exercise.

```python
import tensorflow as tf

mnist = tf.keras.datasets.mnist

(x_train, y_train), (x_test, y_test) = mnist.load_data()
x_train, x_test = x_train / 255.0, x_test / 255.0

model = tf.keras.models.Sequential([tf.keras.layers.Flatten(input_shape=(28, 28)),
tf.keras.layers.Dense(128, activation='relu'),
tf.keras.layers.Dropout(0.2),
tf.keras.layers.Dense(10, activation='softmax')])

model.compile(optimizer='adam',
loss='sparse_categorical_crossentropy',
metrics=['accuracy'])

model.fit(x_train, y_train, epochs=1)

model.evaluate(x_test, y_test)
```

**Step 3: Build the container**

1. In the JupyterLab home directory, open a Jupyter notebook. To open a new notebook, choose the **New Launch** icon and then choose **conda_tensorflow2_p36** in the **Notebook** section.

2. Run the following command in the first notebook cell to change to the `docker_test_folder` directory:

```bash
% cd ~/SageMaker/docker_test_folder
```

This returns your current directory as follows:

```bash
! pwd
```
output: /home/ec2-user/SageMaker/docker_test_folder

3. To build the Docker container, run the following Docker build command, including the space followed by a period at the end:

```
docker build -t tf-custom-container-test .
```

The Docker build command must be run from the Docker directory you created, in this case `docker_test_folder`.

**Note**
If you get the following error message that Docker cannot find the Dockerfile, make sure the Dockerfile has the correct name and has been saved to the directory.

```
unable to prepare context: unable to evaluate symlinks in Dockerfile path:
lstat /home/ec2-user/SageMaker/docker/Dockerfile: no such file or directory
```

Remember that `docker` looks for a file specifically called `Dockerfile` without any extension within the current directory. If you named it something else, you can pass in the file name manually with the `-f` flag. For example, if you named your Dockerfile as `Dockerfile-text.txt`, run the following command:

```
docker build -t tf-custom-container-test -f Dockerfile-text.txt .
```

**Step 4: Test the container**

1. To test the container locally in the notebook instance, open a Jupyter notebook. Choose New Launcher and choose Notebook in `conda_tensorflow_p36` framework.

2. Paste the following example script into the notebook code cell to configure a SageMaker Estimator.

   **SageMaker Python SDK v1**

   ```python
   from sagemaker.estimator import Estimator
   estimator = Estimator(image_name='tf-custom-container-test',
                         role='arn:aws:iam::111122223333:role/role-name',
                         instance_count=1,
                         instance_type='local')
   estimator.fit()
   ```

   **SageMaker Python SDK v2**

   ```python
   from sagemaker.estimator import Estimator
   estimator = Estimator(image_uri='tf-custom-container-test',
                         role='arn:aws:iam::111122223333:role/role-name',
                         instance_count=1,
                         instance_type='local')
   estimator.fit()
   ```

3. Replace the 'Put_Your_ARN_Here' value with the IAM role ARN number you copied to a notepad file when you configured the notebook instance. The ARN should look like the following: 'arn:aws:iam::111122223333:role/service-role/AmazonSageMaker-ExecutionRole-20190429T110788'.
4. Run the code cell. This test outputs the training environment configuration, the values used for the environmental variables, the source of the data, and the loss and accuracy obtained during training.

Step 5: Push the container to Amazon Elastic Container Registry (Amazon ECR)

1. After you successfully run the local mode test, you can push the Docker container to Amazon ECR and use it to run training jobs.

Run the following command lines in a notebook cell.

```sh
# Specify an algorithm name
algorithm_name=tf-custom-container-test

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

Note
This bash shell script may raise a permission issue similar to the following error message:

"denied: User: [ARN] is not authorized to perform: ecr:InitiateLayerUpload on resource:
arn:aws:ecr:us-east-1:[id]:repository/tf-custom-container-test"

If this error occurs, you need to attach the AmazonEC2ContainerRegistryFullAccess policy to your IAM role. Go to the IAM console, choose Roles from the left navigation pane, look up the IAM role you used for the Notebook instance. Under the Permission tab, choose the Attach policies button, and search the AmazonEC2ContainerRegistryFullAccess policy. Mark the check box of the policy, and choose Attach policy to finish.
2. After you push the container, you can call the Amazon ECR image from anywhere in the SageMaker environment. Run the following code example in the next notebook cell.

If you want to use this training container with SageMaker Studio to use its visualization features, you can also run the following code in a Studio notebook cell to call the Amazon ECR image of your training container.

```python
import boto3
account_id = boto3.client('sts').get_caller_identity().get('Account')
ecr_repository = 'sagemaker-byoc-test'
tag = ':latest'
region = boto3.session.Session().region_name
uri_suffix = 'amazonaws.com'
if region in ['cn-north-1', 'cn-northwest-1']:
    uri_suffix = 'amazonaws.com.cn'
byoc_image_uri = '{}.dkr.ecr.{}.{}/{}'.format(account_id, region, uri_suffix, ecr_repository + tag)
byoc_image_uri
# This should return something like
# 111122223333.dkr.ecr.us-east-2.amazonaws.com/sagemaker-byoc-test:latest
```

3. Use the `ecr_image` retrieved from the previous step to configure a SageMaker estimator object. The following code sample configures a SageMaker estimator with the `byoc_image_uri` and initiates a training job on an Amazon EC2 instance.

**SageMaker Python SDK v1**

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator = Estimator(image_name=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.p2.xlarge')

# start training
estimator.fit()

# deploy the trained model
predictor = estimator.deploy(1, instance_type)
```

**SageMaker Python SDK v2**

```python
import sagemaker
from sagemaker import get_execution_role
from sagemaker.estimator import Estimator

estimator = Estimator(image_uri=byoc_image_uri,
                      role=get_execution_role(),
                      base_job_name='tf-custom-container-test-job',
                      instance_count=1,
                      instance_type='ml.p2.xlarge')

# start training
estimator.fit()
```
Adapting Your Own Inference Container

If none of the Amazon SageMaker prebuilt inference containers suffice for your situation, and you want to use your own Docker container, use the SageMaker Inference Toolkit to adapt your container to work with SageMaker hosting. To adapt your container to work with SageMaker hosting, create the inference code in one or more Python script files and a Dockerfile that imports the inference toolkit.

The inference code includes an inference handler, a handler service, and an entrypoint. In this example, they are stored as three separate Python files. All three of these Python files must be in the same directory as your Dockerfile.

For an example Jupyter notebook that shows a complete example of extending a container by using the SageMaker inference toolkit, see Amazon SageMaker Multi-Model Endpoints using your own algorithm container.

Step 1: Create an Inference Handler

The SageMaker inference toolkit is built on the multi-model server (MMS). MMS expects a Python script that implements functions to load the model, pre-process input data, get predictions from the model, and process the output data in a model handler.

The model_fn Function

The model_fn function is responsible for loading your model. It takes a model_dir argument that specifies where the model is stored. How you load your model depends on the framework you are using. There is no default implementation for the model_fn function. You must implement it yourself. The following simple example shows an implementation of a model_fn function that loads a PyTorch model:

```python
def model_fn(self, model_dir):
    import torch
```
print(logger.info('model_fn'))
device = "cuda" if torch.cuda.is_available() else "cpu"
with open(os.path.join(model_dir, 'model.pth'), "rb") as f:
    model = torch.jit.load(f)
return model.to(device)

The input_fn Function

The input_fn function is responsible for deserializing your input data so that it can be passed to your model. It takes input data and content type as parameters, and returns deserialized data. The SageMaker inference toolkit provides a default implementation that deserializes the following content types:

- JSON
- CSV
- Numpy array
- NPZ

If your model requires a different content type, or you want to preprocess your input data before sending it to the model, you must implement the input_fn function. The following example shows a simple implementation of the input_fn function.

```python
from sagemaker_inference import content_types, decoder
def input_fn(self, input_data, content_type):
    """A default input_fn that can handle JSON, CSV and NPZ formats.
    Arguments:
    input_data: the request payload serialized in the content_type format
    content_type: the request content_type
    Returns: input_data deserialized into torch.FloatTensor or torch.cuda.FloatTensor depending on if cuda is available.
    """
    return decoder.decode(input_data, content_type)
```

The predict_fn Function

The predict_fn function is responsible for getting predictions from the model. It takes the model and the data returned from input_fn as parameters, and returns the prediction. There is no default implementation for the predict_fn. You must implement it yourself. The following is a simple implementation of the predict_fn function for a PyTorch model.

```python
def predict_fn(self, data, model):
    """A default predict_fn for PyTorch. Calls a model on data deserialized in input_fn.
    Runs prediction on GPU if cuda is available.
    Arguments:
    data: input data (torch.Tensor) for prediction deserialized by input_fn
    model: PyTorch model loaded in memory by model_fn
    Returns: a prediction
    """
    return model(input_data)
```

The output_fn Function

The output_fn function is responsible for serializing the data that the predict_fn function returns as a prediction. The SageMaker inference toolkit implements a default output_fn function that
serializes Numpy arrays, JSON, and CSV. If your model outputs any other content type, or you want to perform other post-processing of your data before sending it to the user, you must implement your own `output_fn` function. The following shows a simple `output_fn` function for a PyTorch model.

```python
from sagemaker_inference import encoder

def output_fn(self, prediction, accept):
    """A default output_fn for PyTorch. Serializes predictions from predict_fn to JSON, CSV or NPY format.
    """
    Args:
    prediction: a prediction result from predict_fn
    accept: type which the output data needs to be serialized

    Returns: output data serialized
    """
    return encoder.encode(prediction, accept)

Step 2: Implement a Handler Service

The handler service is executed by the model server. The handler service implements `initialize` and `handle` methods. The `initialize` method is invoked when the model server starts, and the `handle` method is invoked for all incoming inference requests to the model server. For more information, see Custom Service in the Multi-model server documentation. The following is an example of a handler service for a PyTorch model server.

```python
from sagemaker_inference.default_handler_service import DefaultHandlerService
from sagemaker_inference.transformer import Transformer
from sagemaker_pytorch_serving_container.default_inference_handler import DefaultPytorchInferenceHandler

class HandlerService(DefaultHandlerService):
    """Handler service that is executed by the model server.
    Determines specific default inference handlers to use based on model being used.
    This class extends `DefaultHandlerService`, which define the following:
    - The `handle` method is invoked for all incoming inference requests to the model server.
    - The `initialize` method is invoked at model server start up.
    Based on: https://github.com/awslabs/mxnet-model-server/blob/master/docs/custom_service.md
    """
    def __init__(self):
        transformer = Transformer(default_inference_handler=DefaultPytorchInferenceHandler())
        super(HandlerService, self).__init__(transformer=transformer)
```

Step 3: Implement an Entrypoint

The entrypoint starts the model server by invoking the handler service. You specify the location of the entrypoint in your Dockerfile. The following is an example of an entrypoint.

```python
from sagemaker_inference import model_server

tf__model_server.start_model_server(handler_service=HANDLER_SERVICE)
```

Step 4: Write a Dockerfile

In your Dockerfile, copy the model handler from step 2 and specify the Python file from the previous step as the entrypoint in your Dockerfile. The following is an example of the lines you can add to your
Dockerfile to copy the model handler and specify the entrypoint. For a full example of a Dockerfile for an inference container, see Dockerfile.

### Step 5: Build and Register Your Container

Now you can build your container and register it in Amazon Elastic Container Registry (Amazon ECR). The following shell script from the sample notebook builds the container and uploads it to an Amazon ECR repository in your AWS account.

**Note**

SageMaker hosting supports using inference containers that are stored in repositories other than Amazon ECR. For information, see Use a Private Docker Registry for Real-Time Inference Containers (p. 2126).

The following shell script shows how to build and register a container.

```bash
# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel
cd container
account=$(aws sts get-caller-identity --query Account --output text)
# Get the region defined in the current configuration (default to us-west-2 if none defined)
region=$(aws configure get region)
region=${region:-us-west-2}
fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null 2>&1
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR with the full name.
docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}
docker push ${fullname}
```

You can now use this container to deploy endpoints in SageMaker. For an example of how to deploy an endpoint in SageMaker, see Deploy the Model to SageMaker Hosting Services (p. 65).
Create a container with your own algorithms and models

If none of the existing SageMaker containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. The following sections show how to create Docker containers with your training and inference algorithms for use with SageMaker.

Topics
- Use Your Own Training Algorithms (p. 2117)
- Use Your Own Inference Code (p. 2123)

Use Your Own Training Algorithms

This section explains how Amazon SageMaker interacts with a Docker container that runs your custom training algorithm. Use this information to write training code and create a Docker image for your training algorithms.

Topics
- How Amazon SageMaker Runs Your Training Image (p. 2117)
- How Amazon SageMaker Provides Training Information (p. 2118)
- Run Training with EFA (p. 2121)
- How Amazon SageMaker Signals Algorithm Success and Failure (p. 2122)
- How Amazon SageMaker Processes Training Output (p. 2123)

How Amazon SageMaker Runs Your Training Image

To configure a Docker container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For model training, Amazon SageMaker runs the container as follows:

  ```bash
docker run image train
  ```

  SageMaker overrides any default CMD statement in a container by specifying the train argument after the image name. The train argument also overrides arguments that you provide using CMD in the Dockerfile.

- In your dockerfile, use the exec form of the ENTRYPOINT instruction:

  ```bash
  ENTRYPOINT ["executable", "param1", "param2", ...]
  ```

  For example:

  ```bash
  ENTRYPOINT ["python", "k-means-algorithm.py"]
  ```

  The exec form of the ENTRYPOINT instruction starts the executable directly, not as a child of /bin/sh. This enables it to receive signals like SIGTERM and SIGHUP from SageMaker APIs. Note the following:
Use Your Own Training Algorithms

- The CreateTrainingJob API has a stopping condition that directs SageMaker to stop model training after a specific time.

- The StopTrainingJob API issues the equivalent of the `docker stop`, with a 2-minute timeout command to gracefully stop the specified container:

  ```
  docker stop -t120
  ```

  The command attempts to stop the running container by sending a SIGTERM signal. After the 2-minute timeout, SIGKILL is sent and the containers are forcibly stopped. If the container handles the SIGTERM gracefully and exits within 120 seconds from receiving it, no SIGKILL is sent.

  **Note**
  If you want access to the intermediate model artifacts after SageMaker stops the training, add code to handle saving artifacts in your SIGTERM handler.

- If you plan to use GPU devices for model training, make sure that your containers are nvidia-docker compatible. Only the CUDA toolkit should be included on containers; don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

- You can't use the tini initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

- `/opt/ml` and all sub-directories are reserved by SageMaker training. When building your algorithm’s Docker image, please ensure you don’t place any data required by your algorithm under them as the data may no longer be visible during training.

### How Amazon SageMaker Provides Training Information

This section explains how SageMaker makes training information, such as training data, hyperparameters, and other configuration information, available to your Docker container.

When you send a CreateTrainingJob request to SageMaker to start model training, you specify the Amazon Elastic Container Registry path of the Docker image that contains the training algorithm. You also specify the Amazon Simple Storage Service (Amazon S3) location where training data is stored and algorithm-specific parameters. SageMaker makes this information available to the Docker container so that your training algorithm can use it. This section explains how we make this information available to your Docker container. For information about creating a training job, see CreateTrainingJob. For more information on the way that SageMaker containers organize information, see Using the SageMaker Training and Inference Toolkits (p. 2106).

**Topics**

- Hyperparameters (p. 2118)
- Environment Variables (p. 2119)
- Input Data Configuration (p. 2119)
- Training Data (p. 2119)
- Distributed Training Configuration (p. 2120)

### Hyperparameters

SageMaker makes the hyperparameters in a CreateTrainingJob request available in the Docker container in the `/opt/ml/input/config/hyperparameters.json` file.
Environment Variables

The following environment variables are set in the container:

- **TRAINING_JOB_NAME** – Specified in the `TrainingJobName` parameter of the `CreateTrainingJob` request.
- **TRAINING_JOB_ARN** – The Amazon Resource Name (ARN) of the training job returned as the `TrainingJobArn` in the `CreateTrainingJob` response.
- All environment variables specified in the `Environment` parameter in the `CreateTrainingJob` request.

Input Data Configuration

You specify data channel information in the `InputDataConfig` parameter in a `CreateTrainingJob` request. SageMaker makes this information available in the `/opt/ml/input/config/inputdataconfig.json` file in the Docker container.

For example, suppose that you specify three data channels (train, evaluation, and validation) in your request. SageMaker provides the following JSON:

```json
{
    "train" : {
        "ContentType": "trainingContentType",
        "TrainingInputMode": "File",
        "S3DistributionType": "FullyReplicated",
        "RecordWrapperType": "None"},
    "evaluation" : {
        "ContentType": "evalContentType",
        "TrainingInputMode": "File",
        "S3DistributionType": "FullyReplicated",
        "RecordWrapperType": "None"},
    "validation" : {
        "TrainingInputMode": "File",
        "S3DistributionType": "FullyReplicated",
        "RecordWrapperType": "None"}
}
```

**Note**

SageMaker provides only relevant information about each data channel (for example, the channel name and the content type) to the container, as shown. `S3DistributionType` will be set as `FullyReplicated` if specify EFS or FSxLustre as input data sources.

Training Data

The `TrainingInputMode` parameter in a `CreateTrainingJob` request specifies how to make data available for model training: in FILE mode or PIPE mode. Depending on the specified input mode, SageMaker does the following:

- **FILE mode**—SageMaker makes the data for the channel available in the `/opt/ml/input/data/channel_name` directory in the Docker container. For example, if you have three channels named training, validation, and testing, SageMaker makes three directories in the Docker container:
  - `/opt/ml/input/data/training`
  - `/opt/ml/input/data/validation`
  - `/opt/ml/input/data/testing`
  - **Note** Channels that use file system data sources such as Amazon Elastic File System (Amazon EFS) and Amazon FSx must use FILE mode. Also to utilize an Amazon FSx file server, you
must specify a path that begins with /fsx. If a file system is specified, the directory path provided in the channel is mounted at /opt/ml/input/data/channel_name.

- PIPE mode—SageMaker makes data for the channel available from the named pipe: /opt/ml/input/data/channel_name_epoch_number. For example, if you have three channels named training, validation, and testing, you will need to read from the following pipes:
  - /opt/ml/input/data/training_0, /opt/ml/input/data/training_1, ...
  - /opt/ml/input/data/validation_0, /opt/ml/input/data/validation_1, ...
  - /opt/ml/input/data/testing_0, /opt/ml/input/data/testing_1, ...

Read the pipes sequentially. For example, if you have a channel called **training**, read the pipes in this sequence:

1. Open /opt/ml/input/data/training_0 in read mode and read it to end-of-file (EOF) or, if you are done with the first epoch, close the pipe file early.
2. After closing the first pipe file, look for /opt/ml/input/data/training_1 and read it until you have completed the second epoch, and so on.

If the file for a given epoch doesn't exist yet, your code may need to retry until the pipe is created. There is no sequencing restriction across channel types. That is, you can read multiple epochs for the **training** channel, for example, and only start reading the **validation** channel when you are ready. Or, you can read them simultaneously if your algorithm requires that.

### Distributed Training Configuration

If you're performing distributed training with multiple containers, SageMaker makes information about all containers available in the /opt/ml/input/config/resourceconfig.json file.

To enable inter-container communication, this JSON file contains information for all containers. SageMaker makes this file available for both FILE and PIPE mode algorithms. The file provides the following information:

- **current_host**—The name of the current container on the container network. For example, algo-1. Host values can change at any time. Don't write code with specific values for this variable.

- **hosts**—The list of names of all containers on the container network, sorted lexicographically. For example, ["algo-1", "algo-2", "algo-3"] for a three-node cluster. Containers can use these names to address other containers on the container network. Host values can change at any time. Don't write code with specific values for these variables.

- **network_interface_name**—The name of the network interface that is exposed to your container. For example, containers running the Message Passing Interface (MPI) can use this information to set the network interface name.

- Do not use the information in /etc/hostname or /etc/hosts because it might be inaccurate.

- Hostname information may not be immediately available to the algorithm container. We recommend adding a retry policy on hostname resolution operations as nodes become available in the cluster.

The following is an example file on node 1 in a three-node cluster:

```json
{
  "current_host": "algo-1",
  "hosts": ["algo-1","algo-2","algo-3"],
  "network_interface_name": "eth1"
}
```
Run Training with EFA

SageMaker provides integration with EFA devices to accelerate High Performance Computing (HPC) and machine learning applications. This integration allows you to leverage an EFA device when running your distributed training jobs. You can add EFA integration to an existing Docker container that you bring to SageMaker. The following information outlines how to configure your own container to use an EFA device for your distributed training jobs.

Prerequisites

Your container must satisfy the SageMaker Training container specification.

Install EFA and required packages

Your container must download and install the EFA software. This allows your container to recognize the EFA device, and provides compatible versions of Libfabric and Open MPI.

Any tools like MPI and NCCL must be installed and managed inside the container to be used as part of your EFA-enabled training job. The following example shows how to modify the Dockerfile of your EFA-enabled container to install EFA, MPI, OFI, NCCL, and NCCL-TEST.

Note

When using PyTorch with EFA on your container, the NCCL version of your container should match the NCCL version of your PyTorch installation. To verify the PyTorch NCCL version, use the following command:

torch.cuda.nccl.version()

ARG OPEN_MPI_PATH=/opt/amazon/openmpi/
ENV NCCL_VERSION=2.7.8
ENV EFA_VERSION=1.11.2
ENV BRANCH_OFI=1.1.1

### EFA and MPI SETUP
RUN cd $HOME 
   && curl -O https://s3-us-west-2.amazonaws.com/aws-efa-installer/aws-efa-installer-#{EFA_VERSION}.tar.gz 
   && tar -xf aws-efa-installer-#{EFA_VERSION}.tar.gz 
   && cd aws-efa-installer 
   && ./efa_installer.sh -y --skip-kmod -g 

ENV PATH="$OPEN_MPI_PATH/bin:$PATH"
ENV LD_LIBRARY_PATH="$OPEN_MPI_PATH/lib:$LD_LIBRARY_PATH"

### NCCL, OFI, NCCL-TEST SETUP
RUN cd $HOME 
   && git clone https://github.com/NVIDIA/nccl.git -b v#{NCCL_VERSION}-1 
   && cd nccl 
   && make -j64 src.build BUILDDIR=/usr/local 

RUN apt-get update && apt-get install -y autoconf 
RUN cd $HOME 
   && git clone https://github.com/aws/aws-ofi-nccl.git -b v#{BRANCH_OFI} 
   && cd aws-ofi-nccl 
   && ./autogen.sh 
   && ./configure --with-libfabric=/opt/amazon/efa 
   --with-mpi=/opt/amazon/openmpi 
   --with-cuda=/usr/local/cuda 
   --with-nccl=/usr/local --prefix=/usr/local 
   && make && make install
Considerations when creating your container

The EFA device is mounted to the container as /dev/infiniband/uverbs0 under the list of device's accessible to the container. On P4d instances, the container has access to 4 EFA devices. The EFA devices can be found in the list of devices accessible to the container as:

- /dev/infiniband/uverbs0
- /dev/infiniband/uverbs1
- /dev/infiniband/uverbs2
- /dev/infiniband/uverbs3

To get information about hostname, peer hostnames, and network interface (for MPI) from the resourceconfig.json file provided to each container instance, see Distributed Training Configuration. Your container handles regular TCP traffic among peers through the default Elastic Network Interfaces (ENI), while handling OFI (kernel bypass) traffic through the EFA device.

Verify that your EFA device is recognized

To verify that the EFA device is recognized, run the following command from within your container.

```
/opt/amazon/efa/bin/fi_info -p efa
```

Your output should look similar to the following.

```
provider: efa
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-rdm
  version: 2.0
  type: FI_EP_RDM
  protocol: FIPROTO_EFA
provider: efa
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-dgrm
  version: 2.0
  type: FI_EP_DGRAM
  protocol: FIPROTO_EFA
provider: ofi_rxd
  fabric: EFA-fe80::e5:56ff:fe34:56a8
  domain: efa_0-dgrm
  version: 1.0
  type: FI_EP_RDM
  protocol: FIPROTO_RXD
```

Running a training job with EFA

Once you’ve created an EFA-enabled container, you can run a training job with EFA using a SageMaker Estimator the same way as you would with any other docker image. For more information on registering your container and using it for training, see Adapting Your Own Training Container.

How Amazon SageMaker Signals Algorithm Success and Failure

A training algorithm indicates whether it succeeded or failed using the exit code of its process.
A successful training execution should exit with an exit code of 0 and an unsuccessful training execution should exit with a non-zero exit code. These will be converted to Completed and Failed in the TrainingJobStatus returned by DescribeTrainingJob. This exit code convention is standard and is easily implemented in all languages. For example, in Python, you can use `sys.exit(1)` to signal a failure exit, and simply running to the end of the main routine will cause Python to exit with code 0.

In the case of failure, the algorithm can write a description of the failure to the failure file. See next section for details.

### How Amazon SageMaker Processes Training Output

As your algorithm runs in a container, it generates output including the status of the training job and model and output artifacts. Your algorithm should write this information to the following files, which are located in the container’s /output directory. Amazon SageMaker processes the information contained in this directory as follows:

- `/opt/ml/output/failure`—If training fails, after all algorithm output (for example, logging) completes, your algorithm should write the failure description to this file. In a DescribeTrainingJob response, SageMaker returns the first 1024 characters from this file as FailureReason.

- `/opt/ml/model`—Your algorithm should write all final model artifacts to this directory. SageMaker copies this data as a single object in compressed tar format to the S3 location that you specified in the CreateTrainingJob request. If multiple containers in a single training job write to this directory they should ensure no file/directory names clash. SageMaker aggregates the result in a tar file and uploads to s3.

### Use Your Own Inference Code

You can use Amazon SageMaker to interact with Docker containers and run your own inference code in one of two ways:

- To use your own inference code with a persistent endpoint to get one prediction at a time, use SageMaker hosting services.
- To use your own inference code to get predictions for an entire dataset, use SageMaker batch transform.

#### Topics

- Use Your Own Inference Code with Hosting Services (p. 2123)
- Use Your Own Inference Code with Batch Transform (p. 2129)

### Use Your Own Inference Code with Hosting Services

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for hosting services. Use this information to write inference code and create a Docker image.

#### Topics

- How SageMaker Runs Your Inference Image (p. 2124)
- How SageMaker Loads Your Model Artifacts (p. 2125)
- How Containers Serve Requests (p. 2125)
How SageMaker Runs Your Inference Image

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

• For model inference, SageMaker runs the container as:

```bash
docker run image serve
```

SageMaker overrides default CMD statements in a container by specifying the `serve` argument after the image name. The `serve` argument overrides arguments that you provide with the CMD command in the Dockerfile.

• We recommend that you use the `exec` form of the ENTRYPOINT instruction:

```bash
ENTRYPOINT ["executable", "param1", "param2"]
```

For example:

```bash
ENTRYPOINT ["python", "k_means_inference.py"]
```

The `exec` form of the ENTRYPOINT instruction starts the executable directly, not as a child of `/bin/sh`. This enables it to receive signals like SIGTERM and SIGKILL from the SageMaker API operations, which is a requirement.

For example, when you use the CreateEndpoint API to create an endpoint, SageMaker provisions the number of ML compute instances required by the endpoint configuration, which you specify in the request. SageMaker runs the Docker container on those instances.

If you reduce the number of instances backing the endpoint (by calling the UpdateEndpointWeightsAndCapacities API), SageMaker runs a command to stop the Docker container on the instances that are being terminated. The command sends the SIGTERM signal, then it sends the SIGKILL signal thirty seconds later.

If you update the endpoint (by calling the UpdateEndpoint API), SageMaker launches another set of ML compute instances and runs the Docker containers that contain your inference code on them. Then it runs a command to stop the previous Docker containers. To stop a Docker container, command sends the SIGTERM signal, then it sends the SIGKILL signal 30 seconds later.

• SageMaker uses the container definition that you provided in your CreateModel request to set environment variables and the DNS hostname for the container as follows:
• It sets environment variables using the ContainerDefinition.Environment string-to-string map.
• It sets the DNS hostname using the ContainerDefinition.ContainerHostname.
• If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your CreateEndpointConfig request), make sure that your containers are nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.
• You can't use the tini initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

How SageMaker Loads Your Model Artifacts

In your CreateModel request, the container definition includes the ModelDataUrl parameter, which identifies the S3 location where model artifacts are stored. SageMaker uses this information to determine from where to copy the model artifacts. It copies the artifacts to the /opt/ml/model directory for use by your inference code.

The ModelDataUrl must point to a tar.gz file. Otherwise, SageMaker won't download the file.

If you trained your model in SageMaker, the model artifacts are saved as a single compressed tar file in Amazon S3. If you trained your model outside SageMaker, you need to create this single compressed tar file and save it in a S3 location. SageMaker decompresses this tar file into /opt/ml/model directory before your container starts.

How Containers Serve Requests

Containers need to implement a web server that responds to /invocations and /ping on port 8080.

How Your Container Should Respond to Inference Requests

To obtain inferences, the client application sends a POST request to the SageMaker endpoint. For more information, see the InvokeEndpoint API. SageMaker passes the request to the container, and returns the inference result from the container to the client. Note the following:

• SageMaker strips all POST headers except those supported by InvokeEndpoint. SageMaker might add additional headers. Inference containers must be able to safely ignore these additional headers.
• To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the /invocations endpoint.
• A customer's model containers must accept socket connection requests within 250 ms.
• A customer's model containers must respond to requests within 60 seconds. The model itself can have a maximum processing time of 60 seconds before responding to the /invocations. If your model is going to take 50-60 seconds of processing time, the SDK socket timeout should be set to be 70 seconds.

How Your Container Should Respond to Health Check (Ping) Requests

The CreateEndpoint and UpdateEndpoint API calls result in SageMaker starting new inference containers. Soon after container startup, SageMaker starts sending periodic GET requests to the /ping endpoint.
The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the /invocations endpoint.

If the container does not begin to pass health checks, by consistently responding with 200s, during the 4 minutes after startup, CreateEndPoint will fail, leaving the endpoint in a failed state, and the update requested by UpdateEndpoint will not be completed.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on /ping attempts is 2 seconds.

Use a Private Docker Registry for Real-Time Inference Containers

Amazon SageMaker hosting enables you to use images stored in Amazon ECR to build your containers for real-time inference by default. Optionally, you can build containers for real-time inference from images in a private Docker registry. The private registry must be accessible from an Amazon VPC in your account. Models that you create based on the images stored in your private Docker registry must be configured to connect to the same VPC where the private Docker registry is accessible. For information about connecting your model to a VPC, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 2451).

Your Docker registry must be secured with a TLS certificate from a known public certificate authority (CA).

Note
Your private Docker registry must allow inbound traffic from the security groups you specify in the VPC configuration for your model, so that SageMaker hosting is able to pull model images from your registry.
SageMaker can pull model images from DockerHub if there's a path to the open internet inside your VPC.

Topics
- Store Images in a Private Docker Registry other than Amazon Elastic Container Registry (p. 2126)
- Use an Image from a Private Docker Registry for Real-time Inference (p. 2126)
- Allow SageMaker to authenticate to a private Docker registry (p. 2128)
- Create the Lambda function (p. 2128)
- Give your execution role permission to Lambda (p. 2129)
- Create an interface VPC endpoint for Lambda (p. 2129)

Store Images in a Private Docker Registry other than Amazon Elastic Container Registry

To use a private Docker registry to store your images for SageMaker real-time inference, create a private registry that is accessible from your Amazon VPC. For information about creating a Docker registry, see Deploy a registry server in the Docker documentation. The Docker registry must comply with the following:

- The registry must be a Docker Registry HTTP API V2 registry.
- The Docker registry must be accessible from the same VPC that you specify in the VpcConfig parameter that you specify when you create your model.

Use an Image from a Private Docker Registry for Real-time Inference

When you create a model and deploy it to SageMaker hosting, you can specify that it use an image from your private Docker registry to build the inference container. Specify this in the ImageConfig object in the PrimaryContainer parameter that you pass to a call to the create_model function.
To use an image stored in your private Docker registry for your inference container

1. Create the image configuration object and specify a value of Vpc for the RepositoryAccessMode field.

   ```python
ing_image_config = {
   'RepositoryAccessMode': 'Vpc'
   }
```

2. If your private Docker registry requires authentication, add a RepositoryAuthConfig object to the image configuration object. For the RepositoryCredentialsProviderArn field of the RepositoryAuthConfig object, specify the Amazon Resource Name (ARN) of an AWS Lambda function that provides credentials that allows SageMaker to authenticate to your private Docker Registry. For information about how to create the Lambda function to provide authentication, see Allow SageMaker to authenticate to a private Docker registry (p. 2128).

   ```python
ing_image_config = {
   'RepositoryAccessMode': 'Vpc',
   'RepositoryAuthConfig': {
   'RepositoryCredentialsProviderArn':
   'arn:aws:lambda:Region:Acct:function:FunctionName'
   }
   }
```

3. Create the primary container object that you want to pass to create_model, using the image configuration object that you created in the previous step.

   ```python
primary_container = {
   'ContainerHostname': 'ModelContainer',
   'Image': 'myteam.myorg.com/docker-local/my-inference-image:latest',
   'ImageConfig': image_config
   }
```

4. Specify the model name and the execution role that you want to pass to create_model.

   ```python
model_name = 'vpc-model'
execution_role_arn = 'arn:aws:iam::123456789012:role/SageMakerExecutionRole'
```

5. Specify one or more security groups and subnets for the VPC configuration for your model. Your private Docker registry must allow inbound traffic from the security groups that you specify. The subnets that you specify must be in the same VPC as your private Docker registry.

   ```python
vpc_config = {
   'SecurityGroupIds': ['sg-0123456789abcdef0'],
   'Subnets': ['subnet-0123456789abcdef0','subnet-0123456789abcdef1']
   }
```

   ```python
import boto3
sm = boto3.client('sagemaker')
```

7. Create the model by calling create_model, using the values you specified in the previous steps for the PrimaryContainer and VpcConfig parameters.

   ```python
try:
   resp = sm.create_model(
   ModelName=model_name,
   PrimaryContainer=primary_container,
```

2127
Use Your Own Inference Code

```python
ExecutionRoleArn=execution_role_arn,
VpcConfig=vpc_config,
)
except Exception as e:
    print(f'error calling CreateModel operation: {e}')
else:
    print(resp)

8. Finally, call `create_endpoint_config` and `create_endpoint` to create the hosting endpoint, using the
model that you created in the previous step.

```python
eponential_config_name = 'my-endpoint-config'
sm.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            'VariantName': 'MyVariant',
            'ModelName': model_name,
            'InitialInstanceCount': 1,
            'InstanceType': 'ml.t2.medium'
        },
    ],
)
endpoint_name = 'my-endpoint'
sm.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
sm.describe_endpoint(EndpointName=endpoint_name)
```

Allow SageMaker to authenticate to a private Docker registry

To pull an inference image from a private Docker registry that requires authentication, create an AWS
Lambda function that provides credentials, and provide the Amazon Resource Name (ARN) of the
Lambda function when you call `create_model`. When SageMaker runs `create_model`, it calls the
Lambda function that you specified to get credentials to authenticate to your Docker registry.

Create the Lambda function

Create an AWS Lambda function that returns a response with the following form:

```python
def handler(event, context):
    response = {
        "Credentials": {"Username": "username", "Password": "password"}
    }
    return response
```

Depending on how you set up authentication for your private Docker registry, the credentials that your
Lambda function returns can mean either of the following:

- If you set up your private Docker registry to use basic authentication, this is the `username` and
  `password` to authenticate to the registry.
- If you set up your private Docker registry to use bearer token authentication, the `username` and
  `password` are sent to your authorization server, which returns a Bearer token that can then be used to
  authenticate to the private Docker registry.
Give your execution role permission to Lambda

The execution role that you use to call create_model must have permissions to call AWS Lambda functions. Add the following to the permissions policy of your execution role.

```json
{
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:*:*:function:*myLambdaFunction*"
    ]
}
```

Where *myLambdaFunction* is the name of your Lambda function. For information about editing a role permissions policy, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

**Note**
An execution role with the AmazonSageMakerFullAccess managed policy attached to it has permission to call any Lambda function with SageMaker in its name.

Create an interface VPC endpoint for Lambda

Create an interface endpoint so that your Amazon VPC can communicate with your AWS Lambda function without sending traffic over the internet. For information about how to do this, see Configuring interface VPC endpoints for Lambda in the AWS Lambda Developer Guide.

SageMaker hosting sends a request through your VPC to lambda.region.amazonaws.com, to call your Lambda function. If you choose Private DNS Name when you create your interface endpoint, Amazon Route 53 routes the call to the Lambda interface endpoint. If you use a different DNS provider, make sure to map lambda.region.amazonaws.com to your Lambda interface endpoint.

Use Your Own Inference Code with Batch Transform

This section explains how Amazon SageMaker interacts with a Docker container that runs your own inference code for batch transform. Use this information to write inference code and create a Docker image.

**Topics**
- How SageMaker Runs Your Inference Image (p. 2129)
- How SageMaker Loads Your Model Artifacts (p. 2130)
- How Containers Serve Requests (p. 2131)
- How Your Container Should Respond to Inference Requests (p. 2131)
- How Your Container Should Respond to Health Check (Ping) Requests (p. 2132)

**How SageMaker Runs Your Inference Image**

To configure a container to run as an executable, use an ENTRYPOINT instruction in a Dockerfile. Note the following:

- For batch transforms, SageMaker runs the container as:

  ```bash
  docker run image serve
  ```
SageMaker overrides default CMD statements in a container by specifying the `serve` argument after the image name. The `serve` argument overrides arguments that you provide with the CMD command in the Dockerfile.

- We recommend that you use the `exec` form of the `ENTRYPOINT` instruction:

  ```sh
  ENTRYPOINT ["executable", "param1", "param2"]
  ```

  For example:

  ```sh
  ENTRYPOINT ["python", "k_means_inference.py"]
  ```

- SageMaker sets environment variables specified in `CreateModel` and `CreateTransformJob` on your container. Additionally, the following environment variables are populated:
  - `SAGEMAKER_BATCH` is always set to `true` when the container runs in Batch Transform.
  - `SAGEMAKER_MAX_PAYLOAD_IN_MB` is set to the largest size payload that is sent to the container via HTTP.
  - `SAGEMAKER_BATCH_STRATEGY` is set to SINGLE_RECORD when the container is sent a single record per call to invocations and MULTI_RECORD when the container gets as many records as will fit in the payload.
  - `SAGEMAKER_MAX_CONCURRENT_TRANSFORMS` is set to the maximum number of /invocations requests that can be opened simultaneously.

  **Note**
  The last three environment variables come from the API call made by the user. If the user doesn't set values for them, they aren't passed. In that case, either the default values or the values requested by the algorithm (in response to the /execution-parameters) are used.

- If you plan to use GPU devices for model inferences (by specifying GPU-based ML compute instances in your `CreateTransformJob` request), make sure that your containers are nvidia-docker compatible. Don't bundle NVIDIA drivers with the image. For more information about nvidia-docker, see NVIDIA/nvidia-docker.

- You can't use the `init` initializer as your entry point in SageMaker containers because it gets confused by the train and serve arguments.

### How SageMaker Loads Your Model Artifacts

In a `CreateModel` request, container definitions include the `ModelDataUrl` parameter, which identifies the location in Amazon S3 where model artifacts are stored. When you use SageMaker to run inferences, it uses this information to determine from where to copy the model artifacts. It copies the artifacts to the `/opt/ml/model` directory in the Docker container for use by your inference code.

The `ModelDataUrl` parameter must point to a tar.gz file. Otherwise, SageMaker can't download the file. If you train a model in SageMaker, it saves the artifacts as a single compressed tar file in Amazon S3. If you train a model in another framework, you need to store the model artifacts in Amazon S3 as a compressed tar file. SageMaker decompresses this tar file and saves it in the `/opt/ml/model` directory in the container before the batch transform job starts.
How Containers Serve Requests

Containers must implement a web server that responds to invocations and ping requests on port 8080. For batch transforms, you have the option to set algorithms to implement execution-parameters requests to provide a dynamic runtime configuration to SageMaker. SageMaker uses the following endpoints:

- **ping**—Used to periodically check the health of the container. SageMaker waits for an HTTP 200 status code and an empty body for a successful ping request before sending an invocations request. You might use a ping request to load a model into memory to generate inference when invocations requests are sent.

- **(Optional) execution-parameters**—Allows the algorithm to provide the optimal tuning parameters for a job during runtime. Based on the memory and CPUs available for a container, the algorithm chooses the appropriate MaxConcurrentTransforms, BatchStrategy, and MaxPayloadInMB values for the job.

Before calling the invocations request, SageMaker attempts to invoke the execution-parameters request. When you create a batch transform job, you can provide values for the MaxConcurrentTransforms, BatchStrategy, and MaxPayloadInMB parameters. SageMaker determines the values for these parameters using this order of precedence:

1. The parameter values that you provide when you create the CreateTransformJob request.
2. The values that the model container returns when SageMaker invokes the execution-parameters endpoint.
3. The default parameter values, listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxConcurrentTransforms</td>
<td>1</td>
</tr>
<tr>
<td>BatchStrategy</td>
<td>MULTI_RECORD</td>
</tr>
<tr>
<td>MaxPayloadInMB</td>
<td>6</td>
</tr>
</tbody>
</table>

The response for a GET execution-parameters request is a JSON object with keys for MaxConcurrentTransforms, BatchStrategy, and MaxPayloadInMB parameters. This is an example of a valid response:

```json
{
    "MaxConcurrentTransforms": 8,
    "BatchStrategy": "MULTI_RECORD",
    "MaxPayloadInMB": 6
}
```

How Your Container Should Respond to Inference Requests

To obtain inferences, Amazon SageMaker sends a POST request to the inference container. The POST request body contains data from Amazon S3. Amazon SageMaker passes the request to the container, and returns the inference result from the container, saving the data from the response to Amazon S3.

To receive inference requests, the container must have a web server listening on port 8080 and must accept POST requests to the /invocations endpoint. Your model containers must respond to requests within 600 seconds.
How Your Container Should Respond to Health Check (Ping) Requests

The simplest requirement on the container is to respond with an HTTP 200 status code and an empty body. This indicates to SageMaker that the container is ready to accept inference requests at the /invocations endpoint.

While the minimum bar is for the container to return a static 200, a container developer can use this functionality to perform deeper checks. The request timeout on /ping attempts is 2 seconds.

Example Notebooks: Use Your Own Algorithm or Model

The following Jupyter notebooks show how to use your own algorithms or pretrained models from an Amazon SageMaker notebook instance. For links to the GitHub repositories with the prebuilt Dockerfiles for the TensorFlow, MXNet, Chainer, and PyTorch frameworks and instructions on using the AWS SDK for Python (Boto3) estimators to run your own training algorithms on SageMaker Learner and your own models on SageMaker hosting, see Prebuilt SageMaker Docker Images for TensorFlow, MXNet, Chainer, and PyTorch (p. 2092)

Setup

1. Create a SageMaker notebook instance. For instructions on how to create and access Jupyter notebook instances, see Use Amazon SageMaker Notebook Instances (p. 119).
2. Open the notebook instance you created.
3. Choose the SageMaker Examples tab for a list of all SageMaker example notebooks.
4. Open the sample notebooks from the Advanced Functionality section in your notebook instance or from GitHub using the provided links. To open a notebook, choose its Use tab, then choose Create copy.

Host Models Trained in Scikit-learn

To learn how to host models trained in Scikit-learn for making predictions in SageMaker by injecting them into first-party k-means and XGBoost containers, see the following sample notebooks.

- kmeans_bring_your_own_model
- xgboost_bring_your_own_model

Package TensorFlow and Scikit-learn Models for Use in SageMaker

To learn how to package algorithms that you have developed in TensorFlow and scikit-learn frameworks for training and deployment in the SageMaker environment, see the following notebooks. They show you how to build, register, and deploy your own Docker containers using Dockerfiles.

- tensorflow_bring_your_own
- scikit_bring_your_own
Train and Deploy a Neural Network on SageMaker

To learn how to train a neural network locally using MXNet or TensorFlow, and then create an endpoint from the trained model and deploy it on SageMaker, see the following notebooks. The MXNet model is trained to recognize handwritten numbers from the MNIST dataset. The TensorFlow model is trained to classify irises.

- mxnet_mnist_byom
- tensorflow_iris_byom

Training Using Pipe Mode

To learn how to use a Dockerfile to build a container that calls the `train.py` script and uses pipe mode to custom train an algorithm, see the following notebook. In pipe mode, the input data is transferred to the algorithm while it is training. This can decrease training time compared to using file mode.

- pipe_bring_your_own

Bring Your Own R Model

To learn how to use an R container to train and host a model with the R kernel installed in a notebook, see the following notebook. To take advantage of the AWS SDK for Python (Boto3), we use Python within the notebook. You can achieve the same results in R by invoking command line arguments.

- r_bring_your_own

Extend a Prebuilt PyTorch Container Image

To learn how to extend a prebuilt SageMaker PyTorch container image when you have additional functional requirements for your algorithm or model that the prebuilt Docker image doesn't support, see the following notebook.

- pytorch_extending_our_containers

Train and Debug Training Jobs on a Custom Container

To learn how to train and debug training jobs using SageMaker Debugger, see the following notebook. A training script provided through this example uses the TensorFlow Keras ResNet 50 model and the CIFAR10 dataset. A Docker custom container is built with the training script and pushed to Amazon ECR. While the training job is running, Debugger collects tensor outputs and identifies debugging problems. With `smdebug` client library tools, you can set a `smdebug` trial object that calls the training job and debugging information, check the training and Debugger rule status, and retrieve tensors saved in an Amazon S3 bucket to analyze training issues.

- build_your_own_container_with_debugger
Troubleshooting your Docker containers

The following are common errors that you might run into when using Docker containers with SageMaker. Each error is followed by a solution to the error.

- **Error: SageMaker has lost the Docker daemon.**

  To fix this error, restart Docker using the following command.

  ```bash
  sudo service docker restart
  ```
SageMaker Workflows

You can manage your Amazon SageMaker training and inference workflows using Amazon SageMaker Studio and the Amazon SageMaker Python SDK. With the available tools, you can simplify your SageMaker process and integrate it into your existing project.

The following workflow technologies are supported.

- **Amazon SageMaker Model Building Pipelines (p. 2135):** SageMaker's tool for building and managing end-to-end ML pipelines.
- **Airflow Workflows:** SageMaker APIs to export configurations for creating and managing Airflow workflows.
- **Kubernetes Orchestration (p. 2213):** SageMaker custom operators for your Kubernetes cluster, as well as custom components for Kubeflow Pipelines.
- **AWS Step Functions:** Create multi-step machine learning workflows in Python that orchestrate SageMaker infrastructure without having to provision your resources separately.

For more information on managing SageMaker training and inference, see Amazon SageMaker Python SDK Workflows.

Topics

- Amazon SageMaker Model Building Pipelines (p. 2135)
- Automate MLOps with SageMaker Projects (p. 2182)
- Amazon SageMaker ML Lineage Tracking (p. 2206)
- Kubernetes Orchestration (p. 2213)

Amazon SageMaker Model Building Pipelines

Amazon SageMaker Model Building Pipelines is a tool for building machine learning pipelines that take advantage of direct SageMaker integration. Because of this integration, you can create a pipeline and set up SageMaker Projects for orchestration using a tool that handles much of the step creation and management for you. SageMaker Pipelines provides the following advantages over other AWS workflow offerings:

**SageMaker Integration**

SageMaker Pipelines is integrated directly with SageMaker, so you don't need to interact with any other AWS services. You also don't need to manage any resources because SageMaker Pipelines is a fully managed service, which means that it creates and manages resources for you.

**SageMaker Python SDK Integration**

Because SageMaker Pipelines is integrated with the SageMaker Python SDK, you can create your pipelines programmatically using a high-level Python interface that you might already be familiar with. To view the SageMaker Python SDK documentation, see Pipelines.

**SageMaker Studio Integration**
SageMaker Studio offers an environment to manage the end-to-end SageMaker Pipelines experience. Using Studio, you can bypass the AWS console for your entire workflow management. For more information on managing SageMaker Pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2169).

Data Lineage Tracking

With SageMaker Pipelines you can track the history of your data within the pipeline execution. Amazon SageMaker ML Lineage Tracking lets you analyze where the data came from, where it was used as an input, and the outputs that were generated from it. For example, you can view the models created from an individual dataset, and you can view the datasets that went into creating an individual model. For more information, see Amazon SageMaker ML Lineage Tracking (p. 2206).

Step Reuse

With SageMaker Pipelines, you can designate steps for caching. When a step is cached, it is indexed for reuse later if the same step is executed again. As a result, you can reuse the output from previous step executions of the same step in the same pipeline without having to run the step again. For more information on step caching, see Caching Pipeline Steps (p. 2147).

Topics

- SageMaker Pipelines Overview (p. 2136)
- Create and Manage SageMaker Pipelines (p. 2153)

SageMaker Pipelines Overview

An Amazon SageMaker Model Building Pipelines pipeline is a series of interconnected steps that is defined by a JSON pipeline definition. This pipeline definition encodes a pipeline using a directed acyclic graph (DAG). This DAG gives information on the requirements for and relationships between each step of your pipeline. The structure of a pipeline's DAG is determined by the data dependencies between steps. These data dependencies are created when the properties of a step's output are passed as the input to another step. The following image is an example of a pipeline DAG:
The following topics describe fundamental SageMaker Pipelines concepts. For a tutorial describing the implementation of these concepts, see Create and Manage SageMaker Pipelines (p. 2153).

Topics
- Pipeline Structure (p. 2138)
- Access Management (p. 2138)
- Pipeline Parameters (p. 2139)
- Pipeline Steps (p. 2140)
- Property Files and JsonGet (p. 2146)
- Caching Pipeline Steps (p. 2147)
- Amazon EventBridge Integration (p. 2148)
Pipeline Structure

A pipeline instance is composed of a name, parameters, and steps. Pipeline names must be unique within an (account, region) pair. All parameters used in step definitions must be defined in the pipeline. Steps passed into the pipeline don't need to be listed in the order of execution because the steps themselves define the relationships between them using data dependencies. The SageMaker Pipelines service resolves the relationships between steps in the data dependency DAG to create a series of steps that the execution completes. The following is an example of a pipeline structure.

```python
from sagemaker.workflow.pipeline import Pipeline

pipeline_name = f"AbalonePipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_type,
        processing_instance_count,
        training_instance_type,
        model_approval_status,
        input_data,
        batch_data,
    ],
    steps=[step_process, step_train, step_eval, step_cond],
)
```

Access Management

The following sections describe the AWS Identity and Access Management (IAM) requirements for Amazon SageMaker Model Building Pipelines. For an example of how you can implement these permissions, see Prerequisites (p. 2155).

Topics
- Pipeline Role Permissions (p. 2138)
- Pipeline Step Permissions (p. 2139)
- Service Control Policies with Pipelines (p. 2139)

Pipeline Role Permissions

Your pipeline requires an IAM pipeline execution role that is passed to SageMaker Pipelines when you create a pipeline. The role for the SageMaker instance that is creating the pipeline must have the `iam:PassRole` permission for the pipeline execution role in order to pass it. For more information on IAM roles, see IAM Roles.

Your pipeline execution role requires the following permissions:

- To pass any role to a SageMaker job within a pipeline, the `iam:PassRole` permission for the role that is being passed.
- Create and Describe permissions for each of the job types in the pipeline.
- Amazon S3 permissions to use the `JsonGet` function. You control access to your Amazon S3 resources using resource-based policies and identity-based policies. A resource-based policy is applied to your Amazon S3 bucket and grants SageMaker Pipelines access to the bucket. An identity-based policy gives your pipeline the ability to make Amazon S3 calls from your account. For more information on
resource-based policies and identity-based policies, see Identity-based policies and resource-based policies.

{
  "Action": [
    "s3:GetObject",
    "s3:HeadObject"
  ],
  "Resource": "arn:aws:s3:::<your-bucket-arn>/*",
  "Effect": "Allow"
}

Pipeline Step Permissions

SageMaker Pipelines include steps that run SageMaker jobs. In order for the pipeline steps to run these jobs, they require an IAM role in your account that provides access for the needed resource. This role is passed to the SageMaker service principal by your pipeline. For more information on IAM roles, see IAM Roles.

By default, each step takes on the pipeline execution role. You can optionally pass a different role to any of the steps in your pipeline. This ensures that the code in each step does not have the ability to impact resources used in other steps unless there is a direct relationship between the two steps specified in the pipeline definition. You pass these roles when defining the processor or estimator for your step. For examples of how to include these roles in these definitions, see the SageMaker Python SDK documentation.

Service Control Policies with Pipelines

Service control policies (SCPs) are a type of organization policy that you can use to manage permissions in your organization. SCPs offer central control over the maximum available permissions for all accounts in your organization. By using SageMaker Pipelines within your organization, you can ensure that data scientists manage your pipeline executions without having to interact with the AWS console.

If you're using a VPC with your SCP that restricts access to Amazon S3, you need to take steps to allow your pipeline to access other Amazon S3 resources.

To allow SageMaker Pipelines to access Amazon S3 outside of your VPC with the JsonGet function, update your organization's SCP to ensure that the role using SageMaker Pipelines can access Amazon S3. To do this, create an exception for roles that are being used by the SageMaker Pipelines executor via the pipeline execution role using a principal tag and condition key.

To allow SageMaker Pipelines to access Amazon S3 outside of your VPC

1. Create a unique tag for your pipeline execution role following the steps in Tagging IAM users and roles.
2. Grant an exception in your SCP using the Aws:PrincipalTag IAM condition key for the tag you created. For more information, see Creating, updating, and deleting service control policies.

Pipeline Parameters

You can introduce variables into your pipeline definition using parameters. Parameters that you define can be referenced throughout your pipeline definition. Parameters have a default value, which you can override by specifying parameter values when starting a pipeline execution. The default value must be an instance matching the parameter type. All parameters used in step definitions must be defined in your pipeline definition. Amazon SageMaker Model Building Pipelines supports the following parameter types:
• **ParameterString** – Representing a `str` Python type.
• **ParameterInteger** – Representing an `int` Python type.
• **ParameterFloat** – Representing a `float` Python type.

Parameters take the following format:

```python
<parameter> = <parameter_type>(
    name="<parameter_name>",
    default_value=<default_value>
)
```

The following shows an example parameter implementation:

```python
from sagemaker.workflow.parameters import (ParameterInteger,
                                           ParameterString,
                                           ParameterFloat)

processing_instance_count = ParameterInteger(
    name="ProcessingInstanceCount",
    default_value=1)
```

You pass the parameter when creating your pipeline as follows:

```python
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_count
    ],
    steps=[step_process]
)
```

You can also pass a parameter value that differs from the default value to a pipeline execution as follows:

```python
execution = pipeline.start(
    parameters=dict(
        ProcessingInstanceType="ml.c5.xlarge",
        ModelApprovalStatus="Approved"
    )
)
```

**Pipeline Steps**

SageMaker Pipelines are composed of steps. These steps define the actions that the pipeline takes, and the relationships between steps using properties.

**Topics**

• Step Types (p. 2141)
• Step Properties (p. 2144)
• Data Dependency Between Steps (p. 2145)
• Custom Dependency Between Steps (p. 2145)
• Use a Custom Image in a Step (p. 2146)
Step Types

The following describes the requirements of each step type and provides an example implementation of the step. These are not functional implementations because they don’t provide the resource and inputs needed. For a tutorial that implements these steps, see Create and Manage SageMaker Pipelines (p. 2153).

Amazon SageMaker Model Building Pipelines support the following step types:

- Processing (p. 2141)
- Training (p. 2142)
- Transform (p. 2143)
- CreateModel (p. 2143)
- RegisterModel (p. 2143)
- Condition (p. 2144)

Processing Step

You use a processing step to create a processing job for data processing. For more information on processing jobs, see Process Data and Evaluate Models.

A processing step requires a processor, a Python script that defines the processing code, outputs for processing, and job arguments. The following example shows how to create a ProcessingStep definition. For more information on processing step requirements, see the sagemaker.workflow.steps.ProcessingStep documentation.

```python
from sagemaker.sklearn.processing import SKLearnProcessor
sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                       role=<role>,
                                       instance_type='ml.m5.xlarge',
                                       instance_count=1)

from sagemaker.processing import ProcessingInput, ProcessingOutput
from sagemaker.workflow.steps import ProcessingStep
step_process = ProcessingStep(
    name="AbaloneProcess",
    processor=sklearn_processor,
    inputs=[
        ProcessingInput(source=<input_data>, destination="/opt/ml/processing/input"),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="abalone/preprocessing.py"
)
```

Pass runtime parameters

You can pass runtime parameters to a processing step using the get_run_args method of the Amazon SageMaker Python SDK. This allows you to use processors besides SKLearnProcessor such as PySparkProcessor and SparkJarProcessor.

The following example shows how to pass runtime parameters from a PySpark processor to a ProcessingStep.
from sagemaker.spark.processing import PySparkProcessor

pyspark_processor = PySparkProcessor(framework_version='2.4',
    role=<role>,
    instance_type='ml.m5.xlarge',
    instance_count=1)

...
Transform Step

You use a transform step for batch transformation to run inference on an entire dataset. For more information on batch transformation, see Run Batch Transforms with Inference Pipelines.

A transform step requires a transformer, and the data to run batch transformation on. The following example shows how to create a Transform step definition. For more information on Transform step requirements, see the sagemaker.workflow.steps.TransformStep documentation.

```python
from sagemaker.inputs import TransformInput
from sagemaker.workflow.steps import TransformStep

step_transform = TransformStep(
    name="AbaloneTransform",
    transformer=transformer,
    inputs=TransformInput(data=batch_data)
)
```

CreateModel Step

You use a CreateModel step to create a SageMaker Model. For more information on SageMaker Models, see Train a Model with Amazon SageMaker.

A CreateModel step requires model artifacts, and information on the SageMaker instance type that you need to use to create the model. The following example shows how to create a CreateModel step definition. For more information on CreateModel step requirements, see the sagemaker.workflow.steps.CreateModelStep documentation.

```python
from sagemaker.workflow.steps import CreateModelStep

step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=model,
    inputs=inputs
)
```

For more information on the available steps and their input requirements, see the Pipelines documentation.

RegisterModel Step

You use a RegisterModel step to register a model to a model group. For more information on registering models, see Register and Deploy Models with Model Registry (p. 1840).

A RegisterModel step requires an estimator, model data output from training, and a model package group name to associate the model package with. The following example shows how to create a RegisterModel definition. For more information on RegisterModel step requirements, see the sagemaker.workflow.step_collections.RegisterModel documentation.

```python
from sagemaker.workflow.step_collections import RegisterModel

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    estimator=xgb_train,
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    content_types=["text/csv"],
)
Condition Step

You use a condition step to evaluate the condition of step properties to assess which action should be taken next in the pipeline.

A condition step requires a list of conditions, and a list of steps to execute if the condition evaluates to true and a list of steps to execute if the condition evaluates to false. The following example shows how to create a Condition step definition. For more information on Condition step requirements, see the sagemaker.workflow.condition_step.ConditionStep documentation.

Limitations

- SageMaker Pipelines doesn't support the use of nested condition steps. You can't pass a condition step as the input for another condition step.
- A condition step can't use identical steps in both branches. If you need the same step functionality in both branches, duplicate the step and give it a different name.

```python
from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.workflow.condition_step import ConditionStep, JsonGet

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step=step_eval,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"),
    right=6.0)

step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[])
```

Step Properties

The `properties` attribute is used to add data dependencies between steps in the pipeline. These data dependencies are then used by SageMaker Pipelines to construct the DAG from the pipeline definition. These properties can be referenced as placeholder values and are resolved at runtime.

The `properties` attribute of a SageMaker Pipelines step matches the object returned by a `Describe` call for the corresponding SageMaker job type. For each job type, the `Describe` call returns the following response object:

- ProcessingStep – DescribeProcessingJob
- TrainingStep – DescribeTrainingJob
Data Dependency Between Steps

You define the structure of your DAG by specifying the data relationships between steps. To create data dependencies between steps, pass the properties of one step as the input to another step in the pipeline. The step receiving the input isn’t started until after the step providing the input finishes execution.

A data dependency uses JsonPath notation in the following format. This format traverses the JSON property file, which means you can append as many <property> instances as needed to reach the desired nested property in the file. For more information on JsonPath notation, see the JsonPath repo.

```python
<step_name>.properties.<property>.<property>
```

The following shows how to specify an Amazon S3 bucket using the `ProcessingOutputConfig` property of a processing step.

```python
step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
```

To create the data dependency, pass the bucket to a training step as follows.

```python
step_train = TrainingStep(
    name="CensusTrain",
    estimator=sklearn_train,
    inputs=TrainingInput(
        s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
    )
)
```

Custom Dependency Between Steps

When you specify a data dependency, SageMaker Pipelines provides the data connection between the steps. Alternatively, one step can access the data from a previous step without directly using SageMaker Pipelines. In this case, you can create a custom dependency that tells SageMaker Pipelines not to start a step until after another step has finished executing. You create a custom dependency by specifying a step’s `DependsOn` attribute.

As an example, the following defines a step C that starts only after both step A and step B finish executing.

```python
{
    'Steps': [
        {'Name': 'A', ...},
        {'Name': 'B', ...},
        {'Name': 'C', 'DependsOn': ['A', 'B']}
    ]
}
```

SageMaker Pipelines throws a validation exception if the dependency would create a cyclic dependency.

The following example creates a training step that starts after a processing step finishes executing.

```python
processing_step = ProcessingStep(...)  
training_step = TrainingStep(...) 
```
The following example creates a training step that doesn't start until two different processing steps finish executing.

```python
custom_dependencies = training_step.depends_on()
```

The following example shows how to retrieve a string list of the custom dependencies of a step.

```python
training_step.add_depends_on([processing_step_1])
training_step.add_depends_on([processing_step_2])
```

The following example creates a training step that receives input from one processing step and waits for a different processing step to finish executing.

```python
...,
inputs=TrainingInput(
    s3_data=processing_step_1.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
)
training_step.add_depends_on([processing_step_2])
```

### Use a Custom Image in a Step

You can use any of the available SageMaker Deep Learning Container images when you create a step in your pipeline.

You can also create a step using SageMaker S3 applications. A SageMaker S3 application is a tar.gz bundle with one or more Python scripts that can run within that bundle. For more information on application package bundling, see Deploying directly from model artifacts.

You can also use your own container with pipeline steps. Because you can't create an image from within SageMaker Studio, you must create your image using another method before using it with Amazon SageMaker Model Building Pipelines.

To use your own container when creating the steps for your pipeline, include the image URI in the estimator definition. For more information on using your own container with SageMaker, see Using Docker Containers with SageMaker.

### Property Files and JsonGet

You use property files to store information from the output of a processing step. This is particularly useful when analyzing the results of a processing step to decide how a conditional step should be
The `JsonGet` function processes a property file and enables you to use JsonPath notation to query the property JSON file. For more information on JsonPath notation, see the JsonPath repo.

To store a property file for later use, you must first create a `PropertyFile` instance with the following format. The `path` parameter is the name of the JSON file that the property file is saved to. `output_name` must match the `output_name` of the `ProcessingOutput` that you define in your processing step. This enables the property file to capture the `ProcessingOutput` in the step.

```python
from sagemaker.workflow.properties import PropertyFile

<property_file_instance> = PropertyFile(
    name="<property_file_name>",
    output_name="<processingoutput_output_name>",
    path="<path_to_json_file>"
)
```

When you create your `ProcessingStep` instance, add the `property_files` parameter to list all of the parameter files that the Amazon SageMaker Model Building Pipelines service must index. This saves the property file for later use.

```
property_files=[<property_file_instance>]
```

To use your property file in a condition step, add the `property_file` to the condition that you pass to your condition step as follows. This enables you to query the JSON file for your desired property using the `json_path` parameter.

```python
cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step=step_eval,
        property_file=<property_file_instance>,
        json_path="mse"
    ),
    right=6.0
)
```

### Caching Pipeline Steps

When you use step signature caching, before SageMaker Pipelines executes a step, it attempts to find a previous execution of a step that was called with the same arguments. SageMaker Pipelines checks that the call signatures are identical. Pipelines doesn't check whether the data or code that the arguments point to has changed. If a previous execution is found, a cache hit is created. Pipelines then propagates the values from the cache hit during execution, rather than recomputing the step.

Step caching only considers successful executions, so no failed executions are ever reused. When multiple successful executions exist within the timeout period, Pipelines uses the result for the most recent successful execution. If no successful executions match in the timeout period, Pipelines won't reuse any steps. If the executor finds a cache hit for a previous step execution that is still in progress, both steps continue executing and update the cache, if they're successful.

You must opt-in to step caching, otherwise it is off by default. When you enable step caching, you must also define a timeout. This timeout defines how old a previous execution can be to be considered for reuse.

Step caching is only scoped for individual pipelines, so you can't reuse a step from another pipeline. Even if there is a step signature match in the other pipeline, the step is not reused.

Step caching is available for the following step types:
- Training
- Processing
- Transform

**Enabling Step Caching**

To enable step caching, you must add a `CacheConfig` property to the step definition. `CacheConfig` properties use the following format in the pipeline definition file.

```
{
  "CacheConfig": {
    "Enabled": false,
    "ExpireAfter": "<time>
  }
}
```

The `Enabled` field may be true or false. `ExpireAfter` is a string that defines the timeout period. Any ISO 8601 duration string is a valid `ExpireAfter` value. The `ExpireAfter` duration can contain a year, month, week, day, hour, and minute value. Each value is consists of a number followed by a letter indicating the duration unit it is for. For example:

- "30d" = Thirty days
- "5y" = Five years
- "T16m" = 16 minutes
- "30dT5h" = 30 days and five hours.

The following example shows how to enable caching for a training step using the Amazon SageMaker Python SDK.

```python
cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
step_train = TrainingStep(
    name="TrainAbaloneModel",
    estimator=xgb_train,
    inputs=inputs,
    cache_config=cache_config
)
```

**Amazon EventBridge Integration**

You can schedule your Amazon SageMaker Model Building Pipelines executions using Amazon EventBridge. Amazon SageMaker Model Building Pipelines is supported as a target in Amazon EventBridge. This allows you to trigger the execution of your model building pipeline based on any event in your event bus. EventBridge enables you to automate your pipeline executions and respond automatically to events such as training job or endpoint status changes. Events include a new file being uploaded to your Amazon S3 bucket, a change in status of your Amazon SageMaker endpoint due to drift, and Amazon Simple Notification Service (SNS) topics.

The following SageMaker Pipelines actions can be automatically triggered:

- StartPipelineExecution

For more information on scheduling SageMaker jobs, see Automating SageMaker with Amazon EventBridge.
Schedule a Pipeline with Amazon EventBridge

To start a pipeline execution with Amazon CloudWatch Events, you must create an EventBridge rule. When you create a rule for events, you specify a target action to take when EventBridge receives an event that matches the rule. When an event matches the rule, EventBridge sends the event to the specified target and triggers the action defined in the rule.

The following tutorials show how to schedule a pipeline execution with EventBridge using the EventBridge console or the AWS CLI.

Prerequisites

- A role that can be assumed by EventBridge with the `SageMaker::StartPipelineExecution` permission. This role can be created automatically if you create a rule from the EventBridge console, otherwise you need to create this role yourself. For information on creating a SageMaker role, see SageMaker Roles.
- An Amazon SageMaker Pipeline to schedule. To create an Amazon SageMaker Pipeline, see Define a Pipeline.

Create an EventBridge rule using the EventBridge console

The following procedure shows how to create an EventBridge rule using the EventBridge console.

1. Navigate to the EventBridge console.
2. Select Rules on the left hand side.
3. Select Create Rule.
4. Enter a name and description for your rule.
5. Select how you want this rule to be triggered. You have the following choices for your rule:
   - **Event pattern**: Your rule is triggered when an event matching the pattern occurs. You can choose a pre-defined pattern that matches a certain type of event, or you can create a custom pattern. If you select a pre-defined pattern, you can edit the pattern to customize it. For more information on Event patterns, see Event Patterns in CloudWatch Events.
   - **Schedule**: Your rule is triggered regularly on a specified schedule. You can use a fixed-rate schedule that triggers regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as “the first Monday of each month at 8am.” Schedule is not supported on a custom or partner event bus.
6. Select your desired Event bus.
7. Select the target(s) to invoke when an event matches your event pattern or when the schedule is triggered. You can add up to 5 targets per rule. Select SageMaker Pipeline in the target drop-down.
8. Select the pipeline you want to trigger from the pipeline drop-down.
9. Add parameters to pass to your pipeline execution using a name and value pair. Parameter values can be static or dynamic. For more information on Amazon SageMaker Pipeline parameters, see AWS::Events::Rule SagemakerPipelineParameters.
   - Static values are passed to the pipeline execution every time the pipeline is triggered. For example, if `{"Name": "Instance_type", "Value": "ml.4xlarge"}` is specified in the parameter list, then it will be passed as a parameter in StartPipelineExecutionRequest every time EventBridge triggers the pipeline.
   - Dynamic values are specified using a json path. EventBridge parses the value from an event payload, then passes it to the pipeline execution. For example: `$.detail.param.value`
10. Select the role to use for this rule. You can either use an existing role or create a new one.
11. (Optional) Add tags.
12. Select Create to finalize your rule.

Your rule is now in effect and ready to trigger your pipeline executions.

Create an EventBridge rule using the AWS CLI

The following procedure shows how to create an EventBridge rule using the AWS CLI.

1. Create a rule to be triggered. When creating an EventBridge rule using the AWS CLI, you have two options for how your rule is triggered, event pattern and schedule.
   - **Event pattern**: Your rule is triggered when an event matching the pattern occurs. You can choose a pre-defined pattern that matches a certain type of event, or you can create a custom pattern. If you select a pre-defined pattern, you can edit the pattern to customize it. You can create a rule with event pattern using the following command:
     
     ```
     aws events put-rule --name <RULE_NAME> --event-pattern <YOUR_EVENT_PATTERN> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

   - **Schedule**: Your rule is triggered regularly on a specified schedule. You can use a fixed-rate schedule that triggers regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as "the first Monday of each month at 8am." Schedule is not supported on a custom or partner event bus. You can create a rule with schedule using the following command:
     
     ```
     aws events put-rule --name <RULE_NAME> --schedule-expression <YOUR_CRON_EXPRESSION> --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
     ```

2. Add target(s) to invoke when an event matches your event pattern or when the schedule is triggered. You can add up to 5 targets per rule. For each target, you must specify:
   - ARN: The resource ARN of your pipeline.
   - Role ARN: The ARN of the role EventBridge should assume to execute the pipeline.
   - Parameters: Amazon SageMaker pipeline parameters to pass.

3. Run the following command to pass a Amazon SageMaker pipeline as a target to your rule using put-targets:

   ```
   aws events put-targets --rule <RULE_NAME> --event-bus-name <EVENT_BUS_NAME> --targets 
   "{"Id": "1D", "Arn": <RESOURCE_ARN>, "RoleArn": <ROLE_ARN>, "SageMakerPipelineParameter": { "SageMakerPipelineParameterList": [{ "Name": <NAME>, "Value": <VALUE>}] } }
   ```

SageMaker Pipelines Quotas

The following tables list the quotas for SageMaker Pipelines resources and requirements for pipeline creation.

### Pipeline Quotas

<table>
<thead>
<tr>
<th>Pipeline Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of pipelines</td>
<td>5000</td>
</tr>
</tbody>
</table>
## Executions Quotas

<table>
<thead>
<tr>
<th>Execution Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum execution time</td>
<td>28 days</td>
</tr>
<tr>
<td>Maximum number of concurrent pipeline executions per account</td>
<td>200</td>
</tr>
<tr>
<td>Maximum number of concurrent pipeline executions per pipeline</td>
<td>200</td>
</tr>
</tbody>
</table>

## Step Quotas

<table>
<thead>
<tr>
<th>Step Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of steps per pipeline</td>
<td>50</td>
</tr>
<tr>
<td>Maximum step name length</td>
<td>64 characters</td>
</tr>
<tr>
<td>Step name regular expression pattern</td>
<td>([A-Za-z0-9-_])*</td>
</tr>
</tbody>
</table>

## Parameters Quotas

<table>
<thead>
<tr>
<th>Parameters Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of parameters per pipeline</td>
<td>200</td>
</tr>
<tr>
<td>Maximum parameter name length</td>
<td>64 characters</td>
</tr>
<tr>
<td>Maximum parameter name regular expression pattern</td>
<td>([A-Za-z0-9-_])*</td>
</tr>
<tr>
<td>Maximum parameter description length</td>
<td>4096 characters</td>
</tr>
<tr>
<td>Maximum number of parameter enum values</td>
<td>16 distinct values</td>
</tr>
<tr>
<td>Maximum parameter enum value length</td>
<td>2048 characters</td>
</tr>
<tr>
<td>Maximum string default value limit</td>
<td>2048 characters</td>
</tr>
</tbody>
</table>

## Condition Step Quotas

<table>
<thead>
<tr>
<th>Condition Step Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of Conditions per ConditionStep</td>
<td>200</td>
</tr>
<tr>
<td>Maximum number of Steps in If-List</td>
<td>20</td>
</tr>
<tr>
<td>Maximum number of Steps in Else-List</td>
<td>20</td>
</tr>
<tr>
<td>Maximum number of Conditions in an Or-list</td>
<td>200</td>
</tr>
</tbody>
</table>
Property Files Quotas

<table>
<thead>
<tr>
<th>Property Files Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum number of PropertyFiles in a pipeline</td>
<td>10</td>
</tr>
<tr>
<td>Maximum number of JsonGet functions in a pipeline</td>
<td>200</td>
</tr>
<tr>
<td>Maximum size of the property file</td>
<td>2MB</td>
</tr>
</tbody>
</table>

Metadata Quotas

<table>
<thead>
<tr>
<th>Metadata Property</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum metadata size</td>
<td>20 key-value pairs</td>
</tr>
<tr>
<td>Maximum metadata key size</td>
<td>128 characters</td>
</tr>
<tr>
<td>Metadata key regular expression pattern</td>
<td>([A-Za-z0-9-_]<em>)</em></td>
</tr>
<tr>
<td>Maximum metadata value size</td>
<td>1024 characters</td>
</tr>
<tr>
<td>Metadata value regular expression pattern</td>
<td>\p(M)\p(L)\p(S)\p(S)\p(N)\p(P)\s</td>
</tr>
</tbody>
</table>

Troubleshooting Amazon SageMaker Model Building Pipelines

When using Amazon SageMaker Model Building Pipelines, you might run into issues for various reasons. This topic provides information about common errors and how to resolve them.

**Pipeline Definition Issues**

Your pipeline definition might not be formatted correctly. This can result in your execution failing or your job being inaccurate. These errors can be caught when the pipeline is created or when an execution occurs. If your definition doesn't validate, SageMaker Pipelines returns an error message identifying the character where the JSON file is malformed. To fix this problem, review the steps created using the SageMaker Python SDK for accuracy.

You can only include steps in a pipeline definition once. Because of this, steps cannot exist as part of a Condition step and a pipeline in the same pipeline.

**Examining Pipeline Logs**

You can view the status of your steps using the following command:

```python
execution.list_steps()
```

Each step includes the following information:

- The ARN of the entity launched by the pipeline – Such as SageMaker job ARN, model ARN, or model package ARN.
- The failure reason – Includes a brief explanation of the step failure.
• Condition step evaluation – If the step is a condition step, it includes whether the condition is evaluated to true or false.

• The CacheHit – If the execution is reusing a previous job execution, it lists the source execution.

You can also view the error messages and logs in the SageMaker Studio interface. For information about how to see the logs in Studio, see View a Pipeline Execution (p. 2173).

Missing Permissions

Correct permissions are required for the role that creates the pipeline execution, and the steps that create each of the jobs in your pipeline execution. Without these permissions, you may not be able to submit your pipeline execution or run your SageMaker jobs as expected. To ensure that your permissions are properly set up, see Access Management (p. 2138).

Job Execution Errors

You may run into issues when executing your steps because of issues in the scripts that define the functionality of your SageMaker jobs. Each job has a set of CloudWatch logs. To view these logs from SageMaker Studio, see View a Pipeline Execution (p. 2173). For information about using CloudWatch logs with SageMaker, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 2470).

Property File Errors

You may have issues when incorrectly implementing property files with your pipeline. To ensure that your implementation of property files works as expected, see Property Files and JsonGet (p. 2146).

Create and Manage SageMaker Pipelines

You can use Amazon SageMaker Model Building Pipelines to create end-to-end workflows that manage and deploy SageMaker jobs. SageMaker Pipelines comes with SageMaker Python SDK integration, so you can build each step of your pipeline using a Python-based interface.

After your pipeline is deployed, you can view the directed acyclic graph (DAG) for your pipeline and manage your executions using Amazon SageMaker Studio. Using SageMaker Studio, you can get information about your current and historical pipelines, compare executions, see the DAG for your executions, get metadata information, and more. To learn how to view pipelines from SageMaker Studio, see View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2169).

Topics

• Define a Pipeline (p. 2153)

• Run a pipeline (p. 2166)

• View, Track, and Execute SageMaker Pipelines in SageMaker Studio (p. 2169)

Define a Pipeline

To orchestrate your workflows with Amazon SageMaker Model Building Pipelines, you need to generate a directed acyclic graph (DAG) in the form of a JSON pipeline definition. The following image is a representation of the pipeline DAG that you create in this tutorial:
You can generate your JSON pipeline definition using the SageMaker Python SDK. The following tutorial shows how to generate a pipeline definition for a pipeline that solves a regression problem to determine the age of an abalone based on its physical measurements. For a Jupyter notebook that includes the content in this tutorial that you can run, see Orchestrating Jobs with Amazon SageMaker Model Building Pipelines.

**Topics**

- Prerequisites (p. 2155)
- Create a Pipeline (p. 2155)
Prerequisites

To run the following tutorial you must do the following:

- Set up your notebook instance as outlined in Create a notebook instance. This gives your role permissions to read and write to Amazon S3, and create training, batch transform, and processing jobs in SageMaker.
- Grant your notebook permissions to get and pass its own role as shown in Modifying a role permissions policy. Add the following JSON snippet to attach this policy to your role. Replace `<your-role-arn>` with the ARN used to create your notebook instance.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iam:GetRole",
            "iam:PassRole"
         ],
         "Resource": "<your-role-arn>"
      }
   ]
}
```

- Trust the SageMaker service principal by following the steps in Modifying a role trust policy. Add the following statement fragment to the trust relationship of your role:

```json
{
   "Sid": ",
   "Effect": "Allow",
   "Principal": {
      "Service": "sagemaker.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
}
```

Set Up Your Environment

Create a new SageMaker session using the following code block. This returns the role ARN for the session. This role ARN should be the execution role ARN that you set up as a prerequisite.

```python
import boto3
import sagemaker
import sagemaker.session

region = boto3.Session().region_name
sagemaker_session = sagemaker.session.Session()
role = sagemaker.get_execution_role()
default_bucket = sagemaker_session.default_bucket()
model_package_group_name = f"AbaloneModelPackageGroupName"
```

Create a Pipeline

Run the following steps from your SageMaker notebook instance to create a pipeline including steps for preprocessing, training, evaluation, conditional evaluation, and model registration.
Step 1: Download the Dataset

This notebook uses the UCI Machine Learning Abalone Dataset. The dataset contains the following features:

- **length** – The longest shell measurement of the abalone.
- **diameter** – The diameter of the abalone perpendicular to its length.
- **height** – The height of the abalone with meat in the shell.
- **whole_weight** – The weight of the whole abalone.
- **shucked_weight** – The weight of the meat removed from the abalone.
- **viscera_weight** – The weight of the abalone viscera after bleeding.
- **shell_weight** – The weight of the abalone shell after meat removal and drying.
- **sex** – The sex of the abalone. One of 'M', 'F', or 'I', where 'I' is an infant abalone.
- **rings** – The number of rings in the abalone shell.

The number of rings in the abalone shell is a good approximation for its age using the formula
\[
\text{age} = \text{rings} + 1.5
\]
However, obtaining this number is a time-consuming task. You must cut the shell through the cone, stain the section, and count the number of rings through a microscope. However, the other physical measurements are easier to determine. This notebook uses the dataset to build a predictive model of the variable rings using the other physical measurements.

To download the dataset

1. Download the dataset into your account’s default Amazon S3 bucket.

   ```bash
   $ mkdir -p data
   local_path = "data/abalone-dataset.csv"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file("dataset/abalone-dataset.csv",
   local_path
   )
   base_uri = f"s3://{default_bucket}/abalone"
   input_data_uri = sagemaker.s3.S3Uploader.upload(
   local_path=local_path,
   desired_s3_uri=base_uri,
   )
   print(input_data_uri)
   
2. Download a second dataset for batch transformation after your model is created.

   ```bash
   local_path = "data/abalone-dataset-batch"
   s3 = boto3.resource("s3")
   s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file("dataset/abalone-dataset-batch",
   local_path
   )
   base_uri = f"s3://{default_bucket}/abalone"
   batch_data_uri = sagemaker.s3.S3Uploader.upload(
   local_path=local_path,
   desired_s3_uri=base_uri,
   )
   print(batch_data_uri)
   ```
Step 2: Define Pipeline Parameters

This code block defines the following parameters for your pipeline:

- **processing_instance_type** – The ml.* instance type of the processing jobs.
- **processing_instance_count** – The instance count of the processing job.
- **training_instance_type** – The ml.* instance type of the training jobs.
- **input_data** – The Amazon S3 location of the input data.
- **batch_data** – The Amazon S3 location of the input data for batch transformation.
- **model_approval_status** – The approval status to register the trained model with for CI/CD. For more information, see Automate MLOps with SageMaker Projects (p. 2182).

```python
from sagemaker.workflow.parameters import (ParameterInteger,
                                           ParameterString,
                                        )

processing_instance_count = ParameterInteger(  
    name="ProcessingInstanceCount",
    default_value=1
 )

processing_instance_type = ParameterString(  
    name="ProcessingInstanceType",
    default_value="ml.m5.xlarge"
 )

training_instance_type = ParameterString(  
    name="TrainingInstanceType",
    default_value="ml.m5.xlarge"
 )

model_approval_status = ParameterString(  
    name="ModelApprovalStatus",
    default_value="PendingManualApproval"
 )

input_data = ParameterString(  
    name="InputData",
    default_value=input_data_uri,
 )

batch_data = ParameterString(  
    name="BatchData",
    default_value=batch_data_uri,
 )
```

Step 3: Define a Processing Step for Feature Engineering

This section shows how to create a processing step to prepare the data from the dataset for training.

**To create a processing step**

1. Create a directory for the processing script.

   ```
   !mkdir -p abalone
   ```

2. Create a file in the /abalone directory named preprocessing.py with the following content. This preprocessing script is passed in to the processing step for execution on the input data. The training step then uses the preprocessed training features and labels to train a model, and the evaluation step uses the trained model and preprocessed test features and labels to evaluate the model. The script uses scikit-learn to do the following:
- Fill in missing `sex` categorical data and encode it so it's suitable for training.
- Scale and normalize all numerical fields except for `rings` and `sex`.
- Split the data into training, test, and validation datasets.

```python
%%writefile abalone/preprocessing.py
import argparse
import os
import requests
import tempfile
import numpy as np
import pandas as pd

from sklearn.compose import ColumnTransformer
from sklearn.impute import SimpleImputer
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import StandardScaler, OneHotEncoder

# Because this is a headerless CSV file, specify the column names here.
feature_columns_names = [
    "sex",
    "length",
    "diameter",
    "height",
    "whole_weight",
    "shucked_weight",
    "viscera_weight",
    "shell_weight",
]
label_column = "rings"

feature_columns_dtype = {
    "sex": str,
    "length": np.float64,
    "diameter": np.float64,
    "height": np.float64,
    "whole_weight": np.float64,
    "shucked_weight": np.float64,
    "viscera_weight": np.float64,
    "shell_weight": np.float64
}
label_column_dtype = {"rings": np.float64}

def merge_two_dicts(x, y):
    z = x.copy()
    z.update(y)
    return z

if __name__ == "__main__":
    base_dir = "/opt/ml/processing"
    df = pd.read_csv(
        f"{base_dir}/input/abalone-dataset.csv",
        header=None,
        names=feature_columns_names + [label_column],
        dtype=merge_two_dicts(feature_columns_dtype, label_column_dtype)
    )
    numeric_features = list(feature_columns_names)
    numeric_features.remove("sex")
```
Create an instance of an SKLearnProcessor to pass in to the processing step.

```python
from sagemaker.sklearn.processing import SKLearnProcessor

framework_version = "0.23-1"

sklearn_processor = SKLearnProcessor(
    framework_version=framework_version,
    instance_type=processing_instance_type,
    instance_count=processing_instance_count,
    base_job_name="sklearn-abalone-process",
    role=role,
)
```

Create a processing step. This step takes in the SKLearnProcessor, the input and output channels, and the preprocesing.py script that you created. This is very similar to a processor instance's run method in the SageMaker Python SDK. The input_data parameter passed into ProcessingStep is the input data of the step itself. This input data is used by the processor instance when it runs.

```
Note the "train", "validation", and "test" named channels specified in the output configuration for the processing job. Step Properties such as these can be used in subsequent steps and resolve to their runtime values at execution.
```
Step 4: Define a Training step

This section shows how to use the SageMaker XGBoost Algorithm to train a logistic regression model on the training data output from the processing steps.

To define a training step

1. Specify the model path where you want to save the models from training.

```python
model_path = f"s3://{default_bucket}/AbaloneTrain"
```

2. Configure an estimator for the XGBoost algorithm and the input dataset. The `training_instance_type` is passed into the estimator. A typical training script loads data from the input channels, configures training with hyperparameters, trains a model, and saves a model to `model_dir` so that it can be hosted later. SageMaker uploads the model to Amazon S3 in the form of a `model.tar.gz` at the end of the training job.

```python
from sagemaker.estimator import Estimator

image_uri = sagemaker.image_uris.retrieve(
    framework="xgboost",
    region=region,
    version="1.0-1",
    py_version="py3",
    instance_type=training_instance_type,
)

xgb_train = Estimator(
    image_uri=image_uri,
    instance_type=training_instance_type,
    instance_count=1,
    output_path=model_path,
    role=role,
)

xgb_train.set_hyperparameters(
    objective="reg:linear",
    num_round=50,
    max_depth=5,
    eta=0.2,
    gamma=4,
    min_child_weight=6,
)
3. Create a TrainingStep using the estimator instance and properties of the ProcessingStep. In particular, pass in the S3Uri of the "train" and "validation" output channel to the TrainingStep.

```python
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TrainingStep

step_train = TrainingStep(
    name="AbaloneTrain",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
            content_type="text/csv" ),
        "validation": TrainingInput(
            s3_data=step_process.properties.ProcessingOutputConfig.Outputs["validation"].S3Output.S3Uri,
            content_type="text/csv" ),
    },
)
```

**Step 5: Define a Processing Step for Model Evaluation**

This section shows how to create a processing step to evaluate the accuracy of the model. The result of this model evaluation is used in the condition step to determine which execute path to take.

**To define a processing step for model evaluation**

1. Create a file in the /abalone directory named evaluation.py. This script is used in a processing step to perform model evaluation. It takes a trained model and the test dataset as input, then produces a JSON file containing classification evaluation metrics. These metrics include a precision, recall, and F1 score for each label, and accuracy and ROC curve for the model.

```python
%%writefile abalone/evaluation.py
import jsonlib
import pickle
import tarfile
import joblib
import numpy as np
import pandas as pd
import xgboost

from sklearn.metrics import mean_squared_error

if __name__ == '__main__':
    model_path = f"/opt/ml/processing/model/model.tar.gz"
    with tarfile.open(model_path) as tar:
        tar.extractall(path=".")
```
model = pickle.load(open("xgboost-model", "rb"))

test_path = "/opt/ml/processing/test/test.csv"
df = pd.read_csv(test_path, header=None)

y_test = df.iloc[:, 0].to_numpy()
df.drop(df.columns[0], axis=1, inplace=True)

X_test = xgboost.DMatrix(df.values)

predictions = model.predict(X_test)

mse = mean_squared_error(y_test, predictions)
std = np.std(y_test - predictions)
report_dict = {
    "regression_metrics": {
        "mse": {
            "value": mse,
            "standard_deviation": std
        },
    },
}

output_dir = "/opt/ml/processing/evaluation"
pathlib.Path(output_dir).mkdir(parents=True, exist_ok=True)

evaluation_path = f"{output_dir}/evaluation.json"
with open(evaluation_path, "w") as f:
    f.write(json.dumps(report_dict))

2. Create an instance of a `ScriptProcessor` that is used to create a `ProcessingStep`.

```python
from sagemaker.processing import ScriptProcessor

script_eval = ScriptProcessor(
    image_uri=image_uri,
    command=["python3"],
    instance_type=processing_instance_type,
    instance_count=1,
    base_job_name="script-abalone-eval",
    role=role,
)
```

3. Create a `ProcessingStep` using the processor instance, the input and output channels, and the `evaluation.py` script. In particular, pass in the `S3ModelArtifacts` property from the `step_train` training step, as well as the `S3Uri` of the "test" output channel of the `step_process` processing step. This is very similar to a processor instance's `run` method in the SageMaker Python SDK.

```python
from sagemaker.workflow.properties import PropertyFile

evaluation_report = PropertyFile(
    name="EvaluationReport",
    output_name="evaluation",
    path="evaluation.json"
)
step_eval = ProcessingStep(
    name="AbaloneEval",
    processor=script_eval,
    inputs=[
        ProcessingInput(
            source=step_train.properties.ModelArtifacts.S3ModelArtifacts,
            ...]]
```
Step 6: Define a CreateModelStep for Batch Transformation

This section shows how to create a SageMaker model from the output of the training step. This model is used for batch transformation on a new dataset. This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a CreateModelStep for batch transformation

   ```python
   from sagemaker.model import Model

   model = Model(
       image_uri=image_uri,
       model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
       sagemaker_session=sagemaker_session,
       role=role,
   )
   ```

2. Define the model input for your SageMaker model.

   ```python
   from sagemaker.inputs import CreateModelInput

   inputs = CreateModelInput(
       instance_type="ml.m5.large",
       accelerator_type="ml.eia1.medium",
   )
   ```

3. Create your CreateModelStep using the CreateModelInput and SageMaker model instance you defined.

   ```python
   from sagemaker.workflow.steps import CreateModelStep

   step_create_model = CreateModelStep(
       name="AbaloneCreateModel",
       model=model,
       inputs=inputs,
   )
   ```
Step 7: Define a TransformStep to Perform Batch Transformation

This section shows how to create a TransformStep to perform batch transformation on a dataset after the model is trained. This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a TransformStep to perform batch transformation

1. Create a transformer instance with the appropriate compute instance type, instance count, and desired output Amazon S3 bucket URI. Pass in the ModelName property from the step_create_model CreateModel step.

   ```python
   from sagemaker.transformer import Transformer
   transformer = Transformer(
       model_name=step_create_model.properties.ModelName,
       instance_type="ml.m5.xlarge",
       instance_count=1,
       output_path=f"s3://{default_bucket}/AbaloneTransform"
   )
   ``

2. Create a TransformStep using the transformer instance you defined and the batch_data pipeline parameter.

   ```python
   from sagemaker.inputs import TransformInput
   from sagemaker.workflow.steps import TransformStep
   step_transform = TransformStep(
       name="AbaloneTransform",
       transformer=transformer,
       inputs=TransformInput(data=batch_data)
   )
   ```

Step 8: Define a RegisterModel Step to Create a Model Package

This section shows how to construct an instance of RegisterModel. The result of executing RegisterModel in a pipeline is a model package. A model package is a reusable model artifacts abstraction that packages all ingredients necessary for inference. It consists of an inference specification that defines the inference image to use along with an optional model weights location. A model package group is a collection of model packages. You can use a ModelPackageGroup for SageMaker Pipelines to add a new version and model package to the group for every pipeline execution. For more information about model registry, see Register and Deploy Models with Model Registry (p. 1840).

This step is passed into the condition step and only executes if the condition step evaluates to true.

To define a RegisterModel step to create a model package

- Construct a RegisterModel step using the estimator instance you used for the training step. Pass in the S3ModelArtifacts property from the step_train training step and specify a ModelPackageGroup. SageMaker Pipelines creates this ModelPackageGroup for you.

   ```python
   from sagemaker.model_metrics import MetricsSource, ModelMetrics
   from sagemaker.workflow.step_collections import RegisterModel

   model_metrics = ModelMetrics(
       model_statistics=MetricsSource(
   ```
Step 9: Define a Condition Step to Verify Model Accuracy

A ConditionStep allows SageMaker Pipelines to support conditional execution in your pipeline DAG based on the condition of step properties. In this case, you only want to register a model package if the accuracy of that model, as determined by the model evaluation step, exceeds the required value. If the accuracy exceeds the required value, the pipeline also creates a SageMaker Model and runs batch transformation on a dataset. This section shows how to define the Condition step.

To define a condition step to verify model accuracy

1. Define a ConditionLessThanOrEqualTo condition using the accuracy value found in the output of the model evaluation processing step, `step_eval`. Get this output using the property file you indexed in the processing step and the respective JSONPath of the mean squared error value, "mse".

```python
from sagemaker.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.workflow.condition_step import (ConditionStep,
JsonGet,
)

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step=step_eval,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"
    ),
    right=6.0
)
```

2. Construct a ConditionStep. Pass the ConditionEquals condition in, then set the model package registration and batch transformation steps as the next steps if the condition passes.

```python
step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[],
)
```
Step 10: Create a pipeline

Now that you've created all of the steps, combine them into a pipeline.

To create a pipeline

1. Define the following for your pipeline: name, parameters, and steps. Names must be unique within an (account, region) pair.

   Note
   A step can only appear once in either the pipeline's step list or the if/else step lists of the condition step. It cannot appear in both.

   ```python
   from sagemaker.workflow.pipeline import Pipeline
   
   pipeline_name = f"AbalonePipeline"
   pipeline = Pipeline(
       name=pipeline_name,
       parameters=[
           processing_instance_type,
           processing_instance_count,
           training_instance_type,
           model_approval_status,
           input_data,
           batch_data,
       ],
       steps=[step_process, step_train, step_eval, step_cond],
   )
   ```

2. (Optional) Examine the JSON pipeline definition to ensure that it's well-formed.

   ```python
   import json
   json.loads(pipeline.definition())
   ```

This pipeline definition is ready to submit to SageMaker. In the next tutorial, you submit this pipeline to SageMaker and start an execution.

Next step: Run a pipeline (p. 2166)

Run a pipeline

After you've created a pipeline definition using the SageMaker Python SDK, you can submit it to SageMaker to start your execution. The following tutorial shows how to submit a pipeline, start an execution, examine the results of that execution, and delete your pipeline.

Topics

- Prerequisites (p. 2166)
- Step 1: Start the Pipeline (p. 2167)
- Step 2: Examine a Pipeline Execution (p. 2167)
- Step 3: Override Default Parameters for a Pipeline Execution (p. 2168)
- Step 4: Stop and Delete a Pipeline Execution (p. 2169)

Prerequisites

This tutorial requires the following:
• A SageMaker notebook instance.
• A SageMaker Pipelines pipeline definition. This tutorial assumes you're using the pipeline definition created by completing the Define a Pipeline (p. 2153) tutorial.

**Step 1: Start the Pipeline**

First, you need to start the pipeline.

**To start the pipeline**

1. Examine the JSON pipeline definition to ensure that it's well-formed.

   ```python
   import json
   json.loads(pipeline.definition())
   ```

2. Submit the pipeline definition to the SageMaker Pipelines service to create a pipeline if it doesn't exist, or update the pipeline if it does. The role passed in is used by SageMaker Pipelines to create all of the jobs defined in the steps.

   ```python
   pipeline.upsert(role_arn=role)
   ```

3. Start a pipeline execution.

   ```python
   execution = pipeline.start()
   ```

**Step 2: Examine a Pipeline Execution**

Next, you need to examine the pipeline execution.

**To examine a pipeline execution**

1. Describe the pipeline execution status to ensure that it has been created and started successfully.

   ```python
   execution.describe()
   ```

2. Wait for the execution to finish.

   ```python
   execution.wait()
   ```

3. List the execution steps and their status.

   ```python
   execution.list_steps()
   ```

Your output should look like the following:

```json
[{'StepName': 'AbaloneTransform',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 27, 870000, tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 45, 50, 492000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
{'StepName': 'AbaloneRegisterModel',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 929000, tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 929000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'RegisterModel': {'Arn': 'arn:aws:sagemaker:us-east-2:111122223333:transform-job/pipelines-cfvy1tjuxdq8-abalonetransform-ptyjoef3jy'}}}]
```
4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```python
evaluation_json = sagemaker.s3.S3Downloader.read_file("/{}/evaluation.json".format(step_eval.arguments["ProcessingOutputConfig"]['Outputs'][0]['S3Output']['S3Or1']))
json.loads(evaluation_json)
```

### Step 3: Override Default Parameters for a Pipeline Execution

You can run additional executions of the pipeline by specifying different pipeline parameters to override the defaults.

#### To override default parameters

1. Create the pipeline execution. This starts another pipeline execution on a compute-optimized instance type and sets the model approval status to "Approved". This means that the model package version generated by the `RegisterModel` step is automatically ready for deployment through CI/CD pipelines, such as with SageMaker Projects. For more information, see Automate MLOps with SageMaker Projects (p. 2182).
2. Wait for the execution to finish.

```python
execution.wait()
```

3. List the execution steps and their status.

```python
execution.list_steps()
```

4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```python
evaluation_json = sagemaker.s3.S3Downloader.read_file("{}/evaluation.json".format( 
    step_eval.arguments["ProcessingOutputConfig"]["Outputs"][0]["S3Output"]["S3Uri"] 
))
json.loads(evaluation_json)
```

Step 4: Stop and Delete a Pipeline Execution

When you're finished with your pipeline, you can stop any ongoing executions and delete the pipeline.

To stop and delete a pipeline execution

1. Stop the pipeline execution.

```python
execution.stop()
```

2. Delete the pipeline.

```python
pipeline.delete()
```

View, Track, and Execute SageMaker Pipelines in SageMaker Studio

To view, track, and execute Amazon SageMaker Pipelines in Amazon SageMaker Studio, you must sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).

Topics

- View a Pipeline (p. 2170)
- View a Pipeline Execution (p. 2173)
- Execute a Pipeline (p. 2176)
- Track the Lineage of a SageMaker ML Pipeline (p. 2178)
View a Pipeline

This procedure shows you how to directly find a pipeline and view its details page. Pipelines that are part of a project can also be found listed in the project's details page. For information on finding a pipeline that is part of a project, see Automate MLOps with SageMaker Projects (p. 2182).

To view a list of pipelines

1. In the left sidebar of Studio, choose the Components and registries icon.
2. In the drop-down menu, select Pipelines.
3. Drag the right border of the Components and registries pane to the right to view all the columns. Use search to narrow the list of pipelines. Search is a two-step process. First, you enter characters that match the column name you want to search. Second, you enter characters to match the item in that column. You can have multiple search filters. An example, the following screenshot limits the displayed pipelines to those with a name that starts with "aba" and created by Me. For more
information on searching in SageMaker Studio, see Search Experiments Using Amazon SageMaker Studio (p. 1529).

4. Double-click a pipeline to view details about the pipeline. The pipeline details tab opens and displays a list of pipeline executions. You can start an execution or choose one of the other tabs for more information about the pipeline. Use the Settings icon (⚙️) on the top right of the screen to choose which columns to display.

5. From the pipeline details page, choose one of the following tabs to view details about the pipeline:
   - **Executions** – Details about the executions. You can start an execution from this tab or the Graph tab.
   - **Graph** – The DAG for the pipeline.
- **Parameters** - Includes the model approval status.

- **Settings** – The metadata associated with the pipeline. You can download the pipeline definition file, and edit the pipeline name and description from this tab.
View a Pipeline Execution

This procedure shows you how to view a pipeline execution. For information on how to view a list of pipeline executions, and how to use SageMaker search to narrow the executions in the list, see View a Pipeline (p. 2170).

To view details of a pipeline execution

1. In the execution list, double-click an execution to view details about the execution. The execution details tab opens and displays a graph of the steps in the pipeline. You can choose one of the other tabs to view information about the pipeline execution, which is similar to that shown when viewing the pipeline details.

2. Use search to find a step in the graph. Type characters that match a step name. You can drag the graph around or use the resizing icons on the lower-left side of the graph. The inset on the lower-right side of the graph displays where you are in the graph.
3. Choose one of the steps in the graph to see details about the step. In the preceding screenshot, a training step is chosen and displays the following tabs:

- **Input** – The training inputs. If an input source is from Amazon Simple Storage Service (Amazon S3), choose the link to view the file in the Amazon S3 console.
- **Output** – The training outputs, such as metrics, charts, files, and evaluation outcome. The graphs were produced using the Tracker APIs.
• **Logs** – The Amazon CloudWatch logs produced by the step.

![Example of CloudWatch logs]

• **Info** – The parameters and metadata associated with the step.

![Example of pipeline execution parameters]

**Execute a Pipeline**

This procedure shows you how to execute a pipeline. For information on how to view a list of pipeline executions, see View a Pipeline (p. 2170).

**To start a pipeline execution**

1. From the **Executions** or **Graph** tab in the execution list, choose **Start an execution**.
2. Enter or update the following required information:
   
   - **Name** – Must be unique to your account in the AWS Region.
   - **ProcessingInstanceType** – The instance type for processing.
   - **ProcessingInstanceCount** – The number of instances to use for processing.
   - **TrainingInstanceType** – The instance type for training.
   - **ModelApprovalStatus** – For your convenience.
   - **InputData** – The S3 URI of the input data.

3. Choose **Submit**.

4. To see details of the execution or to stop the execution, choose **View details** on the status banner.
5. To stop the execution, choose **Stop** on the status banner.

The view the list of registered models, see Automate MLOps with SageMaker Projects (p. 2182).

**Track the Lineage of a SageMaker ML Pipeline**

In this tutorial, you use Amazon SageMaker Studio to track the lineage of an Amazon SageMaker ML Pipeline.

The pipeline was created by the Orchestrating Jobs with Amazon SageMaker Model Building Pipelines notebook in the Amazon SageMaker example GitHub repository. For detailed information on how the pipeline was created, see Define a Pipeline (p. 2153).

Lineage tracking in Studio is centered around a directed acyclic graph (DAG). The DAG represents the steps in a pipeline. From the DAG you can track the lineage from any step to any other step. The following diagram displays the steps in the pipeline. These steps appear as a DAG in Studio.

**Prerequisites**

- Access to Amazon SageMaker Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
- Familiarity with the SageMaker Studio user interface. For more information, see Amazon SageMaker Studio UI Overview (p. 71).
- (Recommended) A completed run of the example notebook.

**To track the lineage of a pipeline**

1. Sign in to SageMaker Studio.
2. In the left sidebar of Studio, choose the **SageMaker Components and registries** icon ((figsize:datasource:fig:dataset-registry:dataset-registry)).
3. In the drop-down menu, select **Pipelines**.
4. Use the **Search** box to filter the pipelines list. To view all available columns, drag the right border of the pane to the right. For more information, see Search Experiments Using Amazon SageMaker Studio (p. 1529).

The following screenshot shows the list filtered by a name that starts with "aba" and that was created on 12/5/20.
5. Double-click the AbalonePipeline pipeline to view the execution list and other details about the pipeline. The following screenshot shows the TABLE PROPERTIES pane open where you can choose which properties to view.

6. Choose the Settings tab and then choose Download pipeline definition file. You can view the file to see how the pipeline graph was defined.

7. On the Execution tab, double-click the first row in the execution list to view its execution graph and other details about the execution. Note that the graph matches the diagram displayed at the beginning of the tutorial.

You can drag the graph around (select an area not on the graph itself) or use the resizing icons on the lower-left side of the graph. The inset on the lower-right side of the graph displays your location in the graph.
8. On the **Graph** tab, choose the **AbaloneProcess** step to view details about the step.

9. Find the Amazon S3 paths to the training, validation, and test datasets in the **Output** tab, under **Files**.
   
   **Note**
   
   To get the full paths, right-click the path and then choose **Copy cell contents**.
Choose the AbaloneTrain step.

Find the Amazon S3 path to the model artifact in the **Output** tab, under **Files**:

```
s3://sagemaker-eu-west-1-acct-id/AbaloneTrain/pipelines-6locnsqz4bfu-AbaloneTrain-NtfEpI0Ahu/output/model.tar.gz
```

Choose the AbaloneRegisterModel step.

Find the ARN of the model package in the **Output** tab, under **Files**:

```
arn:aws:sagemaker:eu-west-1:acct-id:model-package/abalonenmodelpackagegroupname/2
```

Automate MLOps with SageMaker Projects

Create end-to-end ML solutions with CI/CD by using SageMaker projects.

Use SageMaker projects to create an ML ops solution to orchestrate and manage:

- Data preparation and feature engineering
- Training models
- Evaluating models
- Deploying models
What is a SageMaker Project?

By using a SageMaker project, teams of data scientists and developers can work in machine learning business problems. You can create a SageMaker project with a SageMaker provided MLOps template that automates the model building and deployment pipelines using continuous integrations and continuous delivery (CI/CD). A SageMaker provided template provisions the initial setup required for a complete end-to-end MLOps system including model building, training, and deployment, depending on the template you choose. You can also provide your own custom template to provision the resources you need for your MLOps system.

A SageMaker project is an AWS Service Catalog provisioned product that enables you to easily create an end-to-end ML solution. For information about AWS Service Catalog, see What is AWS Service Catalog.

Each SageMaker project has a unique name and ID that are passed to all SageMaker and AWS resources created in the project. By using the name and ID, you can view all entities associated with your project. These include:

- Pipeline executions
- Registered models
- Deployed models (endpoints)
- Datasets
- AWS Service Catalog Products
- AWS CodePipeline pipelines
- AWS CodeCommit repositories

A typical SageMaker project with a CICD template might include the following.

- One or more CodeCommit repositories with sample code for building and deploying ML solutions. These are working examples that you can clone locally to explore the code provided by SageMaker and modify for your needs. You own this code and you can use the repositories as version control for your work.
- A SageMaker pipeline that defines steps for data preparation, training, model evaluation, and model deployment.
- A CodePipeline that runs your SageMaker pipeline every time a new version of the code is checked in. For information about CodePipeline, see What is AWS CodePipeline.
- A model group that contains model versions. Each time the SageMaker pipeline runs, and the resulting model version is accepted in the conditional validation step, a new model version is deployed to a SageMaker endpoint.
Why Should You Use MLOps?

As you move from running individual artificial intelligence and machine learning (AI/ML) projects to using AI/ML to transform your business at scale, the discipline of ML Operations (MLOps) can help. MLOps accounts for the unique aspects of AI/ML projects in project management, CI/CD, and quality assurance, helping customers improve delivery time, reduce defects, and make data scientists more productive. MLOps refers to a methodology that is built on applying DevOps practices to machine learning workloads. You can review the Introduction to DevOps on AWS white paper for a discussion of DevOps principles. Practicing CI/CD on AWS and Infrastructure as Code go deeper into implementation using AWS services.

Like DevOps, MLOps relies on a collaborative and streamlined approach to the machine learning development lifecycle where the intersection of people, process and technology are required to optimize the end-to-end activities required to develop, build, and operate machine learning workloads.

MLOps focuses on the intersection of data science and data engineering in combination with existing DevOps practices to streamline model delivery across the machine learning development lifecycle. MLOps is the discipline of integrating ML workloads into release management, CI/CD, and operations. MLOps requires the integration of software development, operations, data engineering, and data science.

Challenges with MLOps

- **Project management** - ML projects involve data scientists, a relatively new role, and one not often integrated into cross-functional teams. These new team members often speak a very different technical language than product owners and software engineers, compounding the usual problem of translating business requirements into technical requirements.

- **Communication and collaboration** - Building visibility on ML projects and enabling collaboration across different stakeholders such as data engineers, data scientists, ML engineers, and DevOps.

- **Everything is code**
• Use of production data in development activities, longer experimentation lifecycles, dependencies on data pipelines, retraining deployment pipelines, and unique metrics in evaluating the performance of a model.

• Models often have a lifecycle independent of the applications and systems integrating with those models.

• The entire end-to-end system is reproducible through versioned code and artifacts. DevOps projects use Infrastructure-as-Code(IaC) and Configuration-as-Code(CaC) to build environments, and Pipelines-as-code to ensure consistent CI/CD patterns. The pipelines have to integrate with Big Data and ML training workflows. That often means that our pipeline is a combination of a traditional CI/CD tool and another workflow engine. There are important policy concerns for many ML projects, so our pipeline may also need to enforce those policies. Biased input data produces biased results, an increasing concern for business stakeholders.

• CI/CD

• In MLOps, the source data is a first-class input, along with source code. That's why MLOps calls for versioning the source data and triggering pipeline runs when the source or inference data changes.

• Pipelines must also version the ML models along with their inputs and other outputs, in order to provide for traceability.

• Automated testing must include proper validation of the ML model, during build phases and when the model is in production.

• Build phases may include model training and retraining, a time-consuming and resource-intensive process. Pipelines must be granular enough to only perform a full training cycle when the source data or ML code changes, not when related components change.

• Because machine learning code is typically a small part of an overall solution, a deployment pipeline may also incorporate the additional steps required to package your model for consumption as an API by other applications and systems.

• Monitoring and logging

• In the feature engineering and model training phases, we need to capture model training metrics as well as model experiments. Tuning an ML model requires manipulating the form of the input data as well as algorithm hyperparameters, and we need to systematically capture those experiments. Experiment tracking helps data scientists work more effectively and gives us a reproducible snapshot of their work.

• Deployed ML models require monitoring of the data passed to the model for inference, along with the standard endpoint stability and performance metrics. The monitoring system must also capture the quality of model output, as evaluated by an appropriate ML metric.

Benefits of MLOps

Adopting MLOps practices gives you faster time-to-market for ML projects by delivering the following benefits.

• Productivity - Providing self-service environments with access to curated data sets lets data engineers and data scientists move faster and waste less time with missing or invalid data.

• Repeatability - Automating all the steps in the MLDC helps you ensure a repeatable process, including how the model is trained, evaluated, versioned, and deployed.

• Reliability - Incorporating CI/CD practices allows for the ability to not only deploy quickly but with increased quality and consistency.

• Auditability - Versioning all inputs and outputs, from data science experiments to source data to trained model, means that we can demonstrate exactly how the model was built, and where it was deployed.

• Data and model quality - MLOps lets us enforce policies that guard against model bias and track changes to data statistical properties and model quality over time.
SageMaker Studio Permissions Required to Use Projects

To enable users to view SageMaker provided project templates and create projects with those templates, enable Projects permissions for users when you onboard or update SageMaker Studio. There are 2 permissions to enable.

1. Enable Projects permissions for the SageMaker Studio administrator. This enables the SageMaker Studio administrator to view the SageMaker provided templates in the AWS Service Catalog console. The administrator can see what other SageMaker Studio users create if you grant them permission to use SageMaker projects. The administrator can also view the AWS CloudFormation template that the SageMaker provided project templates define in the Service Catalog Console. For information about using the Service Catalog console, see What Is AWS Service Catalog in the AWS Service Catalog User Guide.

2. Enable projects for SageMaker studio users who are configured to use the domain execution role. This grants permission for SageMaker Studio users the ability to use the SageMaker provided project templates to create a project from within SageMaker Studio.

To enable users who use any role other than the domain execution role to view and use SageMaker provided project templates, you need to enable Projects permissions on the individual user profiles.

The following procedures show how to enable Projects permissions when you are onboarding to SageMaker Studio. For more information about onboarding to SageMaker Studio, see Onboard to Amazon SageMaker Studio (p. 35).

To enable Projects permissions for the administrator and domain execution role users

1. Open the SageMaker console.
2. Choose Amazon SageMaker Studio at the top left of the page.
3. If you choose Quick start, under Projects, make sure Enable SageMaker project templates for this account and Studio users is enabled.
4. If you choose Standard setup, under Projects, make sure both Enable SageMaker project templates for this account and Enable SageMaker project templates for Studio users are enabled.

Create an MLOps Project

Create a SageMaker MLOps project by using SageMaker studio.

Prerequisites

To create a project in SageMaker Studio, you need:
• An AWS SSO or IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Studio (p. 35).
• Basic familiarity with the Studio user interface and Jupyter notebooks. For information, see Amazon SageMaker Studio UI Overview (p. 71).

To create a project in SageMaker Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. Choose Components and registries, and then choose Projects in the drop-down list.
3. Choose Create project.
The Create project tab appears.

4. For SageMaker project templates, choose Organization templates to choose a custom template that your organization created, or SageMaker templates to choose a SageMaker-provided template. Then choose a template from the list of available templates, and choose Choose project template. For more information about project templates, see MLOps Project Templates (p. 2190).
5. For **Project details** enter a name and description for your project. Optionally, add tags, which are key value pairs that you can use to track your projects. When you are finished, choose **Create project**
A SageMaker project template automates setting up and implementing MLOps for your projects. A SageMaker project template is an AWS Service Catalog product that SageMaker makes available to SageMaker Studio users. These Service Catalog products are visible in your Service Catalog console after enable permissions when you onboard or update SageMaker Studio. For information about enabling permissions to use SageMaker project templates, see SageMaker Studio Permissions Required to Use Projects (p. 2186). Use SageMaker project templates to create a project that is an end-to-end MLOps solution.

If you are an administrator, you can create your own custom project templates. SageMaker Studio users in your organization can use custom project templates that you create to create projects.

Topics
- Use SageMaker Provided Project Templates (p. 2191)
- Create Custom Project Templates (p. 2191)
Use SageMaker Provided Project Templates

SageMaker provides project templates that create the infrastructure you need to create an MLOps solution. Currently, SageMaker offers the following project templates.

- **MLOps template for model building and training** - This template enables you to build and train machine learning models and register models to the model registry. Use this template when you want a MLOps solution for building and training models. This template provides the following resources:
  - An AWS CodeCommit repository that contains sample code that creates SageMaker pipeline in python code and shows how to create and update a SageMaker pipeline. This repository also has a Python Jupyter notebook that you can open and run in SageMaker Studio.
  - An CodePipeline that has source and build steps. The source step points to the CodeCommit repository and the build step gets the code from that repository, creates and/or updates the SageMaker pipeline, starts a pipeline execution, and waits for the pipeline execution to complete.
  - An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker pipeline runs.

In a collaborative environment with multiple Studio users working on a same project, we recommend creating this project. After data scientists experiment in SageMaker Studio and check their code into CodeCommit, model building and training happens in the common infrastructure so that there is a central, authoritative location to keep track of the ML Models and artifacts that are ready to go to production.

- **MLOps template for model deployment** - This template deploys machine learning models from the Amazon SageMaker model registry to SageMaker hosted endpoints for real-time inference. Use this template when you have trained models that you want to deploy for inference. This template provides the following resources:
  - An AWS CodeCommit repository that contains sample code that deploys models to endpoints in staging and production environments.
  - An CodePipeline that has source, build, deploy to staging, and deploy to production steps. The source step points to the CodeCommit repository, the build step gets the code from that repository, generates AWS CloudFormation stacks to deploy. The deploy to staging and deploy to production steps deploy the AWS CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.

There is also a programmatic approval step with placeholder tests in the example code in the CodeCommit repository. You can add additional tests to replace the placeholders tests.

- **MLOps template for model building, training, and deployment** - This template enables you to easily build, train, and deploy machine learning models. Use this template when you want a complete MLOps solution from data preparation to model deployment.

  This template is a combination of the previous 2 templates, and contains all of the resources provided in those templates.

Create Custom Project Templates

If the SageMaker provided templates do not meet your needs (for example, you want to have more complex orchestration in the CodePipeline with multiple stages, custom approval steps, etc.) create your own templates.
We recommend starting by using SageMaker provided templates to understand how to organize your code and resources and build on top of it. To do this, after you enable administrator access to the SageMaker templates, login to the https://console.aws.amazon.com/servicecatalog/, choose Portfolios, then choose Imported. For information about AWS Service Catalog, see Overview of AWS Service Catalog in the AWS Service Catalog User Guide.

Create your own project templates to customize your MLOps project. SageMaker project templates are AWS Service Catalog provisioned products to provision the resources for your MLOps project.

To create a custom project template, complete the following steps.

1. Create a Portfolio. For information, see Step 3: Create an AWS Service Catalog Portfolio.
2. Create a Product. A Product is a AWS CloudFormation template. You can create multiple versions of the product. For information, see Step 4: Create an AWS Service Catalog Product.

For the Product to work with SageMaker projects, add the following parameters to your Product template.

```
SageMakerProjectName:
Type: String
Description: Name of the project

SageMakerProjectId:
Type: String
Description: Service generated Id of the project
```

3. Add a launch constraint. A launch constraint designates an IAM role that Service Catalog assumes when a user launches a product. For information, see Step 6: Add a Launch Constraint to Assign an IAM Role.

4. Provision the product on the https://console.aws.amazon.com/servicecatalog/ to test the template. If you are satisfied with your template, continue to the next step to make the template available in SageMaker Studio.

5. Grant access to the Service Catalog Portfolio that you created in step 1 to your SageMaker Studio execution role. Use either the SageMaker Studio domain execution role or a user role that has SageMaker Studio access. For information about adding a role to the Portfolio, see Step 7: Grant End Users Access to the Portfolio.

6. To make your project template available in your Organization templates list in SageMaker Studio, create a tag with the following key and value to the Service Catalog Product you created in step 2.

- **key** - sagemaker:studio-visibility
- **value** - true

After you complete these steps, SageMaker Studio users in your organization can create a project with the template you created by following the steps in Create an MLOps Project (p. 2186) and choosing Organization templates when you choose a template.

### View Project Resources

After you create a project, view the resources associated with the project in SageMaker Studio.

#### To create a project in SageMaker Studio

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. Choose Components and registries, and then choose Projects.
3. Double-click the name of the project for which you want to view details.

A tab with the project details appears.
On the product details tab, you can view the following entities associated with the project.

- **Repositories** - code repositories associated with this project. If you use a SageMaker provided template when you create your project, it creates AWS CodeCommit pipelines. For more information about CodeCommit, see What is AWS CodeCommit.
- **Pipelines** - SageMaker ML pipelines that define steps to prepare data, train, and deploy models. For information about SageMaker ML pipelines, see Create and Manage SageMaker Pipelines (p. 2153).
- **Experiments** - one or more SageMaker AutoPilot experiments associated with the project. For information about AutoPilot, see Automate model development with Amazon SageMaker Autopilot (p. 141).
- **Model groups** - groups of model versions that were created by pipeline executions in the project. For information about model groups, see Create a Model Group (p. 1841).
- **Endpoints** - SageMaker endpoints that host deployed models for real-time inference. When a model version is approved, it is deployed to an endpoint.
- **Settings** - Settings for the project. This includes the name and description of the project, information about the project template and SourceModelPackageGroupName, and metadata about the project.

**SageMaker MLOps Project Walkthrough**

This walkthrough demonstrates how to use MLOps projects to create a CI/CD system to build, train, and deploy models.

**Prerequisites**

To complete this walkthrough, you need:

- An AWS SSO or IAM account to sign in to Studio. For information, see Onboard to Amazon SageMaker Studio (p. 35).
- Permission to use SageMaker provided project templates. For information, see SageMaker Studio Permissions Required to Use Projects (p. 2186).
Basic familiarity with the Studio user interface. For information, see Amazon SageMaker Studio UI Overview (p. 71).

Topics
- Step 1: Create the Project (p. 2195)
- Step 2: Clone the Code Repository (p. 2198)
- Step 3: Make a Change in the Code (p. 2200)
- Step 4: Approve the Model (p. 2203)
- (Optional) Step 5: Deploy the Model Version to Production (p. 2205)
- Step 6: Cleanup Resources (p. 2206)

Step 1: Create the Project

In this step, you create a SageMaker MLOps project by using a SageMaker provided project template to build, train, and deploy models.

To create the SageMaker MLOps project

1. Sign in to Studio. For more information, see Onboard to Amazon SageMaker Studio (p. 35).
2. Choose Components and registries, and then choose Projects in the drop-down list.
3. **Choose Create project.**

The **Create project** tab appears.
4. For **SageMaker project templates**, choose **Organization templates**, then choose **MLOps template** for model building, training, and deployment.

5. For **Project details** enter a name and description for your project. **Create project**
When the project appears in the Projects list with a Status of Created, move on to the next step.

**Step 2: Clone the Code Repository**

After you create the project, two CodeCommit repositories are created in the project. One of the repositories contains code to build and train a model, and one contains code to deploy the model. In this step, you clone the repository to the local SageMaker that contains the code to build and train the model to the local SageMaker Studio environment so that you can work with the code.

**To clone the code repository**

1. Choose Components and registries, and then choose Projects in the drop-down list.
2. Find the name of the project you created in the previous step and double-click on it to open the project tab for your project.

3. In the project tab, choose Repositories, and in the Local path column for the repository that ends with modelbuild, choose clone repo....
4. In the dialog box that appears, accept the defaults and choose **Clone repository**.

When clone of the repository is complete, the local path appears in the **Local path** column. Click on the path to open the local folder that contains the repository code in SageMaker Studio.

**Step 3: Make a Change in the Code**

Now make a change to the pipeline code that builds the model and check in the change to trigger a new pipeline run. The pipeline run registers a new model version.
To make a code change

1. In SageMaker Studio, choose the file browser icon ( ), and navigate to the pipelines/abalone folder. Double-click pipeline.py to open the code file.

   ![File Browser](image1)

   - pipeline.py (Selected)

2. In the pipeline.py file, find the line that sets the training instance type.

   ```python
   training_instance_type = ParameterString(
       name="TrainingInstanceType", default_value="ml.m5.xlarge"
   )
   ```

   Change `ml.m5.xlarge` to `ml.m5.large`, then type Ctrl+S to save the change.

3. Choose the Git icon ( ). Stage, commit, and push the change in pipeline.py. For information about using Git in SageMaker Studio, see Clone a Git Repository in SageMaker Studio (p. 115).
After pushing your code change, the MLOps system triggers a run of the pipeline that creates a new model version. In the next step, you approve the new model version to deploy it to production.

**Step 4: Approve the Model**

Now you approve the new model version that was created in the previous step to trigger a deployment of the model version to a SageMaker endpoint.

**To approve the model version**

1. Choose **Components and registries**, and then choose **Projects** in the drop-down list.

2. Find the name of the project you created in the first step and double-click on it to open the project tab for your project.

3. In the project tab, choose **Model groups**, then double-click the name of the model group that appears.
The model group tab appears.

5. In the model Update model version status dialog box, in the Status drop-down, choose Approve, then choose Update status.
Approving the model version causes the MLOps system to deploy the model to staging. To view the endpoint, choose the **Endpoints** tab on the project tab.

**(Optional) Step 5: Deploy the Model Version to Production**

Now you can deploy the model version to the production environment.

**Note**
To complete this step, you need to be an administrator in your SageMaker Studio domain. If you are not an administrator, skip this step.

**To deploy the model version to the production environment**

1. Log in to the CodePipeline console at https://console.aws.amazon.com/codepipeline/
2. Choose **Pipelines**, then choose the pipeline with the name `sagemaker-projectname-projectid-modeldeploy`, where `projectname` is the name of your project, and `projectid` is the ID of your project.
3. In the **DeployStaging** stage, choose **Review**.
4. In the **Review** dialog box, choose **Approve**.

Approving the **DeployStaging** stage causes the MLOps system to deploy the model to production. To view the endpoint, choose the **Endpoints** tab on the project tab in SageMaker Studio.

**Step 6: Cleanup Resources**

To stop incurring charges, clean up the resources that were created in this walkthrough. To do this, complete the following steps.

**Note**

To delete the AWS CloudFormation stack and the Amazon S3 bucket, you need to be an administrator in SageMaker Studio. If you are not an administrator, ask your administrator to complete those steps.

1. From the SageMaker Studio menu, choose **File**, choose **New**, and then choose **Notebook**.
2. In the **Select Kernel** dialog box, choose **Python 3 (Data Science)**, then choose **Select**.
3. In the notebook, enter the following code in a cell, and then run the cell. Replace `MyProject` with the name of your project.

   ```python
   import boto3
   sm_client=boto3.client("sagemaker")
   sm_client.delete_project(ProjectName="MyProject")
   ```

   This deletes the Service Catalog provisioned product that the project created. This includes the CodeCommit, CodePipeline, and CodeBuild resources that were created for the project.

4. Delete the AWS CloudFormation stacks that the project created. There are 2 stacks, one for staging and one for production. The names of the stacks are `sagemaker-projectname-project-id-deploy-staging` and `sagemaker-projectname-project-id-deploy-prod`, where `projectname` is the name of your project, and `project-id` is the ID of your project.

   For information about how to delete a AWS CloudFormation stack, see Deleting a stack on the AWS CloudFormation console in the **AWS CloudFormation User Guide**.

5. Delete the Amazon S3 bucket that the project created. The name of the bucket is `sagemaker-project-project-id`, where `project-id` is the ID of your project.

**Amazon SageMaker ML Lineage Tracking**

Amazon SageMaker ML Lineage Tracking creates and stores information about the steps of a machine learning (ML) workflow from data preparation to model deployment. With the tracking information you can reproduce the workflow steps, track model and dataset lineage, and establish model governance and audit standards.

With SageMaker Lineage Tracking data scientists and model builders can do the following:

- Keep a running history of model discovery experiments.
- Establish model governance by tracking model lineage artifacts for auditing and compliance verification.
- Clone and rerun workflows to experiment with what-if scenarios while developing models.
- Share a workflow that colleagues can reproduce and enhance (for example, while collaborating on solving a business problem).
• Clone and rerun workflows with additional debugging or logging routines, or new input variations for troubleshooting issues in production models.

Topics
• Tracking Entities (p. 2207)
• Amazon SageMaker Created Tracking Entities (p. 2208)
• Manually Create Tracking Entities (p. 2210)

Tracking Entities

Tracking entities maintain a representation of all the elements of your end-to-end machine learning workflow. You can use this representation to establish model governance, reproduce your workflow, and maintain a record of your work history.

Amazon SageMaker automatically creates tracking entities for trial components and their associated trials and experiments when you create SageMaker jobs such as processing jobs, training jobs, and batch transform jobs. For more information, see Manage Machine Learning with Amazon SageMaker Experiments (p. 1514).

SageMaker also automatically creates tracking entities for the other steps in a workflow that enable you to track the workflow from end to end. For more information, see Amazon SageMaker Created Tracking Entities (p. 2208).

You can create additional entities to supplement those created by SageMaker. For more information, see Manually Create Tracking Entities (p. 2210).

SageMaker reuses any existing entities rather than create new ones. For example, there can be only one artifact with a unique SourceUri.

The following tracking entities are defined:

Experiment entities
• Trial component – A stage of a machine learning trial. Includes processing jobs, training jobs, and batch transform jobs.
• Trial – A combination of trial components that generally produces a model.
• Experiment – A grouping of trials generally focused on solving a specific use case.

Lineage entities
• Context – Provides a logical grouping of other tracking or experiment entities. Conceptually, experiments and trials are contexts. Some examples are an endpoint and a model package.
• Action – Represents an action or activity. Generally, an action involves at least one input artifact or output artifact. Some examples are a workflow step and a model deployment.
• Artifact – Represents a URI addressable object or data. An artifact is generally either an input to or an output from a trial component or Action. Some examples include a dataset (Amazon S3 bucket URI), an image (Amazon ECR registry path), or an action (ARN).
• Association – Links other tracking or experiment entities. For example, an association between the location of training data and a training job.

An association has an optional AssociationType property. The following values are available along with the suggested use for each type. SageMaker places no restrictions on their use:
• ContributedTo – The source contributed to the destination or had a part in enabling the destination. For example, the training data contributed to the training job.
• **AssociatedWith** – The source is connected to the destination. For example, an approval workflow is associated with a model deployment.

• **DerivedFrom** – The destination is a modification of the source. For example, a digest output of a channel input for a processing job is derived from the original inputs.

• **Produced** – The source generated the destination. For example, a training job produced a model artifact.

**Common properties**

• **Type property**
  The action, artifact, and context entities have a `type` property, `ActionType`, `ArtifactType`, and `ContextType`, respectively. This property is a custom string which can associate meaningful information with the entity and be used as a filter in the List APIs.

• **Source property**
  The action, artifact, and context entities have a `Source` property. This property provides the underlying URI that the entity represents. Some examples are:
  - An `UpdateEndpoint` action where the source is the `EndpointArn`.
  - An image artifact for a processing job where the source is the `ImageUri`.
  - An `Endpoint` context where the source is the `EndpointArn`.

• **Metadata property**
  The action and artifact entities have an optional `Metadata` property which can provide the following information:
  - `ProjectId` – For example, the ID of the SageMaker MLOps project a model belongs to.
  - `GeneratedBy` – For example, the SageMaker pipeline execution that registered a model package version.
  - `Repository` – For example, the repository that contains an algorithm.
  - `CommitId` – For example, the commit ID of an algorithm version.

---

**Amazon SageMaker Created Tracking Entities**

Amazon SageMaker automatically creates tracking entities for SageMaker jobs, models, model packages, and endpoints if the data is available. There is no limit to the number of lineage entities automatically created by SageMaker.

For information on how you can manually create tracking entities, see [Manually Create Tracking Entities (p. 2210)](#).

**Topics**

- Tracking Entities for SageMaker Jobs (p. 2208)
- Tracking Entities for Model Packages (p. 2209)
- Tracking Entities for Endpoints (p. 2209)

**Tracking Entities for SageMaker Jobs**

A trial component is created for and associated with each SageMaker job. Artifacts are created to track the job metadata. Associations are created between each artifact and the job.

Artifacts are created for the following job properties and associated with the Amazon Resource Name (ARN) of the SageMaker job. The artifact `SourceUri` is listed in parentheses.
Training Job

- The image that contains the training algorithm (TrainingImage)
- The data source of each input channel (S3Uri)
- The location for the model (S3OutputPath)
- The location for the managed spot checkpoint data (S3Uri)

Processing Job

- The container to be run by the processing job (ImageUri)
- The data location for each processing input and processing output (S3Uri)

Transform Job

- The input data source to be transformed (S3Uri)
- The results of the transform (S3OutputPath)

Note

Amazon Simple Storage Service (Amazon S3) artifacts are tracked based on the S3 URI values provided to the create API, for example CreateTrainingJob, and not on the S3 key and hash/etag values from each file.

Tracking Entities for Model Packages

The following entities are created:

Model Packages

- A context for each model package group
- An artifact for each model package
- An association between each model package artifact and the context for each model package group the package belongs to
- An action for the creation of a model package version
- An association between the model package artifact and the creation action
- An association between the model package artifact and each model package group context the package belongs to
- Inference containers
  - An artifact for the image used in each container defined in the model package
  - An artifact for the model used in each container
  - An association between each artifact and the model package artifact
- Algorithms
  - An artifact for each algorithm defined in the model package
  - An artifact for the model created by each algorithm
  - An association between each artifact and the model package artifact

Tracking Entities for Endpoints

The following entities are created:
Endpoints

- A context for each endpoint
- An action for the model deployment that created each endpoint
- An artifact for each model deployed to the endpoint
- An artifact for the image used in the model
- An artifact for the model package for the model
- An artifact for each image deployed to the endpoint
- An association between each artifact and the model deployment action

Manually Create Tracking Entities

You can manually create tracking entities for any property. For information on the tracking entities that Amazon SageMaker automatically creates, see Amazon SageMaker Created Tracking Entities (p. 2208).

You can add tags to all entities except associations. Tags are arbitrary key-value pairs that provide custom information. You can filter or sort a list or search query by tags. For more information, see Tagging AWS resources in the AWS General Reference.

For a sample notebook that demonstrates how to create lineage entities, see the Amazon SageMaker Lineage notebook in the Amazon SageMaker example GitHub repository.

Topics

- Manually Create Entities (p. 2210)
- Manually Track a Workflow (p. 2212)
- Limits (p. 2213)

Manually Create Entities

The following procedure shows you how to create and associate artifacts between a SageMaker training job and endpoint. You perform the following steps:

- Create input artifacts for the source code, training data, and testing data locations.
- Create an output artifact for the generated model location.
- Create a trial component as a training job.
- Associate the input artifact and output artifacts with the training job.
- Train the model and create an endpoint.
- Create a context for the endpoint.
- Associate the training job and the endpoint context.

To create tracking entities and associations

1. Import the tracking entities.

   ```python
   import sys
   !(sys.executable) -m pip install -q sagemaker
   from sagemaker import get_execution_role
   from sagemaker.session import Session
   from sagemaker.lineage import context, artifact, association, action
   ```
2. Create the input and output artifacts.

```python
import boto3
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client("sagemaker")

code_location_arn = artifact.Artifact.create(
    artifact_name='source-code-location',
    source_uri='s3://...',
    artifact_type='code-location'
).artifact_arn

# Similar constructs for train_data_location_arn and test_data_location_arn

model_location_arn = artifact.Artifact.create(
    artifact_name='model-location',
    source_uri='s3://...',
    artifact_type='model-location'
).artifact_arn
```

3. Train the model and get the trial_component_arn that represents the training job.

4. Associate the input artifacts and output artifacts with the training job (trial component).

```python
input_artifacts = [code_location_arn, train_data_location_arn, test_data_location_arn]
for artifact_arn in input_artifacts:
    try:
        association.Association.create(
            source_arn=artifact_arn,
            destination_arn=trial_component_arn,
            association_type='ContributedTo'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)

output_artifacts = [model_location_arn]
for artifact_arn in output_artifacts:
    try:
        association.Association.create(
            source_arn=trial_component_arn,
            destination_arn=artifact_arn,
            association_type='Produced'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn, trial_component_arn)
```

5. Create the inference endpoint.

```python
predictor = mnist_estimator.deploy(initial_instance_count=1,
instance_type='ml.m4.xlarge')
```

6. Create the endpoint context.

```python
from sagemaker.lineage import context
endpoint = sagemaker_client.describe_endpoint(EndpointName=predictor.endpoint_name)
endpoint_arn = endpoint['EndpointArn']

endpoint_context_arn = context.Context.create(
    context_name=predictor.endpoint_name,
    context_type='Endpoint',
)
```
Manually Create Entities

Manually Track a Workflow

You can manually track the workflow created in the previous section.

Given the endpoint Amazon Resource Name (ARN) from the previous example, the following procedure shows you how to track the workflow back to the datasets used to train the model that was deployed to the endpoint. You perform the following steps:

- Given the endpoint ARN, get the endpoint context.
- Get the trial component from the association between the trial component and the endpoint context.
- Get the training data location artifact from the association between the trial component and the endpoint context.
- Get the training data location from the training data location artifact.

To track a workflow from endpoint to training data source

1. Import the tracking entities.

   ```python
   import sys
   !{sys.executable} -m pip install -q sagemaker
   from sagemaker import get_execution_role
   from sagemaker import session import Session
   from sagemaker.lineage import context, artifact, association, action
   import boto3
   boto_session = boto3.Session(region_name=region)
   sagemaker_client = boto_session.client("sagemaker")
   ```

2. Get the endpoint context from the endpoint ARN.

   ```python
   endpoint_context_arn = sagemaker_client.list_contexts(
       SourceUri=endpoint_arn)['ContextSummaries'][0]['ContextArn']
   ```

3. Get the trial component from the association between the trial component and the endpoint context.

   ```python
   trial_component_arn = sagemaker_client.list_associations(
       DestinationArn=endpoint_context_arn)['AssociationSummaries'][0]['SourceArn']
   ```

4. Get the training data location artifact from the association between the trial component and the endpoint context.

   ```python
   train_data_location_artifact_arn = sagemaker_client.list_associations(
       DestinationArn=trial_component_arn, SourceType='Model')['AssociationSummaries'][0][
       'SourceArn']
   ```
5. Get the training data location from the training data location artifact.

```python
train_data_location = sagemaker_client.describe_artifact(
    ArtifactArn=train_data_location_artifact_arn)['Source']['SourceUri']
print(train_data_location)
```

Response:

```
s3://sagemaker-sample-data-us-east-2/mxnet/mnist/train
```

## Limits

An association can be created between any entities, experiment and lineage, except the following:

- An association can't be created between two experiment entities. Experiment entities consist of experiments, trials, and trial components.
- An association can't be created with another association.

An error occurs if you try to create an entity that already exists.

### Maximum number of manually created lineage entities

- Actions: 3000
- Artifacts: 6000
- Associations: 6000
- Contexts: 500

There is no limit to the number of lineage entities automatically created by SageMaker.

## Kubernetes Orchestration

You can orchestrate your SageMaker training and inference jobs with SageMaker Operators for Kubernetes and SageMaker Components for Kubeflow Pipelines. SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. SageMaker Components for Kubeflow Pipelines allow you to move your data processing and training jobs from the Kubernetes cluster to SageMaker's machine learning-optimized managed service.

### Contents

- SageMaker Operators for Kubernetes (p. 2213)
- SageMaker Components for Kubeflow Pipelines (p. 2244)

## SageMaker Operators for Kubernetes

SageMaker Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker. You can install these SageMaker Operators on your Kubernetes cluster in Amazon Elastic Kubernetes Service (Amazon EKS) to create SageMaker jobs natively using the Kubernetes API and command-line Kubernetes tools such as `kubectl`.
This guide shows you how to set up the operators. The guide also explains how to use the operators to run model training, hyperparameter tuning, and inference (real-time and batch).

There is no additional charge to use these operators. You do incur charges for any SageMaker resources that you use through these operators. The procedures and guidelines here assume you are familiar with Kubernetes and its basic commands.

Contents

- What is an operator? (p. 2214)
- IAM role-based setup and operator deployment (p. 2215)
- Delete operators (p. 2224)
- Troubleshooting (p. 2226)
- Images and SMlogs in each Region (p. 2226)
- Using SageMaker Jobs (p. 2227)

What is an operator?

Kubernetes is built on top of what is called the controller pattern. This pattern allows applications and tools to listen to a central state manager (ETCD) and act when something happens. Examples of such applications include cloud-controller-manager and controller-manager. The controller pattern allows you to create decoupled experiences and not have to worry about how other components are integrated. To add new capabilities to Kubernetes, developers can extend the Kubernetes API by creating a custom resource that contains their application-specific or domain-specific logic and components. Operators in Kubernetes allow users to natively invoke these custom resources and automate associated workflows.

Prerequisites

This guide assumes that you’ve completed the following prerequisites:

- Installed the following tools on the client machine used to access your Kubernetes cluster:
  - `kubectl` Version 1.13 or later. Use a kubectl version that is within one minor version of your Amazon EKS cluster control plane. For example, a 1.13 kubectl client works with Kubernetes 1.13 and 1.14 clusters. OpenID Connect (OIDC) is not supported in versions earlier than 1.13.
  - `eksctl` Version 0.7.0 or later
  - AWS CLI Version 1.16.232 or later
  - (optional) Helm Version 3.0 or later
  - `aws-iam-authenticator`
- Have IAM permissions to create roles and attach policies to roles.
- Created a Kubernetes cluster on which to run the operators. It should either be Kubernetes version 1.13 or 1.14. For automated cluster creation using eksctl, see Getting Started with eksctl. It takes 20 to 30 minutes to provision a cluster.

Permissions overview

The SageMaker Operators for Kubernetes allow you to manage jobs in SageMaker from your Kubernetes cluster. The operators access SageMaker resources on your behalf. The IAM role that the operator assumes to interact with AWS resources differs from the credentials you use to access the Kubernetes cluster. The role also differs from the role that SageMaker assumes when running your machine learning jobs. The following image explains this design and flow.
IAM role-based setup and operator deployment

The following sections describe the steps to set up and deploy the operator.
Cluster-scoped deployment

Before you can deploy your operator using an IAM role, associate an OpenID Connect (OIDC) provider with your role to authenticate with the IAM service.

Create an OpenID Connect Provider for Your Cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local CLUSTER_NAME and AWS_REGION environment variables as follows:

```bash
# Set the Region and cluster
export CLUSTER_NAME="<your cluster name>"
export AWS_REGION="<your region>"
```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

```bash
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
--region ${AWS_REGION} --approve
```

Your output should look like the following:

```
[...]
eksctl version 0.10.1
[...]
using region us-east-1
[...]
IAM OpenID Connect provider is associated with cluster "my-cluster" in "us-east-1"
```

Now that the cluster has an OIDC identity provider, you can create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get the OIDC ID

To set up the ServiceAccount, obtain the OpenID Connect issuer URL using the following command:

```bash
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
--query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

In this URL, the value D48675832CA65BD10A532F597OIDCID is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:

```bash
aws eks describe-cluster --region ${AWS_REGION} --query cluster.identity.oidc.issuer --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```
Create an IAM Role

1. Create a file named `trust.json` and insert the following trust relationship code block into it. Be sure to replace all `<OIDC ID>`, `<AWS account number>`, and `<EKS Cluster region>` placeholders with values corresponding to your cluster.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Federated": "arn:aws:iam::<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
            },
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringEquals": {
                    "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud": "sts.amazonaws.com",
                }
            }
        }
    ]
}
```

2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role enables the Amazon EKS cluster to get and refresh credentials from IAM.

```
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ABCDEFGHIJKLMNOPQRSTUVWXYZEXAMPLE   my-role
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
PRINCIPAL      arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN; you pass this value to your operator.

Attach the AmazonSageMakerFullAccess Policy to the Role

To give the role access to SageMaker, attach the `AmazonSageMakerFullAccess` policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach AmazonSageMakerFullAccess, run the following command:

```
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount `sagemaker-k8s-operator-default` should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.
Deploy the Operator

When deploying your operator, you can use either a YAML file or Helm charts.

Deploy the Operator Using YAML

This is the simplest way to deploy your operators. The process is as follows:

1. Download the installer script using the following command:

   ```bash
   ```

2. Edit the `installer.yaml` file to replace `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Use the following command to deploy the cluster:

   ```bash
   kubectl apply -f installer.yaml
   ```

Deploy the Operator Using Helm Charts

Use the provided Helm Chart to install the operator.

1. Clone the Helm installer directory using the following command:

   ```bash
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Install the Helm Chart using the following command:

   ```bash
   kubectl create namespace sagemaker-k8s-operator-system
   helm install --namespace sagemaker-k8s-operator-system sagemaker-operator rolebased/
   ```

   If you decide to install the operator into a namespace other than the one specified, you need to adjust the namespace defined in the IAM role `trust.json` file to match.

4. After a moment, the chart is installed with a randomly generated name. Verify that the installation succeeded by running the following command:

   ```bash
   helm ls
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>sagemaker-k8s-operator-system</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000 UTC deployed</td>
</tr>
</tbody>
</table>

Verify the operator deployment

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:
kubectl get crd | grep sagemaker

Your output should look like the following:

<table>
<thead>
<tr>
<th>CRD</th>
<th>Created</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchtransformjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>endpointconfigs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hostingdeployments.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>hyperparametertuningjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>models.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
<tr>
<td>trainingjobs.sagemaker.aws.amazon.com</td>
<td>2019-11-20T17:12:34Z</td>
</tr>
</tbody>
</table>

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

```
kubectl -n sagemaker-k8s-operator-system get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `sagemaker-k8s-operator-system` as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>23s</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Namespace-scoped deployment**

You have the option to install your operator within the scope of an individual Kubernetes namespace. In this mode, the controller only monitors and reconciles resources with SageMaker if the resources are created within that namespace. This allows for finer-grained control over which controller is managing which resources. This is useful for deploying to multiple AWS accounts or controlling which users have access to particular jobs.

This guide outlines how to install an operator into a particular, predefined namespace. To deploy a controller into a second namespace, follow the guide from beginning to end and change out the namespace in each step.

**Create an OpenID Connect Provider for Your Amazon EKS cluster**

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local `CLUSTER_NAME` and `AWS_REGION` environment variables as follows:

```
# Set the region and cluster
export CLUSTER_NAME="<your cluster name>"
export AWS_REGION="<your region>"
```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see [Enabling IAM Roles for Service Accounts on your Cluster](#).

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} --region ${AWS_REGION} --approve
```

Your output should look like the following:

```
[...] eksctl version 0.10.1
```
Now that the cluster has an OIDC identity provider, create a role and give a Kubernetes ServiceAccount permission to assume the role.

**Get your OIDC ID**

To set up the ServiceAccount, first obtain the OpenID Connect issuer URL using the following command:

```bash
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} --query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

In this URL, the value D48675832CA65BD10A532F597OIDCID is the OIDC ID. The OIDC ID for your cluster will be different. You need this OIDC ID value to create a role.

If your output is `None`, it means that your client version is old. To work around this, run the following command:

```bash
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME} --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

**Create your IAM Role**

1. Create a file named `trust.json` and insert the following trust relationship code block into it. Be sure to replace all `<OIDC ID>`, `<AWS account number>`, `<EKS Cluster region>`, and `<Namespace>` placeholders with values corresponding to your cluster. For the purposes of this guide, `my-namespace` is used for the `<Namespace>` value.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam:{}<AWS account number>:oidc-provider/oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud": "sts.amazonaws.com",
          "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub": "system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default"
        }
      }
    }
  ]
}
```

2220
2. Run the following command to create a role with the trust relationship defined in trust.json. This role enables the Amazon EKS cluster to get and refresh credentials from IAM.

```bash
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ABCDREFSFODNN7EXAMPLE   my-role
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
STRINGEQUALS    sts.amazonaws.com       system:serviceaccount:my-namespace:sagemaker-k8s-operator-default
PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-east-1.amazonaws.com/id/
```

Take note of ROLE ARN. You pass this value to your operator.

### Attach the AmazonSageMakerFullAccess Policy to your Role

To give the role access to SageMaker, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

To attach AmazonSageMakerFullAccess, run the following command:

```bash
aws iam attach-role-policy --role-name <role name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount sagemaker-k8s-operator-default should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.

### Deploy the Operator to Your Namespace

When deploying your operator, you can use either a YAML file or Helm charts.

#### Deploy the Operator to Your Namespace Using YAML

There are two parts to deploying an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself.

If you have not already installed the CRDs into the cluster, apply the CRD installer YAML using the following command:

```bash
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/release/rolebased/namespaced/crd.yaml
```

To install the operator onto the cluster:

1. Download the operator installer YAML using the following command:

   ```bash
   ```

2. Update the installer YAML to place the resources into your specified namespace using the following command:
3. Edit the `operator.yaml` file to place resources into your `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

4. Use the following command to deploy the cluster:

   ```bash
kubectl apply -f operator.yaml
   ```

**Deploy the Operator to Your Namespace Using Helm Charts**

There are two parts needed to deploy an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself. When using helm charts you have to first create the namespace using `kubectl`.

1. Clone the Helm installer directory using the following command:

   ```bash
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer/namespaced` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.

3. Install the Helm Chart using the following command:

   ```bash
   helm install crds crd_chart/
   ```

4. Create the required namespace and install the operator using the following command:

   ```bash
   kubectl create namespace <namespace>
   helm install --n <namespace> op operator_chart/
   ```

5. After a moment, the chart is installed with the name `sagemaker-operator`. Verify that the installation succeeded by running the following command:

   ```bash
   helm ls
   ```

   Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>NAMESPACE</th>
<th>REVISION</th>
<th>UPDATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-operator</td>
<td>my-namespace</td>
<td>1</td>
<td>2019-11-20 23:14:59.6777082 +0000 UTC deployed</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CHART</th>
<th>APP VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-0.1.0</td>
<td></td>
</tr>
</tbody>
</table>

**Verify the operator deployment to your namespace**

1. You should be able to see the SageMaker Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

   ```bash
   kubectl get crd | grep sagemaker
   ```
2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

```
kubectl -n my-namespace get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `my-namespace` as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>sagemaker-k8s-operator-controller-manager-12345678-r8abc</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
</tr>
<tr>
<td>23s</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Install the SageMaker logs kubectl plugin

As part of the SageMaker Operators for Kubernetes, you can use the `smlogs` plugin for `kubectl`. This enables SageMaker CloudWatch logs to be streamed with `kubectl`. `kubectl` must be installed onto your `PATH`. The following commands place the binary in the `sagemaker-k8s-bin` directory in your home directory, and add that directory to your `PATH`.

```bash
export os="linux"

wget https://amazon-sagemaker-operator-for-k8s-us-east-1.s3.amazonaws.com/kubectl-smlogs-plugin/v1/{os}.amd64.tar.gz
tar xvzf {os}.amd64.tar.gz

# Move binaries to a directory in your homedir.
mkdir ~/sagemaker-k8s-bin
cp ./kubectl-smlogs.{os}.amd64/{os}.amd64/kubectl-smlogs ~/sagemaker-k8s-bin/.

# This line adds the binaries to your PATH in your .bashrc.
echo 'export PATH=${PATH}:~/sagemaker-k8s-bin' >> ~/.bashrc

# Source your .bashrc to update environment variables:
source ~/.bashrc
```

Use the following command to verify that the `kubectl` plugin is installed correctly:

```
kubectl smlogs
```

If the `kubectl` plugin is installed correctly, your output should look like the following:

```
View SageMaker logs via Kubernetes

Usage:
    smlogs [command]
```
Aliases:
- smlogs
- SMLogs
- Smlogs

Available Commands:
- BatchTransformJob
  View BatchTransformJob logs via Kubernetes
- TrainingJob
  View TrainingJob logs via Kubernetes
- help
  Help about any command

Flags:
- -h, --help
  help for smlogs

Use "smlogs [command] --help" for more information about a command.

Delete operators

Delete cluster-based operators

Operators installed using YAML

To uninstall the operator from your cluster, make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang. Once you have deleted all SageMaker jobs, use kubectl to delete the operator from the cluster. Run the following commands to stop all jobs and delete the operator from the cluster:

```
# Delete all SageMaker jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com

# Delete the operator and its resources
kubectl delete -f /installer.yaml
```

You should see output like the following:

```
# kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
trainingjobs.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted

# kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted

# kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted

# kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted

# kubectl delete -f raw-yaml/installer.yaml
namespace "sagemaker-k8s-operator-system" deleted
customresourcedefinition.apiextensions.k8s.io "batchtransformjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "endpointconfigs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "hostingdeployments.sagemaker.aws.amazon.com" deleted
"hyperparametertuningjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "models.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "trainingjobs.sagemaker.aws.amazon.com" deleted
role.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-role" deleted
```
Operators installed using Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```bash
# get the helm charts
$ helm ls

# delete the charts
$ helm delete <chart name>
```

Delete namespace-based operators

Operators installed with YAML

To uninstall the operator from your cluster, make sure that all SageMaker resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang. Once you have deleted all SageMaker jobs, use kubectl to first delete the operator from the namespace and then the CRDs from the cluster. Run the following commands to stop all jobs and delete the operator from the cluster:

```bash
# Delete all SageMaker jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com

# Delete the operator using the same yaml file that was used to install the operator
kubectl delete -f operator.yaml

# Now delete the CRDs using the CRD installer yaml

# Now you can delete the namespace if you want
kubectl delete namespace <namespace>
```

Operators installed with Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```bash
# Delete the operator
$ helm delete -n <namespace> op

# delete the crds
$ helm delete crds
```
Troubleshooting

Debugging a Failed Job

- Check the job status by running the following:

```bash
kubectl get <CRD Type> <job name>
```

- If the job was created in SageMaker, you can use the following command to see the `STATUS` and the `SageMaker Job Name`:

```bash
kubectl get <crd type> <job name>
```

- You can use `smlogs` to find the cause of the issue using the following command:

```bash
kubectl smlogs <crd type> <job name>
```

- You can also use the `describe` command to get more details about the job using the following command. The output has an additional field that has more information about the status of the job.

```bash
kubectl describe <crd type> <job name>
```

- If the job was not created in SageMaker, then use the logs of the operator’s pod to find the cause of the issue as follows:

```bash
$ kubectl get pods -A | grep sagemaker
# Output:
sagemaker-k8s-operator-system sagemaker-k8s-operator-controller-manager-5cd7df4d74-wh22z 2/2 Running 0 3h33m
$ kubectl logs -p <pod name> -c manager -n sagemaker-k8s-operator-system
```

Deleting an Operator CRD

If deleting a job is not working, check if the operator is running. If the operator is not running, then you have to delete the finalizer using the following steps:

1. In a new terminal, open the job in an editor using `kubectl edit` as follows:

```bash
$ kubectl edit <crd type> <job name>
```

2. Edit the job to delete the finalizer by removing the following two lines from the file. Save the file and the job is be deleted.

```yaml
finalizers:
  - sagemaker-operator-finalizer
```

Images and SMlogs in each Region

The following table lists the available operator images and SMLogs in each region.
Using SageMaker Jobs

To run a job using the SageMaker Operators for Kubernetes, you can either apply a YAML file or use the supplied Helm Charts.

All operator sample jobs in the following tutorials use sample data taken from a public MNIST dataset. In order to run these samples, download the dataset into your Amazon S3 bucket. You can find the dataset in Download the MNIST Dataset.

Contents

- TrainingJob operator (p. 2227)
- HyperParameterTuningJobs operator (p. 2231)
- BatchTransformJobs operator (p. 2236)
- Real-time inference (p. 648)

TrainingJob operator

Training job operators reconcile your specified training job spec to SageMaker by launching it for you in SageMaker. You can learn more about SageMaker training jobs in the SageMaker CreateTrainingJob API documentation.

Create a TrainingJob Using a Simple YAML File

1. Download the sample YAML file for training using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-trainingjob.yaml
   ```

2. Edit the `xgboost-mnist-trainingjob.yaml` file to replace the `roleArn` parameter with your `<sagemaker-execution-role>`, and `outputPath` with your Amazon S3 bucket that the SageMaker execution role has write access to. The `roleArn` must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see SageMaker Roles. Apply the YAML file using the following command:

   ```bash
   kubectl apply -f xgboost-mnist-trainingjob.yaml
   ```
Create a TrainingJob Using a Helm Chart

You can use Helm Charts to run TrainingJobs.

1. Clone the GitHub repo to get the source using the following command:

   ```bash
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/training-jobs/` folder and edit the `values.yaml` file to replace values like `rolearn` and `outputpath` with values that correspond to your account. The RoleARN must have permissions so that SageMaker can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker ExecutionRole, see SageMaker Roles.

Create the Training Job

With the roles and Amazon S3 buckets replaced with appropriate values in `values.yaml`, you can create a training job using the following command:

```bash
helm install . --generate-name
```

Your output should look like the following:

```
NAME: chart-12345678
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Thanks for installing the sagemaker-k8s-trainingjob.
```

Verify Your Training Helm Chart

To verify that the Helm Chart was created successfully, run:

```bash
helm ls
```

Your output should look like the following:

```
NAME                    NAMESPACE       REVISION        UPDATED                    CHART                        APP VERSION
chart-12345678          default         1               2019-11-20 23:35:49.9136092 +0000 UTC   default/sagemaker-k8s-trainingjob-0.1.0
rolebased-12345678      default         1               2019-11-20 23:14:59.6777082 +0000 UTC   default/sagemaker-k8s-operator-0.1.0
```

helm install creates a TrainingJob Kubernetes resource. The operator launches the actual training job in SageMaker and updates the TrainingJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

**Note:** SageMaker does not allow you to update a running training job. You cannot edit any parameter and re-apply the file/config. Either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, `update` is not supported.
List Training Jobs

Use the following command to list all jobs created using the Kubernetes operator:

```bash
kubectl get TrainingJob
```

The output listing all jobs should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>SECONDARY-STATUS</th>
<th>CREATION-TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAGEMAKER-JOB-NAME</td>
<td>InProgress</td>
<td>Starting</td>
<td>2019-11-20T23:42:35Z</td>
</tr>
<tr>
<td>xgboost-mnist-from-for-s3</td>
<td>Failed</td>
<td></td>
<td></td>
</tr>
<tr>
<td>xgboost-mnist-from-for-s3-examplef1eab94e0ed4671d5a8f</td>
<td>Stopped</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A training job continues to be listed after the job has completed or failed. You can remove a TrainingJob job from the list by following the Delete a Training Job steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

Training Job Status Values

The STATUS field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official API documentation.

In addition to the official SageMaker status, it is possible for STATUS to be SynchronizingK8sJobWithSageMaker. This means that the operator has not yet processed the job.

Secondary Status Values

The secondary statuses come directly from the SageMaker official API documentation. They contain more granular information about the status of the job.

Describe a Training Job

You can get more details about the training job by using the describe kubectl verb. This is typically used for debugging a problem or checking the parameters of a training job. To get information about your training job, use the following command:

```bash
ekubectl describe trainingjob xgboost-mnist-from-for-s3
```

The output for your training job should look like the following:

```
Name:         xgboost-mnist-from-for-s3
Namespace:    default
Labels:       <none>
Annotations:  <none>
API Version:  sagemaker.aws.amazon.com/v1
Kind:         TrainingJob
Metadata:     
Finalizers:    
```

View Logs from Training Jobs

Use the following command to see the logs from the kmeans-mnist training job:

```bash
touch kubectl smlogs trainingjob xgboost-mnist-from-for-s3
```

Your output should look similar to the following. The logs from instances are ordered chronologically.

```
xgboost-mnist-from-for-s3" has SageMaker TrainingJobName "xgboost-mnist-from-for-s3-123456789" in region "us-east-2", status "InProgress" and secondary status "Starting"
xgboost-mnist-from-for-s3-6d7fa0af0bef11ab9aeb94e0ed46exmaple/algo-1-1574293123 2019-11-20
23:45:24.7 +0000 UTC Arguments: train
xgboost-mnist-from-for-s3-6d7fa0af0bef11ab9aeb94e0ed46exmaple/algo-1-1574293123 2019-11-20
xgboost-mnist-from-for-s3-6d7fa0af0bef11ab9aeb94e0ed46exmaple/algo-1-1574293123 2019-11-20
```

Delete Training Jobs

Use the following command to stop a training job on Amazon SageMaker:

```bash
touch kubectl delete trainingjob xgboost-mnist-from-for-s3
```

This command removes the SageMaker training job from Kubernetes. This command returns the following output:

```
trainingjob.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted
```

If the job is still in progress on SageMaker, the job stops. You do not incur any charges for SageMaker resources after your job stops or completes.

**Note:** SageMaker does not delete training jobs. Stopped jobs continue to show on the SageMaker console. The delete command takes about 2 minutes to clean up the resources from SageMaker.

HyperParameterTuningJobs operator

Hyperparameter tuning job operators reconcile your specified hyperparameter tuning job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker hyperparameter tuning jobs in the SageMaker CreateHyperParameterTuningJob API documentation.

Create a Hyperparameter Tuning Job Using a Simple YAML File

1. Download the sample YAML file for the hyperparameter tuning job using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hpo.yaml
   ```

2. Edit the xgboost-mnist-hpo.yaml file to replace the roleArn parameter with your sagemaker-execution-role. For the hyperparameter tuning job to succeed, you must also change the s3InputPath and s3OutputPath to values that correspond to your account. Apply the updates YAML file using the following command:
kubectl apply -f xgboost-mnist-hpo.yaml

Create a Hyperparameter Tuning Job using a Helm Chart

You can use Helm Charts to run hyperparameter tuning jobs.

1. Clone the GitHub repo to get the source using the following command:
   
   ```
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/hyperparameter-tuning-jobs/` folder.

3. Edit the `values.yaml` file to replace the `roleArn` parameter with your `sagemaker-execution-role`. For the hyperparameter tuning job to succeed, you must also change the `s3InputPath` and `s3OutputPath` to values that correspond to your account.

Create the Hyperparameter Tuning Job

With the roles and Amazon S3 paths replaced with appropriate values in `values.yaml`, you can create a hyperparameter tuning job using the following command:

```
helm install . --generate-name
```

Your output should look similar to the following:

```
NAME: chart-1574292948
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
  Thanks for installing the sagemaker-k8s-hyperparametertuningjob.
```

Verify Chart Installation

To verify that the Helm Chart was created successfully, run the following command:

```
helm ls
```

Your output should look like the following:

```
NAME                    NAMESPACE       REVISION        UPDATED
chart-1474292948        default         1               2019-11-20 23:35:49.9136092 +0000

```

`helm install` creates a `HyperParameterTuningJob` Kubernetes resource. The operator launches the actual hyperparameter optimization job in SageMaker and updates the `HyperParameterTuningJob`
Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

**Note:** SageMaker does not allow you to update a running hyperparameter tuning job. You cannot edit any parameter and re-apply the file/config. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

### List Hyperparameter Tuning Jobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get hyperparametertuningjob
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>COMPLETED</th>
<th>INPROGRESS</th>
<th>ERRORS</th>
<th>STOPPED</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEST-TRAINING-JOB</td>
<td>Completed</td>
<td>2019-10-17T01:15:52Z</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>SAGEMAKER-JOB-NAME</td>
<td>xgboost-mnist-hpo</td>
<td>xgboost-mnist-hpo</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>xgboost-mnist-hpo</td>
<td>xgboost-mnist-hpo</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>xgboost-mnist-hpo</td>
<td>xgboost-mnist-hpo</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A hyperparameter tuning job continues to be listed after the job has completed or failed. You can remove a `hyperparametertuningjob` from the list by following the steps in Delete a Hyperparameter Tuning Job. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

### Hyperparameter Tuning Job Status Values

The `STATUS` field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official [API documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/). In addition to the official SageMaker status, it is possible for `STATUS` to be `SynchronizingK8sJobWithSageMaker`. This means that the operator has not yet processed the job.

### Status Counters

The output has several counters, like `COMPLETED` and `INPROGRESS`. These represent how many training jobs have completed and are in progress, respectively. For more information about how these are determined, see [TrainingJobStatusCounters](https://docs.aws.amazon.com/sagemaker/latest/dg/) in the SageMaker API documentation.

### Best Training Job

This column contains the name of the `TrainingJob` that best optimized the selected metric.

To see a summary of the tuned hyperparameters, run:

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

To see detailed information about the `TrainingJob`, run:
Spawned Training Jobs

You can also track all 10 training jobs in Kubernetes launched by HyperparameterTuningJob by running the following command:

```
kubectl describe trainingjobs <job name>
```

Describe a Hyperparameter Tuning Job

You can obtain debugging details using the describe kubectl verb by running the following command.

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

In addition to information about the tuning job, the SageMaker Operator for Kubernetes also exposes the best training job found by the hyperparameter tuning job in the describe output as follows:

```
Name:         xgboost-mnist-hpo

View Logs from Hyperparameter Tuning Jobs

Hyperparameter tuning jobs do not have logs, but all training jobs launched by them do have logs. These logs can be accessed as if they were a normal training job. For more information, see View Logs from Training Jobs.

Delete a Hyperparameter tuning Job

Use the following command to stop a hyperparameter job in SageMaker.

```
kubectl delete hyperparametertuningjob xgboost-mnist-hpo
```

This command removes the hyperparameter tuning job and associated training jobs from your Kubernetes cluster and stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. SageMaker does not delete hyperparameter tuning jobs. Stopped jobs continue to show on the SageMaker Console.

Your output should look like the following:

```
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted
```

Note: The delete command takes about 2 minutes to clean up the resources from SageMaker.

BatchTransformJobs operator

Batch transform job operators reconcile your specified batch transform job spec to SageMaker by launching it in SageMaker. You can learn more about SageMaker batch transform job in the SageMaker CreateTransformJob API documentation.
Create a BatchTransformJob Using a Simple YAML File

1. Download the sample YAML file for the batch transform job using the following command:

   ```bash
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-batchtransform.yaml
   ```

2. Edit the file `xgboost-mnist-batchtransform.yaml` to change necessary parameters to replace the `inputdataconfig` with your input data and `s3OutputPath` with your Amazon S3 buckets that the SageMaker execution role has write access to.

3. Apply the YAML file using the following command:

   ```bash
   kubectl apply -f xgboost-mnist-batchtransform.yaml
   ```

Create a BatchTransformJob Using a Helm Chart

You can use Helm Charts to run batch transform jobs.

Get the Helm installer directory

Clone the GitHub repo to get the source using the following command:

```bash
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

Configure the Helm Chart

Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/batch-transform-jobs/` folder.

Edit the `values.yaml` file to replace the `inputdataconfig` with your input data and `outputPath` with your S3 buckets to which the SageMaker execution role has write access.

Create a Batch Transform Job

1. Use the following command to create a batch transform job:

   ```bash
   helm install . --generate-name
   ```

   Your output should look like the following:

   ```
   NAME: chart-1574292948
   LAST DEPLOYED: Wed Nov 20 23:35:49 2019
   NAMESPACE: default
   STATUS: deployed
   REVISION: 1
   TEST SUITE: None
   NOTES:
   Thanks for installing the sagemaker-k8s-batch-transform-job.
   ```

2. To verify that the Helm Chart was created successfully, run the following command:

   ```bash
   helm ls
   ```

   ```
   NAME          CHART                           APP VERSION
   STATUS        REVISION                       UPDATED     
   +0000 UTC     deployed sagemaker-k8s-batchtransformjob-0.1.0
   ```
This command creates a BatchTransformJob Kubernetes resource. The operator launches the actual transform job in SageMaker and updates the BatchTransformJob Kubernetes resource to reflect the status of the job in SageMaker. You incur charges for SageMaker resources used during the duration of your job. You do not incur any charges once your job completes or stops.

**Note:** SageMaker does not allow you to update a running batch transform job. You cannot edit any parameter and re-apply the file/config. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, update is not supported.

### List Batch Transform Jobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get batchtransformjob
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>CREATION-TIME</th>
<th>SAGEMAKER-JOB-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>xgboost-mnist-batch-transform</td>
<td>Completed</td>
<td>2019-11-18T03:44:00Z</td>
<td>xgboost-mnist-a88fb19809b511eac440aa8axgboost</td>
</tr>
<tr>
<td>a88fb19809b511eac440aa8axgboost</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A batch transform job will continue to be listed after the job has completed or failed. You can remove a hyperparametertuningjob from the list by following the Delete a Batch Transform Job steps. Jobs that have completed or stopped do not incur any charges for SageMaker resources.

### Batch Transform Status Values

The **STATUS** field can be one of the following values:

- Completed
- InProgress
- Failed
- Stopped
- Stopping

These statuses come directly from the SageMaker official [API documentation](https://docs.aws.amazon.com/sagemaker/latest/dg/API_BatchTransform.html).

In addition to the official SageMaker status, it is possible for **STATUS** to be **SynchronizingK8sJobWithSageMaker**. This means that the operator has not yet processed the job.

### Describe a Batch Transform Job

You can obtain debugging details using the `describe kubectl` verb by running the following command.

```
kubectl describe batchtransformjob xgboost-mnist-batch-transform
```

Your output should look like the following:
Name: xgboost-mnist-batch-transform
Namespace: default
Labels: <none>
Annotations: kubectl.kubernetes.io/last-applied-configuration:
API Version: sagemaker.aws.amazon.com/v1
Kind: BatchTransformJob
Metadata:
Creation Timestamp: 2019-11-18T03:44:00Z
Finalizers:
sagemaker-operator-finalizer
Generation: 2
Resource Version: 2199024
Self Link: /apis/sagemaker.aws.amazon.com/v1/namespaces/default/batchtransformjobs/xgboost-mnist
UID: a88fb198-09b5-11ea-ac44-0aa8a9UIDNUM
Spec:
Model Name: TrainingJob-20190814SMJOb-IKEB
Region: us-east-1
Transform Input:
   Content Type: text/csv
   Data Source:
      S3 Data Source: s3://my-bucket/mnist_kmeans_example/input
   S3 Data Type: S3Prefix
   S3 Uri: s3://my-bucket/mnist_kmeans_example/input
Transform Job Name: xgboost-mnist-a88fb19809b511eaac440aa8a9SMJOB
Transform Output:
   S3 Output Path: s3://my-bucket/mnist_kmeans_example/output
Transform Resources:
   Instance Count: 1
   Instance Type: ml.m4.xlarge
Status:
Last Check Time: 2019-11-19T22:50:40Z
SageMaker Transform Job Name: xgboost-mnist-a88fb19809b511eaac440aaSMJOB
Transform Job Status: Completed
Events: <none>

View Logs from Batch Transform Jobs

Use the following command to see the logs from the xgboost-mnist batch transform job:

```
kubectl smlogs batchtransformjob xgboost-mnist-batch-transform
```

Delete a Batch Transform Job

Use the following command to stop a batch transform job in SageMaker.

```
kubectl delete batchTransformJob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted
```

This command removes the batch transform job from your Kubernetes cluster, as well as stops them in SageMaker. Jobs that have stopped or completed do not incur any charges for SageMaker resources. Delete takes about 2 minutes to clean up the resources from SageMaker.

**Note:** SageMaker does not delete batch transform jobs. Stopped jobs continue to show on the SageMaker console.
Real-time inference

HostingDeployments support creating and deleting an endpoint, as well as updating an existing endpoint. The hosting deployment operator reconciles your specified hosting deployment job spec to SageMaker by creating models, endpoint-configs and endpoints in SageMaker. You can learn more about SageMaker inference in the SageMaker CreateEndpoint API documentation.

Configure a HostingDeployment Resource

Download the sample YAML file for the hosting deployment job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/samples/xgboost-mnist-hostingdeployment.yaml
```

The `xgboost-mnist-hostingdeployment.yaml` file has the following components that can be edited as required:

- **ProductionVariants.** A production variant is a set of instances serving a single model. SageMaker load-balances between all production variants according to set weights.
- **Models.** A model is the containers and execution role ARN necessary to serve a model. It requires at least a single container.
- **Containers.** A container specifies the dataset and serving image. If you are using your own custom algorithm instead of an algorithm provided by SageMaker, the inference code must meet SageMaker requirements. For more information, see Using Your Own Algorithms with SageMaker.

Create a HostingDeployment

To create a HostingDeployment, use `kubectl` to apply the file `hosting.yaml` with the following command:

```
kubectl apply -f hosting.yaml
```

SageMaker creates an endpoint with the specified configuration. You incur charges for SageMaker resources used during the lifetime of your endpoint. You do not incur any charges once your endpoint is deleted.

The creation process takes approximately 10 minutes.

List HostingDeployments

To verify that the HostingDeployment was created, use the following command:

```
kubectl get hostingdeployments
```

Your output should look like the following:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>SAGEMAKER-ENDPOINT-NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>host-xgboost</td>
<td>Creating</td>
<td>host-xgboost-def0e83e0d5f11eaaa450aSMLOGS</td>
</tr>
</tbody>
</table>

HostingDeployment Status Values

The status field can be one of several values:

- **SynchronizingK8sJobWithSageMaker:** The operator is preparing to create the endpoint.
- **ReconcilingEndpoint:** The operator is creating, updating, or deleting endpoint resources. If the HostingDeployment remains in this state, use `kubectl describe` to see the reason in the Additional field.
Amazon SageMaker Developer Guide
SageMaker Operators for Kubernetes

•
•
•
•
•

•
•
•

OutOfService: Endpoint is not available to take incoming requests.
Creating: CreateEndpoint is executing.
Updating: UpdateEndpoint or UpdateEndpointWeightsAndCapacities is executing.
SystemUpdating: Endpoint is undergoing maintenance and cannot be updated or deleted or rescaled until it has completed. This maintenance operation does not change any customer-speciﬁed
values such as VPC conﬁg, KMS encryption, model, instance type, or instance count.
RollingBack: Endpoint fails to scale up or down or change its variant weight and is in the
process of rolling back to its previous conﬁguration. Once the rollback completes, endpoint
returns to an InService status. This transitional status only applies to an endpoint that
has autoscaling enabled and is undergoing variant weight or capacity changes as part of an
UpdateEndpointWeightsAndCapacities call or when the UpdateEndpointWeightsAndCapacities
operation is called explicitly.
InService: Endpoint is available to process incoming requests.
Deleting: DeleteEndpoint is executing.
Failed: Endpoint could not be created, updated, or re-scaled. Use DescribeEndpoint:FailureReason for
information about the failure. DeleteEndpoint is the only operation that can be performed on a failed
endpoint.

Describe a Hostingdeployment
You can obtain debugging details using the describe kubectl verb by running the following
command.
kubectl describe hostingdeployment

Your output should look like the following:
Name:
Namespace:
Labels:
Annotations:

host-xgboost
default
<none>
kubectl.kubernetes.io/last-applied-configuration:
{"apiVersion":"sagemaker.aws.amazon.com/
v1","kind":"HostingDeployment","metadata":{"annotations":{},"name":"hostxgboost","namespace":"def..."
API Version: sagemaker.aws.amazon.com/v1
Kind:
HostingDeployment
Metadata:
Creation Timestamp: 2019-11-22T19:40:00Z
Finalizers:
sagemaker-operator-finalizer
Generation:
1
Resource Version: 4258134
Self Link:
/apis/sagemaker.aws.amazon.com/v1/namespaces/default/
hostingdeployments/host-xgboost

xgboost
Production Variants:
Initial Instance Count: 1
Instance Type:
ml.c5.large

2241


The status field provides more information using the following fields:

- **Additional**: Additional information about the status of the hosting deployment. This field is optional and only gets populated in case of error.
- **Creation Time**: When the endpoint was created in SageMaker.
- **Endpoint ARN**: The SageMaker endpoint ARN.
- **Endpoint Config Name**: The SageMaker name of the endpoint configuration.
- **Endpoint Name**: The SageMaker name of the endpoint.
- **Endpoint Status**: The status of the endpoint.
- **Endpoint URL**: The HTTPS URL that can be used to access the endpoint. For more information, see Deploy a Model on SageMaker Hosting Services.
- **FailureReason**: If a create, update, or delete command fails, the cause is shown here.
- **Last Check Time**: The last time the operator checked the status of the endpoint.
- **Last Modified Time**: The last time the endpoint was modified.
- **Model Names**: A key-value pair of HostingDeployment model names to SageMaker model names.

### Invoking the Endpoint

Once the endpoint status is **InService**, you can invoke the endpoint in two ways: using the AWS CLI, which does authentication and URL request signing, or using an HTTP client like cURL. If you use your own client, you need to do AWSv4 URL signing and authentication on your own.

To invoke the endpoint using the AWS CLI, run the following command. Make sure to replace the Region and endpoint-name with your endpoint’s Region and SageMaker endpoint name. This information can be obtained from the output of `kubectl describe`.

```bash
# Invoke the endpoint with mock input data.
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \n  --endpoint-name <endpoint name> \n  --body $(seq 784 | xargs echo | sed 's/ /,/g') \n  >(cat) \n  --content-type text/csv > /dev/null
```

For example, if your Region is `us-east-2` and your endpoint config name is `host-xgboost-f56b6b280d7511ea824b129926example`, then the following command would invoke the endpoint:

```bash
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \n  --endpoint-name host-xgboost-f56b6b280d7511ea824b129926example \n  --body $(seq 784 | xargs echo | sed 's/ /,/g') \n```
Here, 4.95847082138 is the prediction from the model for the mock data.

**Update HostingDeployment**

1. Once a HostingDeployment has a status of `InService`, it can be updated. It might take about 10 minutes for HostingDeployment to be in service. To verify that the status is `InService`, use the following command:

   ```
   kubectl get hostingdeployments
   ```

2. The HostingDeployment can be updated before the status is `InService`. The operator waits until the SageMaker endpoint is `InService` before applying the update.

   To apply an update, modify the `hosting.yaml` file. For example, change the `initialInstanceCount` field from 1 to 2 as follows:

   ```yaml
   apiVersion: sagemaker.aws.amazon.com/v1
   kind: HostingDeployment
   metadata:
     name: host-xgboost
   spec:
     region: us-east-2
     productionVariants:
       - variantName: all-traffic
         modelName: xgboost-model
         initialInstanceCount: 2
         instanceType: ml.c5.large
     models:
       - name: xgboost-model
         executionRoleArn: arn:aws:iam::123456789012:role/service-role/AmazonSageMaker-ExecutionRole
         primaryContainer: xgboost
         containers:
           - xgboost
             containerHostname: xgboost
             modelDataUrl: s3://my-bucket/inference/xgboost-mnist/model.tar.gz
             image: 123456789012.dkr.ecr.us-east-2.amazonaws.com/xgboost:latest
   ```

3. Save the file, then use `kubectl` to apply your update as follows. You should see the status change from `InService` to `ReconcilingEndpoint`, then `Updating`.

   ```
   $ kubectl apply -f hosting.yaml
   hostingdeployment.sagemaker.aws.amazon.com/host-xgboost configured
   $ kubectl get hostingdeployments
   NAME           STATUS                SAGEMAKER-ENDPOINT-NAME
   host-xgboost   ReconcilingEndpoint   host-xgboost-def0e83e0d5f11eaaa450a350abcd
   $ kubectl get hostingdeployments
   NAME           STATUS     SAGEMAKER-ENDPOINT-NAME
   host-xgboost   Updating   host-xgboost-def0e83e0d5f11eaaa450a3507abcd
   ```

SageMaker deploys a new set of instances with your models, switches traffic to use the new instances, and drains the old instances. As soon as this process begins, the status becomes `Updating`. After the update is complete, your endpoint becomes `InService`. This process takes approximately 10 minutes.
Delete the HostingDeployment

1. Use `kubectl` to delete a HostingDeployment with the following command:

```bash
kubectl delete hostingdeployments host-xgboost
```

Your output should look like the following:

```
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted
```

2. To verify that the hosting deployment has been deleted, use the following command:

```bash
kubectl get hostingdeployments
No resources found.
```

Endpoints that have been deleted do not incur any charges for SageMaker resources.

SageMaker Components for Kubeflow Pipelines

This document outlines how to use SageMaker Components for Kubeflow Pipelines (KFP). With these pipeline components, you can create and monitor training, tuning, endpoint deployment, and batch transform jobs in SageMaker. By running Kubeflow Pipeline jobs on SageMaker, you move data processing and training jobs from the Kubernetes cluster to SageMaker’s machine learning-optimized managed service. This document assumes prior knowledge of Kubernetes and Kubeflow.

Contents

- What is Kubeflow Pipelines? (p. 2244)
- Kubeflow Pipeline components (p. 2245)
- IAM permissions (p. 2246)
- Converting Pipelines to use SageMaker (p. 2246)
- Using SageMaker Components (p. 2247)

What is Kubeflow Pipelines?

Kubeflow Pipelines (KFP) is a platform for building and deploying portable, scalable machine learning (ML) workflows based on Docker containers. The Kubeflow Pipelines platform consists of the following:

- A user interface (UI) for managing and tracking experiments, jobs, and runs.
- An engine (Argo) for scheduling multi-step ML workflows.
- A Python SDK for defining and manipulating pipelines and components.
- Notebooks for interacting with the system using the SDK.

A pipeline is a description of an ML workflow expressed as a directed acyclic graph as shown in the following diagram. Every step in the workflow is expressed as a Kubeflow Pipeline component, which is a Python module.

If your data has been preprocessed, the standard pipeline takes a subset of the data and runs hyperparameter optimization of the model. The pipeline then trains a model with the full dataset using the optimal hyperparameters. This model is used for both batch inference and endpoint creation.

For more information on Kubeflow Pipelines, see the Kubeflow Pipelines documentation.
**Kubeflow Pipeline components**

A Kubeflow Pipeline component is a set of code used to execute one step in a Kubeflow pipeline. Components are represented by a Python module that is converted into a Docker image. These components make it fast and easy to write pipelines for experimentation and production environments without having to interact with the underlying Kubernetes infrastructure.

**What do SageMaker Components for Kubeflow Pipelines provide?**

SageMaker Components for Kubeflow Pipelines offer an alternative to launching compute-intensive jobs in SageMaker. These components integrate SageMaker with the portability and orchestration of Kubeflow Pipelines. Using the SageMaker components, each of the jobs in the pipeline workflow runs on SageMaker instead of the local Kubernetes cluster. The job parameters, status, logs, and outputs from SageMaker are still accessible from the Kubeflow Pipelines UI. The following SageMaker components have been created to integrate six key SageMaker features into your ML workflows. You can create a Kubeflow Pipeline built entirely using these components, or integrate individual components into your workflow as needed.

There is no additional charge for using SageMaker Components for Kubeflow Pipelines. You incur charges for any SageMaker resources you use through these components.

**Training components**

**Training**

The Training component allows you to submit SageMaker Training jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Training Kubeflow Pipelines component.

**Hyperparameter Optimization**

The Hyperparameter Optimization component enables you to submit hyperparameter tuning jobs to SageMaker directly from a Kubeflow Pipelines workflow. For more information, see SageMaker hyperparameter optimization Kubeflow Pipeline component.

**Processing**

The Processing component enables you to submit processing jobs to SageMaker directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Processing Kubeflow Pipeline component.

**Inference components**

**Hosting Deploy**

The Deploy component enables you to deploy a model in SageMaker Hosting from a Kubeflow Pipelines workflow. For more information, see SageMaker Hosting Services - Create Endpoint Kubeflow Pipeline component.

**Batch Transform component**

The Batch Transform component enables you to run inference jobs for an entire dataset in SageMaker from a Kubeflow Pipelines workflow. For more information, see SageMaker Batch Transform Kubeflow Pipeline component.

**Ground Truth components**

**Ground Truth** The Ground Truth component enables you to submit SageMaker Ground Truth labeling jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker Ground Truth Kubeflow Pipelines component.
Workteam

The Workteam component enables you to create SageMaker private workteam jobs directly from a Kubeflow Pipelines workflow. For more information, see SageMaker create private workteam Kubeflow Pipelines component.

IAM permissions

Deploying Kubeflow Pipelines with SageMaker components requires the following three levels of IAM permissions:

- An IAM user/role to access your AWS account (**your_credentials**). Note: You don’t need this at all if you already have access to KFP web UI and have your input data in Amazon S3, or if you already have an Amazon Elastic Kubernetes Service (Amazon EKS) cluster with KFP.

  You use this user/role from your gateway node, which can be your local machine or a remote instance, to:
  - Create an Amazon EKS cluster and install KFP
  - Create IAM roles/users
  - Create Amazon S3 buckets for your sample input data

  The IAM user/role needs the following permissions:
  - CloudWatchLogsFullAccess
  - AWSCloudFormationFullAccess
  - IAMFullAccess
  - AmazonS3FullAccess
  - AmazonEC2FullAccess
  - AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)

- An IAM role used by KFP pods to access SageMaker (**kfp-example-pod-role**) The KFP pods use this permission to create SageMaker jobs from KFP components. Note: If you want to limit permissions to the KFP pods, create your own custom policy and attach it.

  The role needs the following permission:
  - AmazonSageMakerFullAccess

- An IAM role used by SageMaker jobs to access resources such as Amazon S3 and Amazon ECR etc. (**kfp-example-sagemaker-execution-role**).

  Your SageMaker jobs use this role to:
  - Access SageMaker resources
  - Input Data from Amazon S3
  - Store your output model to Amazon S3

  The role needs the following permissions:
  - AmazonSageMakerFullAccess
  - AmazonS3FullAccess

These are all the IAM users/roles you need to run KFP components for SageMaker.

When you have run the components and have created the SageMaker endpoint, you also need a role with the sagemaker:InvokeEndpoint permission to query inference endpoints.

Converting Pipelines to use SageMaker

You can convert an existing pipeline to use SageMaker by porting your generic Python processing containers and training containers. If you are using SageMaker for inference, you also need to attach IAM permissions to your cluster and convert an artifact to a model.
Using SageMaker Components

In this tutorial, you run a pipeline using SageMaker Components for Kubeflow Pipelines to train a classification model using Kmeans with the MNIST dataset. This workflow uses Kubeflow pipelines as the orchestrator and SageMaker as the backend to run the steps in the workflow. For the full code for this and other pipeline examples, see the Sample SageMaker Kubeflow Pipelines. For information on the components used, see the KubeFlow Pipelines GitHub repository.

Contents
- Setup (p. 2247)
- Running the Kubeflow Pipeline (p. 2253)

Setup

To use Kubeflow Pipelines (KFP), you need an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and a gateway node to interact with that cluster. The following sections show the steps needed to set up these resources.

Topics
- Set up a gateway node (p. 2247)
- Set up an Amazon EKS cluster (p. 2248)
- Install Kubeflow Pipelines (p. 2248)
- Access the KFP UI (p. 2249)
- Create IAM Users/Roles for KFP pods and the SageMaker service (p. 2250)
- Add access to additional IAM users or roles (p. 2252)

Set up a gateway node

A gateway node is used to create an Amazon EKS cluster and access the Kubeflow Pipelines UI. Use your local machine or an Amazon EC2 instance as your gateway node. If you want to use a new Amazon EC2 instance, create one with the latest Ubuntu 18.04 DLAMI version from the AWS console using the steps in Launching and Configuring a DLAMI.

Complete the following steps to set up your gateway node. Depending on your environment, you may have certain requirements already configured.

1. If you don’t have an existing Amazon EKS cluster, create a user named your_credentials using the steps in Creating an IAM User in Your AWS Account. If you have an existing Amazon EKS cluster, use the credentials of the IAM role or user that has access to it.
2. Add the following permissions to your user using the steps in Changing Permissions for an IAM User:
   - CloudWatchLogsFullAccess
   - AWSCloudFormationFullAccess
   - IAMFullAccess
   - AmazonS3FullAccess
   - AmazonEC2FullAccess
   - AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)
3. Install the following on your gateway node to access the Amazon EKS cluster and KFP UI.
   - AWS CLI. If you are using an IAM user, configure your Access Key ID, Secret Access Key and preferred AWS Region by running: aws configure
   - aws-iam-authenticator version 0.1.31 and above
   - eksctl version above 0.15.
- **kubectl** (The version needs to match your Kubernetes version within one minor version)

4. Install `boto3`.

```bash
pip install boto3
```

### Set up an Amazon EKS cluster

Run the following steps from the command line of your gateway node to set up an Amazon EKS cluster:

1. If you do not have an existing Amazon EKS cluster, complete the following substeps. If you already have an Amazon EKS cluster, skip this step.
   a. Run the following from your command line to create an Amazon EKS Cluster with version 1.14 or above. Replace `<your-cluster-name>` with any name for your cluster.

   ```bash
   eksctl create cluster --name <your-cluster-name> --region us-east-1 --auto-kubeconfig --timeout=50m --managed --nodes=1
   ```

   b. When cluster creation is complete, verify that you have access to the cluster using the following command.

   ```bash
   kubectl get nodes
   ```

2. Verify that the current `kubectl` context is the cluster you want to use with the following command. The current context is marked with an asterisk (*) in the output.

   ```bash
   kubectl config get-contexts
   ```

<table>
<thead>
<tr>
<th>CURRENT NAME</th>
<th>CLUSTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>* &lt;username&gt;@&lt;clustername&gt;.us-east-1.eksctl.io</td>
<td>&lt;clustername&gt;.us-east-1.eksctl.io</td>
</tr>
</tbody>
</table>

3. If the desired cluster is not configured as your current default, update the default with the following command.

   ```bash
   aws eks update-kubeconfig --name <clustername> --region us-east-1
   ```

### Install Kubeflow Pipelines

Run the following steps from the command line of your gateway node to install Kubeflow Pipelines on your cluster.

1. Install Kubeflow Pipelines on your cluster by following step 1 of **Deploying Kubeflow Pipelines documentation**. Your KFP version must be 0.5.0 or above.

2. Verify that the Kubeflow Pipelines service and other related resources are running.

   ```bash
   kubectl -n kubeflow get all | grep pipeline
   ```

   Your output should look like the following.

<table>
<thead>
<tr>
<th>NAME</th>
<th>REPS</th>
<th>STATUS</th>
<th>AGE</th>
<th>PHASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/ml-pipeline-6b88c67994-kdtjv</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>2d</td>
</tr>
<tr>
<td>pod/ml-pipeline-persistenceagent-64d74dfdbf-66stk</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>2d</td>
</tr>
<tr>
<td>pod/ml-pipeline-scheduledworkflow-65bdf46db7-5x9qj</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>2d</td>
</tr>
</tbody>
</table>
Access the KFP UI

The Kubeflow Pipelines UI is used for managing and tracking experiments, jobs, and runs on your cluster. You can use port forwarding to access the Kubeflow Pipelines UI from your gateway node.

Set up port forwarding to the KFP UI service

Run the following from the command line of your gateway node:

1. Verify that the KFP UI service is running using the following command:

   kubectl -n kubeflow get service ml-pipeline-ui

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>ml-pipeline-ui</td>
<td>ClusterIP</td>
<td>10.100.38.71</td>
<td>&lt;none&gt;</td>
<td>80/TCP</td>
<td>2d22h</td>
</tr>
</tbody>
</table>

2. Run the following command to set up port forwarding to the KFP UI service. This forwards the KFP UI to port 8080 on your gateway node and allows you to access the KFP UI from your browser.

   kubectl port-forward -n kubeflow service/ml-pipeline-ui 8080:80

   The port forward from your remote machine drops if there is no activity. Run this command again if your dashboard is unable to get logs or updates. If the commands return an error, ensure that there is no process already running on the port you are trying to use.

Access the KFP UI service

Your method of accessing the KFP UI depends on your gateway node type.
• Local machine as the gateway node

1. Access the dashboard in your browser as follows:

http://localhost:8080

2. Choose **Pipelines** to access the pipelines UI.

• Amazon EC2 instance as the gateway node

1. You need to set up an SSH tunnel on your Amazon EC2 instance to access the Kubeflow dashboard from your local machine’s browser.

From a new terminal session in your local machine, run the following. Replace `<public-DNS-of-gateway-node>` with the IP address of your instance found on the Amazon EC2 console. You can also use the public DNS. Replace `<path_to_key>` with the path to the pem key used to access the gateway node.

```bash
public_DNS_address=<public-DNS-of-gateway-node>
key=<path_to_key>

on Ubuntu:
ssh -i ${key} -L 9000:localhost:8080 ubuntu@${public_DNS_address}

or on Amazon Linux:
ssh -i ${key} -L 9000:localhost:8080 ec2-user@${public_DNS_address}
```

2. Access the dashboard in your browser.

http://localhost:9000

3. Choose **Pipelines** to access the KFP UI.

Create IAM Users/Roles for KFP pods and the SageMaker service

You now have a Kubernetes cluster with Kubeflow set up. To run SageMaker Components for Kubeflow Pipelines, the Kubeflow Pipeline pods need access to SageMaker. In this section, you create IAM users/roles to be used by Kubeflow Pipeline pods and SageMaker.

Create a KFP execution role

Run the following from the command line of your gateway node:

1. Enable OIDC support on the Amazon EKS cluster with the following command. Replace `<cluster_name>` with the name of your cluster and `<cluster_region>` with the region your cluster is in.

```bash
eksctl utils associate-iam-oidc-provider --cluster <cluster-name> \
--region <cluster-region> --approve
```

2. Run the following to get the OIDC issuer URL. This URL is in the form `https://oidc.eks.<region>.amazonaws.com/id/<OIDC_ID>`.

```bash
aws eks describe-cluster --region <cluster-region> --name <cluster-name> --query "cluster.identity.oidc.issuer" --output text
```

3. Run the following to create a file named `trust.json`. Replace `<OIDC_URL>` with your OIDC issuer URL. Don’t include `https://` when in your OIDC issuer URL. Replace `<AWS_account_number>` with your AWS account number.
# Run this to create trust.json file

```
cat <<EOF > trust.json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Federated": "arn:aws:iam::${AWS_ACC_NUM}:oidc-provider/${OIDC_URL}"
      },
      "Action": "sts:AssumeRoleWithWebIdentity",
      "Condition": {
        "StringEquals": {
          "${OIDC_URL}:aud": "sts.amazonaws.com",
          "${OIDC_URL}:sub": "system:serviceaccount:kubeflow:pipeline-runner"
        }
      }
    }
  ]
}
EOF
```

4. Create an IAM role named `kfp-example-pod-role` using `trust.json` using the following command. This role is used by KFP pods to create SageMaker jobs from KFP components. Note the ARN returned in the output.

```
aws iam create-role --role-name kfp-example-pod-role --assume-role-policy-document file://trust.json
aws iam attach-role-policy --role-name kfp-example-pod-role --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam get-role --role-name kfp-example-pod-role --output text --query 'Role.Arn'
```

5. Edit your pipeline-runner service account with the following command.

```
kubectl edit -n kubeflow serviceaccount pipeline-runner
```

6. In the file, add the following Amazon EKS role annotation and replace `<role_arn>` with your role ARN.

```
eks.amazonaws.com/role-arn: <role_arn>
```

7. Your file should look like the following when you’ve added the Amazon EKS role annotation. Save the file.

```
apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/role-arn: <role_arn>
    kubectl.kubernetes.io/last-applied-configuration: |
    {"apiVersion":"v1","kind":"ServiceAccount","metadata":{"annotations":
    },"labels":{"app":"pipeline-runner","app.kubernetes.io/component":"pipelines-runner","app.kubernetes.io/instance":"pipelines-runner-0.2.0","app.kubernetes.io/managed-by":"kfctl","app.kubernetes.io/name":"pipelines-runner","app.kubernetes.io/part-of":"kubeflow","app.kubernetes.io/version":"0.2.0"},"name":"pipeline-runner","namespace":"kubeflow"}
  creationTimestamp: "2020-04-16T05:48:06Z"
labels:
```
Create an SageMaker execution role

The kfp-example-sagemaker-execution-role IAM role is used by SageMaker jobs to access AWS resources. For more information, see the IAM Permissions section. You provide this role as an input parameter when running the pipeline.

Run the following to create the role. Note the ARN that is returned in your output.

```
SAGEMAKER_EXECUTION_ROLE_NAME=kfp-example-sagemaker-execution-role

TRUST="{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}

aws iam create-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --assume-role-policy-document "$TRUST"
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess
aws iam get-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --output text --query 'Role.Arn'
```

Add access to additional IAM users or roles

If you use an intuitive IDE like Jupyter or want other people in your organization to use the cluster you set up, you can also give them access. The following steps run through this workflow using SageMaker notebooks. An SageMaker notebook instance is a fully managed Amazon EC2 compute instance that runs the Jupyter Notebook App. You use the notebook instance to create and manage Jupyter notebooks to create ML workflows. You can define, compile, deploy, and run your pipeline using the KFP Python SDK or CLI. If you’re not using an SageMaker notebook to run Jupyter, you need to install the AWS CLI and the latest version of kubectl.

1. Follow the steps in Create an SageMaker Notebook Instance to create a SageMaker notebook instance if you do not already have one. Give the IAM role for this instance the S3FullAccess permission.
2. Amazon EKS clusters use IAM users and roles to control access to the cluster. The rules are implemented in a config map named aws-auth. Only the user/role that has access to the cluster will be able to edit this config map. Run the following from the command line of your gateway node to get the IAM role of the notebook instance you created. Replace <instance-name> with the name of your instance.

```
aws sagemaker describe-notebook-instance --notebook-instance-name <instance-name> --region <region> --output text --query 'Role.Arn'
```
This command outputs the IAM role ARN in the `arn:aws:iam::<account-id>:role/<role-name>` format. Take note of this ARN.

3. Run the following to attach the policies the IAM role. Replace `<role-name>` with the `<role-name>` in your ARN.

   ```bash
   aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
   aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
   aws iam attach-role-policy --role-name <role-name> --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess
   ```

4. `eksctl` provides commands to read and edit the `aws-auth config map`. `system:masters` is one of the default user groups. You add the user to this group. The `system:masters` group has super user permissions to the cluster. You can also create a group with more restrictive permissions or you can bind permissions directly to users. Replace `<IAM-Role-arn>` with the ARN of the IAM role. `<your_username>` can be any unique username.

   ```bash
   eksctl create iamidentitymapping
   --cluster <cluster-name>
   --arn <IAM-Role-arn>
   --group system:masters
   --username <your-username>
   --region <region>
   ```

5. Open the Jupyter notebook on your SageMaker instance and run the following to verify that it has access to the cluster.

   ```bash
   aws eks --region <region> update-kubeconfig --name <cluster-name>
   kubectl -n kubeflow get all | grep pipeline
   ```

Running the Kubeflow Pipeline

Now that setup of your gateway node and Amazon EKS cluster is complete, you can create your classification pipeline. To create your pipeline, you need to define and compile it. You then deploy it and use it to run workflows. You can define your pipeline in Python and use the KFP dashboard, KFP CLI, or Python SDK to compile, deploy, and run your workflows. The full code for the MNIST classification pipeline example is available in the Kubeflow Github repository. To use it, clone the example Python files to your gateway node.

Topics

- Prepare datasets (p. 2253)
- Create a Kubeflow Pipeline using SageMaker Components (p. 2254)
- Compile and deploy your pipeline (p. 2254)
- Running predictions (p. 2256)
- View results and logs (p. 2258)
- Cleanup (p. 2258)

Prepare datasets

To run the pipelines, you need to upload the data extraction pre-processing script to an Amazon S3 bucket. This bucket and all resources for this example must be located in the `us-east-1` Amazon Region. If you don't have a bucket, create one using the steps in Creating a bucket.
From the mnist-kmeans-sagemaker folder of the Kubeflow repository you cloned on your gateway node, run the following command to upload the kmeans_preprocessing.py file to your Amazon S3 bucket. Change <bucket-name> to the name of the Amazon S3 bucket you created.

```bash
aws s3 cp mnist-kmeans-sagemaker/kmeans_preprocessing.py s3://<bucket-name>/mnist_kmeans_example/processing_code/kmeans_preprocessing.py
```

Create a Kubeflow Pipeline using SageMaker Components

The full code for the MNIST classification pipeline is available in the Kubeflow Github repository. To use it, clone the example Python files to your gateway node.

Input Parameters

The full MNIST classification pipeline has run-specific parameters for which you must provide values when creating a run. You must provide these parameters for each component of your pipeline. These parameters can also be updated when using other pipelines. We have provided default values for all parameters in the sample classification pipeline file.

The following are the only parameters you need to pass to run the sample pipelines. To pass these parameters, update their entries when creating a new run.

- **Role-ARN:** This must be the ARN of an IAM role that has full SageMaker access in your AWS account. Use the ARN of kfp-example-pod-role.
- **Bucket:** This is the name of the Amazon S3 bucket that you uploaded the kmeans_preprocessing.py file to.

You can adjust any of the input parameters using the KFP UI and trigger your run again.

Compile and deploy your pipeline

After defining the pipeline in Python, you must compile the pipeline to an intermediate representation before you can submit it to the Kubeflow Pipelines service. The intermediate representation is a workflow specification in the form of a YAML file compressed into a tar.gz file. You need the KFP SDK to compile your pipeline.

Install KFP SDK

Run the following from the command line of your gateway node:

1. Install the KFP SDK following the instructions in the [Kubeflow pipelines documentation](https://kubeflow.org/docs/pipelines/).
2. Verify that the KFP SDK is installed with the following command:

   ```bash
   pip show kfp
   ```

3. Verify that dsl-compile has been installed correctly as follows:

   ```bash
   which dsl-compile
   ```

Compile your pipeline

You have three options to interact with Kubeflow Pipelines: KFP UI, KFP CLI, or the KFP SDK. The following sections illustrate the workflow using the KFP UI and CLI.

Complete the following from your gateway node to compile your pipeline.
1. Modify your Python file with your Amazon S3 bucket name and IAM role ARN.
2. Use the dsl-compile command from the command line to compile your pipeline as follows. Replace `<path-to-python-file>` with the path to your pipeline and `<path-to-output>` with the location where you want your tar.gz file to be.

```
dsl-compile --py <path-to-python-file> --output <path-to-output>
```

**Upload and run the pipeline using the KFP CLI**

Complete the following steps from the command line of your gateway node. KFP organizes runs of your pipeline as experiments. You have the option to specify an experiment name. If you do not specify one, the run will be listed under Default experiment.

1. Upload your pipeline as follows:

```
kfp pipeline upload --pipeline-name <pipeline-name> <path-to-output-tar.gz>
```

Your output should look like the following. Take note of the ID.

```
Pipeline 29c3ff21-49f5-4dfe-94f6-618c0e2420fe has been submitted
Pipeline Details
------------------
ID 29c3ff21-49f5-4dfe-94f6-618c0e2420fe
Name sm-pipeline
Description
Uploaded at 2020-04-30T20:22:39+00:00
...
```

2. Create a run using the following command. The KFP CLI run command currently does not support specifying input parameters while creating the run. You need to update your parameters in the Python pipeline file before compiling. Replace `<experiment-name>` and `<job-name>` with any names. Replace `<pipeline-id>` with the ID of your submitted pipeline. Replace `<your-role-arn>` with the ARN of kfp-example-pod-role. Replace `<your-bucket-name>` with the name of the Amazon S3 bucket you created.

```
kfp run submit --experiment-name <experiment-name> --run-name <job-name> --pipeline-id <pipeline-id> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
```

You can also directly submit a run using the compiled pipeline package created as the output of the dsl-compile command.

```
kfp run submit --experiment-name <experiment-name> --run-name <job-name> --package-file <path-to-output> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
```

Your output should look like the following:

```
Creating experiment aws.
Run 9508a4ac-f18d-4b77-a9da-eba00bf01e63 is submitted
+---------------------------------------------------+
| run id                  | name     | status   | created at |
+---------------------------------------------------+
```
3. Navigate to the UI to check the progress of the job.

**Upload and run the pipeline using the KFP UI**

1. On the left panel, choose the **Pipelines** tab.
2. In the upper-right corner, choose **+UploadPipeline**.
3. Enter the pipeline name and description.
4. Choose **Upload a file** and enter the path to the tar.gz file you created using the CLI or with the Python SDK.
5. On the left panel, choose the **Pipelines** tab.
6. Find the pipeline you created.
7. Choose **+CreateRun**.
8. Enter your input parameters.
9. Choose **Run**.

**Running predictions**

Once your classification pipeline is deployed, you can run classification predictions against the endpoint that was created by the Deploy component. Use the KFP UI to check the output artifacts for `sagemaker-deploy-model-endpoint_name`. Download the .tgz file to extract the endpoint name or check the SageMaker console in the region you used.

**Configure permissions to run predictions**

If you want to run predictions from your gateway node, skip this section.

1. To use any other machine to run predictions, assign the `sagemaker:InvokeEndpoint` permission to the IAM role or IAM user used by the client machine. This permission is used to run predictions.
2. On your gateway node, run the following to create a policy file:

   ```bash
   cat <<EoF > ./sagemaker-invoke.json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "sagemaker:InvokeEndpoint",
           "sagemaker:DescribeEndpoint"
         ],
         "Resource": "*"
       }
     ]
   }
   EoF
   ```

3. Attach the policy to the client node’s IAM role or IAM user.
4. If your client machine has an IAM role attached, run the following. Replace `<your-instance-IAM-role>` with the name of the client node’s IAM role. Replace `<path-to-sagemaker-invoke-json>` with the path to the policy file you created.
aws iam put-role-policy --role-name <your-instance-IAM-role> --policy-name sagemaker-involve-for-worker --policy-document file:///<path-to-sagemaker-inverse-json>

5. If your client machine has IAM user credentials configured, run the following. Replace <your_IAM_user_name> with the name of the client node's IAM user. Replace <path-to-sagemaker-inverse-json> with the path to the policy file you created.

aws iam put-user-policy --user-name <your-IAM-user-name> --policy-name sagemaker-involve-for-worker --policy-document file:///<path-to-sagemaker-inverse-json>

Run predictions

1. Create a Python file from your client machine named mnist-predictions.py with the following content. Replace the ENDPOINT_NAME variable. This script loads the MNIST dataset, then creates a CSV from those digits and sends it to the endpoint for prediction. It then outputs the results.

```python
import boto3
import gzip
import io
import json
import numpy
import pickle

ENDPOINT_NAME='<endpoint-name>'
region = boto3.Session().region_name

# S3 bucket where the original mnist data is downloaded and stored
downloaded_data_bucket = f"jumpstart-cache-prod-{region}"
downloaded_data_prefix = "lp-notebooks-datasets/mnist"

# Download the dataset
s3 = boto3.client("s3")
s3.download_file(downloaded_data_bucket, f"{downloaded_data_prefix}/mnist.pkl.gz", "mnist.pkl.gz")

# Load the dataset
with gzip.open('mnist.pkl.gz', 'rb') as f:
    train_set, valid_set, test_set = pickle.load(f, encoding='latin1')

# Simple function to create a csv from our numpy array
def np2csv(arr):
    csv = io.BytesIO()
    numpy.savetxt(csv, arr, delimiter=',', fmt='%g')
    return csv.getvalue().decode().rstrip()

runtime = boto3.Session(region).client('sagemaker-runtime')
payload = np2csv(train_set[0][30:31])
response = runtime.invoke_endpoint(EndpointName=ENDPOINT_NAME,
                                  ContentType='text/csv',
                                  Body=payload)
result = json.loads(response['Body'].read().decode())
print(result)
```

2. Run the Python file as follows:

```bash
python mnist-predictions.py
```
View results and logs

When the pipeline is running, you can choose any component to check execution details, such as inputs and outputs. This lists the names of created resources.

If the KFP request is successfully processed and an SageMaker job is created, the component logs in the KFP UI provide a link to the job created in SageMaker. The CloudWatch logs are also provided if the job is successfully created.

If you run too many pipeline jobs on the same cluster, you may see an error message that indicates you do not have enough pods available. To fix this, log in to your gateway node and delete the pods created by the pipelines you are not using as follows:

```bash
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

Cleanup

When you're finished with your pipeline, you need to clean up your resources.

1. From the KFP dashboard, terminate your pipeline runs if they do not exit properly by choosing Terminate.
2. If the Terminate option doesn't work, log in to your gateway node and manually terminate all the pods created by your pipeline run as follows:

```bash
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```
3. Using your AWS account, log in to the SageMaker service. Manually stop all training, batch transform, and HPO jobs. Delete models, data buckets, and endpoints to avoid incurring any additional costs. Terminating the pipeline runs does not stop the jobs in SageMaker.
Using Amazon Augmented AI for Human Review

When you use AI applications such as Amazon Rekognition, Amazon Textract, or your custom machine learning (ML) models, you can use Amazon Augmented AI to get human review of low-confidence predictions or random prediction samples.

What is Amazon Augmented AI?

Amazon Augmented AI (Amazon A2I) is a service that brings human review of ML predictions to all developers by removing the heavy lifting associated with building human review systems or managing large numbers of human reviewers.

Many ML applications require humans to review low-confidence predictions to ensure the results are correct. For example, extracting information from scanned mortgage application forms can require human review due to low-quality scans or poor handwriting. Building human review systems can be time-consuming and expensive because it involves implementing complex processes or workflows, writing custom software to manage review tasks and results, and managing large groups of reviewers.

Amazon A2I streamlines building and managing human reviews for ML applications. Amazon A2I provides built-in human review workflows for common ML use cases, such as content moderation and text extraction from documents. You can also create your own workflows for ML models built on SageMaker or any other tools. Using Amazon A2I, you can allow human reviewers to step in when a model is unable to make a high-confidence prediction or to audit its predictions on an ongoing basis.

Amazon A2I Use Case Examples

The following examples demonstrate how you can use Amazon A2I to integrate a human review loop into your ML application. For each of these examples, you can find a Jupyter Notebook that demonstrates that workflow in Use Cases and Examples Using Amazon A2I (p. 2280).

- **Use Amazon A2I with Amazon Textract** – Have humans review important key-value pairs in single-page documents or have Amazon Textract randomly sample and send documents from your dataset to humans for review.

- **Use Amazon A2I with Amazon Rekognition** – Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low-confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.

- **Use Amazon A2I to review real-time ML inferences** – Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker hosted endpoint and incrementally train your model using Amazon A2I output data.

- **Use Amazon A2I with Amazon Comprehend** – Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.

- **Use Amazon A2I with Amazon Transcribe** – Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.

- **Use Amazon A2I with Amazon Translate** – Have humans review low-confidence translations returned from Amazon Translate.
• **Use Amazon A2I to review tabular data** – Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Get Started with Amazon Augmented AI

To get started using Amazon Augmented AI, review the **Core Components of Amazon A2I (p. 2260)** and **Prerequisites to Using Augmented AI (p. 2264)**. Then, use the following documentation to learn how to use the Amazon A2I console and API.

- Tutorial: Get Started in the Amazon A2I Console (p. 2264)
- Tutorial: Get Started Using the Amazon A2I API (p. 2270)

You can also get stared using the Amazon A2I API by following a Jupyter Notebook tutorial. See **Use Cases and Examples Using Amazon A2I (p. 2280)** for a list of notebooks and use cases.

Core Components of Amazon A2I

Review the following terms to familiarize yourself with the core components of Amazon A2I.

**Task Types**

The AI/ML workflow into which you integrate Amazon A2I defines an Amazon A2I task type.
Amazon A2I supports:

- **Two built-in task types**: Amazon Textract key-value pair extraction and Amazon Rekognition image moderation.

- **A custom task type**: Use a custom task type to integrate a human review loop into any machine learning workflow. You can use a custom task type to integrate Amazon A2I with other AWS services like Amazon Comprehend, Amazon Transcribe, and Amazon Translate, as well as your own custom machine learning workflows. To learn more, see Use Cases and Examples Using Amazon A2I (p. 2280).

Select a tab in the following table to see diagrams that illustrate how Amazon A2I works with each task type. Select the task type page using the links in the preceding list to learn more about that task type.

**Amazon Textract – Key-value pair extraction**

This image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

**Amazon Rekognition – Image moderation**

This image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.
**Custom Task Type**

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

**Human Review Workflow (Flow Definition)**

You use a human review workflow to specify your human work team, to set up your worker UI using a worker task template, and to provide information about how workers should complete the review task.

For built-in task types, you also use the human review workflow to identify the conditions under which a human loop is initiated. For example, Amazon Rekognition can perform image content moderation using machine learning. You can use the human review workflow to specify that an image is sent to a human for content moderation review if Amazon Rekognition's confidence is too low.

You can use a human review workflow to create multiple human loops.
You can create a flow definition in the SageMaker console or with the SageMaker API. To learn more about both of these options, see Create a Human Review Workflow (p. 2288).

Work Team

A *work team* is a group of human workers to whom you send your human review tasks.

When you create a human review workflow, you specify a single work team.

Your work team can come from the Amazon Mechanical Turk workforce, a vendor-managed workforce, or your own private workforce. When you use the private workforce, you can create multiple work teams. Each work team can be used in multiple human review workflows. To learn how to create a workforce and work teams, see Create and Manage Workforces (p. 457).

Worker Task Template and Human Task UI

You use a *worker task template* to create a worker UI (a *human task UI*) for your human review tasks.

The human task UI displays your input data, such as documents or images, and instructions to workers. It also provides interactive tools that the worker uses to complete your tasks.

For built-in task types, you must use the Amazon A2I worker task template provided for that task type.

Human Loops

A *human loop* is used to create a single human review job. For each human review job, you can choose the number of workers that are sent a task to review a single data object. For example, if you set the number of workers per object to 3 for an image classification labeling job, three workers classify each input image. Increasing the number of workers per object can improve label accuracy.

A human loop is created using a human review workflow as follows:

- For built-in task types, the conditions specified in the human review workflow determine when the human loop is created.
- Human review tasks are sent to the work team specified in the human review workflow.
- The worker task template specified in the human review workflow is used to render the human task UI.

When do human loops get created?

When you use one of the *built-in task types*, the corresponding AWS service creates and starts a human loop on your behalf when the conditions specified in your human review workflow are met. For example:

- When you use Augmented AI with Amazon Textract, you can integrate Amazon A2I into a document review task using the API operation *AnalyzeDocument*. A human loop is created every time Amazon Textract returns inferences about key-value pairs that meet the conditions you specify in your human review workflow.
- When you use Augmented AI with Amazon Rekognition, you can integrate Amazon A2I into an image moderation task using the API operation *DetectModerationLabels*. A human loop is created every time Amazon Rekognition returns inferences about image content that meet the conditions you specify in your human review workflow.

When using a *custom task type*, you start a human loop using the Amazon Augmented AI Runtime API. When you call *StartHumanLoop* in your custom application, a task is sent to human reviewers.

To learn how to create and start a human loop, see Create and Start a Human Loop (p. 2307).
To generate these resources and create a human review workflow, Amazon A2I integrates multiple APIs, including the Amazon Augmented AI Runtime Model, the SageMaker APIs, and APIs associated with your task type. To learn more, see Use APIs in Amazon Augmented AI (p. 2343).

**Note**
AWS Region availability may differ when you use Augmented AI with other AWS services, such as Amazon Textract. Create Augmented AI resources in the same AWS Region that you use to interact with those AWS services. For AWS Region availability for all services, see the Region Table.

### Prerequisites to Using Augmented AI

Amazon A2I uses resources in IAM, SageMaker, and Amazon S3 to create and run your human review workflows. You can create some of these resources in the Amazon A2I console when you create a human review workflow. To learn how, see Tutorial: Get Started in the Amazon A2I Console (p. 2264).

To use Amazon A2I, you need the following resources:

- One or more Amazon S3 buckets in the same AWS Region as the workflow for your input and output data. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
- An IAM role with required permissions to create a human review workflow and an IAM user or role with permission to access Augmented AI. For more information, see Permissions and Security in Amazon Augmented AI (p. 2335).
- A public, private, or vendor workforce for your human review workflows. If you plan to use a private workforce, you need to set one up ahead of time in the same AWS Region as your Amazon A2I workflow. To learn more about these workforce types, see Create and Manage Workforces (p. 457).

**Important**
To learn about the compliance programs that cover Amazon Augmented AI at this time, see AWS Services in Scope by Compliance Program. If you use Amazon Augmented AI in conjunction with other AWS services (such as Amazon Rekognition and Amazon Textract), note that Amazon Augmented AI may not be in scope for the same compliance programs as those other services. You are responsible for how you use Amazon Augmented AI, including understanding how the service processes or stores customer data and any impact on the compliance of your data environment. You should discuss your workload objectives and goals with your AWS account team; they can help you evaluate whether the service is a good fit for your proposed use case and architecture.

### Tutorial: Get Started in the Amazon A2I Console

The following tutorial shows you how to get started using Amazon A2I in the Amazon A2I console.

The tutorial gives you the option to use Augmented AI with Amazon Textract for document review or Amazon Rekognition for image content review.

**Prerequisites**

To get started using Amazon A2I, complete the following prerequisites.

- Create an Amazon S3 bucket in the same AWS Region as the workflow for your input and output data. For example, if you are using Amazon A2I with Amazon Textract in us-east-1, create your bucket in us-east-1. To create a bucket, follow the instructions in Create a Bucket in the Amazon Simple Storage Service Console User Guide.
- Do one of the following:
• If you want to complete the tutorial using Amazon Textract, download this sample document and place it in your Amazon S3 bucket.
• If you want to complete the tutorial using Amazon Rekognition, download this image and place it in your Amazon S3 bucket.

**Note**
The Amazon A2I console is embedded in the SageMaker console.

### Step 1: Create a Work Team

First, create a work team in the Amazon A2I console and add yourself as a worker so that you can preview the worker review task.

**Important**
This tutorial uses a private work team. The Amazon A2I private workforce is configured in the Ground Truth area of the SageMaker console and is shared between Amazon A2I and Ground Truth.

**To create a private workforce using worker emails**

2. In the navigation pane, choose **Labeling workforces** under **Ground Truth**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. For this tutorial, enter your email and any others that you want to be able to preview the human task UI. You can paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an Amazon SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to Amazon SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Choose **Create private team**.

If you add yourself to a private work team, you receive an email from no-reply@verificationemail.com with login information. Use the link in this email to reset your password and log in to your worker portal. This is where your human review tasks appear when you create a human loop.

### Step 2: Create a Human Review Workflow

In this step, you create a human review workflow. Each human review workflow is created for a specific task type. This tutorial allows you to choose between the built-in task types: Amazon Rekognition and Amazon Textract.

**To create a human review workflow:**

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the **Human review workflows** page.
2. Select **Create human review workflow**.
3. In **Workflow settings**, enter a workflow **Name**, **S3 bucket**, and the **IAM role** that you created for this tutorial, with the AWS managed policy AmazonAugmentedAIIntegratedAPIAccess attached.
4. For **Task type**, select **Textract – Key-value pair extraction** or **Rekognition – Image moderation**.
5. Select the task type that you chose from the following table for instructions for that task type.

**Amazon Textract – Key-value pair extraction**

1. Select **Trigger a human review for specific form keys based on the form key confidence score or when specific form keys are missing**.

2. For **Key name**, enter **Mail Address**.

3. Set the identification confidence threshold between 0 and 99.

4. Set the qualification confidence threshold between 0 and 99.

5. Select **Trigger a human review for all form keys identified by Amazon Textract with confidence scores in a specific range**.

6. Set the identification confidence threshold between 0 and 90.

7. Set the qualification confidence threshold between 0 and 90.

This initiates a human review if Amazon Textract returns a confidence score that is less than 99 for **Mail Address** and its key, or if it returns a confidence score less than 90 for any key value pair detected in the document.

The following image shows the Amazon Textract form extraction - Conditions for invoking human review section of the Amazon A2I console. In the image, the check boxes for the two types of triggers explained in the proceeding paragraph are checked, and **Mail Address** is used as a **Key name** for the first trigger. The identification confidence threshold is defined using confidence scores for key-value pairs detect within the form and is set between 0 and 99. The qualification confidence threshold is defined using confidence scores for text contained within keys and values in a form and is set between 0 and 99.
Amazon SageMaker Developer Guide
Tutorial: Get Started in the Amazon A2I Console

Amazon Rekognition – Image moderation

1. Select Trigger human review for labels identified by Amazon Rekognition based on label confidence score.

2. Set the Threshold between 0 and 98.

This initiates a human review if Amazon Rekognition returns a confidence score that is less than 98 for an image moderation job.

The following image shows how you can select the Trigger human review for labels identified by Amazon Rekognition based on label confidence score option and enter a Threshold between 0 and 98 in the Amazon A2I console.
6. Under Worker task template creation, select Create from a default template.
7. Enter a Template name.
8. In Task description field, enter the following text:
   
   Read the instructions carefully and complete the task.
10. Select the private team that you created.
11. Choose Create.

Once your human review workflow is created, it appears in the table on the Human review workflows page. When the Status is Active, copy and save the Workflow ARN. You need it for the next step.

Step 3: Start a Human Loop

You must use an API operation to start a human loop. There are a variety of language-specific SDKs that you can use to interact with these API operations. To see documentation for each of these SDKs, refer to the See Also section in the API documentation, as shown in the following image.

For this tutorial, you use one of the following APIs:

- If you chose the Amazon Textract task type, you use the AnalyzeDocument operation.
- If you chose the Amazon Rekognition task type, you use the DetectModerationLabels operation.
You can interact with these APIs using a SageMaker notebook instance (recommended for new users) or the AWS Command Line Interface (AWS CLI). Choose one of the following to learn more about these options:

- To learn more about and set up a notebook instance, see Use Amazon SageMaker Notebook Instances (p. 119).
- To learn more about and get started using the AWS CLI, see What Is the AWS Command Line Interface? in the AWS Command Line Interface User Guide.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

### Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `analyze_document` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.analyze_document(
    Document={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "document-name.pdf"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            ContentClassifiers: [
                "FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"
            ]
        },
        FeatureTypes=["TABLES", "FORMS"]
    }
)
```

### Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `detect_moderation_labels` documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={
        "S3Object": {
            "Bucket": "AWSDOC-EXAMPLE-BUCKET",
            "Name": "image-name.png"
        }
    },
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {
            ContentClassifiers: [
                "FreeOfPersonallyIdentifiableInformation", "FreeOfAdultContent"
            ]
        }
    }
)
```
Step 4: View Human Loop Status in Console

When you start a human loop, you can view its status in the Amazon A2I console.

To view your human loop status

1. Open the Augmented AI console at https://console.aws.amazon.com/a2i to access the Human review workflows page.
2. Select the human review workflow that you used to start your human loop.
3. In the Human loops section, you can see your human loop. View its status in the Status column.

Step 5: Download Output Data

Your output data is stored in the Amazon S3 bucket you specified when you created a human review workflow.

To view your Amazon A2I output data

1. Open the Amazon S3 console.
2. Select the Amazon S3 bucket you specified when you created your human review workflow in step 2 of this example.
3. Starting with the folder that is named after your human review workflow, navigate to your output data by selecting the folder with the following naming convention:

   `s3://output-bucket-specified-in-human-review-workflow/human-review-workflow-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json`

4. Select `output.json` and choose Download.

Tutorial: Get Started Using the Amazon A2I API

This tutorial explains the API operations you can use to get started using Amazon A2I.

To use a Jupyter Notebook to run these operations, select a Jupyter Notebook from Use Cases and Examples Using Amazon A2I (p. 2280) and use Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2282) to learn how to use it in a SageMaker notebook instance.

To learn more about the API operations you can use with Amazon A2I, see Use APIs in Amazon Augmented AI (p. 2343).

Create a Private Work Team

You can create a private work team and add yourself as a worker so that you can preview Amazon A2I.

If you are not familiar with Amazon Cognito, we recommend that you use the SageMaker console to create a private workforce and add yourself as a private worker. For instructions, see Step 1: Create a Work Team (p. 2265).

If you are familiar with Amazon Cognito, you can use the following instructions to create a private work team using the SageMaker API. After you create a work team, note the work team ARN (`WorkteamArn`).

To learn more about the private workforce and other available configurations, see Use a Private Workforce (p. 462).
Create a private workforce

If you have not created a private workforce, you can do so using an Amazon Cognito user pool. Make sure that you have added yourself to this user pool. You can create a private work team using the AWS SDK for Python (Boto3) `create_workforce` function. For other language-specific SDKs, refer to the list in `CreateWorkforce`.

```python
response = client.create_workforce(
    CognitoConfig={
        "UserPool": "Pool_ID",
        "ClientId": "app-client-id"
    },
    WorkforceName="workforce-name"
)
```

Create a private work team

After you have created a private workforce in the AWS Region to configure and start your human loop, you can create a private work team using the AWS SDK for Python (Boto3) `create_workteam` function. For other language-specific SDKs, refer to the list in `CreateWorkteam`.

```python
response = client.create_workteam(
    WorkteamName="work-team-name",
    WorkforceName="workforce-name",
    MemberDefinitions=[
        {
            "CognitoMemberDefinition": {
                "UserPool": "<aws-region>_ID",
                "UserGroup": "user-group",
                "ClientId": "app-client-id"
            },
        }
    ]
)
```

Access your work team ARN as follows:

```python
workteamArn = response["WorkteamArn"]
```

List private work teams in your account

If you have already created a private work team, you can list all work teams in a given AWS Region in your account using the AWS SDK for Python (Boto3) `list_workteams` function. For other language-specific SDKs, refer to the list in `ListWorkteams`.

```python
response = client.list_workteams()
```

If you have numerous work teams in your account, you may want to use MaxResults, SortBy, and NameContains to filter your results.

**Create a Human Review Workflow**

You can create a human review workflow using the Amazon A2I `CreateFlowDefinition` operation. Before you create your human review workflow, you need to create a human task UI. You can do this with the `CreateHumanTaskUi` operation.
If you are using Amazon A2I with the Amazon Textract or Amazon Rekognition integrations, you can specify activation conditions using a JSON.

Create a Human Task UI

If you are creating a human review workflow to be used with Amazon Textract or Amazon Rekognition integrations, you need to use and modify pre-made worker task template. For all custom integrations, you can use your own custom worker task template. Use the following table to learn how to create a human task UI using a worker task template for the two built-in integrations. Replace the template with your own to customize this request.

Amazon Textract – Key-value pair extraction

To learn more about this template, see Custom Template Example for Amazon Textract (p. 2318).

```html
<template>
  <script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
  {% capture s3_uri %}http://s3.amazonaws.com/
  {{ task.input.aiServiceRequest.document.s3Object.bucket }}/</script>
  {{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}
  <crowd-form>
    <crowd-textract-analyze-document
      src="{{ s3_uri | grant_read_access }}"
      initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
      header="Review the key-value pairs listed on the right and correct them if they
      don't match the following document."
      no-key-edit=""
      no-geometry-edit=""
      keys="{{ task.input.humanLoopContext.importantFormKeys }}"
      block-types=['"KEY_VALUE_SET"]">
      <short-instructions header="Instructions">
        <p>Click on a key-value block to highlight the corresponding key-value pair in
        the document.</p>
        <p>If it is a valid key-value pair, review the content for the value. If the
        content is incorrect, correct it.</p>
        <p>The text of the value is incorrect, correct it.</p>
        <p>A wrong value is identified, correct it.</p>
        <p>If it is not a valid key-value relationship, choose No.</p>
        <p>If you can't find the key in the document, choose Key not found.</p>
        <p>Key and value are often displayed next or below to each other.</p>
        <p>Key and value displayed in one line.</p>
        <p>Key and value displayed in two lines.</p>
      </short-instructions>
    </crowd-textract-analyze-document>
  </crowd-form>
</template>
```
Amazon Rekognition – Image moderation

To learn more about this template, see Custom Template Example for Amazon Rekognition (p. 2320).

```python
{% set s3_uri = task.input.aiServiceRequest.image.s3Object.bucket %}{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

crowd-form

crowd-rekognition-detect-moderation-labels
categories='['
  {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
    name: "{{ label.name }}",
    parentName: "{{ label.parentName }}",
  },
  {% endfor %}
']
src="{{ s3_uri | grant_read_access }}"
header="Review the image and choose all applicable categories."

<short-instructions header="Instructions">
  .instructions {
    white-space: pre-wrap;
  }
</short-instructions>
<p class="instructions">Review the image and choose all applicable categories. If no categories apply, choose None.

<b>Nudity</b>
Visuals depicting nude male or female person or persons

<b>Partial Nudity</b>
Visuals depicting covered up nudity, for example using hands or pose

<b>Revealing Clothes</b>
Visuals depicting revealing clothes and poses

<b>Physical Violence</b>
Visuals depicting violent physical assault, such as kicking or punching

<b>Weapon Violence</b>
Visuals depicting violence using weapons like firearms or blades, such as shooting

<b>Weapons</b>
Visuals depicting weapons like firearms and blades
</short-instructions>

<full-instructions header="Instructions"></full-instructions>
```
Custom Integration

The following is an example template that can be used in a custom integration. This template is used in this notebook, demonstrating a custom integration with Amazon Comprehend.

```python
import boto3

client = boto3.client('comprehend')

template = r'"
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>

<crowd-form>
  <crowd-classifier
    name="sentiment"
    categories=['"Positive", "Negative", "Neutral", "Mixed"']
    initial-value="{{ task.input.initialValue }}"
    header="What sentiment does this text convey?"
  >
    <classification-target>
      {{ task.input.taskObject }}
    </classification-target>

    <full-instructions header="Sentiment Analysis Instructions">
      <p><strong>Positive</strong> sentiment include: joy, excitement, delight</p>
      <p><strong>Negative</strong> sentiment include: anger, sarcasm, anxiety</p>
      <p><strong>Neutral</strong>: neither positive or negative, such as stating a fact</p>
      <p><strong>Mixed</strong>: when the sentiment is mixed</p>
    </full-instructions>

  </crowd-classifier>
</crowd-form>
"

Using the template specified above, you can create a template using the AWS SDK for Python (Boto3) `create_human_task_ui` function. For other language-specific SDKs, refer to the list in CreateHumanTaskUI.

```python
response = client.create_human_task_ui(
    HumanTaskUiName="human-task-ui-name",
    UiTemplate={
      "Content": template
    }
)
```

This response element contains the human task UI ARN. Save this as follows:

```python
humanTaskUiArn = response["HumanTaskUiArn"]
```

Create JSON to specify activation conditions

For Amazon Textract and Amazon Rekognition built-in integrations, you can save activation conditions in a JSON object and use this in your CreateFlowDefinition request.
Next, select a tab to see example activation conditions you can use for these built-in integrations. For additional information about activation condition options, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294).

Amazon Textract – Key-value pair extraction

This example specifies conditions for specific keys (such as Mail address) in the document. If Amazon Textract’s confidence falls outside of the thresholds set here, the document is sent to a human for review, with the specific keys that initiated the human loop prompted to the worker.

```python
import json

humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
                "Or": [
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "MissingImportantFormKey",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail address:","Mailing Add:","Mailing Addresses"]
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Phone Number",
                            "ImportantFormKeyAliases": ["Phone number:","Phone No.:","Number:"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "*",
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "*",
                            "KeyValueBlockConfidenceGreaterThan": 0,
                            "WordBlockConfidenceGreaterThan": 0
                        }
                    }
                ]
            }
        ]
    }
)
```
Amazon Rekognition – Image moderation

The human loop activation conditions used here are tailored towards Amazon Rekognition content moderation; they are based on the confidence thresholds for the Suggestive and Female Swimwear Or Underwear moderation labels.

```python
import json

humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
                "Or": [
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Suggestive",
                            "ConfidenceLessThan": 98
                        }
                    },
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Female Swimwear Or Underwear",
                            "ConfidenceGreaterThan": 98
                        }
                    }
                ]
            }
        ]
    }
)
```

Create a human review workflow

This section gives an example of the `create_flow_definition` AWS SDK for Python (Boto3) request using the resources created in the previous sections. For other language-specific SDKs, refer to the list in `create_flow_definition`. Use the tabs in the following table to see the requests to create a human review workflow for Amazon Textract and Amazon Rekognition built-in integrations.

**Amazon Textract – Key-value pair extraction**

If you use the built-in integration with Amazon Textract, you must specify "AWS/Textract/AnalyzeDocument/Forms/V1" for "AwsManagedHumanLoopRequestSource" in `HumanLoopRequestSource`.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "HumanLoopActivationConditions": humanLoopActivationConditions
    }
)
```
Amazon SageMaker Developer Guide
Tutorial: Get Started Using the Amazon A2I API

Amazon Rekognition – Image moderation

If you use the built-in integration with Amazon Rekognition, you must specify "AWS/Rekognition/DetectModerationLabels/Image/V3" for "AwsManagedHumanLoopRequestSource" in HumanLoopRequestSource.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopRequestSource={
        "AwsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3"
    },
    HumanLoopActivationConfig={
        "HumanLoopActivationConditionsConfig": {
            "humanLoopActivationConditions": humanLoopActivationConditions
        }
    },
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {
            "Key": "string",
            "Value": "string"
        },
    ]
)
```
Custom Integration

If you use a custom integration, exclude the following parameters: HumanLoopRequestSource, HumanLoopActivationConfig.

```python
response = client.create_flow_definition(
    FlowDefinitionName="human-review-workflow-name",
    HumanLoopConfig={
        "WorkteamArn": workteamArn,
        "HumanTaskUiArn": humanTaskUiArn,
        "TaskTitle": "Image content moderation",
        "TaskDescription": "Review the image and instructions. Complete the task",
        "TaskCount": 1,
        "TaskAvailabilityLifetimeInSeconds": 43200,
        "TaskTimeLimitInSeconds": 3600,
        "TaskKeywords": [
            "content moderation",
        ],
    },
    OutputConfig={
        "S3OutputPath": "s3://DOC-EXAMPLE-BUCKET/prefix/",
    },
    RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
    Tags=[
        {"Key": "string",
         "Value": "string"
        },
    ]
)
```

After you create a human review workflow, you can retrieve the flow definition ARN from the response:

```python
humanReviewWorkflowArn = response["FlowDefinitionArn"]
```

Create a Human Loop

The API operation you use to start a human loop depends on the Amazon A2I integration you use.

- If you use the Amazon Textract built-in integration, you use the AnalyzeDocument operation.
- If you use the Amazon Rekognition built-in integration, you use the DetectModerationLabels operation.
- If you use a custom integration, you use the StartHumanLoop operation.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the AWS SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the AWS SDK for Python (Boto3) to call analyze_document in us-west-2. Replace the italicized red text with your resources. Include the DataAttributes
parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the
analyze_document documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.analyze_document(
    Document={"S3Object": {"Bucket": "AWSDOC-EXAMPLE-BUCKET", "Name": "document-name.pdf"},
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
    )
) FeatureTypes=["FORMS"]
```

Human loops are only created if Amazon Textract's confidence for document analysis task meets the
activation conditions you specified in your human review workflow. You can check the response
element to determine if a human loop has been created. To see everything included in this response,
see HumanLoopActivationOutput.

```python
if "HumanLoopArn" in analyzeDocumentResponse["HumanLoopActivationOutput"]:
    # A human loop has been started:
    print("A human loop has been started with ARN: 
    {analyzeDocumentResponse["HumanLoopActivationOutput"]["HumanLoopArn"]}
```

Amazon Rekognition – Image moderation

The following example uses the AWS SDK for Python (Boto3) to call detect_moderation_labels
in us-west-2. Replace the italicized red text with your resources. Include the DataAttributes
parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the
detect_moderation_labels documentation in the AWS SDK for Python (Boto) API Reference.

```python
response = client.detect_moderation_labels(
    Image={"S3Object": {"Bucket": "AWSDOC-EXAMPLE-BUCKET", "Name": "image-name.png"}},
    HumanLoopConfig={
        "HumanLoopName": "human-loop-name",
        "DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
    }
)```

Human loops are only created if Amazon Rekognition's confidence for an image moderation task
meets the activation conditions you specified in your human review workflow. You can check the
response element to determine if a human loop has been created. To see everything included in
this response, see HumanLoopActivationOutput.

```python
if "HumanLoopArn" in response["HumanLoopActivationOutput"]:    # A human loop has been started:
    print("A human loop has been started with ARN: 
    {response["HumanLoopActivationOutput"]["HumanLoopArn"]}
```
Custom Integration

The following example uses the AWS SDK for Python (Boto3) to call `start_human_loop` in us-west-2. Replace the italicized red text with your resources. Include the `DataAttributes` parameter if you are using the Amazon Mechanical Turk workforce. For more information, see the `start_human_loop` documentation in the `AWS SDK for Python (Boto) API Reference`.

```python
response = client.start_human_loop(
    HumanLoopName= "human-loop-name",
    HumanLoopInput={"InputContent": inputContentJson},
    DataAttributes={"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}
)
```

This example stores input content in the variable `inputContentJson`. Assume that the input content contains two elements: a text blurb and sentiment (such as Positive, Negative, or Neutral), and it is formatted as follows:

```python
inputContent = {
    "initialValue": sentiment,
    "taskObject": blurb
}
```

The keys `initialValue` and `taskObject` must correspond to the keys used in the liquid elements of the worker task template. Refer to the custom template in Create a Human Task UI (p. 2272) to see an example.

To create `inputContentJson`, do the following:

```python
import json
inputContentJson = json.dumps(inputContent)
```

A human loop starts each time you call `start_human_loop`. To check the status of your human loop, use `describe_human_loop`:

```python
human_loop_info = a2i.describe_human_loop(HumanLoopName="human_loop_name")
print(f"HumanLoop Status: {resp["HumanLoopStatus"]}")
print(f"HumanLoop Output Destination: {resp["HumanLoopOutput"]}")
```

Use Cases and Examples Using Amazon A2I

You can use Amazon Augmented AI to incorporate a human review into your workflow for built-in task types, Amazon Textract and Amazon Rekognition, or your own custom tasks using a custom task type.

When you create a human review workflow using one of the built-in task types, you can specify conditions, such as confidence thresholds, that initiate a human review. The service (Amazon Rekognition or Amazon Textract) creates a human loop on your behalf when these conditions are met and supplies your input data directly to Amazon A2I to send to human reviewers. To learn more about the built-in task types, use the following:
• Use Amazon Augmented AI with Amazon Textract (p. 2282)
• Use Amazon Augmented AI with Amazon Rekognition (p. 2285)

When you use a custom task type, you create and start a human loop using the Amazon A2I Runtime API. Use the custom task type to incorporate a human review workflow with other AWS services or your own custom ML application.

• For more details, see Use Amazon Augmented AI with Custom Task Types (p. 2286)

The following table outlines a variety of Amazon A2I use cases that you can explore using SageMaker Jupyter Notebooks. To get started with a Jupyter Notebook, use the instructions in Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2282). For more examples, see this GitHub repository.

### Topics
- Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2282)
- Use Amazon Augmented AI with Amazon Textract (p. 2282)
- Use Amazon Augmented AI with Amazon Rekognition (p. 2285)
- Use Amazon Augmented AI with Custom Task Types (p. 2286)

### Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook

For an end-to-end example that demonstrates how to integrate an Amazon A2I human review loop into a machine learning workflow, you can use a Jupyter Notebook from this GitHub Repository in a SageMaker notebook instance.

To use an Amazon A2I custom task type sample notebook in an Amazon SageMaker notebook instance:

1. If you do not have an active SageMaker notebook instance, create one by following the instructions in Step 1: Create an Amazon SageMaker Notebook Instance (p. 55).
2. When your notebook instance is active, choose Open JupyterLab to the right of the notebook instance's name. It may take a few moments for JupyterLab to load.
3. Choose the icon to clone a GitHub repository into your workspace.
4. Enter the amazon-a2i-sample-jupyter-notebooks repository HTTPS URL.
5. Choose CLONE.
6. Open the notebook that you would like to run.
7. Follow the instructions in the notebook to configure your human review workflow and human loop and run the cells.
8. To avoid incurring unnecessary charges, when you are done with the demo, stop and delete your notebook instance in addition to any Amazon S3 buckets, IAM roles, and CloudWatch Events resources created during the walkthrough.

### Use Amazon Augmented AI with Amazon Textract

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract's AnalyzeDocument API operation. You can use AnalyzeDocument to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an AnalyzeDocument request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for
review when the conditions specified in your flow definition are met. For example, if you want a human to review a specific key like `Full name:` and their associated input values, you can create an activation condition that starts a human review any time the `Full name:` key is detected or when the inference confidence for that key falls within a range that you specify.

The following image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can specify when Amazon Textract sends a task to a human worker for review when creating a human review workflow or flow definition by specifying activation conditions.

You can set the following activation conditions when using the Amazon Textract task type:

- Initiate a human review for specific form keys based on the form key confidence score.
- Initiate a human review when specific form keys are missing.
- Initiate human review for all form keys identified by Amazon Textract with confidence scores in a specified range.
- Randomly send a sample of forms to humans for review.

When your activation condition depends on form key confidence scores, you can use two types of prediction confidence to initiate human loops:

- **Identification confidence** – The confidence score for key-value pairs detected within a form.
- **Qualification confidence** – The confidence score for text contained within key and value in a form.

In the image in the following section, `Full Name: Jane Doe` is the key-value pair, `Full Name` is the key, and `Jane Doe` is the value.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the `HumanLoopActivationConditions` parameter of `CreateFlowDefinition` API operation. To
learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294) and Use Human Loop Activation Conditions JSON Schema with Amazon Textract (p. 2296).

**Note**
When using Augmented AI with Amazon Textract, create Augmented AI resources in the same AWS Region you use to call `AnalyzeDocument`.

Get Started: Integrate a Human Review into an Amazon Textract Analyze Document Job

To integrate a human review into an Amazon Textract text detection and analysis job, you need to create a flow definition, and then use the Amazon Textract API to integrate that flow definition into your workflow. To learn how to create a flow definition using the SageMaker console or Augmented AI API, see the following topics:

- Create a Human Review Workflow (Console) (p. 2289)
- Create a Human Review Workflow (API) (p. 2291)

After you've created your flow definition, see Using Augmented AI with Amazon Textract to learn how to integrate your flow definition into your Amazon Textract task.

End-to-End Example Using Amazon Textract and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Textract with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 2264).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Textract’s Analyze Document [Example] in a SageMaker Notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2282).

A2I Textract Worker Console Preview

When they're assigned a review task in an Amazon Textract workflow, workers might see a user interface similar to the following:
You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 2315).

**Use Amazon Augmented AI with Amazon Rekognition**

Amazon Rekognition makes it easy to add image analysis to your applications. The Amazon Rekognition DetectModerationLabels API operation is directly integrated with Amazon A2I so that you can easily create a human loop to review unsafe images, such as explicit adult or violent content. You can use DetectModerationLabels to configure a human loop using a flow definition ARN. This enables Amazon A2I to analyze predictions made by Amazon Rekognition and send results to a human for review to ensure they meet the conditions set in your flow definition.

The following image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can set the following activation conditions when using the Amazon Rekognition task type:

- Initiate human review for labels identified by Amazon Rekognition based on the label confidence score.
- Randomly send a sample of images to humans for review.

You can set these activation conditions using the Amazon SageMaker console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the HumanLoopActivationConditions parameter of the CreateFlowDefinition API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294) and Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition (p. 2302).

**Note**
When using Augmented AI with Amazon Rekognition, create Augmented AI resources in the same AWS Region you use to call DetectModerationLabels.
Get Started: Integrate a Human Review into an Amazon Rekognition Image Moderation Job

To integrate a human review into an Amazon Rekognition, see the following topics:

- Create a Human Review Workflow (Console) (p. 2289)
- Create a Human Review Workflow (API) (p. 2291)

After you've created your flow definition, see Using Augmented AI with Amazon Rekognition to learn how to integrate your flow definition into your Amazon Rekognition task.

End-to-end Demo Using Amazon Rekognition and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Rekognition with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console (p. 2264).

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition [Example] in a SageMaker notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook (p. 2282).

A2I Rekognition Worker Console Preview

When they're assigned a review task in an Amazon Rekognition workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates (p. 2315).

Use Amazon Augmented AI with Custom Task Types

You can use Amazon Augmented AI (Amazon A2I) to incorporate a human review (human loop) into any machine learning workflow using the custom task type. This options gives you the most flexibility to customize the conditions under which your data objects are sent to humans for review, as well as the look and feel of your worker user interface.
When you use a custom task type, you create a custom human review workflow and specify the conditions under which a data object is sent for human review directly in your application.

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Use the procedures on this page to learn how to integrate Amazon A2I into any machine learning workflow using the custom task type.

**Create a human loop using a flow definition, integrate it into your application, and monitor the results**

1. Complete the Amazon A2I Prerequisites to Using Augmented AI (p. 2264). Note the following:
   - The path to the Amazon Simple Storage Service (Amazon S3) bucket or buckets where you store your input and output data.
   - The Amazon Resource Name (ARN) of an AWS Identity and Access Management (IAM) role with required permissions attached.
   - (Optional) The ARN of your private workforce, if you plan to use one.
2. Using HTML elements, create a custom worker template which Amazon A2I uses to generate your worker task UI. To learn how to create a custom template, see Create Custom Worker Task Templates (p. 2317).
3. Use the custom worker template from step 2 to generate a worker task template in the Amazon SageMaker console. To learn how, see Create a Worker Task Template (p. 2316).

In the next step, you create a flow definition:

   - If you want to create a flow definition using the SageMaker API, note the ARN of this worker task template for the next step.
   - If you are creating a flow definition using the console, your template automatically appears in the *Worker task template* section when you choose Create human review workflow.
4. When creating your flow definition, provide the path to your S3 buckets, your IAM role ARN, and your worker template.
   - To learn how to create a flow definition using the SageMaker CreateFlowDefinition API, see Create a Human Review Workflow (API) (p. 2291).
Create a Human Review Workflow

Use an Amazon Augmented AI (Amazon A2I) human review workflow, or flow definition, to specify the following:

- For the Amazon Textract and Amazon Rekognition built-in task types, the conditions under which your human loop is called
- The workforce to which your tasks are sent
- The set of instructions that your workforce receives, which is called a worker task template
- The configuration of your worker tasks, including the number of workers that receive a task and time limits to complete tasks
- Where your output data is stored

You can create a human review workflow in the SageMaker console or using the SageMaker CreateFlowDefinition operation. You can build a worker task template using the console for Amazon Textract and Amazon Rekognition task types while creating your flow definition.

**Important**

Human loop activation conditions, which initiate the human loop—for example, confidence thresholds—are not available for Amazon A2I custom task types. When using the console to create a flow definition for a custom task type, you can't specify activation conditions. When using the Amazon A2I API to create a flow definition for a custom task type, you can't set the HumanLoopActivationConditions attribute of the HumanLoopActivationConditionsConfig parameter. To control when human reviews are initiated, specify conditions under which StartHumanLoop is called in your custom application. In this case, every StartHumanLoop invocation results in a human review. For more information, see Use Amazon Augmented AI with Custom Task Types (p. 2286).

**Prerequisites**

To create a human review workflow definition, you must have completed the prerequisites described in Prerequisites to Using Augmented AI (p. 2264).
If you use the API to create a flow definition for any task type, or if you use a custom task type when creating a flow definition in the console, first create a worker task template. For more information, see Create and Manage Worker Task Templates (p. 2315).

If you want to preview your worker task template while creating a flow definition for a built-in task type in the console, ensure that you grant the role that you use to create the flow definition permission to access the Amazon S3 bucket that contains your template artifacts using a policy like the one described in Enable Worker Task Template Previews (p. 2339).

Topics
- Create a Human Review Workflow (Console) (p. 2289)
- Create a Human Review Workflow (API) (p. 2291)
- JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294)

Create a Human Review Workflow (Console)

Use this procedure to create a Amazon Augmented AI (Amazon A2I) human review workflow using the SageMaker console. If you are new to Amazon A2I, we recommend that you create a private work team using people in your organization, and use this work team's ARN when creating your flow definition. To learn how to set up a private workforce and create a work team, see Create a Private Workforce (Amazon SageMaker Console) (p. 463). If you have already set up a private workforce, see Create a Work Team Using the SageMaker Console (p. 466) to learn how to add a work team to that workforce.

If you are using Amazon A2I with one of the built-in task types, you can create worker instructions using a default worker task template provided by Augmented AI while creating a human review workflow in the console. To see samples of the default templates provided by Augmented AI, see the built-in task types in Use Cases and Examples Using Amazon A2I (p. 2280).

To create flow definition (console)

2. In the navigation pane, under the Augmented AI section, choose Human review workflows and then choose Create human review workflow.
3. In Overview, do the following:
   a. For Name, enter a unique workflow name. The name must be lowercase, unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
   b. For S3 location for output, enter the S3 bucket where you want to store the human review results. The bucket must be located in the same AWS Region as the workflow.
   c. For IAM role, choose the role that has the required permissions. If you choose a built-in task type and want to preview your worker template in the console, provide a role with the type of policy described in Enable Worker Task Template Previews (p. 2339) attached.
4. For Task type, choose the task type that you want the human worker to perform.
5. If you chose the Amazon Rekognition or Amazon Textract task type, specify the conditions that invoke human review.
   - For Amazon Rekognition image moderation tasks, choose an inference confidence score threshold interval that initiates human review.
   - For Amazon Textract tasks, you can initiate a human review when specific form keys are missing or when form key detection confidence is low. You can also initiate a human review if, after evaluating all of the form keys in the text, confidence is lower than your required threshold for
any form key. Two variables specify your confidence thresholds: **Identification confidence** and **Qualification confidence**. To learn more about these variables, see *Use Amazon Augmented AI with Amazon Textract* (p. 2282).

- For both task types, you can randomly send a percentage of data objects (images or forms) and their labels to humans for review.

6. Configure and specify your worker task template:
   a. If you are using the Amazon Rekognition or Amazon Textract task type:
      - In the **Create template** section:
         - To create instructions for your workers using the Amazon A2I default template for Amazon Rekognition and Amazon Textract task types, choose **Build from a default template**.
         - If you choose **Build from a default template**, create your instructions under **Worker task design**:
            - Provide a **Template name** that is unique in the AWS Region you are in.
            - In the **Instructions** section, provide detailed instructions on how to complete your task. To help workers achieve greater accuracy, provide good and bad examples.
            - (Optional) In **Additional instructions**, provide your workers with additional information and instructions.
            
            For information on creating effective instructions, see *Creating Good Worker Instructions* (p. 2324).
         - To select a custom template that you've created, choose it from the **Template** menu and provide a **Task description** to briefly describe the task for your workers. To learn how to create a custom template, see *Create a Worker Task Template* (p. 2316).
   
   b. If you are using the custom task type:
      - In the **Worker task template** section, select your template from the list. All of the templates that you have created in the SageMaker console appear in this list. To learn how to create a template for custom task types, see *Create and Manage Worker Task Templates* (p. 2315).

7. (Optional) Preview your worker template:

   For Amazon Rekognition and Amazon Textract task types, you have the option to choose **See a sample worker task** to preview your worker task UI.

   If you are creating a flow definition for a custom task type, you can preview your worker task UI using the **RenderUiTemplate** operation. For more information, see *Preview a Worker Task Template* (p. 2324).

8. For **Workers**, choose a workforce type.

9. Choose **Create**.

**Next Steps**

After you've created a human review workflow, it appears in the console under **Human review workflows**. To see your flow definition's Amazon Resource Name (ARN) and configuration details, choose the workflow by selecting its name.

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (for example, the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both options, see *Create and Start a Human Loop* (p. 2307).
Create a Human Review Workflow (API)

To create a flow definition using the SageMaker API, you use the `CreateFlowDefinition` operation. After you complete the Prerequisites to Using Augmented AI (p. 2264), use the following procedure to learn how to use this API operation.

For an overview of the `CreateFlowDefinition` operation, and details about each parameter, see `CreateFlowDefinition`.

**To create a flow definition (API)**

1. For `FlowDefinitionName`, enter a unique name. The name must be unique within the AWS Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
2. For `RoleArn`, enter the ARN of the role that you configured to grant access to your data sources.
3. For `HumanLoopConfig`, enter information about the workers and what they should see. See `HumanLoopConfig` for information about each parameter.
4. (Optional) If you are using a built-in task type, provide conditions that initiate a human loop in `HumanLoopActivationConfig`. To learn how to create the input required for the `HumanLoopActivationConfig` parameter, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294). If you do not specify conditions here, when you provide a flow definition to the AWS service associated with a built-in task type (for example, Amazon Textract or Amazon Rekognition), that service sends every task to a human worker for review.

   If you are using a custom task type, `HumanLoopActivationConfig` is disabled. To learn how to control when tasks are sent to human workers using a custom task type, see Use Amazon Augmented AI with Custom Task Types (p. 2286).

5. (Optional) If you are using a built-in task type, specify the integration source (for example, Amazon Rekognition or Amazon Textract) in the `HumanLoopRequestSource` parameter.
6. For `OutputConfig`, indicate where in Amazon Simple Storage Service (Amazon S3) to store the output of the human loop.
7. (Optional) Use `Tags` to enter key-value pairs to help you categorize and organize a flow definition. Each tag consists of a key and a value, both of which you define.

**Amazon Textract – Key-value pair extraction**

The following is an example of a request to create an Amazon Textract human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use `AWS/Texttract/AnalyzeDocument/Forms/V1` to create a Textract human loop. Only include `PublicWorkforceTaskPrice` if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
        'AwsManagedHumanLoopRequestSource': 'AWS/Texttract/AnalyzeDocument/Forms/V1'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig':{
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-task-ui/template_name'
    }
)
```
Amazon SageMaker Developer Guide

Create a Human Review Workflow (API)

Amazon Rekognition – Image moderation

The following is an example of a request to create an Amazon Rekognition human review workflow (flow definition) using the AWS SDK for Python (Boto3). You must use 'AWS/Rekognition/DetectModerationLabels/Image/V3' to create an Amazon Rekognition flow definition. Only include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
        'AwsManagedHumanLoopRequestSource': 'AWS/Rekognition/DetectModerationLabels/Image/V3'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1', 'Keyword2'
        ],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {'Key': 'KeyName',
         'Value': 'ValueName'}
    ]
)
```
Custom Workflow

The following is an example of a request to create a human review workflow (flow definition) for a custom integration. To create this type of human review workflow, omit HumanLoopRequestSource from the flow definition request. You only need to include PublicWorkforceTaskPrice if you are using the Mechanical Turk workforce.

```python
sagemaker_client = boto3.client('sagemaker', aws_region)
response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig':{
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': ['Keyword1','Keyword2'],
        'PublicWorkforceTaskPrice': {
            'AmountInUsd': {
                'Dollars': 123,
                'Cents': 123,
                'TenthFractionsOfACent': 123
            }
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        { 'Key': 'KeyName',
          'Value': 'ValueName'
        }
    ]
)
```

Next Steps

The return value of a successful call of the CreateFlowDefinition API operation is a flow definition Amazon Resource Name (ARN).

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that AWS service's API (i.e. the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both of these options, see Create and Start a Human Loop (p. 2307).

JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

The HumanLoopActivationConditions is an input parameter of the CreateFlowDefinition API. This parameter is a JSON-formatted string. The JSON models the conditions under which a human loop is created when those conditions are evaluated against the response from an integrating AI service API (such as Rekognition.DetectModerationLabels or Textract.AnalyzeDocument). This response is referred to as an inference. For example, Amazon Rekognition sends an inference of a moderation label with an associated confidence score. In this example, the inference is the model's best estimate of the appropriate label for an image. For Amazon Textract, inference is made on the association between blocks of text (key-value pairs), such as the association between Name: and Sue in a form as well as content within a block of text, or word block, such as 'Name'.

The following is the schema for the JSON. At the top level, the HumanLoopActivationConditions has a JSON array, Conditions. Each member of this array is an independent condition that, if evaluated to true, results in Amazon A2I creating a human loop. Each such independent condition can be a simple condition or a complex condition. A simple condition has the following attributes:

- **ConditionType**: This attribute identifies the type of condition. Each AWS AI service API that integrates with Amazon A2I defines its own set of allowed ConditionTypes.
  - Rekognition DetectModerationLabels – This API supports the ModerationLabelConfidenceCheck and Sampling ConditionType values.
  - Textract AnalyzeDocument – This API supports the ImportantFormKeyConfidenceCheck, MissingImportantFormKey, and Sampling ConditionType values.
- **ConditionParameters** – This is a JSON object that parameterizes the condition. The set of allowed attributes of this object is dependent on the value of the ConditionType. Each ConditionType defines its own set of ConditionParameters.

A member of the Conditions array can model a complex condition. This is accomplished by logically connecting simple conditions using the And and Or logical operators and nesting the underlying simple conditions. Up to two levels of nesting are supported.

```json
{
  "$schema": "http://json-schema.org/draft-07/schema#",
  "definitions": {
    "Condition": {
      "type": "object",
      "properties": {
        "ConditionType": {
          "type": "string"
        }
      }
    }
  }
}
```
JSON Schema for Human Loop Activation

Conditions in Amazon Augmented AI

Note

Human loop activation conditions aren't available for human review workflows that are integrated with custom task types. The `HumanLoopActivationConditions` parameter is disabled for custom task types.

Topics
• Use Human Loop Activation Conditions JSON Schema with Amazon Textract (p. 2296)
• Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition (p. 2302)

Use Human Loop Activation Conditions JSON Schema with Amazon Textract

When used with Amazon A2I, the AnalyzeDocument operation supports the following inputs in the ConditionType parameter:

• ImportantFormKeyConfidenceCheck – Use this condition to create a human loop when inference confidence is within a specified range for document form keys and word blocks. A form key is any word in a document that is associated with an input. The input is called a value. Together, form keys and values are referred to as key-value pairs. A word block refers to the words that Amazon Textract recognizes inside of a detected block of text. To learn more about Amazon Textract document blocks, see Documents and Block Objects in the Amazon Textract Developer Guide.

• MissingImportantFormKey – Use this condition to create a human loop when Amazon Textract did not identify the key or its associated aliases within the document.

• Sampling – Use this condition to specify a percentage of forms to send to humans for review, regardless of inference confidence scores. Use this condition to do the following:
  • Audit your ML model by randomly sampling all forms analyzed by your model and sending a specified percentage to humans for review.
  • Using the ImportantFormKeyConfidenceCheck condition, randomly sample a percentage of the inferences that met the conditions specified in ImportantFormKeyConfidenceCheck to start a human loop and send only the specified percentage to humans for review.

Note
If you send the same request to AnalyzeDocument multiple times, the result of Sampling does not change for the inference of that input. For example, if you make an AnalyzeDocument request once, and Sampling doesn't initiate a human loop, subsequent requests to AnalyzeDocument with the same configuration do not initiate a human loop.

ImportantFormKeyConfidenceCheck Inputs and Results

The ImportantFormKeyConfidenceCheck ConditionType supports the following ConditionParameters:

• ImportantFormKey – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers. If the value of this parameter is the special catch-all value (*), then all keys are considered to be matched to the condition. You can use this to model the case where any key-value pair satisfying certain confidence thresholds needs human review.

• ImportantFormKeyAliases – An array that represents alternate spellings or logical equivalents for the important form key.
  • KeyValueBlockConfidenceEquals
  • KeyValueBlockConfidenceLessThan
  • KeyValueBlockConfidenceLessThanEquals
  • KeyValueBlockConfidenceGreaterThan
  • KeyValueBlockConfidenceGreaterThanEquals
  • WordBlockConfidenceEquals
  • WordBlockConfidenceLessThan
  • WordBlockConfidenceLessThanEquals
• WordBlockConfidenceGreaterThan
• WordBlockConfidenceGreaterThanOrEquals

When you use the ImportantFormKeyConfidenceCheck ConditionType, Amazon A2I sends the key-value block and word block inferences of the key-value blocks and associated aliases that you specified in ImportantFormKey and ImportantFormKeyAliases for human review.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the Amazon SageMaker console, key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the {{ task.input.selectedAiServiceResponse.blocks }} element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract (p. 2318).

**MissingImportantFormKey Inputs and Results**

The MissingImportantFormKey ConditionType supports the following ConditionParameters:

• ImportantFormKey – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers.

• ImportantFormKeyAliases – An array that represents alternate spellings or logical equivalents for the important form key.

When you use the MissingImportantFormKey ConditionType, if the key in ImportantFormKey or aliases in ImportantFormKeyAliases are not included in the Amazon Textract inference, that form is sent to human for review and no predicted key-value pairs are included. For example, if Amazon Textract only identified Address and Phone in a form, but was missing the ImportantFormKey Name (in the MissingImportantFormKey condition type) that form would be sent to humans for review without any of the form keys detected (Address and Phone).

If you use the default worker task template that is provided in the SageMaker console, a task is created asking workers to identify the key in ImportantFormKey and associated value. If you use a custom worker task template, you need to include the <task.input.humanLoopContext> custom HTML element to configure this task.

**Sampling Inputs and Results**

The Sampling ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for RandomSamplingPercentage must be real number between 0.01 and 100. This number represents the percentage of data that qualifies for a human review and is sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all resulting inferences made by the AnalyzeDocument operation from a single request that is sent to humans for review.

If you specify the Sampling condition without any other condition type, all key-value and block inferences are sent to workers for review.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the SageMaker console, all key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the {{ task.input.selectedAiServiceResponse.blocks }} element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract (p. 2318).
Examples

While only one condition needs to evaluate to true to initiate a human loop, Amazon A2I evaluates all conditions for each object analyzed by Amazon Textract. The human reviewers are asked to review the important form keys for all the conditions that evaluated to true.

Example 1: Detect important form keys with confidence scores in a specified range that initiate a human loop

The following example shows a HumanLoopActivationConditions JSON that initiates a human loop if any one of the following three conditions is met:

- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Employee Name, Name, or EmployeeName, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block being less than 65 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract AnalyzeDocument API returns a key-value pair whose key is one of Gross Pay, GrossPay, or GrossAmount, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.

```json
{
  "Conditions": [
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Employee Name",
        "ImportantFormKeyAliases": ["Name", "EmployeeName"],
        "KeyValueBlockConfidenceLessThan": 60,
        "WordBlockConfidenceLessThan": 85
      }
    },
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Pay Date",
        "ImportantFormKeyAliases": ["PayDate", "DateOfPay", "pay-date"],
        "KeyValueBlockConfidenceLessThan": 65,
        "WordBlockConfidenceLessThan": 85
      }
    },
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "Gross Pay",
        "ImportantFormKeyAliases": ["GrossPay", "GrossAmount"],
        "KeyValueBlockConfidenceLessThan": 60,
        "WordBlockConfidenceLessThan": 85
      }
    }
  ]
}```
Example 2: Use ImportantFormKeyConfidenceCheck

In the following example, if Amazon Textract detects a key-value pair whose confidence for the key-value block is less than 60 and is less than 90 for any underlying word blocks, it creates a human loop. The human reviewers are asked to review all the form key-value pairs that matched the confidence value comparisons.

```json
{
  "Conditions": [
    {
      "ConditionType": "ImportantFormKeyConfidenceCheck",
      "ConditionParameters": {
        "ImportantFormKey": "*",
        "KeyValueBlockConfidenceLessThan": 60,
        "WordBlockConfidenceLessThan": 90
      }
    }
  ]
}
```

Example 3: Use Sampling

In the following example, 5% of inferences resulting from an Amazon Textract AnalyzeDocument request are sent to human workers for review. All detected key-value pairs returned by Amazon Textract are sent to workers for review.

```json
{
  "Conditions": [
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use MissingImportantFormKey

In the following example, if Mailing Address or its alias, Mailing Address:, is missing from keys detected by Amazon Textract, a human review is initiated. When using the default worker task template, the worker UI asks workers to identify the key Mailing Address or Mailing Address: and its associated value.

```json
{
  "ConditionType": "MissingImportantFormKey",
  "ConditionParameters": {
    "ImportantFormKey": "Mailing Address",
    "ImportantFormKeyAliases": ["Mailing Address:"]
  }
}
```

Example 5: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

In this example, 5% of key-value pairs detected by Amazon Textract whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85, are sent to workers for review.

```json
{
  "ConditionType": "Sampling and ImportantFormKeyConfidenceCheck with the And operator",
  "ConditionParameters": {
    "RandomSamplingPercentage": 5,
    "ConditionType": "ImportantFormKeyConfidenceCheck",
    "ConditionParameters": {
      "ImportantFormKey": "*",
      "KeyValueBlockConfidenceLessThan": 60,
      "WordBlockConfidenceLessThan": 90
    }
  }
}
```
Example 6: Use Sampling and ImportantFormKeyConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low confidence inferences of a specified key-value pair for human review and sample high confidence inference of a key-value pair at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences less than 60, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.
- 5% of key-value pairs detected whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with key-value and word block confidences greater than 90, are sent for human review. Only the Pay Date form key (and its aliases) and associated values are sent to workers to review.
"And": [  
  {  
    "ConditionType": "Sampling",  
    "ConditionParameters": {  
      "RandomSamplingPercentage": 5  
    }  
  },  
  {  
    "ConditionType": "ImportantFormKeyConfidenceCheck",  
    "ConditionParameters": {  
      "ImportantFormKey": "Pay Date",  
      "ImportantFormKeyAliases": [  
        "PayDate",  
        "DateOfPay",  
        "pay-date"  
      ],  
      "KeyValueBlockConfidenceLessThan": 90,  
      "WordBlockConfidenceGreaterThan": 90  
    }  
  }  
]  
]  
]  
]  
}

Example 7: Use Sampling and ImportantFormKeyConfidenceCheck with the Or operator

In the following example, the Amazon Textract AnalyzeDocument operation returns a key-value pair whose key is one of Pay Date, PayDate, DateOfPay, or pay-date, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85. Additionally, 5% of all other forms initiate a human loop. For each form randomly chosen, all key-value pairs detected for that form are sent to humans for review.

{  
  "Conditions": [  
    {  
      "Or": [  
        {  
          "ConditionType": "Sampling",  
          "ConditionParameters": {  
            "RandomSamplingPercentage": 5  
          }  
        },  
        {  
          "ConditionType": "ImportantFormKeyConfidenceCheck",  
          "ConditionParameters": {  
            "ImportantFormKey": "Pay Date",  
            "ImportantFormKeyAliases": [  
              "PayDate",  
              "DateOfPay",  
              "pay-date"  
            ],  
            "KeyValueBlockConfidenceLessThan": 65,  
            "WordBlockConfidenceLessThan": 85  
          }  
        }  
      ]  
    }  
  ]  
}
Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

When used with Amazon A2I, the Amazon Rekognition DetectModerationLabels operation supports the following inputs in the ConditionType parameters:

- **ModerationLabelConfidenceCheck** – Use this condition type to create a human loop when inference confidence is low for one or more specified labels.
- **Sampling** – Use this condition to specify a percentage of all inferences to send to humans for review. Use this condition to do the following:
  - Audit your ML model by randomly sampling all of your model's inferences and sending a specified percentage to humans for review.
  - Using the ModerationLabelConfidenceCheck condition, randomly sample a percentage of the inferences that met the conditions specified in ModerationLabelConfidenceCheck to start a human loop and send only the specified percentage to humans for review.

**Note**
If you send the same request to DetectModerationLabels multiple times, the result of Sampling does not change for the inference of that input. For example, if you make a DetectModerationLabels request once, and Sampling does not initiate a human loop, subsequent requests to DetectModerationLabels with the same configuration don't initiate a human loop.

When creating a flow definition, if you use the default worker task template that is provided in the Human review workflows section of the Amazon SageMaker console, inferences sent for human review by these activation conditions are included in the worker UI when a worker opens your task. If you use a custom worker task template, you need to include the `<task.input.selectedAiServiceResponse.blocks>` custom HTML element to access these inferences. For an example of a custom template that uses this HTML element, see Custom Template Example for Amazon Rekognition (p. 2320).

**ModerationLabelConfidenceCheck Inputs**

For the ModerationLabelConfidenceCheck ConditionType, the following ConditionParameters are supported:

- **ModerationLabelName** – The exact (case-sensitive) name of a ModerationLabel detected by the Amazon Rekognition DetectModerationLabels operation. You can specify the special catch-all value (*) to denote any moderation label.
  - ConfidenceEquals
  - ConfidenceLessThan
  - ConfidenceLessThanEquals
  - ConfidenceGreaterThan
  - ConfidenceGreaterThanEquals

When you use the ModerationLabelConfidenceCheck ConditionType, Amazon A2I sends label inferences for the labels that you specified in ModerationLabelName for human review.

**Sampling Inputs**

The Sampling ConditionType supports the RandomSamplingPercentage ConditionParameters. The input for the RandomSamplingPercentage parameter should be real number between 0.01 and
100. This number represents the percentage of inferences that qualifies for a human review that are sent to humans for review. If you use the Sampling condition without any other conditions, this number represents the percentage of all inferences that result from a single DetectModerationLabel request that are sent to humans for review.

**Examples**

**Example 1: Use ModerationLabelConfidenceCheck with the And operator**

The following example of a HumanLoopActivationConditions condition initiates a human loop when one or more of the following conditions are met:

- Amazon Rekognition detects the Graphic Male Nudity moderation label with a confidence between 90 and 99.
- Amazon Rekognition detects the Graphic Female Nudity moderation label with a confidence between 80 and 99.

Note the use of the Or and And logical operators to model this logic.

Although only one of the two conditions under the Or operator needs to evaluate to true for a human loop to be created, Amazon Augmented AI evaluates all conditions. Human reviewers are asked to review the moderation labels for all the conditions that evaluated to true.

```json
{
  "Conditions": [
    {
      "Or": [
        {
          "And": [
            {
              "ConditionType": "ModerationLabelConfidenceCheck",
              "ConditionParameters": {
                "ModerationLabelName": "Graphic Male Nudity",
                "ConfidenceLessThanEquals": 99
              }
            },
            {
              "ConditionType": "ModerationLabelConfidenceCheck",
              "ConditionParameters": {
                "ModerationLabelName": "Graphic Male Nudity",
                "ConfidenceGreaterThanEquals": 90
              }
            }
          ]
        },
        {
          "And": [
            {
              "ConditionType": "ModerationLabelConfidenceCheck",
              "ConditionParameters": {
                "ModerationLabelName": "Graphic Female Nudity",
                "ConfidenceLessThanEquals": 99
              }
            },
            {
              "ConditionType": "ModerationLabelConfidenceCheck",
              "ConditionParameters": {
                "ModerationLabelName": "Graphic Female Nudity",
                "ConfidenceGreaterThanEquals": 80
              }
            }
          ]
        }
      ]
    }
  ]
}
```
Example 2: Use ModerationLabelConfidenceCheck with the catch-all value (*)

In the following example, if any moderation label with a confidence greater than or equal to 75 is detected, a human loop is initiated. Human reviewers are asked to review all moderation labels with confidence scores greater than or equal to 75.

```
{  
  "Conditions": [  
    {  
      "ConditionType": "ModerationLabelConfidenceCheck",  
      "ConditionParameters": {  
        "ModerationLabelName": "*",  
        "ConfidenceGreaterThanEquals": 75  
      }  
    }  
  ]
}
```

Example 3: Use Sampling

In the following example, 5% of Amazon Rekognition inferences from a DetectModerationLabels request are sent to human workers. When using the default worker task template provided in the SageMaker console, all moderation labels returned by Amazon Rekognition are sent to workers for review.

```
{  
  "Conditions": [  
    {  
      "ConditionType": "Sampling",  
      "ConditionParameters": {  
        "RandomSamplingPercentage": 5  
      }  
    }  
  ]
}
```

Example 4: Use Sampling and ModerationLabelConfidenceCheck with the And operator

In this example, 5% of Amazon Rekognition inferences of the Graphic Male Nudity moderation label with a confidence greater than 50 are sent workers for review. When using the default worker task template provided in the SageMaker console, only the inferences of the Graphic Male Nudity label are sent to workers for review.

```
{  
  "Conditions": [  
    {  
      "And": [  
        {  
          "ConditionType": "Sampling",  
          "ConditionParameters": {  
            "RandomSamplingPercentage": 5  
          }  
        },  
        {  
          "ConditionType": "ModerationLabelConfidenceCheck",  
          "ConditionParameters": {  
            "ModerationLabelName": "Graphic Male Nudity",  
            "ConfidenceGreaterThan": 50  
          }  
        }  
      ]  
    }  
  ]
}
```
Example 5: Use Sampling and ModerationLabelConfidenceCheck with the And operator

Use this example to configure your human review workflow to always send low-confidence inferences of a specified label for human review and sample high-confidence inferences of a label at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Inferences for the Graphic Male Nudity moderation label with confidence scores less than 60 are always sent for human review. Only the Graphic Male Nudity label is sent to workers to review.
- 5% of all inferences for the Graphic Male Nudity moderation label with confidence scores greater than 90 are sent for human review. Only the Graphic Male Nudity label is sent to workers to review.

```json
{
   "Conditions": [
      {
         "Or": [
            {
               "ConditionType": "ModerationLabelConfidenceCheck",
               "ConditionParameters": {
                  "ModerationLabelName": "Graphic Male Nudity",
                  "ConfidenceLessThan": 60
               }
            },
            {
               "And": [
                  {
                     "ConditionType": "Sampling",
                     "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                     }
                  },
                  {
                     "ConditionType": "ModerationLabelConfidenceCheck",
                     "ConditionParameters": {
                        "ModerationLabelName": "Graphic Male Nudity",
                        "ConfidenceGreaterThan": 90
                     }
                  }
               ]
            }
         ]
      }
   ]
}
```

Example 6: Use Sampling and ModerationLabelConfidenceCheck with the Or operator

In the following example, a human loop is created if the Amazon Rekognition inference response contains the 'Graphic Male Nudity' label with inference confidence greater than 50. Additionally, 5% of all other inferences initiate a human loop.

```json
{
   "Conditions": [
      {
         "ConditionType": "ModerationLabelConfidenceCheck",
         "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
         }
      },
      {
         "ConditionType": "Sampling",
         "ConditionParameters": {
            "RandomSamplingPercentage": 5
         }
      }
   ]
}
```
Delete a Human Review Workflow

When you delete a human review workflow or you delete your AWS account while a human loop is in process, your human review workflow status changes to Deleting. Amazon A2I automatically stops and deletes all associated human loops if workers have not started tasks created by those human loops. If human workers are already working on a task, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human review workflow's status is Deleting. If these tasks are completed, the results are stored in the Amazon S3 bucket specified in your flow definition.

Deleting a flow definition does not remove any worker answers from your S3 bucket. If the tasks are completed, but you deleted your AWS account, the results are stored in the Augmented AI service bucket for 30 days and then permanently deleted.

After all human loops have been deleted, the human review workflow is permanently deleted. When a human review workflow has been deleted, you can reuse its name to create a new human review workflow.

You might want to delete a human review workflow for any of the following reasons:

• You have sent data to a set of human reviewers and you want to delete all non-started human loops because you do not want those workers to work on those tasks any longer.

• The worker task template used to generate your worker UI does not render correctly or is not functioning as expected.

After you delete a human review workflow, the following changes occur:

• The human review workflow no longer appears on the Human review workflows page in the Augmented AI area of the Amazon SageMaker console.

• When you use the human review workflow name as input to the API operations DescribeFlowDefinition or DeleteFlowDefinition, Augmented AI returns a ResourceNotFound error.

• When you use ListFlowDefinitions, deleted human review workflows aren't included in the results.

• When you use the human review workflow ARN as input to the Augmented AI Runtime API operation ListHumanLoops, Augmented AI returns a ResourceNotFoundException.
Delete a Flow Definition Using the Console or the SageMaker API

You can delete a human review workflow on the Human review workflows page in the Augmented AI area of the SageMaker console or by using the SageMaker API.

Flow definitions can only be deleted if their status is Active.

Delete a human review workflow (console)

1. Navigate to the Augmented AI console at https://console.aws.amazon.com/a2i/.
2. In the navigation pane, under the Augmented AI section, choose Human review workflows.
3. Select the hyperlinked name of the human review workflow that you want to delete.
4. On the Summary page of your human review workflow, choose Delete.
5. In the dialog box asking you to confirm that you want to delete your human review workflow, choose Delete.

You're automatically redirected to the Human review workflows page. While your human review workflow is being deleted, the status Deleting appears in the status column for that workflow. After it's deleted, it doesn't appear in the list of workflows on this page.

Delete a human review workflow (API)

You can delete a human review workflow (flow definition) using the SageMaker DeleteFlowDefinition API operation. This API operation is supported through the AWS CLI and a variety of language specific SDKs. The following table shows example requests using SDK for Python (Boto3) and the AWS CLI to delete the human review workflow, example-flow-definition.

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3) to delete the human review workflow. For more information, see delete_flow_definition in the AWS SDK for Python (Boto) API Reference.

```python
import boto3

sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.delete_flow_definition(FlowDefinitionName='example-flow-definition')
```

AWS CLI

The following request example uses the AWS CLI to delete the human review workflow. For more information, see delete-flow-definition in the AWS CLI Command Reference.

```bash
$ aws sagemaker delete-flow-definition --flow-definition-name 'example-flow-definition'
```

If the action is successful, Augmented AI sends back an HTTP 200 response with an empty HTTP body.

Create and Start a Human Loop

A human loop starts your human review workflow and sends data review tasks to human workers. When you use one of the Amazon A2I built-in task types, the corresponding AWS service creates and
starts a human loop on your behalf when the conditions specified in your flow definition are met. If no conditions are specified in your flow definition, a human loop is created for each object. When using Amazon A2I for a custom task, a human loop starts when your application calls StartHumanLoop.

Use the following instructions to configure a human loop with Amazon Rekognition or Amazon Textract built-in task types and custom task types.

**Prerequisites**

To create and start a human loop, you must attach the AmazonAugmentedAIFullAccess policy to the AWS Identity and Access Management (IAM) user or role that configures or starts the human loop. This is the identity that you use to configure the human loop using HumanLoopConfig for built-in task types. For custom task types, this is the identity that you use to call StartHumanLoop.

Additionally, when using a built-in task type, your IAM user or role must have permission to invoke API operations of the AWS service associated with your task type. For example, if you are using Amazon Rekognition with Augmented AI, you must attach permissions required to call DetectModerationLabels. For examples of identity-based policies you can use to grant these permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples. You can also use the more general policy AmazonAugmentedAIIIntegratedAPIAccess to grant these permissions. For more information, see Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 2338).

To create and start a human loop, you need a flow definition ARN. To learn how to create a flow definition (or human review workflow), see Create a Human Review Workflow (p. 2288).

**Important**

Amazon A2I requires all S3 buckets that contain human loop input image data to have a CORS policy attached. To learn more about this change, see CORS Permission Requirement (p. 2336).

**Create and Start a Human Loop for a Built-in Task Type**

To start a human loop using a built-in task type, use the corresponding service's API to provide your input data and to configure the human loop. For Amazon Textract, you use the AnalyzeDocument API operation. For Amazon Rekognition, you use the DetectModerationLabels API operation. You can use the AWS CLI or a language-specific SDK to create requests using these API operations.

**Important**

When you create a human loop using a built-in task type, you can use DataAttributes to specify a set of ContentClassifiers related to the input provided to the StartHumanLoop operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA. Include the FreeOfPersonallyIdentifiableInformation content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the 'FreeOfAdultContent' classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.

After you start your ML job using your built-in task type's AWS service API, Amazon A2I monitors the inference results of that service. For example, when running a job with Amazon Rekognition, Amazon A2I checks the inference confidence score for each image and compares it to the confidence thresholds specified in your flow definition. If the conditions to start a human review task are satisfied, or if you didn't specify conditions in your flow definition, a human review task is sent to workers.
Create an Amazon Textract Human Loop

Amazon A2I integrates with Amazon Textract so that you can configure and start a human loop using the Amazon Textract API. To send a document file to Amazon Textract for document analysis, you use the Amazon Textract `AnalyzeDocument` API operation. To add a human loop to this document analysis job, you must configure the parameter `HumanLoopConfig`.

When you configure your human loop, the flow definition you specify in `FlowDefinitionArn` of `HumanLoopConfig` must be located in the same AWS Region as the bucket identified in `Bucket` of the `Document` parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

**AWS SDK for Python (Boto3)**

The following request example uses the SDK for Python (Boto3). For more information, see `analyze_document` in the *AWS SDK for Python (Boto) API Reference*.

```python
import boto3
textract = boto3.client('textract', aws_region)
response = textract.analyze_document(
    Document={'S3Object': {'Bucket': bucket_name, 'Name': document_name}},
    FeatureTypes=['TABLES', 'FORMS'],
    HumanLoopConfig={
        'HumanLoopName': 'human_loop_name',
        'DataAttributes': {'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}
    }
)
```

**AWS CLI**

The following request example uses the AWS CLI. For more information, see `analyze-document` in the *AWS CLI Command Reference*.

```bash
$ aws textract analyze-document \
  --human-loop-config \
  HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name",DataAttributes={"ContentClassifiers=['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']"} \
  --feature-types ['"TABLES", "FORMS"]
```

```bash
$ aws textract analyze-document \
  --human-loop-config \
  "{'HumanLoopName":"human_loop_name","FlowDefinitionArn":"arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name","DataAttributes": {"ContentClassifiers": ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]}}" \
  --feature-types ['"TABLES", "FORMS"]
```
Create and Start a Human Loop for a Built-in Task Type

After you run AnalyzeDocument with a human loop configured, Amazon A2I monitors the results from AnalyzeDocument and checks it against the flow definition's activation conditions. If the Amazon Textract inference confidence score for one or more key-value pairs meets the conditions for review, Amazon A2I starts a human review loop and includes the HumanLoopActivationOutput object in the AnalyzeDocument response.

Create an Amazon Rekognition Human Loop

Amazon A2I integrates with Amazon Rekognition so that you can configure and start a human loop using the Amazon Rekognition API. To send images to Amazon Rekognition for content moderation, you use the Amazon Rekognition DetectModerationLabels API operation. To configure a human loop, set the HumanLoopConfig parameter when you configure DetectModerationLabels.

When you configure your human loop, the flow definition you specify in FlowDefinitionArn of HumanLoopConfig must be located in the same AWS Region as the S3 bucket identified in Bucket of the Image parameter.

The following table shows examples of how to use this operation with the AWS CLI and AWS SDK for Python (Boto3).

AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see detect_moderation_labels in the AWS SDK for Python (Boto) API Reference.

```python
import boto3
rekognition = boto3.client("rekognition", aws_region)
response = rekognition.detect_moderation_labels( 
    Image={'S3Object': {'Bucket': bucket_name, 'Name': image_name}}, 
    HumanLoopConfig={ 
        'HumanLoopName': human_loop_name, 
        'FlowDefinitionArn': 'arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name' 
    }, 
    DataAttributes={
        'ContentClassifiers': ['FreeOfPersonallyIdentifiableInformation', 'FreeOfAdultContent']
    })
```

AWS CLI

The following request example uses the AWS CLI. For more information, see detect-moderation-labels in the AWS CLI Command Reference.

```bash
$ aws rekognition detect-moderation-labels 
    --image "S3Object={Bucket='bucket_name',Name='image_name'}" 
    --human-loop-config 
    HumanLoopName="human_loop_name",FlowDefinitionArn="arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name",DataAttributes='{ContentClassifiers=['FreeOfPersonallyIdentifiableInformation','FreeOfAdultContent']}'
```

```bash
$ aws rekognition detect-moderation-labels 
    --image "S3Object={Bucket='bucket_name',Name='image_name'}" 
    --human-loop-config 
    "{"HumanLoopName": "human_loop_name", "FlowDefinitionArn": "arn:aws:sagemaker:aws_region:aws_account_number:flow-definition/flow_def_name",}"
```
Create and Start a Human Loop for a Custom Task Type

To configure a human loop for a custom human review task, use the `StartHumanLoop` operation within your application. This section provides an example of a human loop request using the AWS SDK for Python (Boto3) and the AWS Command Line Interface (AWS CLI). For documentation on other language-specific SDKs that support `StartHumanLoop`, use the See Also section of `StartHumanLoop` in the Amazon Augmented AI Runtime API documentation. Refer to Use Cases and Examples Using Amazon A2I (p. 2280) to see examples that demonstrate how to use Amazon A2I with a custom task type.

Prerequisites

To complete this procedure, you need:

- Input data formatted as a string representation of a JSON-formatted file
- The Amazon Resource Name (ARN) of your flow definition
- A flow definition ARN

To configure the human loop

1. For `DataAttributes`, specify a set of `ContentClassifiers` related to the input provided to the `StartHumanLoop` operation. Use content classifiers to declare that your content is free of personally identifiable information or adult content.

   To use Amazon Mechanical Turk, ensure your data is free of personally identifiable information, including protected health information under HIPAA, and include the `FreeOfPersonallyIdentifiableInformation` content classifier. If you do not use this content classifier, SageMaker does not send your task to Mechanical Turk. If your data is free of adult content, also include the `FreeOfAdultContent` classifier. If you do not use these content classifiers, SageMaker may restrict the Mechanical Turk workers that can view your task.

2. For `FlowDefinitionArn`, enter the Amazon Resource Name (ARN) of your flow definition.

3. For `HumanLoopInput`, enter your input data as a string representation of a JSON-formatted file. Structure your input data and custom worker task template so that your input data is properly displayed to human workers when you start your human loop. See Preview a Worker Task Template (p. 2324) to learn how to preview your custom worker task template.

4. For `HumanLoopName`, enter a name for the human loop. The name must be unique within the Region in your account and can have up to 63 characters. Valid characters are a-z, 0-9, and - (hyphen).

To start a human loop

- To start a human loop, submit a request similar to the following examples using your preferred language-specific SDK.
AWS SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3). For more information, see Boto 3 Augmented AI Runtime in the AWS SDK for Python (Boto) API Reference.

```python
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')

response = a2i_runtime_client.start_human_loop(
    HumanLoopName='human_loop_name',
    HumanLoopInput={
        'InputContent': '{"InputContent": "{"prompt":"What is the answer?"}"}
    },
    DataAttributes={
        'ContentClassifiers': ["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]
    }
)
```

AWS CLI

The following request example uses the AWS CLI. For more information, see start-human-loop in the AWS CLI Command Reference.

```bash
# aws sagemaker-a2i-runtime start-human-loop
--human-loop-name 'human_loop_name'
--human-loop-input '{"InputContent": "{"prompt":"What is the answer?"}"}'
--data-attributes ContentClassifiers="FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"
```

When you successfully start a human loop by invoking StartHumanLoop directly, the response includes a HumanLoopARN and a HumanLoopActivationResults object which is set to NULL. You can use this the human loop name to monitor and manage your human loop.

Next Steps:

After starting a human loop, you can manage and monitor it with the Amazon Augmented AI Runtime API and Amazon CloudWatch Events. To learn more, see Monitor and Manage Your Human Loop (p. 2325).

Delete a Human Loop

When you delete a human loop, the status changes to Deleting. When the human loop is deleted, the associated human review task is no longer available to workers. You might want to delete a human loop in one of the following circumstances:

- The worker task template used to generate your worker user interface does not render correctly or is not functioning as expected.
- A single data object was accidentally sent to workers multiple times.
- You no longer need a data object reviewed by a human.
If the status of a human loop is **InProgress**, you must stop the human loop before deleting it. When you stop a human loop, the status changes to **Stopping** while it is being stopped. When the status changes to **Stopped**, you can delete the human loop.

If human workers are already working on a task when you stop the associated human loop, that task continues to be available until it is completed or expires. As long as workers are still working on a task, your human loop's status is **Stopping**. If these tasks are completed, the results are stored in the Amazon S3 bucket URI specified in your human review workflow. If the worker leaves the task without submitting work, it is stopped and the worker can't return to the task. If no worker has started working on the task, it is stopped immediately.

If you delete the AWS account used to create the human loop, it is stopped and deleted automatically.

**Human Loop Data Retention and Deletion**

When a human worker completes a human review task, the results are stored in the Amazon S3 output bucket you specified in the human review workflow used to create the human loop. Deleting or stopping a human loop does not remove any worker answers from your S3 bucket.

Additionally, Amazon A2I temporarily stores human loop input and output data internally for the following reasons:

- If you configure your human loops so that a single data object is sent to multiple workers for review, Amazon A2I does not write output data to your S3 bucket until all workers have completed the review task. Amazon A2I stores partial answers—answers from individual workers—internally so that it can write full results to your S3 bucket.
- If you report a low-quality human review result, Amazon A2I can investigate and respond to your issue.
- If you lose access to or delete the output S3 bucket specified in the human review workflow used to create a human loop, and the task has already been sent to one or more workers, Amazon A2I needs a place to temporarily store human review results.

Amazon A2I deletes this data internally 30 days after a human loop's status changes to one of the following: **Deleted**, **Stopped**, or **Completed**. In other words, data is deleted 30 days after the human loop has been completed, stopped, or deleted. Additionally, this data is deleted after 30 days if you close the AWS account used to create associated human loops.

**Stop and Delete a Flow Definition Using the Console or the Amazon A2I API**

You can stop and delete a human loop in the Augmented AI console or by using the SageMaker API. When the human loop has been deleted, the status changes to **Deleted**.

**Delete a human loop (console)**

2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows**.
3. Choose the hyperlinked name of the human review workflow you used to create the human loop you want to delete.
4. In the **Human loops** section at the bottom of the page, select the human loop you want to stop and delete.
5. If the human loop status is **Completed**, **Stopped**, or **Failed**, select **Delete**.

If the human loop status is **InProgress**, select **Stop**. When the status changes to **Stopped**, select **Delete**.
Delete a human loop (API)

1. Check the status of your human loop using the Augmented AI Runtime API operation `DescribeHumanLoop`. See examples using this operation in the following table.

   **AWS SDK for Python (Boto3)**
   
   The following example uses the SDK for Python (Boto3) to describe the human loop named `example-human-loop`. For more information, see `describe_human_loop` in the `AWS SDK for Python (Boto) API Reference`.
   
   ```python
   import boto3
   a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
   response = a2i_runtime_client.describe_human_loop(HumanLoopName='example-human-loop')
   human_loop_status = response['HumanLoopStatus']
   print(f'example-human-loop status is: {human_loop_status}')
   ```
   
   **AWS CLI**
   
   The following example uses the AWS CLI to describe the human loop named `example-human-loop`. For more information, see `describe-human-loop` in the `AWS CLI Command Reference`.
   
   ```bash
   $ aws sagemaker-a2i-runtime describe-human-loop --human-loop-name 'example-human-loop'
   ```

2. If the flow definition status is `Completed`, `Stopped`, or `Failed`, delete the flow definition using the Augmented AI Runtime API operation `DeleteHumanLoop`.

   **AWS SDK for Python (Boto3)**
   
   The following example uses the SDK for Python (Boto3) to delete the human loop named `example-human-loop`. For more information, see `delete_human_loop` in the `AWS SDK for Python (Boto) API Reference`.
   
   ```python
   import boto3
   a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
   response = a2i_runtime_client.delete_human_loop(HumanLoopName='example-human-loop')
   ```
   
   **AWS CLI**
   
   The following example uses the AWS CLI to delete the human loop named `example-human-loop`. For more information, see `delete-human-loop` in the `AWS CLI Command Reference`.
   
   ```bash
   $ aws sagemaker-a2i-runtime delete-human-loop --human-loop-name 'example-human-loop'
   ```

If the human loop status is `InProgress`, stop the human loop using `StopHumanLoop` and then use `DeleteHumanLoop` to delete it.

**AWS SDK for Python (Boto3)**

The following example uses the SDK for Python (Boto3) to describe the human loop named `example-human-loop`. For more information, see `stop_human_loop` in the `AWS SDK for Python (Boto) API Reference`.

```python
import boto3
a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
response = a2i_runtime_client.stop_human_loop(HumanLoopName='example-human-loop')
```
import boto3

a2i_runtime_client = boto3.client('sagemaker-a2i-runtime')
response = a2i_runtime_client.stop_human_loop(HumanLoopName='example-human-loop')

AWS CLI

The following example uses the AWS CLI to describe the human loop named example-human-loop. For more information, see stop-human-loop in the AWS CLI Command Reference.

$ aws sagemaker-a2i-runtime stop-human-loop --human-loop-name 'example-human-loop'

Create and Manage Worker Task Templates

You can create a task user interface for your workers by creating a worker task template. A worker task template is an HTML file that is used to display your input data and instructions to help workers complete your task.

For Amazon Rekognition or Amazon Textract task types, you can customize a pre-made worker task template using a graphical user interface (GUI) and avoid interacting with HTML code. For this option, use the instructions in Create a Human Review Workflow (Console) (p. 2289) to create a human review workflow and customize your worker task template in the Amazon SageMaker console. Once you create a template using these instructions, it appears on the worker task templates page of the Augmented AI console.

If you are creating a human review workflow for a custom task type, you must create a custom worker task template using HTML code. For more information, see Create Custom Worker Task Templates (p. 2317).

If you create your template using HTML, you must use this template to generate an Amazon A2I human task UI Amazon Resource Name (ARN) in the Amazon A2I console. This ARN has the following format: arn:aws:sagemaker:<aws-region>:<aws-account-number>:human-task-ui/<template-name>. This ARN is associated with a worker task template resource that you can use in one or more human review workflows (flow definitions).

Generate a human task UI ARN using a worker task template by following the instructions found in Create a Worker Task Template (p. 2316) or by using the CreateHumanTaskUi API operation.

Topics
- Create and Delete Worker Task Templates (p. 2315)
- Create Custom Worker Task Templates (p. 2317)
- Creating Good Worker Instructions (p. 2324)

Create and Delete Worker Task Templates

You can use a worker template to customize the interface and instructions that your workers see when working on your tasks. Use the instructions on this page to create a worker task template in the Augmented AI area of the Amazon SageMaker console. A starter template is provided for Amazon Textract and Amazon Rekognition tasks. To learn how to customize your template using HTML crowd elements, see Create Custom Worker Task Templates (p. 2317).

When you create a worker template in the worker task templates page of the Augmented AI area of the SageMaker console, a worker task template ARN is generated. Use this ARN as the input to
HumanTaskUiArn when you create a flow definition using the API operation CreateFlowDefinition. You can choose this template when creating a human review workflow on the human review workflows page of the console.

If you are creating a worker task template resource for an Amazon Textract or Amazon Rekognition task type, you can preview the worker UI that is generated from your template on the worker task templates console page. You must attach the policy described in Enable Worker Task Template Previews (p. 2339) to the IAM role that you use to preview the template.

Create a Worker Task Template

You can create a worker task template using the SageMaker console and using the SageMaker API operation CreateHumanTaskUi.

Create a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i.
2. Under Amazon Augmented AI in the left navigation pane, choose Worker task templates.
3. Choose Create template.
4. In Template name, enter a unique name.
5. (Optional) Enter an IAM role that grants Amazon A2I the permissions necessary to call services on your behalf.
6. In Template type, choose a template type from the dropdown list. If you are creating a template for a Textract-form extraction or Rekognition-image moderation task, choose the appropriate option.
7. Enter your custom template elements as follows:
   • If you selected the Amazon Textract or Amazon Rekognition task template, the Template editor autopopulates with a default template that you can customize.
   • If you are using a custom template, enter your predefined template in the editor.
8. (Optional) To complete this step, you must provide an IAM role ARN with permission to read Amazon S3 objects that get rendered on your user interface in Step 5.

You can only preview your template if you are creating templates for Amazon Textract or Amazon Rekognition.

Choose See preview to preview the interface and instructions that workers see. This is an interactive preview. After you complete the sample task and choose Submit, you see the resulting output from the task that you just performed.

If you are creating a worker task template for a custom task type, you can preview your worker task UI using RenderUiTemplate. For more information, see Preview a Worker Task Template (p. 2324).

9. When you're satisfied with your template, choose Create.

After you've created your template, you can select that template when you create a human review workflow in the console. Your template also appears in the Amazon Augmented AI section of the SageMaker console under Worker task templates. Choose your template to view its ARN. Use this ARN when using the CreateFlowDefinition API operation.

Create a worker task template using a worker task template (API)

To generate a worker task template using the SageMaker API operation CreateHumanTaskUi, specify a name for your UI in HumanTaskUiName and input your HTML template in Content under UiTemplate.

Find documentation on language-specific SDKs that support this API operation in the See Also section of the CreateHumanTaskUi.
Delete a Worker Task Template

Once you have created a worker task template, you can delete it using the SageMaker console or the SageMaker API operation `DeleteHumanTaskUi`.

When you delete a worker task template, you are not able to use human review workflows (flow definitions) created using that template to start human loops. Any human loops that have already been created using the worker task template that you delete continue to be processed until completion and are not impacted.

Delete a worker task template (console)

1. Open the Amazon A2I console at https://console.aws.amazon.com/a2i.
2. Under Amazon Augmented AI in the left navigation pane, choose Worker task templates.
3. Select the template that you want to delete.
4. Select Delete.
5. A modal appears to confirm your choice. Select Delete.

Delete a worker task template (API)

To delete a worker task template using the SageMaker API operation `DeleteHumanTaskUi`, specify a name of your UI in `HumanTaskUiName`.

Create Custom Worker Task Templates

`Crowd HTML Elements` are web components that provide a number of task widgets and design elements that you can tailor to the question you want to ask. You can use these crowd elements to create a custom worker template and integrate it with an Amazon Augmented AI (Amazon A2I) human review workflow to customize the worker console and instructions.

For a list of all HTML crowd elements available to Amazon A2I users, see `Crowd HTML Elements Reference` (p. 483). For examples of templates, see the AWS GitHub repository, which contains over 60 sample custom task templates.

Develop Templates Locally

When in the console to test how your template processes incoming data, you can test the look and feel of your template's HTML and custom elements in your browser by adding the following code to the top of your HTML file.

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
```

This loads the necessary code to render the custom HTML elements. Use this code if you want to develop your template's look and feel in your preferred editor instead of in the console.

This code won't parse your variables. You might want to replace them with sample content while developing locally.

Use External Assets

Amazon Augmented AI custom templates enable you to embed external scripts and style sheets. For example, the following header embeds a `text/css` style sheet name `stylesheet` located at https://www.example.com/my-enhancement-styles.css into the custom template.
Example

```html
<script src="https://www.example.com/my-enhancement-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding type for remote scripts is `application/javascript; CHARSET=UTF-8`.

The MIME and encoding type for remote stylesheets is `text/css; CHARSET=UTF-8`.

**Track Your Variables**

When building a custom template, you must add variables to it to represent the pieces of data that might change from task to task, or worker to worker. If you're starting with one of the sample templates, you need to make sure you're aware of the variables it already uses.

For example, for a custom template that integrates an Augmented AI human review loop with a Amazon Textract text review task, ```{{ task.input.selectedAiServiceResponse.blocks }}``` is used for initial-value input data. For Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition, ```{{ task.input.selectedAiServiceResponse.moderationLabels }}``` is used. For a custom task type, you need to determine the input parameter for your task type.

Use ```{{ task.input.customInputValuesForStartHumanLoop }}``` where you specify ```customInputValuesForStartHumanLoop```.

**Custom Template Example for Amazon Textract**

All custom templates begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements.

For an Amazon Textract document analysis task, use the `<crowd-textract-analyze-document>` element. It uses the following attributes:

- `src` – Specifies the URL of the image file to be annotated.
- `initialValue` – Sets initial values for attributes found in the worker UI.
- `blockTypes` (required) – Determines the kind of analysis that the workers can do. Only `KEY_VALUE_SET` is currently supported.
- `keys` (required) – Specifies new keys and the associated text value that the worker can add.
- `no-key-edit` (required) – Prevents the workers from editing the keys of annotations passed through `initialValue`.
- `no-geometry-edit` – Prevents workers from editing the polygons of annotations passed through `initialValue`.

For children of the `<crowd-textract-analyze-document>` element, you must have two Regions. You can use arbitrary HTML and CSS elements in these Regions.

- `<full-instructions>` – Instructions that are available from the View full instructions link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- `<short-instructions>` – A brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.
An Amazon Textract template would look similar to the following.

**Example**

```html
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.document.s3Object.bucket }}/
{{ task.input.aiServiceRequest.document.s3Object.name }}{% endcapture %}

<crowd-form>
  <crowd-textract-analyze-document
    src="{{ s3_uri | grant_read_access }}"
    initial-value="{{ task.input.selectedAiServiceResponse.blocks }}"
    header="Review the key-value pairs listed on the right and correct them if they don't
match the following document."
    no-key-edit
    no-geometry-edit
    keys="{{ task.input.humanLoopContext.importantFormKeys }}"
    block-types="["KEY_VALUE_SET"]"
  >
  <short-instructions header="Instructions">
    <style>
      .instructions {white-space: pre-wrap;}
      .instructionsImage {
display: inline-block;
max-width: 100%;
      }
    </style>
    <p class='instructions'>Choose a key-value block to highlight the corresponding key-
value pair in the document.
If it is a valid key-value pair, review the content for the value. If the content is
incorrect, correct it.
The text of the value is incorrect, correct it.
<img class='instructionsImage' src="https://example-site/correct-value-text.png" />
A wrong value is identified, correct it.
<img class='instructionsImage' src="https://example-site/correct-value.png" />
If it is not a valid key-value relationship, choose No.
<img class='instructionsImage' src="https://example-site/not-a-key-value-pair.png" />
If you can't find the key in the document, choose Key not found.
<img class='instructionsImage' src="https://example-site/key-is-not-found.png" />
If the content of a field is empty, choose Value is blank.
<img class='instructionsImage' src="https://example-site/value-is-blank.png" />
<br>Examples<br>Key and value are often displayed next to or below to each other.
Key and value displayed in one line.
<img class='instructionsImage' src="https://example-site/sample-key-value-pair-1.png" />
Key and value displayed in two lines.
<img class='instructionsImage' src="https://example-site/sample-key-value-pair-2.png" />
If the content of the value has multiple lines, enter all the text without a line break.
Include all value text even if it extends beyond the highlight box.
</p>
  </short-instructions>
</crowd-textract-analyze-document>
</crowd-form>
```
Custom Template Example for Amazon Rekognition

All custom templates begin and end with the `<crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between these elements. For an Amazon Rekognition custom task template, use the `<crowd-rekognition-detect-moderation-labels>` element. This element supports the following attributes:

- **categories** – An array of strings or an array of objects where each object has a `name` field.
  - If the categories come in as objects, the following applies:
    - The displayed categories are the value of the `name` field.
    - The returned answer contains the *full* objects of any selected categories.
  - If the categories come in as strings, the following applies:
    - The returned answer is an array of all the strings that were selected.

- **exclusion-category** – By setting this attribute, you create a button underneath the categories in the UI. When a user selects the button, all categories are deselected and disabled. If the worker selects the button again, you re-enable users to choose categories. If the worker submits the task by selecting *Submit* after you select the button, that task returns an empty array.

For children of the `<crowd-rekognition-detect-moderation-labels>` element, you must have two Regions.

- **`<full-instructions>`** – Instructions that are available from the View full instructions link in the tool. You can leave this blank, but we recommend that you provide complete instructions to get better results.
- **`<short-instructions>`** – Brief description of the task that appears in the tool's sidebar. You can leave this blank, but we recommend that you provide complete instructions to get better results.

A template using these elements would look similar to the following.

```html
<scrip src="https://assets.crowd.aws/crowd-html-elements.js"></script>
{% capture s3_uri %}http://s3.amazonaws.com/
{{ task.input.aiServiceRequest.image.s3Object.bucket }}/\n{{ task.input.aiServiceRequest.image.s3Object.name }}{% endcapture %}

<crowd-form>
<crowd-rekognition-detect-moderation-labels
categories='[
  {% for label in task.input.selectedAiServiceResponse.moderationLabels %}
    name: "{{ label.name }}",
    parentName: "{{ label.parentName }}",
  ,
  {% endfor %}
']
src="{{ s3_uri | grant_read_access }}"
header="Review the image and choose all applicable categories."
>
<short-instructions header="Instructions">
<style>
  .instructions {
    white-space: pre-wrap;
  }
```
Create Custom Worker Task Templates

Review the image and choose all applicable categories. If no categories apply, choose None.

Nudity
Visuals depicting nude male or female person or persons

Graphic Male Nudity
Visuals depicting full frontal male nudity, often close ups

Graphic Female Nudity
Visuals depicting full frontal female nudity, often close ups

Sexual Activity
Visuals depicting various types of explicit sexual activities and pornography

Illustrated Nudity or Sexual Activity
Visuals depicting animated or drawn sexual activity, nudity, or pornography

Adult Toys
Visuals depicting adult toys, often in a marketing context

Female Swimwear or Underwear
Visuals depicting female person wearing only swimwear or underwear

Male Swimwear Or Underwear
Visuals depicting male person wearing only swimwear or underwear

Partial Nudity
Visuals depicting covered up nudity, for example using hands or pose

Revealing Clothes
Visuals depicting revealing clothes and poses, such as deep cut dresses

Graphic Violence or Gore
Visuals depicting prominent blood or bloody injuries

Physical Violence
Visuals depicting violent physical assault, such as kicking or punching

Weapon Violence
Visuals depicting violence using weapons like firearms or blades, such as shooting

Weapons
Visuals depicting weapons like firearms and blades

Self Injury
Visuals depicting self-inflicted cutting on the body, typically in distinctive patterns using sharp objects

Emaciated Bodies
Visuals depicting extremely malnourished human bodies

Corpses
Visuals depicting human dead bodies

Hanging
Visuals depicting death by hanging

Full-instructions header="Instructions"
Add Automation with Liquid

The custom template system uses Liquid for automation. Liquid is an open-source inline markup language. For more information and documentation, see the Liquid homepage.

In Liquid, the text between single curly braces and percent symbols is an instruction or tag that performs an operation like control flow or iteration. Text between double curly braces is a variable or object that outputs its value. The following list includes two types of liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you are redirected to the Liquid documentation.

- **Control flow**: Includes programming logic operators like if/else, unless, and case/when.
- **Iteration**: Enables you to run blocks of code repeatedly using statements like for loops.

For example, the following code example demonstrates how you can use the Liquid for tag to create a for loop. This example loops through the moderationLabels returned from Amazon Rekognition and displays the moderationLabels attributes name and parentName for workers to review:

```liquid
{% for label in task.input.selectedAiServiceResponse.moderationLabels %}
    {
        name: &quot;{{ label.name }}&quot;, \\
        parentName: &quot;{{ label.parentName }}&quot;,
    },
{% endfor %}
```

Use Variable Filters

In addition to the standard Liquid filters and actions, Amazon Augmented AI (Amazon A2I) offers additional filters. You apply filters by placing a pipe (|) character after the variable name, and then specifying a filter name. To chain filters, use the following format.

**Example**

```liquid
{{ <content> | <filter> | <filter> }}
```

Autoescape and Explicit Escape

By default, inputs are HTML-escaped to prevent confusion between your variable text and HTML. You can explicitly add the escape filter to make it more obvious to someone reading the source of your template that escaping is being done.

- **escape_once**

  escape_once ensures that if you’ve already escaped your code, it doesn’t get re-escaped again. For example, it ensures that &amp; doesn't become &amp;amp;.

- **skip_autoescape**

  skip_autoescape is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

  **Note**

  Use skip_autoescape sparingly. As a best practice for templates, avoid passing in functional code or markup with skip_autoescape unless you are absolutely sure that you have strict control over what’s being passed. If you’re passing user input, you could be opening your workers up to a cross-site scripting attack.
to_json

to_json encodes data that you provide to JavaScript Object Notation (JSON). If you provide an object, it serializes it.

grant_read_access

grant_read_access takes an Amazon Simple Storage Service (Amazon S3) URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

Note

If the Amazon S3 bucket that contains your input data is encrypted using AWS KMS, the execution role that you use to create a human review workflow (flow definition) must have permission to perform the action kms:Decrypt. To learn more, see Using Amazon A2I with AWS KMS Encrypted Buckets (p. 2340).

Example Example of the to_json and grant_read_access filters

Input

| auto-escape: {{ "Have you read 'James & the Giant Peach'?” }} |
| explicit escape: {{ “Have you read 'James & the Giant Peach'?” | escape }} |
| explicit escape_once: {{ "Have you read 'James & the Giant Peach'?” | escape_once }} |
| skip_autoescape: {{ "Have you read 'James & the Giant Peach'?” | skip_autoescape }} |
| to_json: {{ jsObject | to_json }} |
| grant_read_access: {{ "s3://examplebucket/myphoto.png" | grant_read_access }} |

Example Output

| auto-escape: Have you read 'James & the Giant Peach'?” |
| explicit escape: Have you read 'James & the Giant Peach'?” |
| explicit escape_once: Have you read 'James & the Giant Peach'?” |
| skip_autoescape: Have you read 'James & the Giant Peach'?” |
| to_json: { "point_number": 8, "coords": [ 59, 76 ] } |
| grant_read_access: https://s3.amazonaws.com/examplebucket/myphoto.png?<access token and other params> |

Example Example of an automated classification template.

To automate this simple text classification sample, include the Liquid tag {{ task.input.source }}. This example uses the crowd-classifier (p. 497) element.

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-classifier
    name="tweetFeeling"
    categories="[‘positive’, ‘negative’, ‘neutral’, ‘cannot determine’]"
    header="Which term best describes this tweet?"
  >
    <classification-target>
      {{ task.input.source }}
    </classification-target>

    <full-instructions header="Analyzing a sentiment">
      Try to determine the feeling the author of the tweet is trying to express.
      If none seems to match, choose "other."
    </full-instructions>
```

2323
Preview a Worker Task Template

To preview a custom worker task template, use the SageMaker RenderUiTemplate operation. You can use the RenderUiTemplate operation with the AWS CLI or your preferred AWS SDK. For documentation on the supported language specific SDKs for this API operation, see the See Also section of the RenderUiTemplate.

Prerequisites

To preview your worker task template, the AWS Identity and Access Management (IAM) role Amazon Resource Name (ARN), or RoleArn, that you use must have permission to access to the S3 objects that are used by the template. To learn how to configure your role or user see Enable Worker Task Template Previews (p. 2339).

To preview your worker task template using the RenderUiTemplate operation:

1. Provide a RoleArn of the role with required policies attached to preview your custom template.
2. In the Input parameter of Task, provide a JSON object that contains values for the variables defined in the template. These are the variables that are substituted for the task.input.source variable. For example, if you define a task.input.text variable in your template, you can supply the variable in the JSON object as text: sample text.
3. In the Content parameter of UiTemplate, insert your template.

Once you've configured RenderUiTemplate, use your preferred SDK or the AWS CLI to submit a request to render your template. If your request was successful, the response includes RenderedContent, a Liquid template that renders the HTML for the worker UI.

Important
To preview your template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. For a sample policy that you can attach to your IAM role to grant these permissions, see Enable Worker Task Template Previews (p. 2339).

Creating Good Worker Instructions

Creating good instructions for your human review jobs improves your worker’s accuracy in completing their task. You can modify the default instructions that are provided in the console when creating a human review workflow, or you can use the console to create a custom worker template and include your instructions in this template. The instructions are shown to the worker on the UI page where they complete their labeling task.

Create Good Worker Instructions

There are three kinds of instructions in the Amazon Augmented AI console:

- **Task Description** – The description should provide a succinct explanation of the task.
- **Instructions** – These instructions are shown on the same webpage where workers complete a task. These instructions should provide an easy reference to show the worker the correct way to complete the task.
Additional Instructions – These instructions are shown in a dialog box that appears when a worker chooses View full instructions. We recommend that you provide detailed instructions for completing the task, and include several examples showing edge cases and other difficult situations for labeling objects.

Add Example Images to Your Instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions, do the following:

1. Place the cursor where the image should go in the instructions editor.
2. Choose the image icon in the editor toolbar.
3. Enter the URL of your image.

If your instruction image is in an S3 bucket that isn't publicly accessible, do the following:

- For the image URL, enter: `{{ 'https://s3.amazonaws.com/your-bucket-name/image-file-name' | grant_read_access }}`.

This renders the image URL with a short-lived, one-time access code that's appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview. See grant_read_access (p. 2323) for more information about the grant_read_access element.

Monitor and Manage Your Human Loop

Once you've started a human review loop, you can check the results of tasks sent to the loop and manage it using the Amazon Augmented AI Runtime API. Additionally, Amazon A2I integrates with Amazon EventBridge (also known as Amazon CloudWatch Events) to alert you when a human review loop changes status.

Use the procedures below to learn how to use the Amazon A2I Runtime API to monitor and manage your human loops. See Use Amazon CloudWatch Events in Amazon Augmented AI (p. 2340) to learn how Amazon A2I integrates with Amazon EventBridge.

**To check your output data:**

1. Check the results of your human loop by calling the DescribeHumanLoop operation. The result of this API operation contains information about the reason for and outcome of the loop activation.
2. Check the output data from your human loop in Amazon Simple Storage Service (Amazon S3). In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (YYYY), month (MM), and day (DD), and the creation time with hour (hh), minute (mm), and second (ss).

   ```
   s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
   ```

   You can integrate this structure with AWS Glue or Amazon Athena to partition and analyze your output data. For more information, see Managing Partitions for ETL Output in AWS Glue.

   To learn more about Amazon A2I output data format, see Amazon A2I Output Data (p. 2326).
To stop and delete your human loop:

1. Once a human loop has been started, you can stop your human loop by calling the `StopHumanLoop` operation using the `HumanLoopName`. If a human loop was successfully stopped, the server sends back an HTTP 200 response.
2. To delete a human loop for which the status equals `Failed`, `Completed`, or `Stopped`, use the `DeleteHumanLoop` operation.

To list human loops:

1. You can list all active human loops by calling the `ListHumanLoops` operation. You can filter human loops by the creation date of the loop using the `CreationTimeAfter` and `CreateTimeBefore` parameters.
2. If successful, `ListHumanLoops` returns `HumanLoopSummaries` and `NextToken` objects in the response element. `HumanLoopSummaries` contains information about a single human loop. For example, it lists a loop's status and, if applicable, its failure reason.

Use the string returned in `NextToken` as an input in a subsequent call to `ListHumanLoops` to see the next page of human loops.

Amazon A2I Output Data

When your machine learning workflow sends Amazon A2I a data object, a `human loop` is created and human reviewers receive a `task` to review that data object. The output data from each human review task is stored in the Amazon Simple Storage Service (Amazon S3) output bucket you specify in your human review workflow. In the path to the data, `YYYY/MM/DD/hh/mm/ss` represents the human loop creation date with year (`YYYY`), month (`MM`), and day (`DD`), and the creation time with hour (`hh`), minute (`mm`), and second (`ss`).

```
s3://customer-output-bucket-specified-in-flow-definition/flow-definition-name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
```

The content of your output data depends on the type of `task type` (built-in or custom) and the type of `workforce` you use. Your output data always includes the response from the human worker. Additionally, output data may include metadata about the human loop, the human reviewer (worker), and the data object.

Use the following sections to learn more about Amazon A2I output data format for different task types and workforces.

Output Data From Built-In Task Types

Amazon A2I built-in task types include Amazon Textract and Amazon Rekognition. In addition to human responses, the output data from one of these tasks includes details about the reason the human loop was created and information about the integrated service used to create the human loop. Use the following table to learn more about the output data schema for all built-in task types. The `value` for each of these parameters depends on the service you use with Amazon A2I. Refer to the second table in this section for more information about these service-specific values.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Example Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>awsManagedHumanLoopRequestSource</code></td>
<td><code>String</code></td>
<td>AWS/Rekognition/DetectModerationLabels</td>
<td>The API operation and associated AWS services</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value Type</td>
<td>Example Values</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>---------------------</td>
<td>--------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>flowDefinitionArn</td>
<td>String</td>
<td>arn:aws:sagemaker:us-west-2:111122223333:flow-definition/flow-definition-name</td>
<td>The Amazon Resource Number (ARN) of the human review workflow (flow definition) used to create the human loop.</td>
</tr>
<tr>
<td>humanAnswers</td>
<td>List of JSON objects</td>
<td></td>
<td>A list of JSON objects that contain worker responses in answerContent. This object also contains submission details and, if a private workforce was used, worker metadata. To learn more, see Track Worker Activity (p. 2334).</td>
</tr>
<tr>

<td>A JSON object in inputContent that contains the reason a human loop was created. This includes a list of the activation conditions (Conditions) included in your human review workflow (flow definition), and the evaluation result for each condition—this result is either true or false. To learn more about activation conditions, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI (p. 2294).</td>
</tr>
</tbody>
</table>

Select a tab on the following table to learn about the task type–specific parameters and see an example output-data code block for each of the built-in task types.

### Amazon Textract Task Type Output Data

When you use the Amazon Textract built-in integration, you see 'AWS/Textract/AnalyzeDocument/Forms/V1' as the value for awsManagedHumanLoopRequestSource in your output data.

The answerContent parameter contains a Block object that includes human responses for all blocks sent to Amazon A2I.

The aiServiceResponse parameter also includes a Block object with Amazon Textract's response to the original request sent using to AnalyzeDocument.

To learn more about the parameters you see in the block object, refer to Block in the Amazon Textract Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Textract document analysis inferences.

```json
{
  "awsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/V1",
  "humanAnswers": [
    {
      "answerContent": {

            ]
          },
          "ConditionType": "ImportantFormKeyConfidenceCheck",
          "EvaluationResult": true
        }
      ]
    }
Amazon Rekognition Task Type Output Data

When you use the Amazon Textract built-in integration, you see the string 'AWS/Rekognition/DetectModerationLabels/Image/V3' as the value for awsManagedHumanLoopRequestSource in your output data.

The answerContent parameter contains a moderationLabels object that contains human responses for all moderation labels sent to Amazon A2I.

The aiServiceResponse parameter also includes a moderationLabels object with Amazon Rekognition's response to the original request sent to DetectModerationLabels.

To learn more about the parameters you see in the block object, refer to ModerationLabel in the Amazon Rekognition Developer Guide.

The following is an example of the output data from an Amazon A2I human review of Amazon Rekognition image moderation inferences.

```json
{
  "awsManagedHumanLoopRequestSource": "AWS/Rekognition/DetectModerationLabels/Image/V3",
  "humanAnswers": [
    {
      "answerContent": {
        "AWS/Rekognition/DetectModerationLabels/Image/V3": {
          "moderationLabels": [...]
        }
      },
      "submissionTime": "2020-09-28T19:22:35.508Z",
      "workerId": "ef7294f850a3d9d1",
      "workerMetadata": {
        "identityData": {
          "identityProviderType": "Cognito",
          "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
        }
      }
    }
  ],
  "humanLoopName": "human-loop-name",
  "inputContent": {
    "aiServiceRequest": {
      "humanLoopConfig": {
```
Output Data From Custom Task Types

When you add Amazon A2I to a custom human review workflow, you see the following parameters in the output data returned from human review tasks.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowDefinitionArn</td>
<td>String</td>
<td>The Amazon Resource Number (ARN) of the human review</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>humanAnswers</td>
<td>List of JSON objects</td>
<td>A list of JSON objects that contain worker responses in answerContent. The value in this parameter is determined by the output received from your worker task template. If you are using a private workforce, worker metadata is included. To learn more, see Track Worker Activity (p. 2334).</td>
</tr>
<tr>
<td>humanLoopName</td>
<td>String</td>
<td>The name of the human loop.</td>
</tr>
<tr>
<td>inputContent</td>
<td>JSON Object</td>
<td>The input content sent to Amazon A2I in the request to StartHumanLoop.</td>
</tr>
</tbody>
</table>

The following is an example of output data from a custom integration with Amazon A2I and Amazon Transcribe. In this example, the inputContent consists of:

- A path to an .mp4 file in Amazon S3 and the video title
- The transcription returned from Amazon Transcribe (parsed from Amazon Transcribe output data)
- A start and end time used by the worker task template to clip the .mp4 file and show workers a relevant portion of the video

```json
{
  "humanAnswers": [
    {
      "answerContent": {
        "transcription": "use lambda to turn your notebook",
        "submissionTime": "2020-06-18T17:08:26.246Z",
        "workerId": "ef7294f850a3d9d1",
        "workerMetadata": {
          "identityData": {
            "identityProviderType": "Cognito",
            "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
          }
        }
      }
    },
    {
      "answerContent": {
        "transcription": "use lambda to turn your notebook",
        "submissionTime": "2020-06-18T17:08:26.246Z",
        "workerId": "ef7294f850a3d9d1",
        "workerMetadata": {
          "identityData": {
            "identityProviderType": "Cognito",
            "sub": "c6aa8eb7-9944-42e9-a6b9-111122223333"
          }
        }
      }
    }
  ],
  "humanLoopName": "human-loop-name",
  "inputContent": {
    "audioPath": "s3://DOC-EXAMPLE-BUCKET1/a2i_transcribe_demo/Fully-Managed Notebook Instances with Amazon SageMaker - a Deep Dive.mp4",
    "end_time": 950.27,
    "original_words": "but definitely use Lambda to turn your",
    "start_time": 948.51
  }
}

2333
Track Worker Activity

Amazon A2I provides information that you can use to track individual workers in task output data. To identify the worker that worked on the human review task, use the following from the output data in Amazon S3:

- The `acceptanceTime` is the time that the worker accepted the task. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- The `submissionTime` is the time that the worker submitted their annotations using the Submit button. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`), and millisecond (`mmm`). The date and time are separated by a `T`.
- `timeSpentInSeconds` reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- The `workerId` is unique to each worker.
- If you use a private workforce, in `workerMetadata`, you see the following.
  - The `identityProviderType` is the service used to manage the private workforce.
  - The `issuer` is the Amazon Cognito user pool or OpenID Connect (OIDC) Identity Provider (IdP) issuer associated with the work team assigned to this human review task.
  - A unique `sub` identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) associated with this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the `identityProviderType`.

```json
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3defg4h5i67",
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Cognito",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```

The following is an example of the output you may see if you use your own OIDC IdP to create a private workforce:

```json
"workerMetadata": {
  "identityData": {
    "identityProviderType": "Oidc",
    "issuer": "https://example-oidc-ipd.com/adfs",
    "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
  }
}
```
Permissions and Security in Amazon Augmented AI

When using Amazon Augmented AI (Amazon A2I) to create a human review workflow for your ML/AI application, you create and configure resources in Amazon SageMaker such as a human workforce and worker task templates. To configure and start a human loop, you either integrate Amazon A2I with other AWS services such as Amazon Textract or Amazon Rekognition, or use the Amazon Augmented AI Runtime API. To create a human review workflow and start a human loop, you must attach certain policies to your AWS Identity and Access Management (IAM) role or user. Specifically:

- When you start a human loop using image input data on or after January 12th, 2020, you must add a CORS header policy to the Amazon S3 bucket that contains your input data. See CORS Permission Requirement (p. 2336) to learn more.
- When you create a flow definition, you need to provide a role that grants Amazon A2I permission to access Amazon S3 both for reading objects that are rendered in a human task UI and for writing the results of the human review.

This role must also have a trust policy attached to give SageMaker permission to assume the role. This allows Amazon A2I to perform actions in accordance with permissions that you attach to the role.

See Add Permissions to the IAM Role Used to Create a Flow Definition (p. 2336) for example policies that you can modify and attach to the role you use to create a flow definition. These are the policies that are attached to the IAM role that is created in the Human review workflows section of the Amazon A2I area of the SageMaker console.

- To create and start human loops, you either use an API operation from a built-in task type (such as DetectModerationLabel or AnalyzeDocument) or the Amazon A2I Runtime API operation StartHumanLoop in a custom ML application. You need to attach the AmazonAugmentedAIFullAccess managed policy to the IAM user that invokes these API operations to grant permission to these services to use Amazon A2I operations. To learn how, see Create an IAM User That Can Invoke Amazon A2I API Operations (p. 2338).

This policy does not grant permission to invoke the API operations of the AWS service associated with built-in task types. For example, AmazonAugmentedAIFullAccess does not grant permission to call the Amazon Rekognition DetectModerationLabel API operation or Amazon Textract AnalyzeDocument API operation. You can use the more general policy, AmazonAugmentedAIIntegratedAPIAccess, to grant these permissions. For more information, see Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 2338). This is a good option when you want to grant an IAM user broad permissions to use Amazon A2I and integrated AWS services’ API operations.

If you want to configure more granular permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples for identity-based policies you can use to grant permission to use these individual services.

- To preview your custom worker task UI template, you need an IAM role with permissions to read Amazon S3 objects that get rendered on your user interface. See a policy example in Enable Worker Task Template Previews (p. 2339).

Topics
- CORS Permission Requirement (p. 2336)
- Add Permissions to the IAM Role Used to Create a Flow Definition (p. 2336)
- Create an IAM User That Can Invoke Amazon A2I API Operations (p. 2338)
- Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations (p. 2338)
CORS Permission Requirement

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, images would always display in browsers exactly how they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called orientation value. This has important implications for the entire machine learning (ML) community. For example, if the EXIF orientation is not considered, applications that are used to annotate images may display images in unexpected orientations and result in incorrect labels.

Starting with Chrome 89, AWS can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web's Same-Origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a human loop, you must add a CORS header policy to the S3 buckets that contain your input images.

**Important**
If you do not add a CORS configuration to the S3 buckets that contains your input data, human review tasks for those input data objects fail.

You can add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

**JSON**

```json

[{
   "AllowedHeaders": [],
   "AllowedMethods": ["GET"],
   "AllowedOrigins": ["*"]
}]

```

**XML**

```xml

<CORSConfiguration>
  <CORSRule>
    <AllowedOrigin>*</AllowedOrigin>
    <AllowedMethod>GET</AllowedMethod>
  </CORSRule>
</CORSConfiguration>

```

Add Permissions to the IAM Role Used to Create a Flow Definition

To create a flow definition, attach the policies in this section to the role that you use when creating a human review workflow in the SageMaker console, or when using the CreateFlowDefinition API operation.
• If you are using the console to create a human review workflow, enter the role Amazon Resource Name (ARN) in the IAM role field when creating a human review workflow in the console.

• When creating a flow definition using the API, attach these policies to the role that is passed to the RoleArn parameter of the CreateFlowDefinition operation.

When you create a human review workflow (flow definition), Amazon A2I invokes Amazon S3 to complete your task. To grant Amazon A2I permission to retrieve and store your files in your Amazon S3 bucket, create the following policy and attach it to your role. For example, if the images, documents, and other files that you are sending for human review are stored in an S3 bucket named my_input_bucket, and if you want the human reviews to be stored in a bucket named my_output_bucket, create the following policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["s3:GetObject"],
      "Resource": ["arn:aws:s3:::my_input_bucket/*"]
    },
    {
      "Effect": "Allow",
      "Action": ["s3:PutObject"],
      "Resource": ["arn:aws:s3:::my_output_bucket/*"]
    }
  ]
}
```

In addition, the IAM role must have the following trust policy to give SageMaker permission to assume the role. To learn more about IAM trust policies, see Resource-Based Policies section of Policies and Permissions in the AWS Identity and Access Management documentation.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSageMakerToAssumeRole",
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

For more information about creating and managing IAM roles and policies, see the following topics in the AWS Identity and Access Management User Guide:

• To create an IAM role, see Creating a Role to Delegate Permissions to an IAM User.
• To learn how to create IAM policies, see Creating IAM Policies.
Create an IAM User That Can Invoke Amazon A2I API Operations

To use Amazon A2I to create and start human loops for Amazon Rekognition, Amazon Textract, or the Amazon A2I runtime API, you must use an IAM user that has permissions to invoke Amazon A2I operations. To do this, use the IAM console to attach the AmazonAugmentedAIFullAccess managed policy to a new or existing IAM user.

This policy grants permission to an IAM user to invoke API operations from the SageMaker API for flow definition creation and management and the Amazon Augmented AI Runtime API for human loop creation and management. To learn more about these API operations, see Use APIs in Amazon Augmented AI.

AmazonAugmentedAIFullAccess does not grant permissions to use Amazon Rekognition or Amazon Textract API operations.

**Note**
You can also attach the AmazonAugmentedAIFullAccess policy to an IAM role that is used to create and start a human loop.

To create the required IAM user

2. Choose **Users** and choose an existing user, or create a new user by choosing **Add user**. To learn how to create a new user, see Creating an IAM User in Your AWS Account in the AWS Identity and Access Management User Guide.
   - If you chose to attach the policy to an existing user, choose **Add permissions**.
   - While creating a new user, follow the next step on the **Set permissions** page.
3. Choose **Attach existing policies directly**.
4. In the **Search** bar, enter AmazonAugmentedAIFullAccess and check the box next to that policy.
   - To enable this IAM user to create a flow definition with the public work team, also attach the AmazonSageMakerMechanicalTurkAccess managed policy.
5. After attaching the policy or policies:
   - If you are using an existing user, choose **Next: Review**, and then choose **Add permissions**.
   - If you are creating a new user, choose **Next: Tags** and complete the process of creating your user.

For more information, see Adding and Removing IAM Identity Permissions in the AWS Identity and Access Management User Guide.

Create an IAM User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations

To create an IAM user that has permission to invoke the API operations used by the built-in task types (that is, DetectModerationLables for Amazon Rekognition and AnalyzeDocument for Amazon
Enable Worker Task Template Previews

To customize the interface and instructions that your workers see when working on your tasks, you create a worker task template. You can create the template using the CreateHumanTaskUi operation or the SageMaker console.

To preview your template, you need an IAM role with the following permissions to read Amazon S3 objects that get rendered on your user interface.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::my_input_bucket/*"
      ]
    }
  ]
}
```
For Amazon Rekognition and Amazon Textract task types, you can preview your template using the Amazon Augmented AI section of the SageMaker console. For custom task types, you preview your template by invoking the `RenderUiTemplate` operation. To preview your template, follow the instructions for your task type:

- Amazon Rekognition and Amazon Textract task types – In the SageMaker console, use the role's Amazon Resource Name (ARN) in the procedure documented in Create a Worker Task Template (p. 2316).
- Custom task types – In the `RenderUiTemplate` operation, use the role's ARN in the `RoleArn` parameter.

**Using Amazon A2I with AWS KMS Encrypted Buckets**

If the Amazon S3 bucket that contains your input data is encrypted using AWS KMS, the execution role that you use to create a human review workflow (flow definition) must have permission to perform the action `kms:Decrypt`. You can attach a policy similar to the following to grant an IAM role permission to decrypt the AWS KMS key, `kms_key`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": ["kms:Decrypt"],
      "Resource": ["arn:aws:kms:region:aws_account_id:key/kms_key"],
      "Effect": "Allow"
    }
  ]
}
```

**Additional Permissions and Security Resources**

- the section called “Control Access to SageMaker Resources by Using Tags” (p. 2396).
- the section called “SageMaker Identity-Based Policies” (p. 2373)
- the section called “Control Creation of SageMaker Resources with Condition Keys” (p. 2386)
- the section called “Amazon SageMaker API Permissions Reference” (p. 2416)
- Security (p. 2362)

**Use Amazon CloudWatch Events in Amazon Augmented AI**

Amazon Augmented AI uses Amazon CloudWatch Events (CloudWatch Events) to alert you when a human review loop changes status. When a review loop changes to the Completed, Failed, or Stopped status, Augmented AI sends an event to CloudWatch Events similar to the following:

```json
{
  "version": "0",
  "id": "12345678-1111-2222-3333-12345EXAMPLE",
  "detail-type": "SageMaker A2I HumanLoop Status Change",
  "source": "aws.sagemaker",
  "detail": {
    "event": "completed",
    "taskType": "worker"
  }
}
```
The details in the JSON output include the following:

**creationTime**

The timestamp when Augmented AI created the human loop.

**failureCode**

A failure code denoting a specific type of failure.

**failureReason**

The reason why a human loop has failed. The failure reason is only returned when the human review loop status is failed.

**flowDefinitionArn**

The Amazon Resource Name (ARN) of the flow definition, or human review workflow.

**humanLoopArn**

The Amazon Resource Name (ARN) of the human loop.

**humanLoopName**

The name of the human loop.

**humanLoopOutput**

An object containing information about the output of the human loop.

**outputS3Uri**

The location of the Amazon S3 object where Augmented AI stores your human loop output.

**humanLoopStatus**

The status of the human loop.

---

**Send Events from Your Human Loop to CloudWatch Events**

To configure a CloudWatch Events rule to get status updates, or events, for your Amazon A2I human loops, use the AWS Command Line Interface (AWS CLI) `put-rule` command. When using the `put-rule` command, specify the following to receive human loop statuses:
Set Up a Target to Process Events

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace "A2IHumanLoopStatusChanges" with a unique CloudWatch Events rule name and "arn:aws:iam::111122223333:role/MyRoleForThisRule" with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached. Replace region with the AWS Region in which you want to create the rule.

```bash
aws events put-rule --name "A2IHumanLoopStatusChanges" --event-pattern "{"source": ["aws.sagemaker"], "detail-type": ["SageMaker A2I HumanLoop Status Change"]}" --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule" --region "region"
```

To learn more about the put-rule request, see Event Patterns in CloudWatch Events in the Amazon CloudWatch Events User Guide.

Set Up a Target to Process Events

To process events, you need to set up a target. For example, if you want to receive an email when a human loop status changes, use a procedure in Setting Up Amazon SNS Notifications in the Amazon CloudWatch User Guide to set up an Amazon SNS topic and subscribe your email to it. Once you have created a topic, you can use it to create a target.

To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.aws.amazon.com/cloudwatch/home
2. In the navigation pane, choose Rules.
3. Choose the rule to which you want to add a target.
4. Choose Actions, and then choose Edit.
5. Under Targets, choose Add Target and choose the AWS service you want to act when a human loop status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the AWS documentation for that service.
7. Choose Configure details.
8. For Name, enter a name and, optionally, provide details about the purpose of the rule in Description.
9. Make sure that the check box next to State is selected so that your rule is listed as Enabled.
10. Choose Update rule.

Use Human Review Output

After you receive human review results, you can analyze the results and compare them to machine learning predictions. The JSON that is stored in the Amazon S3 bucket contains both the machine learning predictions and the human review results.

More Information

Automating Amazon SageMaker with Amazon EventBridge (p. 2473)
Use APIs in Amazon Augmented AI

You can create a human review workflow or a worker task template programmatically. The APIs you use depend on whether you are creating a Amazon Rekognition, Amazon Textract, or custom task type. This topic provides links to API reference documentation for each task type and programming task.

The following APIs can be used with Augmented AI:

**Amazon Augmented AI**

Use the Augmented AI API to start, stop, and delete human review loops. You can also list all human review loops and return information about human review loops in your account.

Learn more about human review loop APIs in the Amazon Augmented AI Runtime API Reference.

**Amazon Rekognition**

Use the `HumanLoopConfig` parameter of the `DetectModerationLabels` API to initiate a human review workflow using Amazon Rekognition.

**Amazon SageMaker**

Use the Amazon SageMaker API to create a `FlowDefinition`, also known as a human review workflow. You can also create a `HumanTaskUi` or worker task template.

For more information, see the CreateFlowDefinition or the CreateHumanTaskUi API documentation.

**Amazon Textract**

Use the `HumanLoopConfig` parameter of the AnalyzeDocument API to initiate a human review workflow using Amazon Textract.

### Programmatic Tutorials

The following tutorials provide example code and step-by-step instructions for creating human review workflows and worker task templates programmatically.

- Tutorial: Get Started Using the Amazon A2I API (p. 2270)
- Create a Human Review Workflow (API) (p. 2291)
- Create and Start a Human Loop (p. 2307)
- Using Amazon Augmented AI with Amazon Rekognition in the Amazon Rekognition Developer Guide
- Using Amazon Augmented AI with Amazon Textract AnalyzeDocument in the Amazon Textract Developer Guide
Buy and Sell Amazon SageMaker Algorithms and Models in AWS Marketplace

Amazon SageMaker integrates with AWS Marketplace, enabling developers to charge other SageMaker users for the use of their algorithms and model packages. AWS Marketplace is a curated digital catalog that makes it easy for customers to find, buy, deploy, and manage third-party software and services that customers need to build solutions and run their businesses. AWS Marketplace includes thousands of software listings in popular categories, such as security, networking, storage, machine learning, business intelligence, database, and DevOps. It simplifies software licensing and procurement with flexible pricing options and multiple deployment methods.

For information, see AWS Marketplace Documentation.

Topics

- SageMaker Algorithms (p. 2344)
- SageMaker Model Packages (p. 2344)
- Sell Amazon SageMaker Algorithms and Model Packages (p. 2358)
- Find and Subscribe to Algorithms and Model Packages on AWS Marketplace (p. 2361)
- Use Algorithm and Model Package Resources (p. 2351)

SageMaker Algorithms

An algorithm enables you to perform end-to-end machine learning. It has two logical components: training and inference. Buyers can use the training component to create training jobs in SageMaker and build a machine learning model. SageMaker saves the model artifacts generated by the algorithm during training to an Amazon S3 bucket. For more information, see Train a Model with Amazon SageMaker (p. 8).

 Buyers use the inference component with the model artifacts generated during a training job to create a deployable model in their SageMaker account. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 10).

SageMaker Model Packages

Buyers use a model package to build a deployable model in SageMaker. They can use the deployable model for real-time inference by using SageMaker hosting services. Or, they can get inferences for an entire dataset by running batch transform jobs. For more information, see Deploy a Model in Amazon SageMaker (p. 10). As a seller, you can build your model artifacts by training in SageMaker, or you can use your own model artifacts from a model that you trained outside of SageMaker. You can charge buyers for inference.
Use your own algorithms and models with the AWS Marketplace

The following sections show how to create algorithm and model package resources that you can use locally and publish to the AWS Marketplace.

Topics
- Create Algorithm and Model Package Resources (p. 2345)
- Use Algorithm and Model Package Resources (p. 2351)

Create Algorithm and Model Package Resources

After your training and/or inference code is packaged in Docker containers, create algorithm and model package resources that you can use in your Amazon SageMaker account and, optionally, publish on AWS Marketplace.

Topics
- Create an Algorithm Resource (p. 2345)
- Create a Model Package Resource (p. 2348)

Create an Algorithm Resource

To create an algorithm resource that you can use to run training jobs in Amazon SageMaker and publish on AWS Marketplace specify the following information:

- The Docker containers that contains the training and, optionally, inference code.
- The configuration of the input data that your algorithm expects for training.
- The hyperparameters that your algorithm supports.
- Metrics that your algorithm sends to Amazon CloudWatch during training jobs.
- The instance types that your algorithm supports for training and inference, and whether it supports distributed training across multiple instances.
- Validation profiles, which are training jobs that SageMaker uses to test your algorithm's training code and batch transform jobs that SageMaker runs to test your algorithm's inference code.

To ensure that buyers and sellers can be confident that products work in SageMaker, we require that you validate your algorithms before listing them on AWS Marketplace. You can list products in the AWS Marketplace only if validation succeeds. To validate your algorithms, SageMaker uses your validation profile and sample data to run the following validations tasks:

1. Create a training job in your account to verify that your training image works with SageMaker.
2. If you included inference code in your algorithm, create a model in your account using the algorithm's inference image and the model artifacts produced by the training job.
3. If you included inference code in your algorithm, create a transform job in your account using the model to verify that your inference image works with SageMaker.

When you list your product on AWS Marketplace, the inputs and outputs of this validation process persist as part of your product and are made available to your buyers. This helps buyers understand and evaluate the product before they buy it. For example, buyers can inspect the input data that you used, the outputs generated, and the logs and metrics emitted by your code. The more comprehensive your validation specification, the easier it is for customers to evaluate your product.
Note
In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the Training jobs and Transform jobs pages. If validation fails, you can access the scan and validation reports from the SageMaker console. If any issues are found, you will have to create the algorithm again.

Note
To publish your algorithm on AWS Marketplace, at least one validation profile is required.

You can create an algorithm by using either the SageMaker console or the SageMaker API.

Topics
• Create an Algorithm Resource (Console) (p. 2346)
• Create an Algorithm Resource (API) (p. 2348)

Create an Algorithm Resource (Console)

To create an algorithm resource (console)
2. Choose Algorithms, then choose Create algorithm.
3. On the Training specifications page, provide the following information:
   a. For Algorithm name, type a name for your algorithm. The algorithm name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
   b. Type a description for your algorithm. This description appears in the SageMaker console and in the AWS Marketplace.
   c. For Training image, type the path in Amazon ECR where your training container is stored.
   d. For Support distributed training, Choose Yes if your algorithm supports training on multiple instances. Otherwise, choose No.
   e. For Support instance types for training, choose the instance types that your algorithm supports.
   f. For Channel specification, specify up to 8 channels of input data for your algorithm. For example, you might specify 3 input channels named train, validation, and test. For each channel, specify the following information:
      i. For Channel name, type a name for the channel. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).
      ii. To require the channel for your algorithm, choose Channel required.
      iii. Type a description for the channel.
      iv. For Supported input modes, choose Pipe mode if your algorithm supports streaming the input data, and File mode if your algorithm supports downloading the input data as a file. You can choose both.
      v. For Supported content types, type the MIME type that your algorithm expects for input data.
      vi. For Supported compression type, choose Gzip if your algorithm supports Gzip compression. Otherwise, choose None.
      vii. Choose Add channel to add another data input channel, or choose Next if you are done adding channels.
4. On the **Tuning specifications** page, provide the following information:

   a. For **Hyperparameter specification**, specify the hyperparameters that your algorithm supports by editing the JSON object. For each hyperparameter that your algorithm supports, construct a JSON block similar to the following:

   ```json
   {
     "DefaultValue": "5",
     "Description": "The first hyperparameter",
     "IsRequired": true,
     "IsTunable": false,
     "Name": "intRange",
     "Range": {
       "IntegerParameterRangeSpecification": {
         "MaxValue": "10",
         "MinValue": "1"
       }
     },
     "Type": "Integer"
   }
   
   In the JSON, supply the following:
   
   i. For **DefaultValue**, specify a default value for the hyperparameter, if there is one.
   
   ii. For **Description**, specify a description for the hyperparameter.
   
   iii. For **IsRequired**, specify whether the hyperparameter is required.
   
   iv. For **IsTunable**, specify true if this hyperparameter can be tuned when a user runs a hyperparameter tuning job that uses this algorithm. For information, see Perform Automatic Model Tuning with SageMaker (p. 1715).
   
   v. For **Name**, specify a name for the hyperparameter.
   
   vi. For **Range**, specify one of the following:

   - IntegerParameterRangeSpecification - the values of the hyperparameter are integers. Specify minimum and maximum values for the hyperparameter.
   
   - ContinuousParameterRangeSpecification - the values of the hyperparameter are floating-point values. Specify minimum and maximum values for the hyperparameter.
   
   - CategoricalParameterRangeSpecification - the values of the hyperparameter are categorical values. Specify a list of all of the possible values.
   
   vii. For **Type**, specify Integer, Continuous, or Categorical. The value must correspond to the type of Range that you specified.

   b. For **Metric definitions**, specify any training metrics that you want your algorithm to emit. SageMaker uses the regular expression that you specify to find the metrics by parsing the logs from your training container during training. Users can view these metrics when they run training jobs with your algorithm, and they can monitor and plot the metrics in Amazon CloudWatch. For information, see Monitor and Analyze Training Jobs Using Metrics (p. 1832). For each metric, provide the following information:

   i. For **Metric name**, type a name for the metric.
   
   ii. For **Regex**, type the regular expression that SageMaker uses to parse training logs so that it can find the metric value.
   
   iii. For **Objective metric support** choose Yes if this metric can be used as the objective metric for a hyperparameter tuning job. For information, see Perform Automatic Model Tuning with SageMaker (p. 1715).
   
   iv. Choose **Add metric** to add another metric, or choose **Next** if you are done adding metrics.
5. On the **Inference specifications** page, provide the following information if your algorithm supports inference:
   a. For **Container definition**, type path in Amazon ECR where your inference container is stored.
   b. For **Container DNS host name**, type the name of a DNS host for your image.
   c. For **Supported instance types for real-time inference**, choose the instance types that your algorithm supports for models deployed as hosted endpoints in SageMaker. For information, see Deploy a Model on SageMaker Hosting Services (p. 10).
   d. For **Supported instance types for batch transform jobs**, choose the instance types that your algorithm supports for batch transform jobs. For information, see Get Inferences for an Entire Dataset with Batch Transform (p. 13).
   e. For **Supported content types**, type the type of input data that your algorithm expects for inference requests.
   f. For **Supported response MIME types**, type the MIME types that your algorithm supports for inference responses.
   g. Choose **Next**.

6. On the **Validation specifications** page, provide the following information:
   a. For **Publish this algorithm on AWS Marketplace**, choose **Yes** to publish the algorithm on AWS Marketplace.
   b. For **Validate this algorithm**, choose **Yes** if you want SageMaker to run training jobs and/or batch transform jobs that you specify to test the training and/or inference code of your algorithm.
      
      **Note**
      
      To publish your algorithm on AWS Marketplace, your algorithm must be validated.
   c. For **IAM role**, choose an IAM role that has the required permissions to run training jobs and batch transform jobs in SageMaker, or choose **Create a new role** to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 2399).
   d. For **Validation profile**, specify the following:
      
      • A name for the validation profile.
      • A **Training job definition**. This is a JSON block that describes a training job. This is in the same format as the `TrainingJobDefinition` input parameter of the `CreateAlgorithm` API.
      • A **Transform job definition**. This is a JSON block that describes a batch transform job. This is in the same format as the `TransformJobDefinition` input parameter of the `CreateAlgorithm` API.
   e. Choose **Create algorithm**.

**Create an Algorithm Resource (API)**

To create an algorithm resource by using the SageMaker API, call the `CreateAlgorithm` API.

**Create a Model Package Resource**

To create a model package resource that you can use to create deployable models in Amazon SageMaker and publish on AWS Marketplace specify the following information:

• The Docker container that contains the inference code, or the algorithm resource that was used to train the model.
• The location of the model artifacts. Model artifacts can either be packaged in the same Docker container as the inference code or stored in Amazon S3.
• The instance types that your model package supports for both real-time inference and batch transform jobs.

• Validation profiles, which are batch transform jobs that SageMaker runs to test your model package's inference code.

Before listing model packages on AWS Marketplace, you must validate them. This ensures that buyers and sellers can be confident that products work in Amazon SageMaker. You can list products on AWS Marketplace only if validation succeeds.

The validation procedure uses your validation profile and sample data to run the following validations tasks:

1. Create a model in your account using the model package's inference image and the optional model artifacts that are stored in Amazon S3.

   **Note**
   A model package is specific to the region in which you create it. The S3 bucket where the model artifacts are stored must be in the same region where your created the model package.

2. Create a transform job in your account using the model to verify that your inference image works with SageMaker.

3. Create a validation profile.

   **Note**
   In your validation profile, provide only data that you want to expose publicly.

Validation can take up to a few hours. To see the status of the jobs in your account, in the SageMaker console, see the **Transform jobs** pages. If validation fails, you can access the scan and validation reports from the SageMaker console. After fixing issues, recreate the algorithm. When the status of the algorithm is **COMPLETED**, find it in the SageMaker console and start the listing process.

   **Note**
   To publish your model package on AWS Marketplace, at least one validation profile is required.

You can create an model package either by using the SageMaker console or by using the SageMaker API.

**Topics**

- Create a Model Package Resource (Console)  (p. 2349)
- Create a Model Package Resource (API)  (p. 2350)

**Create a Model Package Resource (Console)**

**To create a model package in the SageMaker console:**

2. Choose **Model packages**, then choose **Create model package**.
3. On the **Inference specifications** page, provide the following information:

   a. **For Model package name**, type a name for your model package. The model package name must be unique in your account and in the AWS region. The name must have 1 to 64 characters. Valid characters are a-z, A-Z, 0-9, and - (hyphen).

   b. Type a description for your model package. This description appears in the SageMaker console and in the AWS Marketplace.

   c. **For Inference specification options**, choose **Provide the location of the inference image and model artifacts** to create a model package by using an inference container and model artifacts.
Choose **Provide the algorithm used for training and its model artifacts** to create a model package from an algorithm resource that you created or subscribe to from AWS Marketplace.

d. **If you chose Provide the location of the inference image and model artifacts for Inference specification options**, provide the following information for **Container definition** and **Supported resources**:

   i. **For Location of inference image**, type the path to the image that contains your inference code. The image must be stored as a Docker container in Amazon ECR.

   ii. **For Location of model data artifacts**, type the location in S3 where your model artifacts are stored.

   iii. **For Container DNS host name**, type the name of the DNS host to use for your container.

   iv. **For Supported instance types for real-time inference**, choose the instance types that your model package supports for real-time inference from SageMaker hosted endpoints.

   v. **For Supported instance types for batch transform jobs**, choose the instance types that your model package supports for batch transform jobs.

   vi. **Supported content types**, type the content types that your model package expects for inference requests.

   vii. **Supported response MIME types**, type the MIME types that your model package uses to provide inferences.

e. **If you chose Provide the algorithm used for training and its model artifacts for Inference specification options**, provide the following information:

   i. **For Algorithm ARN**, type the Amazon Resource Name (ARN) of the algorithm resource to use to create the model package.

   ii. **For Location of model data artifacts**, type the location in S3 where your model artifacts are stored.

f. Choose **Next**.

4. On the **Validation and scanning** page, provide the following information:

   a. **For Publish this model package on AWS Marketplace**, choose **Yes** to publish the model package on AWS Marketplace.

   b. **For Validate this model package**, choose **Yes** if you want SageMaker to run batch transform jobs that you specify to test the inference code of your model package.

   **Note**

   To publish your model package on AWS Marketplace, your model package must be validated.

   c. **For IAM role**, choose an IAM role that has the required permissions to run batch transform jobs in SageMaker, or choose **Create a new role** to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see [SageMaker Roles](#p. 2399).

   d. **For Validation profile**, specify the following:

      - A name for the validation profile.

      - **A Transform job definition**. This is a JSON block that describes a batch transform job. This is in the same format as the **TransformJobDefinition** input parameter of the **CreateAlgorithm** API.

5. Choose **Create model package**.

**Create a Model Package Resource (API)**

To create a model package by using the SageMaker API, call the **CreateModelPackage** API.
Use Algorithm and Model Package Resources

You can create algorithms and model packages as resources in your Amazon SageMaker account, and you can find and subscribe to algorithms and model packages on AWS Marketplace.

Use algorithms to:

- Run training jobs. For information, see Use an Algorithm to Run a Training Job (p. 2352).
- Run hyperparameter tuning jobs. For information, see Use an Algorithm to Run a Hyperparameter Tuning Job (p. 2354).
- Create model packages. After you use an algorithm resource to run a training job or a hyperparameter tuning job, you can use the model artifacts that these jobs output along with the algorithm to create a model package. For information, see Create a Model Package Resource (p. 2348).

Note
If you subscribe to an algorithm on AWS Marketplace, you must create a model package before you can use it to get inferences by creating hosted endpoint or running a batch transform job.

Use model packages to:

- Create models that you can use to get real-time inference or run batch transform jobs. For information, see Use a Model Package to Create a Model (p. 2357).
Use Algorithm and Model Package Resources

- Create hosted endpoints to get real-time inference. For information, see Deploy the Model to SageMaker Hosting Services (p. 65).
- Create batch transform jobs. For information, see (Optional) Make Prediction with Batch Transform (p. 66).

Topics

- Use an Algorithm to Run a Training Job (p. 2352)
- Use an Algorithm to Run a Hyperparameter Tuning Job (p. 2354)
- Use a Model Package to Create a Model (p. 2357)

Use an Algorithm to Run a Training Job

You can create use an algorithm resource to create a training job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics

- Use an Algorithm to Run a Training Job (Console) (p. 2352)
- Use an Algorithm to Run a Training Job (API) (p. 2353)
- Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK) (p. 2353)

Use an Algorithm to Run a Training Job (Console)

To use an algorithm to run a training job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create training job.
   The algorithm you chose will automatically be selected.
5. On the Create training job page, provide the following information:
   a. For Job name, type a name for the training job.
   b. For IAM role, choose an IAM role that has the required permissions to run training jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 2399).
   c. For Resource configuration, provide the following information:
      i. For Instance type, choose the instance type to use for training.
      ii. For Instance count, type the number of ML instances to use for the training job.
      iii. For Additional volume per instance (GB), type the size of the ML storage volume that you want to provision. ML storage volumes store model artifacts and incremental states.
      iv. For Encryption key, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instance, specify the key.
      v. For Stopping condition, specify the maximum amount of time in seconds, minutes, hours, or days, that you want the training job to run.
d. For **VPC**, choose a Amazon VPC that you want to allow your training container to access. For more information, see *Give SageMaker Training Jobs Access to Resources in Your Amazon VPC* (p. 2448).

e. For **Hyperparameters**, specify the values of the hyperparameters to use for the training job.

f. For **Input data configuration**, specify the following values for each channel of input data to use for the training job. You can see what channels the algorithm you're using for training sports, and the content type, supported compression type, and supported input modes for each channel, under *Channel specification* section of the *Algorithm summary* page for the algorithm.

   i. For **Channel name**, type the name of the input channel.
   
   ii. For **Content type**, type the content type of the data that the algorithm expects for the channel.
   
   iii. For **Compression type**, choose the data compression type to use, if any.
   
   iv. For **Record wrapper**, choose RecordIO if the algorithm expects data in the RecordIO format.
   
   v. For **S3 data type**, **S3 data distribution type**, and **S3 location**, specify the appropriate values. For information about what these values mean, see *S3DataSource*.
   
   vi. For **Input mode**, choose **File** to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose **Pipe** to stream data directly from Amazon S3 to the container.

   vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

g. For **Output location**, specify the following values:

   i. For **S3 output path**, choose the S3 location where the training job stores output, such as model artifacts.

   **Note**
   You use the model artifacts stored at this location to create a model or model package from this training job.

   ii. For **Encryption key**, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

h. For **Tags**, specify one or more tags to manage the training job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.

   i. Choose **Create training job** to run the training job.

**Use an Algorithm to Run a Training Job (API)**

To use an algorithm to run a training job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) as the *AlgorithmName* field of the *AlgorithmSpecification* object that you pass to *CreateTrainingJob*. For information about training models in SageMaker, see *Train a Model with Amazon SageMaker* (p. 8).

**Use an Algorithm to Run a Training Job (Amazon SageMaker Python SDK)**

Use an algorithm that you created or subscribed to on AWS Marketplace to create a training job, create an *AlgorithmEstimator* object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the *algorithm_arn* argument. Then call the *fit* method of the estimator. For example:

```python
from sagemaker import AlgorithmEstimator
data_path = os.path.join(DATA_DIR, 'marketplace', 'training')
```
Use an Algorithm to Run a Hyperparameter Tuning Job

A hyperparameter tuning job finds the best version of a model by running many training jobs on your dataset using the algorithm and ranges of hyperparameters that you specify. It then chooses the hyperparameter values that result in a model that performs the best, as measured by a metric that you choose. For more information, see Perform Automatic Model Tuning with SageMaker (p. 1715).

You can create use an algorithm resource to create a hyperparameter tuning job by using the Amazon SageMaker console, the low-level Amazon SageMaker API, or the Amazon SageMaker Python SDK.

Topics
- Use an Algorithm to Run a Hyperparameter Tuning Job (Console) (p. 2354)
- Use an Algorithm to Run a Hyperparameter Tuning Job (API) (p. 2356)
- Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK) (p. 2356)

Use an Algorithm to Run a Hyperparameter Tuning Job (Console)

To use an algorithm to run a hyperparameter tuning job (console)

2. Choose Algorithms.
3. Choose an algorithm that you created from the list on the My algorithms tab or choose an algorithm that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create hyperparameter tuning job.
   The algorithm you chose will automatically be selected.
5. On the Create hyperparameter tuning job page, provide the following information:
   a. For Warm start, choose Enable warm start to use the information from previous hyperparameter tuning jobs as a starting point for this hyperparameter tuning job. For more information, see Run a Warm Start Hyperparameter Tuning Job (p. 1733).
      i. Choose Identical data and algorithm if your input data is the same as the input data for the parent jobs of this hyperparameter tuning job, or choose Transfer learning to use additional or different input data for this hyperparameter tuning job.
      ii. For Parent hyperparameter tuning job(s), choose up to 5 hyperparameter tuning jobs to use as parents to this hyperparameter tuning job.
   b. For Hyperparameter tuning job name, type a name for the tuning job.
   c. For IAM role, choose an IAM role that has the required permissions to run hyperparameter tuning jobs in SageMaker, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 2399).
For **VPC**, choose a Amazon VPC that you want to allow the training jobs that the tuning job launches to access. For more information, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 2448).

**Choose Next.**

For **Objective metric**, choose the metric that the hyperparameter tuning job uses to determine the best combination of hyperparameters, and choose whether to minimize or maximize this metric. For more information, see View the Best Training Job (p. 1731).

For **Hyperparameter configuration**, choose ranges for the tunable hyperparameters that you want the tuning job to search, and set static values for hyperparameters that you want to remain constant in all training jobs that the hyperparameter tuning job launches. For more information, see Define Hyperparameter Ranges (p. 1718).

**Choose Next.**

For **Input data configuration**, specify the following values for each channel of input data to use for the hyperparameter tuning job. You can see what channels the algorithm you're using for hyperparameter tuning supports, and the content type, supported compression type, and supported input modes for each channel, under Channel specification section of the Algorithm summary page for the algorithm.

i. **For Channel name**, type the name of the input channel.

ii. **For Content type**, type the content type of the data that the algorithm expects for the channel.

iii. **For Compression type**, choose the data compression type to use, if any.

iv. **For Record wrapper**, choose RecordIO if the algorithm expects data in the RecordIO format.

v. **For S3 data type, S3 data distribution type, and S3 location**, specify the appropriate values. For information about what these values mean, see S3DataSource.

vi. For **Input mode**, choose File to download the data from to the provisioned ML storage volume, and mount the directory to a Docker volume. Choose PipeTo stream data directly from Amazon S3 to the container.

vii. To add another input channel, choose **Add channel**. If you are finished adding input channels, choose **Done**.

For **Output location**, specify the following values:

i. **For S3 output path**, choose the S3 location where the training jobs that this hyperparameter tuning job launches store output, such as model artifacts.

   **Note**
   You use the model artifacts stored at this location to create a model or model package from this hyperparameter tuning job.

ii. **For Encryption key**, if you want SageMaker to use a AWS KMS key to encrypt output data at rest in the S3 location.

For **Resource configuration**, provide the following information:

i. **For Instance type**, choose the instance type to use for each training job that the hyperparameter tuning job launches.

ii. **For Instance count**, type the number of ML instances to use for each training job that the hyperparameter tuning job launches.

iii. **For Additional volume per instance (GB)**, type the size of the ML storage volume that you want to provision each training job that the hyperparameter tuning job launches. ML storage volumes store model artifacts and incremental states.

iv. **For Encryption key**, if you want Amazon SageMaker to use an AWS Key Management Service key to encrypt data in the ML storage volume attached to the training instances, specify the key.
l. For **Resource limits**, provide the following information:
   
   i. For **Maximum training jobs**, specify the maximum number of training jobs that you want the hyperparameter tuning job to launch. A hyperparameter tuning job can launch a maximum of 500 training jobs.
   
   ii. For **Maximum parallel training jobs**, specify the maximum number of concurrent training jobs that the hyperparameter tuning job can launch. A hyperparameter tuning job can launch a maximum of 10 concurrent training jobs.
   
   iii. For **Stopping condition**, specify the maximum amount of time in seconds, minutes, hours, or days, that you want each training job that the hyperparameter tuning job launches to run.
   
   m. For **Tags**, specify one or more tags to manage the hyperparameter tuning job. Each tag consists of a key and an optional value. Tag keys must be unique per resource.
   
   n. Choose **Create jobs** to run the hyperparameter tuning job.

### Use an Algorithm to Run a Hyperparameter Tuning Job (API)

To use an algorithm to run a hyperparameter tuning job by using the SageMaker API, specify either the name or the Amazon Resource Name (ARN) of the algorithm as the `AlgorithmName` field of the `AlgorithmSpecification` object that you pass to `CreateHyperParameterTuningJob`. For information about hyperparameter tuning in SageMaker, see Perform Automatic Model Tuning with SageMaker (p. 1715).

### Use an Algorithm to Run a Hyperparameter Tuning Job (Amazon SageMaker Python SDK)

Use an algorithm that you created or subscribed to on AWS Marketplace to create a hyperparameter tuning job, create an `AlgorithmEstimator` object and specify either the Amazon Resource Name (ARN) or the name of the algorithm as the value of the `algorithm_arn` argument. Then initialize a `HyperparameterTuner` object with the `AlgorithmEstimator` you created as the value of the `estimator` argument. Finally, call the `fit` method of the `AlgorithmEstimator`. For example:

```
from sagemaker import AlgorithmEstimator
from sagemaker.tuner import HyperparameterTuner

data_path = os.path.join(DATA_DIR, 'marketplace', 'training')

algo = AlgorithmEstimator(
    algorithm_arn='arn:aws:sagemaker:us-east-2:764419575721:algorithm/scikit-
    decision-trees-1542410022',
    role='SageMakerRole',
    instance_count=1,
    instance_type='ml.c4.xlarge',
    sagemaker_session=sagemaker_session,
    base_job_name='test-marketplace')

train_input = algo.sagemaker_session.upload_data(
    path=data_path, key_prefix='integ-test-data/marketplace/train')

algo.set_hyperparameters(max_leaf_nodes=10)

tuner = HyperparameterTuner(estimator=algo, base_tuning_job_name='some-name',
                              objective_metric_name='validation:accuracy',
                              hyperparameter_ranges=hyperparameter_ranges,
                              max_jobs=2, max_parallel_jobs=2)

tuner.fit({'training': train_input}, include_cls_metadata=False)
tuner.wait()
```
Use a Model Package to Create a Model

Use a model package to create a deployable model that you can use to get real-time inferences by creating a hosted endpoint or to run batch transform jobs. You can create a deployable model from a model package by using the Amazon SageMaker console, the low-level SageMaker API, or the Amazon SageMaker Python SDK.

Topics

- Use a Model Package to Create a Model (Console) (p. 2357)
- Use a Model Package to Create a Model (API) (p. 2357)
- Use a Model Package to Create a Model (Amazon SageMaker Python SDK) (p. 2358)

Use a Model Package to Create a Model (Console)

To create a deployable model from a model package (console)

2. Choose Model packages.
3. Choose a model package that you created from the list on the My model packages tab or choose a model package that you subscribed to on the AWS Marketplace subscriptions tab.
4. Choose Create model.
5. For Model name, type a name for the model.
6. For IAM role, choose an IAM role that has the required permissions to call other services on your behalf, or choose Create a new role to allow SageMaker to create a role that has the AmazonSageMakerFullAccess managed policy attached. For information, see SageMaker Roles (p. 2399).
7. For VPC, choose a Amazon VPC that you want to allow the model to access. For more information, see Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC (p. 2451).
8. Leave the default values for Container input options and Choose model package.
9. For environment variables, provide the names and values of environment variables you want to pass to the model container.
10. For Tags, specify one or more tags to manage the model. Each tag consists of a key and an optional value. Tag keys must be unique per resource.
11. Choose Create model.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Use a Model Package to Create a Model (API)

To use a model package to create a deployable model by using the SageMaker API, specify the name or the Amazon Resource Name (ARN) of the model package as the ModelPackageName field of the ContainerDefinition object that you pass to the CreateModel API.

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosted endpoints in SageMaker, see Deploy Models for Inference.
Use a Model Package to Create a Model (Amazon SageMaker Python SDK)

To use a model package to create a deployable model by using the SageMaker Python SDK, initialize a `ModelPackage` object, and pass the Amazon Resource Name (ARN) of the model package as the `model_package_arn` argument. For example:

```python
from sagemaker import ModelPackage
model = ModelPackage(role='SageMakerRole',
                      model_package_arn='training-job-scikit-decision-trees-1542660466-6f92',
                      sagemaker_session=sagemaker_session)
```

After you create a deployable model, you can use it to set up an endpoint for real-time inference or create a batch transform job to get inferences on entire datasets. For information about hosting endpoints in SageMaker, see Deploy Models for Inference.

Sell Amazon SageMaker Algorithms and Model Packages

Selling Amazon SageMaker algorithms and model packages is a three-step process:

1. Develop your algorithm or model, and package it in a Docker container. For information, see Develop Algorithms and Models in Amazon SageMaker (p. 2359).
2. Create an algorithm or model package resource in SageMaker. For information, see Create Algorithm and Model Package Resources (p. 2345).
3. Register as a seller on AWS Marketplace and list your algorithm or model package on AWS Marketplace. For information about registering as a seller, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. For information about listing and monetizing your algorithms and model packages, see Listing Algorithms and Model Packages in AWS Marketplace for Machine Learning in the User Guide for AWS Marketplace Providers.
Develop Algorithms and Models in Amazon SageMaker

Before you can create algorithm and model package resources to use in Amazon SageMaker or list on AWS Marketplace, you have to develop them and package them in Docker containers.

**Note**
When algorithms and model packages are created for listing on AWS Marketplace, SageMaker scans the containers for security vulnerabilities on supported operating systems. Only the following operating system versions are supported:

- Debian: 6.0, 7, 8, 9, 10
- CentOS: 5, 6, 7
- Oracle Linux: 5, 6, 7
- Alpine: 3.3, 3.4, 3.5
- Amazon Linux

Develop Algorithms in SageMaker

An algorithm should be packaged as a docker container and stored in Amazon ECR to use it in SageMaker. The Docker container contains the training code used to run training jobs and, optionally, the inference code used to get inferences from models trained by using the algorithm.

For information about developing algorithms in SageMaker and packaging them as containers, see Using Docker containers with SageMaker (p. 2090). For a complete example of how to create an algorithm container, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/scikitbring_your_own/scikitbring_your_own.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named scikitbring_your_own.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks (p. 130).

Always thoroughly test your algorithms before you create algorithm resources to publish on AWS Marketplace.

**Note**
When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.
Develop Models in SageMaker

A deployable model in SageMaker consists of inference code, model artifacts, an IAM role that is used to access resources, and other information required to deploy the model in SageMaker. Model artifacts are the results of training a model by using a machine learning algorithm. The inference code must be packaged in a Docker container and stored in Amazon ECR. You can either package the model artifacts in the same container as the inference code, or store them in Amazon S3.

You create a model by running a training job in SageMaker, or by training a machine learning algorithm outside of SageMaker. If you run a training job in SageMaker, the resulting model artifacts are available in the ModelArtifacts field in the response to a call to the DescribeTrainingJob operation. For information about how to develop a SageMaker model container, see Use Your Own Inference Code (p. 2123). For a complete example of how to create a model container from a model trained outside of SageMaker, see the sample notebook at https://sagemaker-examples.readthedocs.io/en/latest/advanced_functionality/xgboost_bring_your_own_model/xgboost_bring_your_own_model.html. You can also find the sample notebook in a SageMaker notebook instance. The notebook is in the Advanced Functionality section, and is named xgboost_bring_your_own_model.ipynb. For information about using the sample notebooks in a notebook instance, see Example Notebooks (p. 130).

Always thoroughly test your models before you create model packages to publish on AWS Marketplace.

Note

When a buyer subscribes to your containerized product, the Docker containers run in an isolated (internet-free) environment. When you create your containers, do not rely on making outgoing calls over the internet. Calls to AWS services are also not allowed.

List Your Algorithm or Model Package on AWS Marketplace

After creating and validating your algorithm or model in Amazon SageMaker, list your product on AWS Marketplace. The listing process makes your products available in the AWS Marketplace and the SageMaker console.

To list products on AWS Marketplace, you must be a registered seller. To register, use the self-registration process from the AWS Marketplace Management Portal (AMMP). For information, see Getting Started as a Seller in the User Guide for AWS Marketplace Providers. When you start the product listing process from the Amazon SageMaker console, we check your seller registration status. If you have not registered, we direct you to do so.

To start the listing process, do one of the following:

- From the SageMaker console, choose the product, choose Actions, and choose Publish new ML Marketplace listing. This carries over your product reference, the Amazon Resource Name (ARN), and directs you to the AMMP to create the listing.
- Go to ML listing process, manually enter the Amazon Resource Name (ARN), and start your product listing. This process carries over the product metadata that you entered when creating the product in SageMaker. For an algorithm listing, the information includes the supported instance types and hyperparameters. In addition, you can enter a product description, promotional information, and support information as you would with other AWS Marketplace products.
Find and Subscribe to Algorithms and Model Packages on AWS Marketplace

With AWS Marketplace, you can browse and search for hundreds of machine learning algorithms and models in a broad range of categories, such as computer vision, natural language processing, speech recognition, text, data, voice, image, video analysis, fraud detection, predictive analysis, and more.

To find algorithms on AWS Marketplace

1. Open the Amazon SageMaker console at https://console.aws.amazon.com/sagemaker/.
2. Choose Algorithms, then choose Find algorithms.

This takes you to the AWS Marketplace algorithms page. For information about finding and subscribing to algorithms on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

To find model packages on AWS Marketplace

2. Choose Model packages, then choose Find model packages.

This takes you to the AWS Marketplace model packages page. For information about finding and subscribing to model packages on AWS Marketplace, see Machine Learning Products in the AWS Marketplace User Guide for AWS Consumers.

Use Algorithms and Model Packages

For information about using algorithms and model packages that you subscribe to in SageMaker, see Use Algorithm and Model Package Resources (p. 2351).

Note
When you create a training job, inference endpoint, and batch transform job from an algorithm or model package that you subscribe to on AWS Marketplace, the training and inference containers do not have access to the internet. Because the containers do not have access to the internet, the seller of the algorithm or model package does not have access to your data.
Security in Amazon SageMaker

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon SageMaker, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using SageMaker. The following topics show you how to configure SageMaker to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your SageMaker resources.

**Topics**
- Access Control (p. 2362)
- Data Protection in Amazon SageMaker (p. 2364)
- Identity and Access Management for Amazon SageMaker (p. 2369)
- Logging and Monitoring (p. 2430)
- Compliance Validation for Amazon SageMaker (p. 2431)
- Resilience in Amazon SageMaker (p. 2431)
- Infrastructure Security in Amazon SageMaker (p. 2432)

Access Control

Amazon SageMaker Studio notebooks and SageMaker notebook instances differ in their runtime environments. The following topics describe how to control root access to these notebooks.

**Topics**
- Access control and SageMaker Studio notebooks (p. 2362)
- Control root access to a SageMaker notebook instance (p. 2364)

Access control and SageMaker Studio notebooks

Amazon SageMaker Studio uses filesystem and container permissions for access control and isolation of Studio users and notebooks. This is one of the major differences between Studio notebooks and
SageMaker notebook instances. This topic describes how permissions are set up to avoid security threats, what SageMaker does by default, and how the customer can customize the permissions. For more information about Studio notebooks and their runtime environment, see Use Amazon SageMaker Studio Notebooks (p. 78).

**SageMaker app permissions**

A *run-as user* is a POSIX user/group which is used to run the JupyterServer app and KernelGateway apps inside the container.

The run-as user for the JupyterServer app is sagemaker-user (1000) by default. This user has sudo permissions to enable the installation of dependencies such as yum packages.

The run-as user for the KernelGateway apps is root (0) by default. This user is able to install dependencies using pip/apt-get/conda.

Due to the previously mentioned user remapping, neither user is able to access resources or make changes to the host instance.

**User remapping**

SageMaker performs user-remapping to map a user inside the container to a user on the host instance outside the container. The range of user IDs (0 - 65535) in the container are mapped to non-privileged user IDs above 65535 on the instance. For example, sagemaker-user (1000) inside the container might map to user (200001) on the instance, where the number in parentheses is the user ID. If the customer creates a new user/group inside the container, it won't be privileged on the host instance regardless of the user/group ID. The root user of the container is also mapped to a non-privileged user on the instance. For more information, see Isolate containers with a user namespace.

**Custom image permissions**

Customers can bring their own custom SageMaker images. These images can specify a different run-as user/group to launch the KernelGateway app. The customer can implement fine grained permission control inside the image, for example, to disable root access or perform other actions. The same user remapping applies here. For more information, see Bring your own SageMaker image (p. 97).

**Container isolation**

Docker keeps a list of default capabilities that the container can use. SageMaker doesn't add additional capabilities. SageMaker adds specific route rules to block requests to Amazon EFS and the instance metadata service (IMDS) from the container. Customers can't change these route rules from the container. For more information, see Runtime privilege and Linux capabilities.

**App metadata access**

Metadata used by running apps are mounted to the container with read-only permission. Customers aren't able to modify this metadata from the container. For the available metadata, see Get Notebook and App Metadata (p. 86).

**User isolation on EFS**

When you onboard to Studio, SageMaker creates an Amazon Elastic File System (EFS) volume for your domain that is shared by all Studio users in the domain. Each user gets their own private home directory on the EFS volume. This home directory is used to store the user's notebooks, Git repositories, and other data. To prevent other users in the domain from accessing the user's data, SageMaker creates a globally unique user ID for the user's profile and applies it as a POSIX user/group ID for the user's home directory.

**EBS access**
An Amazon Elastic Block Store (Amazon EBS) volume is attached to the host instance and shared across all images. It's used for the root volume of the notebooks and stores temporary data that's generated inside the container. The storage isn't persisted when the instance running the notebooks is deleted. The root user inside the container can't access the EBS volume.

**IMDS access**

Due to security concerns, access to the Amazon Elastic Compute Cloud (Amazon EC2) Instance Metadata Service (IMDS) is unavailable in SageMaker Studio. For more information on IMDS, see Instance metadata and user data.

**Control root access to a SageMaker notebook instance**

By default, when you create a notebook instance, users that log into that notebook instance have root access. Data science is an iterative process that might require the data scientist to test and use different software tools and packages, so many notebook instance users need to have root access to be able to install these tools and packages. Because users with root access have administrator privileges, users can access and edit all files on a notebook instance with root access enabled.

If you don't want users to have root access to a notebook instance, when you call `CreateNotebookInstance` or `UpdateNotebookInstance` operations, set the `RootAccess` field to `Disabled`. You can also disable root access for users when you create or update a notebook instance in the Amazon SageMaker console. For information, see Step 1: Create an Amazon SageMaker Notebook Instance (p. 55).

**Note**

Lifecycle configurations need root access to be able to set up a notebook instance. Because of this, lifecycle configurations associated with a notebook instance always run with root access even if you disable root access for users.

**Note**

For security reasons, Rootless Docker is installed on root-disabled notebook instances instead of regular Docker. For more information, see Run the Docker daemon as a non-root user (Rootless mode)

**Data Protection in Amazon SageMaker**

The AWS shared responsibility model applies to data protection in Amazon SageMaker. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. This content includes the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual user accounts with AWS Identity and Access Management (IAM). That way each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We recommend TLS 1.2 or later.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
• Use advanced managed security services such as Amazon Macie, which assists in discovering and securing personal data that is stored in Amazon S3.
• If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put sensitive identifying information, such as your customers' account numbers, into free-form fields such as a Name field. This includes when you work with Amazon SageMaker or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into Amazon SageMaker or other services might get picked up for inclusion in diagnostic logs. When you provide a URL to an external server, don’t include credentials information in the URL to validate your request to that server.

Topics
• Protect Data at Rest Using Encryption (p. 2365)
• Protecting Data in Transit with Encryption (p. 2366)
• Key Management (p. 2368)
• Internetwork Traffic Privacy (p. 2369)

Protect Data at Rest Using Encryption

To protect your Amazon SageMaker Studio notebooks and SageMaker notebook instances, along with your model-building data and model artifacts, SageMaker uses the AWS Key Management Service (AWS KMS) to encrypt the notebooks and data. SageMaker uses AWS managed customer master keys (CMKs) by default. For more control, you can specify your own customer managed CMKs. For more information on AWS KMS, see What is AWS Key Management Service?.

Topics
• Studio notebooks (p. 2365)
• Notebook instances and SageMaker jobs (p. 2366)

Studio notebooks

In Amazon SageMaker Studio, your SageMaker Studio notebooks and data can be stored in the following locations:

• An S3 bucket – When you onboard to Studio and enable shareable notebook resources, SageMaker shares notebook snapshots and metadata in an Amazon Simple Storage Service (Amazon S3) bucket.
• An EFS volume – When you onboard to Studio, SageMaker attaches an Amazon Elastic File System (Amazon EFS) volume to your domain for storing your Studio notebooks and data files. The EFS volume persists after the domain is deleted.
• An EBS volume – When you open a notebook in Studio, an Amazon Elastic Block Store (Amazon EBS) is attached to the instance that the notebook runs on. The EBS volume persists for the duration of the instance.

SageMaker uses the AWS Key Management Service (AWS KMS) to encrypt the S3 bucket and both volumes with an AWS managed customer master key (CMK) by default. For more control, you can specify your own customer managed CMK when you onboard to Studio or through the SageMaker API. For more information, see Onboard to Amazon SageMaker Studio (p. 35) and CreateDomain.

In the CreateDomain API, you use the S3KmsKeyId parameter to specify the custom CMK for shareable notebooks. You use the KmsKeyId parameter to specify the custom CMK for the EFS and EBS volumes.
The same CMK is used for both volumes. The custom CMK for shareable notebooks can be the same CMK as used for the volumes or a different CMK.

**Notebook instances and SageMaker jobs**

To encrypt the machine learning (ML) storage volume that is attached to notebooks, processing jobs, training jobs, hyperparameter tuning jobs, batch transform jobs, and endpoints, you can pass an AWS KMS key to SageMaker. If you don't specify a KMS key, SageMaker encrypts storage volumes with a transient key and discards it immediately after encrypting the storage volume. For notebook instances, if you don't specify a KMS key, SageMaker encrypts both OS volumes and ML data volumes with a system-managed KMS key.

You can use an AWS managed KMS key to encrypt all instance OS volumes. You can encrypt all ML data volumes for all SageMaker instances with a KMS key that you specify. ML storage volumes are mounted as follows:

- **Notebooks** - /home/ec2-user/SageMaker
- **Processing** - /opt/ml/processing and /tmp/
- **Training** - /opt/ml/ and /tmp/
- **Batch** - /opt/ml/ and /tmp/
- **Endpoints** - /opt/ml/ and /tmp/

Processing, batch transform, and training job containers and their storage are ephemeral in nature. When the job completes, output is uploaded to Amazon S3 using AWS KMS encryption (with an optional KMS key you specify) and the instance is torn down.

**Important**

Sensitive data that needs to be encrypted with a KMS key for compliance reasons should be stored in the ML storage volume or in Amazon S3, both of which can be encrypted using a KMS key you specify.

When you open a notebook instance, SageMaker saves it and any files associated with it in the SageMaker folder in the ML storage volume by default. When you stop a notebook instance, SageMaker creates a snapshot of the ML storage volume. Any customizations to the operating system of the stopped instance, such as installed custom libraries or operating system level settings, are lost. Consider using a lifecycle configuration to automate customizations of the default notebook instance. When you terminate an instance, the snapshot and the ML storage volume are deleted. Any data that you need to persist beyond the lifespan of the notebook instance should be transferred to an Amazon S3 bucket.

**Note**

Certain Nitro-based SageMaker instances include local storage, depending on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can't use a KMS key on an instance type with local storage. For a list of instance types that support local instance storage, see the [Instance Store Volumes](https://docs.aws.amazon.com/en_us/sagemaker/latest/dg/instance-store-volumes.html). For more information about storage volumes on Nitro-based instances, see [Amazon EBS and NVMe on Linux Instances](https://docs.aws.amazon.com/en_us/sagemaker/latest/dg/nitro-storage.html).

For more information about local instance storage encryption, see [SSD Instance Store Volumes](https://docs.aws.amazon.com/en_us/sagemaker/latest/dg/instance-store-volumes.html).

**Protecting Data in Transit with Encryption**

All inter-network data in transit supports TLS 1.2 encryption.

Amazon SageMaker ensures that machine learning (ML) model artifacts and other system artifacts are encrypted in transit and at rest. Requests to the SageMaker API and console are made over a secure (SSL) connection. You pass AWS Identity and Access Management roles to SageMaker to provide permissions to access resources on your behalf for training and deployment. You can use encrypted Amazon S3 buckets for model artifacts and data, as well as pass a AWS KMS key to SageMaker instances to encrypt the attached ML storage volumes.
Some intra-network data in-transit (inside the service platform) is unencrypted. This includes:

- Command and control communications between the service control plane and training job instances (not customer data).
- Communications between nodes in distributed processing jobs (intra-network).
- Communications between nodes in distributed training jobs (intra-network).

There are no inter-node communications for batch processing.

You can choose to encrypt communication between nodes in a training cluster. For information about how to do this, see Protect Communications Between ML Compute Instances in a Distributed Training Job (p. 2367). Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

FIPS validated endpoints are available for the SageMaker API and request router for hosted models (runtime). For information about FIPS compliant endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Protect Communications Between ML Compute Instances in a Distributed Training Job

By default, Amazon SageMaker runs training jobs in an Amazon Virtual Private Cloud (Amazon VPC) to help keep your data secure. You can add another level of security to protect your training containers and data by configuring a private VPC. Distributed ML frameworks and algorithms usually transmit information that is directly related to the model such as weights, not the training dataset. When performing distributed training, you can further protect data that is transmitted between instances. This can help you to comply with regulatory requirements. To do this, use inter-container traffic encryption.

Enabling inter-container traffic encryption can increase training time, especially if you are using distributed deep learning algorithms. Enabling inter-container traffic encryption doesn't affect training jobs with a single compute instance. However, for training jobs with several compute instances, the effect on training time depends on the amount of communication between compute instances. For affected algorithms, adding this additional level of security also increases cost. The training time for most SageMaker built-in algorithms, such as XGBoost, DeepAR, and linear learner, typically aren't affected.

You can enable inter-container traffic encryption for training jobs or hyperparameter tuning jobs. You can use SageMaker APIs or console to enable inter-container traffic encryption.

For information about running training jobs in a private VPC, see Give SageMaker Training Jobs Access to Resources in Your Amazon VPC (p. 2448).

Enable Inter-Container Traffic Encryption (API)

Before enabling inter-container traffic encryption on training or hyperparameter tuning jobs with APIs, you need to add inbound and outbound rules to your private VPC’s security group.

To enable inter-container traffic encryption (API)

1. Add the following inbound and outbound rules in the security group for your private VPC:

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port Range</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>500</td>
<td>Self Security Group ID</td>
</tr>
</tbody>
</table>
2. When you send a request to the `CreateTrainingJob` or `CreateHyperParameterTuningJob` API, specify `true` for the `EnableInterContainerTrafficEncryption` parameter.

**Note**

The AWS Security Group Console might show display ports range as "All", however EC2 ignores the specified port range because it is not applicable for the ESP 50 IP protocol.

### Enable Inter-Container Traffic Encryption (Console)

#### Enable Inter-container Traffic Encryption in a Training Job

**To enable inter-container traffic encryption in a training job**

2. In the navigation pane, choose **Training**, then choose **Training jobs**.
3. Choose **Create training job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you have created.
5. Choose **Enable inter-container traffic encryption**.

After you enable inter-container traffic encryption, finish creating the training job. For more information, see Step 4: Train a Model (p. 61).

#### Enable Inter-container Traffic Encryption in a Hyperparameter Tuning Job

**To enable inter-container traffic encryption in a hyperparameter tuning job**

2. In the navigation pane, choose **Training**, then choose **Hyperparameter tuning jobs**.
3. Choose **Create hyperparameter tuning job**.
4. Under **Network**, choose a **VPC**. You can use the default VPC or one that you have created.
5. Choose **Enable inter-container traffic encryption**.

After enabling inter-container traffic encryption, finish creating the hyperparameter tuning job. For more information, see Configure and Launch a Hyperparameter Tuning Job (p. 1725).

### Key Management

Customers can specify AWS KMS keys, including bringing your own keys (BYOK), to use for envelope encryption with Amazon S3 input/output buckets and machine learning (ML) Amazon EBS volumes. ML volumes for notebook instances and for processing, training, and hosted model Docker containers can be optionally encrypted by using AWS KMS customer-owned keys. All instance OS volumes are encrypted with an AWS-managed AWS KMS key.

**Note**

Certain Nitro-based instances include local storage, dependent on the instance type. Local storage volumes are encrypted using a hardware module on the instance. You can’t request a `VolumeKmsKeyId` when using an instance type with local storage.

For a list of instance types that support local instance storage, see [Instance Store Volumes](https://console.aws.amazon.com/sagemaker/). For more information about local instance storage encryption, see [SSD Instance Store Volumes](https://console.aws.amazon.com/sagemaker/).
For more information about storage volumes on nitro-based instances, see Amazon EBS and NVMe on Linux Instances.

For information about AWS KMS keys see What is AWS Key Management Service? in the AWS Key Management Service Developer Guide.

**Internetwork Traffic Privacy**

This topic describes how Amazon SageMaker secures connections from the service to other locations.

Internetwork communications support TLS 1.2 encryption between all components and clients.

Instances can be connected to Customer VPC, providing access to S3 VPC endpoints or customer repositories. Internet egress can be managed through this interface by the customer if service platform internet egress is disabled for notebooks. For training and hosting, egress through the service platform is not available when connected to the customer's VPC.

By default, API calls made to published endpoints traverse the public network to the request router. SageMaker supports Amazon Virtual Private Cloud interface endpoints powered by AWS PrivateLink for private connectivity between the customer's VPC and the request router to access hosted model endpoints. For information about Amazon VPC, see Connect to SageMaker Through a VPC Interface Endpoint (p. 2436)

**Identity and Access Management for Amazon SageMaker**

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use SageMaker resources. IAM is an AWS service that you can use with no additional charge.

**Topics**

- Audience (p. 2369)
- Authenticating with Identities (p. 2370)
- Managing Access Using Policies (p. 2372)
- How Amazon SageMaker Works with IAM (p. 2373)
- Amazon SageMaker Identity-Based Policy Examples (p. 2376)
- SageMaker Roles (p. 2399)
- AWS Managed (Predefined) Policies for Amazon SageMaker (p. 2415)
- Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference (p. 2416)
- Troubleshooting Amazon SageMaker Identity and Access (p. 2429)

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in SageMaker.

**Service user** – If you use the SageMaker service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more SageMaker features to do your work, you might need additional permissions. Understanding how access is managed can help you
request the right permissions from your administrator. If you cannot access a feature in SageMaker, see Troubleshooting Amazon SageMaker Identity and Access (p. 2429).

**Service administrator** – If you’re in charge of SageMaker resources at your company, you probably have full access to SageMaker. It’s your job to determine which SageMaker features and resources your employees should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with SageMaker, see How Amazon SageMaker Works with IAM (p. 2373).

**IAM administrator** – If you’re an IAM administrator, you might want to learn details about how you can write policies to manage access to SageMaker. To view example SageMaker identity-based policies that you can use in IAM, see Amazon SageMaker Identity-Based Policy Examples (p. 2376).

## Authenticating with Identities

Authentication is how you sign in to AWS using your identity credentials. For more information about signing in using the AWS Management Console, see Signing in to the AWS Management Console as an IAM user or root user in the IAM User Guide.

You must be authenticated (signed in to AWS) as the AWS account root user, an IAM user, or by assuming an IAM role. You can also use your company's single sign-on authentication or even sign in using Google or Facebook. In these cases, your administrator previously set up identity federation using IAM roles. When you access AWS using credentials from another company, you are assuming a role indirectly.

To sign in directly to the AWS Management Console, use your password with your root user email address or your IAM user name. You can access AWS programmatically using your root user or IAM users access keys. AWS provides SDK and command line tools to cryptographically sign your request using your credentials. If you don’t use AWS tools, you must sign the request yourself. Do this using Signature Version 4, a protocol for authenticating inbound API requests. For more information about authenticating requests, see Signature Version 4 signing process in the AWS General Reference.

Regardless of the authentication method that you use, you might also be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

### AWS account root user

When you first create an AWS account, you begin with a single sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you do not use the root user for your everyday tasks, even the administrative ones. Instead, adhere to the best practice of using the root user only to create your first IAM user. Then securely lock away the root user credentials and use them to perform only a few account and service management tasks.

### IAM Users and Groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. An IAM user can have long-term credentials such as a user name and password or a set of access keys. To learn how to generate access keys, see Managing access keys for IAM users in the IAM User Guide. When you generate access keys for an IAM user, make sure you view and securely save the key pair. You cannot recover the secret access key in the future. Instead, you must generate a new access key pair.

An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to...
manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM Roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary IAM user permissions** – An IAM user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – Instead of creating an IAM user, you can use existing identities from AWS Directory Service, your enterprise user directory, or a web identity provider. These are known as federated users. AWS assigns a role to a federated user when access is requested through an identity provider. For more information about federated users, see Federated users and roles in the IAM User Guide.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
- **Principal permissions** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. Policies grant permissions to a principal. When you use some services, you might perform an action that then triggers another action in a different service. In this case, you must have permissions to perform both actions. To see whether an action requires additional dependent actions in a policy, see Actions, Resources, and Condition Keys for Amazon SageMaker in the Service Authorization Reference.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. Service roles provide access only within your account and cannot be used to grant access to services in other accounts. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your IAM account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 Instances in the IAM User Guide.
Managing Access Using Policies

You control access in AWS by creating policies and attaching them to IAM identities or AWS resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. You can sign in as the root user or an IAM user, or you can assume an IAM role. When you then make a request, AWS evaluates the related identity-based or resource-based policies. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

Every IAM entity (user or role) starts with no permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the iam:GetRole action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-Based Policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

Resource-Based Policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can’t use AWS managed policies from IAM in a resource-based policy.

Access Control Lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.
Other Policy Types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity’s identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the *AWS Organizations User Guide*.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple Policy Types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon SageMaker Works with IAM

Before you use IAM to manage access to SageMaker, you should understand what IAM features are available to use with SageMaker. To get a high-level view of how SageMaker and other AWS services work with IAM, see AWS Services That Work with IAM in the *IAM User Guide*.

Topics

- SageMaker Identity-Based Policies (p. 2373)

SageMaker Identity-Based Policies

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. SageMaker supports specific actions, resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON Policy Elements Reference in the *IAM User Guide*.

Actions

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.
The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in SageMaker use the following prefix before the action: **sagemaker:**. For example, to grant someone permission to run a SageMaker training job with the SageMaker CreateTrainingJob API operation, you include the `sagemaker:CreateTrainingJob` action in their policy. Policy statements must include either an **Action** or **NotAction** element. SageMaker defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [
   "sagemaker:action1",
   "sagemaker:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "sagemaker:Describe*"
```

To see a list of SageMaker actions, see [Actions, resources, and condition keys for Amazon SageMaker](https://docs.aws.amazon.com/sagemaker/latest/dg/service-authorization-reference.html) in the *Service Authorization Reference*.

**Resources**

SageMaker does not support specifying resource ARNs in a policy.

**Condition Keys**

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

The **Condition** element (or **Condition** block) lets you specify conditions in which a statement is in effect. The **Condition** element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple **Condition** elements in a statement, or multiple keys in a single **Condition** element, AWS evaluates them using a logical **AND** operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical **OR** operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](https://docs.aws.amazon.com/IAM/latest/UserGuide/id passphrase-defined-variables.html) in the *IAM User Guide*.

SageMaker defines its own set of condition keys and also supports using some global condition keys. To see all AWS global condition keys, see [AWS Global Condition Context Keys](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_condition-keys-aws.html) in the *IAM User Guide*.
SageMaker supports a number of service-specific condition keys that you can use for fine-grained access control for the following operations:

- CreateProcessingJob
- CreateTrainingJob
- CreateModel
- CreateEndpointConfig
- CreateTransformJob
- CreateHyperParameterTuningJob
- CreateLabelingJob
- CreateNotebookInstance
- UpdateNotebookInstance

To see a list of SageMaker condition keys, see Condition keys for Amazon SageMaker in the IAM User Guide. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon SageMaker.

For examples of using SageMaker condition keys, see the following: Control Creation of SageMaker Resources with Condition Keys (p. 2386).

**Examples**

To view examples of SageMaker identity-based policies, see Amazon SageMaker Identity-Based Policy Examples (p. 2376).

**SageMaker Resource-Based Policies**

SageMaker does not support resource-based policies.

**Authorization Based on SageMaker Tags**

You can attach tags to SageMaker resources or pass tags in a request to SageMaker. To control access based on tags, you provide tag information in the condition element of a policy using the sagemaker:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys. For more information about tagging SageMaker resources, see Control Access to SageMaker Resources by Using Tags (p. 2396).

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Control Access to SageMaker Resources by Using Tags (p. 2396).

**SageMaker IAM Roles**

An IAM role is an entity within your AWS account that has specific permissions.

**Using Temporary Credentials with SageMaker**

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling AWS STS API operations such as AssumeRole or GetFederationToken.

SageMaker supports using temporary credentials.

**Service-Linked Roles**

SageMaker doesn't support service-linked roles.
Service Roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles appear in your IAM account and are owned by the account. This means that an IAM administrator can change the permissions for this role. However, doing so might break the functionality of the service.

SageMaker supports service roles.

Choosing an IAM Role in SageMaker

When you create a notebook instance, processing job, training job, hosted endpoint, or batch transform job resource in SageMaker, you must choose a role to allow SageMaker to access SageMaker on your behalf. If you have previously created a service role or service-linked role, then SageMaker provides you with a list of roles to choose from. It's important to choose a role that allows access to the AWS operations and resources you need. For more information, see SageMaker Roles (p. 2399).

Amazon SageMaker Identity-Based Policy Examples

By default, IAM users and roles don't have permission to create or modify SageMaker resources. They also can't perform tasks using the AWS Management Console, AWS CLI, or AWS API. An IAM administrator must create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the IAM users or groups that require those permissions. To learn how to attach policies to an IAM user or group, see Adding and Removing IAM Identity Permissions in the IAM User Guide.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating Policies on the JSON Tab in the IAM User Guide.

- Control Creation of SageMaker Resources with Condition Keys (p. 2386)
- Control Access to the SageMaker API by Using Identity-based Policies (p. 2393)
- Limit Access to SageMaker API and Runtime Calls by IP Address (p. 2394)
- Limit Access to a Notebook Instance by IP Address (p. 2395)
- Control Access to SageMaker Resources by Using Tags (p. 2396)
- Require the Presence or Absence of Tags for API Calls (p. 2398)
- Use Tags with Hyperparameter Tuning Jobs (p. 2398)

Policy Best Practices

Identity-based policies are very powerful. They determine whether someone can create, access, or delete SageMaker resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- Get started using AWS managed policies – To start using SageMaker quickly, use AWS managed policies to give your employees the permissions they need. These policies are already available in your account and are maintained and updated by AWS. For more information, see Get started using permissions with AWS managed policies in the IAM User Guide.
- Grant least privilege – When you create custom policies, grant only the permissions required to perform a task. Start with a minimum set of permissions and grant additional permissions as
necessary. Doing so is more secure than starting with permissions that are too lenient and then trying to tighten them later. For more information, see Grant least privilege in the IAM User Guide.

- **Enable MFA for sensitive operations** – For extra security, require IAM users to use multi-factor authentication (MFA) to access sensitive resources or API operations. For more information, see Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

- **Use policy conditions for extra security** – To the extent that it’s practical, define the conditions under which your identity-based policies allow access to a resource. For example, you can write conditions to specify a range of allowable IP addresses that a request must come from. You can also write conditions to allow requests only within a specified date or time range, or to require the use of SSL or MFA. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

### Using the SageMaker Console

To access the Amazon SageMaker console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the SageMaker resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won’t function as intended for entities (IAM users or roles) with that policy.

To ensure that those entities can still use the SageMaker console, also attach the following AWS managed policy to the entities. For more information, see Adding Permissions to a User in the IAM User Guide:

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

**Topics**

- Permissions Required to Use the Amazon SageMaker Console (p. 2377)
- Permissions Required to Use the Amazon SageMaker Ground Truth Console (p. 2379)
- Permissions Required to Use the Amazon Augmented AI (Preview) Console (p. 2380)

### Permissions Required to Use the Amazon SageMaker Console

The permissions reference table lists the Amazon SageMaker API operations and shows the required permissions for each operation. For more information about Amazon SageMaker API operations, see Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference (p. 2416).

To use the Amazon SageMaker console, you need to grant permissions for additional actions. Specifically, the console needs permissions that allow the ec2 actions to display subnets, VPCs, and security groups. Optionally, the console needs permission to create execution roles for tasks such as CreateNotebook, CreateTrainingJob, and CreateModel. Grant these permissions with the following permissions policy:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "SageMakerApis",
         "Effect": "Allow",
         "Action": [
            "sagemaker:*"
         ],
         "Resource": "*"
      },
      {
          "Action": 
```
"Sid": "VpcConfigurationForCreateForms",
"Effect": "Allow",
"Action": [
  "ec2:DescribeVpcs",
  "ec2:DescribeSubnets",
  "ec2:DescribeSecurityGroups"
],
"Resource": "*"
},
{
  "Sid": "KmsKeysForCreateForms",
  "Effect": "Allow",
  "Action": [
    "kms:DescribeKey",
    "kms:ListAliases"
  ],
  "Resource": "*"
},
{
  "Sid": "AccessAwsMarketplaceSubscritions",
  "Effect": "Allow",
  "Action": [
    "aws-marketplace:ViewSubscriptions"
  ],
  "Resource": "*"
},
{
  "Effect": "Allow",
  "Action": [
    "codecommit:BatchGetRepositories",
    "codecommit:CreateRepository",
    "codecommit:GetRepository",
    "codecommit:ListRepositories",
    "codecommit:ListBranches",
    "secretsmanager:CreateSecret",
    "secretsmanager:DescribeSecret",
    "secretsmanager:ListSecrets"
  ],
  "Resource": "*"
},
{
  "Sid": "ListAndCreateExecutionRoles",
  "Effect": "Allow",
  "Action": [
    "iam:ListRoles",
    "iam:CreateRole",
    "iam:CreatePolicy",
    "iam:AttachRolePolicy"
  ],
  "Resource": "*"
},
{
  "Sid": "DescribeECRMetaData",
  "Effect": "Allow",
  "Action": [
    "ecr:Describe*
  ],
  "Resource": "*"
},
{
  "Sid": "PassRoleForExecutionRoles",
  "Effect": "Allow",
  "Action": [
    "iam:PassRole"
  ],
  "Resource": "*"
Permissions Required to Use the Amazon SageMaker Ground Truth Console

To use the Amazon SageMaker Ground Truth console, you need to grant permissions for additional resources. Specifically, the console needs permissions for the AWS Marketplace to view subscriptions, Amazon Cognito operations to manage your private workforce, Amazon S3 actions for access to your input and output files, and AWS Lambda actions to list and invoke functions. Grant these permissions with the following permissions policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "GroundTruthConsole",
      "Effect": "Allow",
      "Action": [
        "aws-marketplace:DescribeListings",
        "aws-marketplace:ViewSubscriptions",
        "cognito-idp:AdminAddUserToGroup",
        "cognito-idp:AdminCreateUser",
        "cognito-idp:AdminDeleteUser",
        "cognito-idp:AdminDisableUser",
        "cognito-idp:AdminEnableUser",
        "cognito-idp:AdminRemoveUserFromGroup",
        "cognito-idp:CreateGroup",
        "cognito-idp:CreateUserPool",
        "cognito-idp:CreateUserPoolClient",
        "cognito-idp:CreateUserPoolDomain",
        "cognito-idp:DescribeUserPool",
        "cognito-idp:DescribeUserPoolClient",
        "cognito-idp:DescribeUserPoolDomain",
        "cognito-idp:DescribeUserPoolClient",
        "cognito-idp:ListGroups",
        "cognito-idp:ListIdentityProviders",
        "cognito-idp:ListGroups",
        "cognito-idp:ListUsers",
        "cognito-idp:ListUsersInGroup",
        "cognito-idp:ListUserPoolClients",
        "cognito-idp:ListUserPools",
        "cognito-idp:UpdateUserPool",
        "cognito-idp:UpdateUserPoolClient",
        "groundtruthlabeling:DescribeConsoleJob",
        "groundtruthlabeling:ListDatasetObjects",
        "groundtruthlabeling:RunFilterOrSampleManifestJob",
        "groundtruthlabeling:RunGenerateManifestByCrawlingJob",
        "lambda:InvokeFunction",
        "lambda:ListFunctions",
        "s3:GetObject",
        "s3:PutObject",
        "s3:SelectObjectContent"
      ],
      "Resource": "*"
    }
  ]
}
```
Permissions Required to Use the Amazon Augmented AI (Preview) Console

To use the Augmented AI console, you need to grant permissions for additional resources. Grant these permissions with the following permissions policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*Algorithm",
        "sagemaker:*Algorithms",
        "sagemaker:*App",
        "sagemaker:*Apps",
        "sagemaker:*AutoMLJob",
        "sagemaker:*AutoMLJobs",
        "sagemaker:*CodeRepositories",
        "sagemaker:*CodeRepository",
        "sagemaker:*CompilationJob",
        "sagemaker:*CompilationJobs",
        "sagemaker:*Endpoint",
        "sagemaker:*EndpointConfig",

Identity-Based Policy Examples

Allow Users to View Their Own Permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
            ],
            "Resource": "arn:aws:iam::*:role/*",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "sagemaker.amazonaws.com",
                        "glue.amazonaws.com",
                        "robomaker.amazonaws.com",
                        "states.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```
Control Creation of SageMaker Resources with Condition Keys

Control fine-grained access to allow the creation of SageMaker resources by using SageMaker-specific condition keys. For information about using condition keys in IAM policies, see IAM JSON Policy Elements: Condition in the IAM User Guide.

The condition keys, along with related API actions, and links to relevant documentation are listed in Condition Keys for SageMaker in the IAM User Guide.

The following examples show how to use the SageMaker condition keys to control access.

Topics
- Control Access to SageMaker Resources by Using File System Condition Keys (p. 2386)
- Restrict Training to a Specific VPC (p. 2388)
- Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows (p. 2389)
- Enforce Encryption of Input Data (p. 2390)
- Enforce Encryption of Notebook Instance Storage Volume (p. 2390)
- Enforce Network Isolation for Training Jobs (p. 2391)
- Enforce a Specific Instance Type for Training Jobs (p. 2391)
- Enforce a Specific EI Accelerator for Training Jobs (p. 2392)
- Enforce Disabling Internet Access and Root Access for Creating Notebook Instances (p. 2392)

Control Access to SageMaker Resources by Using File System Condition Keys

SageMaker training provides a secure infrastructure for the training algorithm to run in, but for some cases you may want increased defense in depth. For example, you minimize the risk of running untrusted code in your algorithm, or you have specific security mandates in your organization. For these scenarios, you can use the service-specific condition keys in the Condition element of an IAM policy to scope down the user to specific file systems, directories, access modes (read-write, read-only) and security groups.

Topics
Restrict an IAM User to Specific Directories and Access Modes

The policy below restricts an IAM user to the `/sagemaker/xgboost-dm/train` and `/sagemaker/xgboost-dm/validation` directories of an EFS file system to `ro` (read-only) AccessMode:

**Note**
When a directory is allowed, all of its subdirectories are also accessible by the training algorithm. POSIX permissions are ignored.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToElasticFileSystem",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:FileSystemId": "fs-12345678",
          "sagemaker:FileSystemAccessMode": "ro",
          "sagemaker:FileSystemType": "EFS",
          "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/train"
        }
      }
    },
    {
      "Sid": "AccessToElasticFileSystemValidation",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "sagemaker:FileSystemId": "fs-12345678",
          "sagemaker:FileSystemAccessMode": "ro",
          "sagemaker:FileSystemType": "EFS",
          "sagemaker:FileSystemDirectoryPath": "/sagemaker/xgboost-dm/validation"
        }
      }
    }
  ]
}
```

Restrict an IAM User to a Specific File System

To prevent a malicious algorithm using a user space client from accessing any file system directly in your account, you can restrict networking traffic by allowing ingress from a specific security group. In the following example, the IAM user can only use the specified security group to access the file system:

```json
{
  "Version": "2012-10-17",
  "Statement": []
}
```
Although the above example can restrict an algorithm to a specific file system, it does not prevent an algorithm from accessing any directory within that file system using the user space client. To mitigate this, you can:

- Ensure that the file system only contains data that you trust your IAM users to access
- Create an IAM role that restricts your IAM users to launching training jobs with algorithms from approved ECR repositories

For more information on how to use roles with SageMaker, see SageMaker Roles.

**Restrict Training to a Specific VPC**

Restrict an AWS user to creating training jobs from within an Amazon VPC. When a training job is created within a VPC, you can use VPC flow logs to monitor all traffic to and from the training cluster. For information about using VPC flow logs, see VPC Flow Logs in the Amazon Virtual Private Cloud User Guide.

The following policy enforces that a training job is created by an IAM user calling CreateTrainingJob from within a VPC:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowFromVpc",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreateTrainingJob",
        "sagemaker:CreateHyperParameterTuningJob"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "sagemaker:VpcSubnets": ["subnet-a1234"],
          "sagemaker:VpcSecurityGroupIds": ["sg-12345678", "sg-67890"]
        }
      }
    }
  ]
}
```
Restrict Access to Workforce Types for Ground Truth Labeling Jobs and Amazon A2I Human Review Workflows

Amazon SageMaker Ground Truth and Amazon Augmented AI work teams fall into one of three workforce types: public (with Amazon Mechanical Turk), private, and vendor. To restrict IAM user access to a specific work team using one of these types or the work team ARN, use the sagemaker:WorkteamType and/or the sagemaker:WorkteamArn condition keys.

For the sagemaker:WorkteamType condition key, use string condition operators. For the sagemaker:WorkteamArn condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker returns an access denied error.

The policies below demonstrate different ways to use the sagemaker:WorkteamType and sagemaker:WorkteamArn condition keys with appropriate condition operators and valid condition values.

The following example uses the sagemaker:WorkteamType condition key with the StringEquals condition operator to restrict access to a public work team. It accepts condition values in the following format: workforcetype-crowd, where workforcetype can equal public, private, or vendor.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:WorkteamType": "public-crowd"
                }
            }
        }
    ]
}
```

The following policies show how to restrict access to a public work team using the sagemaker:WorkteamArn condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the ArnLike condition operator. The second shows how to use it with the ArnEquals condition operator and the work team ARN.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                }
            }
        }
    ]
}
```
Enforce Encryption of Input Data

The following policy restricts an IAM user to specify an AWS KMS key to encrypt input data when creating training, hyperparameter tuning, and labeling jobs by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EnforceEncryption",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreateTrainingJob",
                "sagemaker:CreateHyperParameterTuningJob",
                "sagemaker:CreateLabelingJob",
                "sagemaker:CreateFlowDefinition"
            ],
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                    "sagemaker:VolumeKmsKey": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
                }
            }
        }
    ]
}
```

Enforce Encryption of Notebook Instance Storage Volume

The following policy restricts an IAM user to specify an AWS KMS key to encrypt the attached storage volume when creating or updating a notebook instance by using the `sagemaker:VolumeKmsKey` condition key:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                    "sagemaker:WorkteamArn": "arn:aws:sagemaker:*:*:workteam/public-crowd/*"
                }
            }
        }
    ]
}
```

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                }
            }
        }
    ]
}
```
Identity-Based Policy Examples

Enforce Encryption for Creating Notebook Instances

The following policy restricts an IAM user to enable encryption when creating notebook instances by using the `sagemaker:CreateNotebookInstance` action:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceEncryption",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "ArnLike": {
               "sagemaker:VolumeKmsKey": "*key/volume-kms-key-12345"
            }
         }
      }
   ]
}
```

Enforce Network Isolation for Training Jobs

The following policy restricts an IAM user to enable network isolation when creating training jobs by using the `sagemaker:NetworkIsolation` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceIsolation",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateTrainingJob",
            "sagemaker:CreateHyperParameterTuningJob"
         ],
         "Resource": "*",
         "Condition": {
            "Bool": {
               "sagemaker:NetworkIsolation": "true"
            }
         }
      }
   ]
}
```

Enforce a Specific Instance Type for Training Jobs

The following policy restricts an IAM user to use a specific instance type when creating training jobs by using the `sagemaker:InstanceTypes` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceInstanceType",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateTrainingJob",
            "sagemaker:CreateHyperParameterTuningJob"
         ],
         "Resource": "*",
         "Condition": {
            "StringLike": {
               "sagemaker:InstanceTypes": "*key/instance-type-12345"
            }
         }
      }
   ]
}
```
Identity-Based Policy Examples

Enforce a Specific EI Accelerator for Training Jobs

The following policy restricts an IAM user to use a specific elastic inference (EI) accelerator, if an accelerator is provided, when creating or updating notebook instances and when creating endpoint configurations by using the `sagemaker:AcceleratorTypes` condition key:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnforceAcceleratorType",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateNotebookInstance",
            "sagemaker:UpdateNotebookInstance",
            "sagemaker:CreateEndpointConfig"
         ],
         "Resource": "*",
         "Condition": {
            "ForAllValues:StringEquals": {
               "sagemaker:AcceleratorTypes": ["ml.eia1.medium"]
            }
         }
      }
   ]
}
```

Enforce Disabling Internet Access and Root Access for Creating Notebook Instances

You can disable both internet access and root access to notebook instances to help make them more secure. For information about controlling root access to a notebook instance, see Control root access to a SageMaker notebook instance (p. 2364). For information about disabling internet access for a notebook instance, see Connect a Notebook Instance to Resources in a VPC (p. 2434).

The following policy requires an IAM user to disable network access when creating instance, and disable root access when creating or updating a notebook instance.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "LockDownCreateNotebookInstance",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreateNotebookInstance"
         ],
         "Resource": "*",
         "Condition": {
            "ForAllValues:StringLike": {
               "sagemaker:InstanceTypes": ["ml.c5.*"]
            }
         }
      }
   ]
}
```
Control Access to the SageMaker API by Using Identity-based Policies

To control access to SageMaker API calls and calls to SageMaker hosted endpoints, use identity-based IAM policies.

Topics
- Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC (p. 2393)

Restrict Access to SageMaker API and Runtime to Calls from Within Your VPC

If you set up an interface endpoint in your VPC, individuals outside the VPC can still connect to the SageMaker API and runtime over the internet unless you attach an IAM policy that restricts access to calls coming from within the VPC to all users and groups that have access to your SageMaker resources. For information about creating a VPC interface endpoint for the SageMaker API and runtime, see Connect to SageMaker Through a VPC Interface Endpoint (p. 2436).

Important
If you apply an IAM policy similar to one of the following, users can’t access the specified SageMaker APIs through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the SageMaker API or runtime.

Note
This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
  "Id": "api-example-1",
  "Version": "2012-10-17",
  "StringEquals": {
    "sagemaker:DirectInternetAccess": "Disabled",
    "sagemaker:RootAccess": "Disabled"
  },
  "Null": {
    "sagemaker:VpcSubnets": "false",
    "sagemaker:VpcSecurityGroupIds": "false"
  }
}
```
"Statement": [
  {
    "Sid": "Enable API Access",
    "Effect": "Allow",
    "Action": [
      "sagemaker:*"
    ],
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "aws:SourceVpc": "vpc-111bbaaa"
      }
    }
  }
]

If you want to restrict access to the API to only calls made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

{
  "Id": "api-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable API Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedNotebookInstanceUrl"
      ],
      "Resource": "*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "aws:SourceVpce": ["vpce-111bbccc", "vpce-111bbddd"
        ]
      }
    }
  ]
}

Limit Access to SageMaker API and Runtime Calls by IP Address

To allow access to SageMaker API calls and runtime invocations only from IP addresses in a list that you specify, attach an IAM policy that denies access to the API unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the API or runtime. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the API call, use the `IpAddress` condition operator and the `aws:SourceIP` condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to the CreateTrainingJob only from IP addresses in the ranges `192.0.2.0-192.0.2.255` and `203.0.113.0-203.0.113.255`:

{  "Version": "2012-10-17",  }
"Statement": [

  {
    "Effect": "Allow",
    "Action": "sagemaker:CreateTrainingJob",
    "Resource": "*",
    "Condition": {
      "IpAddress": {
        "aws:SourceIp": [
          "192.0.2.0/24",
          "203.0.113.0/24"
        ]
      }
    }
  }
]

Limit Access to a Notebook Instance by IP Address

To allow access to a notebook instance only from IP addresses in a list that you specify, attach an IAM policy that denies access to CreatePresignedNotebookInstanceUrl unless the call comes from an IP address in the list to every AWS Identity and Access Management user, group, or role used to access the notebook instance. For information about creating IAM policies, see Creating IAM Policies in the AWS Identity and Access Management User Guide. To specify the list of IP addresses that you want to have access to the notebook instance, use the IpAddress condition operator and the aws:SourceIp condition context key. For information about IAM condition operators, see IAM JSON Policy Elements: Condition Operators in the AWS Identity and Access Management User Guide. For information about IAM condition context keys, see AWS Global Condition Context Keys.

For example, the following policy allows access to a notebook instance only from IP addresses in the ranges 192.0.2.0-192.0.2.255 and 203.0.113.0-203.0.113.255:

```json
{
  "Version": "2012-10-17",
  "Statement": [

    {
      "Effect": "Allow",
      "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
      "Resource": "*",
      "Condition": {
        "IpAddress": {
          "aws:SourceIp": [
            "192.0.2.0/24",
            "203.0.113.0/24"
          ]
        }
      }
    }
  ]
}
```

The policy restricts access to both the call to CreatePresignedNotebookInstanceUrl and to the URL that the call returns. The policy also restricts access to opening a notebook instance in the console and is enforced for every HTTP request and WebSocket frame that attempts to connect to the notebook instance.

**Note**

Using this method to filter by IP address is incompatible when connecting to SageMaker through a VPC interface endpoint. For information about restricting access to a notebook.
instance when connecting through a VPC interface endpoint, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 2438).

## Control Access to SageMaker Resources by Using Tags

Control access to groups of SageMaker resources by attaching tags to the resources and specifying `ResourceTag` conditions in IAM policies.

**Note**

Tag-based policies don’t work to restrict the following API calls:

- ListAlgorithms
- ListCodeRepositories
- ListCompilationJobs
- ListEndpointConfigs
- ListEndpoints
- ListFlowDefinitions
- ListHumanTaskUis
- ListHyperparameterTuningJobs
- ListLabelingJobs
- ListLabelingJobsForWorkteam
- ListModelPackages
- ListModels
- ListNotebookInstanceLifecycleConfigs
- ListNotebookInstances
- ListSubscribedWorkteams
- ListTags
- ListProcessingJobs
- ListTrainingJobs
- ListTrainingJobsForHyperParameterTuningJob
- ListTransformJobs
- ListWorkteams
- Search

For example, suppose you’ve defined two different IAM groups, named DevTeam1 and DevTeam2, in your AWS account. Suppose also that you’ve created 10 notebook instances, 5 of which are used for one project, and 5 of which are used for a second project. You want to allow members of DevTeam1 to make API calls on notebook instances used for the first project, and members of DevTeam2 to make API calls on notebook instances used for the second project.

**To control access to API calls (example)**

1. Add a tag with the key `Project` and value `A` to the notebook instances used for the first project. For information about adding tags to SageMaker resources, see AddTags.
2. Add a tag with the key `Project` and value `B` to the notebook instances used for the second project.
3. Create an IAM policy with a `ResourceTag` condition that denies access to the notebook instances used for the second project, and attach that policy to DevTeam1. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of `Project` and a value of `B`:

For information about creating IAM policies and attaching them to identities, see Controlling Access Using Policies in the AWS Identity and Access Management User Guide.

4. Create an IAM policy with a ResourceTag condition that denies access to the notebook instances used for the first project, and attach that policy to DevTeam2. The following is an example of a policy that denies all API calls on any notebook instance that has a tag with a key of Project and a value of A:

Require the Presence or Absence of Tags for API Calls

Require the presence or absence of specific tags or specific tag values by using RequestTag condition keys in an IAM policy. For example, if you want to require that every endpoint created by any member of an IAM group to be created with a tag with the key `environment` and value `dev`, create a policy as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "*",
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": "sagemaker:CreateEndpoint",
            "Resource": "arn:aws:sagemaker:*:*:endpoint/*",
            "Condition": {
                "StringNotEquals": {
                    "aws:RequestTag/environment": "dev"
                }
            }
        }
    ]
}
```

Use Tags with Hyperparameter Tuning Jobs

You can add tags to a hyperparameter tuning job when you create the tuning job by specifying the tags as the `Tags` parameter when you call `CreateHyperParameterTuningJob`. If you do this, the tags you specify for the hyperparameter tuning job are also added to all training jobs that the hyperparameter tuning job launches.

If you add tags to a hyperparameter tuning job by calling `AddTags`, the tags you add are also added to any training jobs that the hyperparameter tuning job launches after you call `AddTags`, but are not added to training jobs the hyperparameter tuning jobs launched before you called `AddTags`. Similarly, when you remove tags from a hyperparameter tuning job by calling `DeleteTags`, those tags are not removed from training jobs that the hyperparameter tuning job launched previously. Because of this, the tags associated with training jobs can be out of sync with the tags associated with the hyperparameter tuning job that launched them. If you use tags to control access to a hyperparameter tuning job and the training jobs it launches, you might want to keep the tags in sync. To make sure the tags associated with training jobs stay sync with the tags associated with the hyperparameter tuning job that launched them, first call `ListTrainingJobsForHyperParameterTuningJob` for the hyperparameter tuning job to get a list of the training jobs that the hyperparameter tuning job launched. Then, call `AddTags` or `DeleteTags` for the hyperparameter tuning job and for each of the training jobs in the list of training jobs to add or delete the same set of tags for all of the jobs. The following Python example demonstrates this:

```python
tuning_job_arn = 
  smclient.describe_hyper_parameter_tuning_job(HyperParameterTuningJobName='MyTuningJob')
  ['HyperParameterTuningJobArn']
sclient.add_tags(ResourceArn=tuning_job_arn, Tags=[{'Key':'Env', 'Value':'Dev'}])
training_jobs = smclient.list_training_jobs_for_hyper_parameter_tuning_job(
    HyperParameterTuningJobName='MyTuningJob')['TrainingJobSummaries']
for training_job in training_jobs:
    
```
time.sleep(1)  # Wait for 1 second between calls to avoid being throttled
smclient.add_tags(ResourceArn=training_job['TrainingJobArn'], Tags=[{'Key': 'Env', 'Value': 'Dev'}])

SageMaker Roles

As a managed service, SageMaker performs operations on your behalf on the AWS hardware that is managed by SageMaker. SageMaker can perform only operations that the user permits.

A SageMaker user can grant these permissions with an IAM role (referred to as an execution role).

To create and use a locally available execution role, you can use the following procedures.

Get execution role

When you run a notebook within SageMaker you can access the execution role with the following code:

```python
sagemaker_session = sagemaker.Session()
role = sagemaker.get_execution_role()
```

Note

The execution role is intended to be available only when running a notebook within SageMaker. If you run `get_execution_role` in a notebook not on SageMaker, expect a "region" error.

To find the IAM role ARN created when you created your the notebook instance or Studio application, go to the Notebook instances page in the console and select the relevant notebook from the list of Names. In the configuration detail page the IAM role ARN is given in the Permissions and encryption section.

Use the following procedure to create an execution role with the IAM managed policy, AmazonSageMakerFullAccess, attached. If your use case requires more granular permissions, use other sections on this page to create an execution role that meets your business needs.

Important

The IAM managed policy, AmazonSageMakerFullAccess, used in the following procedure only grants the execution role permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. To learn how to add an additional policy to an execution role to grant it access to other Amazon S3 buckets and objects, see Add Additional Amazon S3 Permissions to an SageMaker Execution Role (p. 2400).

To create a new role

2. Select Roles and then select Create role.
4. Select Next: Permissions.
5. The IAM managed policy, AmazonSageMakerFullAccess is automatically attached to this role. To see the permissions included in this policy, select the sideways arrow next to the policy name. Select Next: Tags.
6. (Optional) Add tags and select Next: Review.
7. Give the role a name in the text field under Role name and select Create role.
8. On the Roles section of the IAM console, select the role you just created. If needed, use the text box to search for the role using the role name you entered in step 7.
9. On the role summary page, make note of the ARN.

With a known ARN for your role, you can programmatically check the role when running the notebook locally or on SageMaker. Replace RoleName with your known ARN:
try:
    role = sagemaker.get_execution_role()
except ValueError:
    iam = boto3.client('iam')
    role = iam.get_role(RoleName='AmazonSageMaker-ExecutionRole-20201200T100000')['Role']['Arn']

Add Additional Amazon S3 Permissions to an SageMaker Execution Role

When you use an SageMaker feature with resources in Amazon S3, such as input data, the execution role you specify in your request (for example CreateTrainingJob) is used to access these resources.

If you attach the IAM managed policy, AmazonSageMakerFullAccess, to an execution role, that role has permission to perform certain Amazon S3 actions on buckets or objects with SageMaker, Sagemaker, sagemaker, or aws-glue in the name. It also has permission to perform the following actions on any Amazon S3 resource:

"s3:CreateBucket",
"s3:GetBucketLocation",
"s3:ListBucket",
"s3:ListAllMyBuckets",
"s3:GetBucketCors",
"s3:PutBucketCors"

To give an execution role permissions to access one or more specific buckets in Amazon S3, you can attach a policy similar to the following to the role. This policy grants an IAM role permission to perform all actions that AmazonSageMakerFullAccess allows but restricts this access to the buckets DOC-EXAMPLE-BUCKET1 and DOC-EXAMPLE-BUCKET2. Refer to the security documentation for the specific SageMaker feature you are using to learn more about the Amazon S3 permissions required for that feature.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
                "s3:AbortMultipartUpload"
            ],
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*", "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:GetBucketLocation",
                "s3:ListBucket",
                "s3:ListAllMyBuckets",
                "s3:GetBucketCors",
                "s3:PutBucketCors"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:DeleteObject",
                "s3:AbortMultipartUpload"
            ],
            "Resource": ["arn:aws:s3:::DOC-EXAMPLE-BUCKET1/*", "arn:aws:s3:::DOC-EXAMPLE-BUCKET2/*"]
        }
    ]
}
```
Passing Roles

Actions like passing a role between services are a common function within SageMaker. You can find more details on Actions, Resources, and Condition Keys for SageMaker in the IAM User Guide.

You pass the role (iam:PassRole) when making these API calls: CreateAutoMLJob, CreateCompilationJob, CreateDomain, CreateFlowDefinition, CreateHyperParameterTuningJob, CreateImage, CreateLabelingJob, CreateModel, CreateMonitoringSchedule, CreateNotebookInstance, CreateProcessingJob, CreateTrainingJob, CreateUserProfile, RenderUiTemplate, and UpdateImage.

You attach the following trust policy to the IAM role which grants SageMaker principal permissions to assume the role, and is the same for all of the execution roles:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The permissions that you need to grant to the role vary depending on the API that you call. The following sections explain these permissions.

**Note**
Instead of managing permissions by crafting a permission policy, you can use the AWS-managed AmazonSageMakerFullAccess permission policy. The permissions in this policy are fairly broad, to allow for any actions you might want to perform in SageMaker. For a listing of the policy including information about the reasons for adding many of the permissions, see AmazonSageMakerFullAccess Policy (p. 2414). If you prefer to create custom policies and manage permissions to scope the permissions only to the actions you need to perform with the execution role, see the following topics.

For more information about IAM roles, see IAM Roles in the IAM User Guide.

**Topics**
- CreateDomain API: Execution Role Permissions (p. 2402)
- CreateImage and UpdateImage APIs: Execution Role Permissions (p. 2402)
- CreateNotebookInstance API: Execution Role Permissions (p. 2403)
- CreateHyperParameterTuningJob API: Execution Role Permissions (p. 2406)
- CreateProcessingJob API: Execution Role Permissions (p. 2408)
CreateDomain API: Execution Role Permissions

The execution role for AWS SSO domains and the user/execution role for IAM domains need the following permissions when you pass an AWS KMS customer managed key (CMK) as the KmsKeyId in the CreateDomain API request. The permissions are enforced during the CreateApp API call.

For an execution role that you can pass in the CreateDomain API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "arn:aws:kms:region:account-id:key/kms-key-id"
        }
    ]
}
```

Alternatively, if the permissions are specified in a KMS policy, you can attach the following policy to the role:

```json
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::account-id:role/ExecutionRole"
        ]
    },
    "Action": [
        "kms:DescribeKey",
        "kms:CreateGrant"
    ],
    "Resource": "*"
}
```

CreateImage and UpdateImage APIs: Execution Role Permissions

For an execution role that you can pass in a CreateImage or UpdateImage API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ecr:BatchGetImage",
                "ecr:GetDownloadUrlForLayer"
            ],
        }
    ]
}
```
CreateNotebookInstance API: Execution Role Permissions

The permissions that you grant to the execution role for calling the CreateNotebookInstance API depend on what you plan to do with the notebook instance. If you plan to use it to invoke SageMaker APIs and pass the same role when calling the CreateTrainingJob and CreateModel APIs, attach the following permissions policy to the role:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*",
        "ecr:GetAuthorizationToken",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage",
        "ecr:BatchCheckLayerAvailability",
        "ecr:SetRepositoryPolicy",
        "ecr:CompleteLayerUpload",
        "ecr:BatchDeleteImage",
        "ecr:UploadLayerPart",
        "ecr:DeleteRepositoryPolicy",
        "ecr:InitiateLayerUpload",
        "ecr:DeleteRepository",
        "ecr:GetImage",
        "ecr:CreateRepository",
        "cloudwatch:PutMetricData",
        "cloudwatch:GetMetricData",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch:ListMetrics",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:GetLogEvents",
        "logs:PutLogEvents",
        "s3:CreateBucket",
        "s3:ListBucket",
        "s3:GetBucketLocation",
        "s3:GetObject",
        "s3:PutObject",
        "s3:DeleteObject",
        "robomaker:CreateSimulationApplication",
        "robomaker:DescribeSimulationApplication",
        "robomaker:DeleteSimulationApplication",
        "robomaker:CreateSimulationJob"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```
To tighten the permissions, limit them to specific Amazon S3 and Amazon ECR resources, by restricting
"Resource": "*", as follows:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:*",
        "ecr:GetAuthorizationToken",
        "cloudwatch:PutMetricData",
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutLogEvents",
        "logs:GetLogEvents"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "iam:PassedToService": "sagemaker.amazonaws.com"
        }
      }
    }
  ]
}
```
If you plan to access other resources, such as Amazon DynamoDB or Amazon Relational Database Service, add the relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- **Scope the s3:ListBucket permission to the specific bucket that you specify as InputDataConfig.DataSource.S3DataSource.S3Uri in a CreateTrainingJob request.**
- **Scope s3:GetObject, s3:PutObject, and s3:DeleteObject permissions as follows:**
  - Scope to the following values that you specify in a CreateTrainingJob request:
    
    ```
    InputDataConfig.DataSource.S3DataSource.S3Uri
    OutputDataConfig.S3OutputPath
    ```
  - Scope to the following values that you specify in a CreateModel request:
    ```
    PrimaryContainer.ModelDataUrl
    ```
    ```
    SuplementalContainers.ModelDataUrl
    ```
  - **Scope ecr permissions as follows:**
• Scope to the `AlgorithmSpecification.TrainingImage` value that you specify in a `CreateTrainingJob` request.
• Scope to the `PrimaryContainer.Image` value that you specify in a `CreateModel` request:

The `cloudwatch` and `logs` actions are applicable for `*` resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

**CreateHyperParameterTuningJob API: Execution Role Permissions**

For an execution role that you can pass in a `CreateHyperParameterTuningJob` API request, you can attach the following permission policy to the role:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "s3:GetObject",
            "s3:PutObject",
            "s3:ListBucket",
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage"
         ],
         "Resource": "*"
      }
   ]
}
```

Instead of specifying `"Resource": "*"`, you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "cloudwatch:PutMetricData",
            "logs:CreateLogStream",
            "logs:PutLogEvents",
            "logs:CreateLogGroup",
            "logs:DescribeLogStreams",
            "ecr:GetAuthorizationToken"
         ],
         "Resource": "*"
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:ListBucket"
         ],
         "Resource": "*"
      }
   ]
}
```
If the training container associated with the hyperparameter tuning job needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the `s3:ListBucket` permission to a specific bucket that you specify as the `InputDataConfig.DataSource.S3DataSource.S3Uri` in a `CreateTrainingJob` request.
- Scope the `s3:GetObject` and `s3:PutObject` permissions to the following objects that you specify in the input and output data configuration in a `CreateHyperParameterTuningJob` request:
  - `InputDataConfig.DataSource.S3DataSource.S3Uri`
  - `OutputDataConfig.S3OutputPath`
- Scope Amazon ECR permissions to the registry path (`AlgorithmSpecification.TrainingImage`) that you specify in a `CreateHyperParameterTuningJob` request.

The `cloudwatch` and `logs` actions are applicable for `*` resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your hyperparameter tuning job, add the following permissions:
If your input is encrypted using server-side encryption with an AWS KMS-managed key (SSE-KMS), add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ]
}
```

If you specify a KMS key in the output configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt"
    ]
}
```

If you specify a volume KMS key in the resource configuration of your hyperparameter tuning job, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant"
    ]
}
```

CreateProcessingJob API: Execution Role Permissions

For an execution role that you can pass in a `CreateProcessingJob` API request, you can attach the following permission policy to the role:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListBucket",
                "ecr:GetAuthorizationToken",
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "*"
        }
    ]
}
```
Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": [
        "arn:aws:s3:::inputbucket/object",
        "arn:aws:s3:::outputbucket/path"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "arn:aws:ecr:::repository/my-repo"
    }
  ]
}
```

If CreateProcessingJob.AppSpecification.ImageUri needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the s3:ListBucket permission to a specific bucket that you specify as the ProcessingInputs in a CreateProcessingJob request.
- Scope the s3:GetObject and s3:PutObject permissions to the objects that will be downloaded or uploaded in the ProcessingInputs and ProcessingOutputConfig in a CreateProcessingJob request.
• Scope Amazon ECR permissions to the registry path (AppSpecification.ImageUri) that you specify in a CreateProcessingJob request.

The cloudwatch and logs actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
    ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt"
    ]
}
```

If you specify a KMS key in the output configuration of your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt"
    ]
}
```

If you specify a volume KMS key in the resource configuration of your processing job, add the following permissions:

```
{
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant"
    ]
}
```

CreateTrainingJob API: Execution Role Permissions

For an execution role that you can pass in a CreateTrainingJob API request, you can attach the following permission policy to the role:

```
{

}
```
Instead of specifying "Resource": "*", you could scope these permissions to specific Amazon S3 and Amazon ECR resources:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "s3:GetObject",
                "s3:PutObject",
                "s3:ListBucket",
                "ecr:GetAuthorizationToken",
                "ecr:BatchCheckLayerAvailability",
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage"
            ],
            "Resource": "*
        },
        {
            "Effect": "Allow",
            "Action": ["s3:ListBucket"],
            "Resource": ["arn:aws:s3:::inputbucket"]
        },
        {
            "Effect": "Allow",
            "Action": ["s3:GetObject", "s3:PutObject"],
            "Resource": ["arn:aws:s3:::inputbucket/object", "arn:aws:s3:::outputbucket/path"]
        },
        {
            "Effect": "Allow",
            "Action": ["s3:ListBucket"],
            "Resource": ["arn:aws:s3:::outputbucket"
```
If CreateTrainingJob.AlgorithmSpecifications.TrainingImage needs to access other data sources, such as DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope the s3:ListBucket permission to a specific bucket that you specify as the InputDataConfig.DataSource.S3DataSource.S3Uri in a CreateTrainingJob request.
- Scope the s3:GetObject and s3:PutObject permissions to the following objects that you specify in the input and output data configuration in a CreateTrainingJob request:
  
  - InputDataConfig.DataSource.S3DataSource.S3Uri
  - OutputDataConfig.S3OutputPath
- Scope Amazon ECR permissions to the registry path (AlgorithmSpecification.TrainingImage) that you specify in a CreateTrainingJob request.

The cloudwatch and logs actions are applicable for "*" resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your training job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
    "ec2:DescribeSecurityGroups"
  ]
}
```

If your input is encrypted using server-side encryption with an AWS KMS–managed key (SSE-KMS), add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ]
}
```

If you specify a KMS key in the output configuration of your training job, add the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt"
  ]
}
```
If you specify a volume KMS key in the resource configuration of your training job, add the following permissions:

```
{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant"
  ]
}
```

**CreateModel API: Execution Role Permissions**

For an execution role that you can pass in a `CreateModel` API request, you can attach the following permission policy to the role:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "s3:GetObject",
        "ecr:GetAuthorizationToken",
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*"
    }
  ]
}
```

Instead of specifying "Resource": "*", you can scope these permissions to specific Amazon S3 and Amazon ECR resources:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:PutMetricData",
        "logs:CreateLogStream",
        "logs:PutLogEvents",
        "logs:CreateLogGroup",
        "logs:DescribeLogStreams",
        "ecr:GetAuthorizationToken"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ]
    }
  ]
}
```
If `CreateModel.PrimaryContainer.Image` need to access other data sources, such as Amazon DynamoDB or Amazon RDS resources, add relevant permissions to this policy.

In the preceding policy, you scope the policy as follows:

- Scope S3 permissions to objects that you specify in the `PrimaryContainer.ModelDataUrl` in a `CreateModel` request.
- Scope Amazon ECR permissions to a specific registry path that you specify as the `PrimaryContainer.Image` and `SecondaryContainer.Image` in a `CreateModel` request.

The `cloudwatch` and `logs` actions are applicable for `*:*` resources. For more information, see CloudWatch Resources and Operations in the Amazon CloudWatch User Guide.

If you specify a private VPC for your model, add the following permissions:

```json
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterface",
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterface",
        "ec2:DeleteNetworkInterfacePermission",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeVpcs",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeSubnets",
        "ec2:DescribeSecurityGroups"
    ],
    "Resource": ["arn:aws:*:*"]
}
```

**AmazonSageMakerFullAccess Policy**

The `AmazonSageMakerFullAccess` managed policy includes all of the necessary permissions to perform most actions in SageMaker. You can use attach this policy to any role that you pass to a SageMaker execution role. You can also create more narrowly-scoped policies if you want more granular control of the permissions that you grant to your execution role.

The following list explains why some of the categories of permissions in the `AmazonSageMakerFullAccess` policy are needed.

**application-autoscaling**

Needed for automatically scaling a SageMaker real-time inference endpoint.
aws-marketplace
   Needed to view AWS AI Marketplace subscriptions.
cloudwatch
   Needed to post CloudWatch metrics, interact with alarms, and upload CloudWatch Logs logs in your account.
codecommit
   Needed for AWS CodeCommit integration with SageMaker notebook instances.
cognito
   Needed for SageMaker Ground Truth to define your private workforce and work teams.
ec2
   Needed to manage elastic network interfaces when you specify a Amazon VPC for your SageMaker jobs and notebook instances.
ec2:DescribeVpcs
   All SageMaker services launch Amazon EC2 instances and require this permission set.
ecr
   Needed to pull and store Docker artifacts for training and inference. This is required only if you use your own container in SageMaker.
glue
   Needed for inference pipeline pre-processing from within SageMaker notebook instances.
groundtruthlabeling
   Needed for SageMaker Ground Truth.
iam:ListRoles
   Needed to give the SageMaker console access to list available roles.
kms
   Needed to give the SageMaker console access to list the available AWS KMS keys.
logs
   Needed to allow SageMaker jobs and endpoints to publish log streams.

AWS Managed (Predefined) Policies for Amazon SageMaker

AWS addresses many common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate which permissions are needed. For more information, see AWS Managed Policies in the IAM User Guide.

Important
We recommend that you use the most restricted policy that allows you to perform your use case.

The following AWS managed policies, which you can attach to users in your account, are specific to Amazon SageMaker:
• **AmazonSageMakerReadOnly** – Grants read-only access to Amazon SageMaker resources.
• **AmazonSageMakerFullAccess** – Grants full access to Amazon SageMaker resources and the supported operations. (This does not provide unrestricted S3 access, but supports buckets/objects with specific sagemaker tags.)

The following AWS managed policies can also be attached to users in your account but are not recommended:

• **AdministratorAccess** – Grants all actions for all AWS services and for all resources in the account.
• **DataScientist** – Grants a wide range of permissions to cover most of the use cases (primarily for analytics and business intelligence) encountered by data scientists.

You can review these permissions policies by signing in to the IAM console and searching for them.

You can also create your own custom IAM policies to allow permissions for Amazon SageMaker actions and resources as you need them. You can attach these custom policies to the IAM users or groups that require them.

**Amazon SageMaker API Permissions: Actions, Permissions, and Resources Reference**

When you are setting up access control and writing a permissions policy that you can attach to an IAM identity (an identity-based policy), use the following as a reference. The each Amazon SageMaker API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

**Note**
Except for the ListTags API, resource-level restrictions are not available on List- calls. Any user calling a List- API will see all resources of that type in the account.

To express conditions in your Amazon SageMaker policies, you can use AWS-wide condition keys. For a complete list of AWS-wide keys, see Available Keys in the IAM User Guide.

Troubleshooting Amazon SageMaker Identity and Access

Use the following information to help you diagnose and fix common issues that you might encounter when working with SageMaker and IAM.

Topics
- I Am Not Authorized to Perform an Action in SageMaker (p. 2429)
- I Am Not Authorized to Perform iam:PassRole (p. 2429)
- I Want to View My Access Keys (p. 2429)
- I'm an Administrator and Want to Allow Others to Access SageMaker (p. 2430)
- I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources (p. 2430)

I Am Not Authorized to Perform an Action in SageMaker

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson IAM user tries to use the console to view details about a training job but does not have sagemaker:sagemaker:DescribeTrainingJob permissions.

User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: sagemaker:DescribeTrainingJob on resource: my-example-widget

In this case, Mateo asks his administrator to update his policies to allow him to access the TrainingJob resource using the sagemaker:DescribeTrainingJob action.

I Am Not Authorized to Perform iam:PassRole

If you receive an error that you're not authorized to perform the iam:PassRole action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password. Ask that person to update your policies to allow you to pass a role to SageMaker.

Some AWS services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in SageMaker. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole

In this case, Mary asks her administrator to update her policies to allow her to perform the iam:PassRole action.

I Want to View My Access Keys

After you create your IAM user access keys, you can view your access key ID at any time. However, you can’t view your secret access key again. If you lose your secret key, you must create a new access key pair.
Access keys consist of two parts: an access key ID (for example, AKIAIOSFODNN7EXAMPLE) and a secret access key (for example, wJalrXUtntFEMI/K7MDENG/bPxRfiCYEXAMPEKEY). Like a user name and password, you must use both the access key ID and secret access key together to authenticate your requests. Manage your access keys as securely as you do your user name and password.

Important
Do not provide your access keys to a third party, even to help find your canonical user ID. By doing this, you might give someone permanent access to your account.

When you create an access key pair, you are prompted to save the access key ID and secret access key in a secure location. The secret access key is available only at the time you create it. If you lose your secret access key, you must add new access keys to your IAM user. You can have a maximum of two access keys. If you already have two, you must delete one key pair before creating a new one. To view instructions, see Managing access keys in the IAM User Guide.

I'm an Administrator and Want to Allow Others to Access SageMaker

To allow others to access SageMaker, you must create an IAM entity (user or role) for the person or application that needs access. They will use the credentials for that entity to access AWS. You must then attach a policy to the entity that grants them the correct permissions in SageMaker.

To get started right away, see Creating your first IAM delegated user and group in the IAM User Guide.

I Want to Allow People Outside of My AWS Account to Access My SageMaker Resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether SageMaker supports these features, see How Amazon SageMaker Works with IAM (p. 2373).
- To learn how to provide access to your resources across AWS accounts that you own, see Providing access to an IAM user in another AWS account that you own in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see Providing access to AWS accounts owned by third parties in the IAM User Guide.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

Logging and Monitoring

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. You can also set alarms that watch for certain thresholds and send notifications or take actions when those thresholds are met. For more information, see Monitor Amazon SageMaker with Amazon CloudWatch (p. 2459).
Amazon CloudWatch Logs enables you to monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, and other sources. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see Log Amazon SageMaker Events with Amazon CloudWatch (p. 2470).

AWS CloudTrail provides a record of actions taken by a user, role, or an AWS service in SageMaker. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, Log Amazon SageMaker API Calls with AWS CloudTrail (p. 2471).

**Note**
CloudTrail does not monitor calls to `runtime_InvokeEndpoint`.

You can create rules in Amazon CloudWatch Events to react to status changes in status in a SageMaker training, hyperparameter tuning, or batch transform job. For more information, see Automating Amazon SageMaker with Amazon EventBridge (p. 2473).

### Compliance Validation for Amazon SageMaker

Third-party auditors assess the security and compliance of Amazon SageMaker as part of multiple AWS compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using Amazon SageMaker is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on AWS.
- **Architecting for HIPAA Security and Compliance Whitepaper** – This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.
- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Config** – This AWS service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS that helps you check your compliance with security industry standards and best practices.

### Resilience in Amazon SageMaker

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption.
Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon SageMaker offers several features to help support your data resiliency and backup needs.

Infrastructure Security in Amazon SageMaker

As a managed service, Amazon SageMaker is protected by the AWS global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use AWS published API calls to access Amazon SageMaker through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Ephemeral Diffie-Hellman (ECDHE). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

Connect SageMaker Studio Notebooks to Resources in a VPC

Amazon SageMaker Studio allows direct internet access by default. This could provide an avenue for unauthorized access to your data. For example, if you install malicious code on your computer (in the form of a publicly available notebook or a publicly available source code library), it could access your data. You can choose to restrict which traffic can access the internet by launching Studio in a Virtual Private Cloud (VPC) of your choosing. This allows you fine-grained control of the network access and internet connectivity of your SageMaker Studio notebooks. You can disable direct internet access to add an additional layer of security.

By default, SageMaker Studio provides a network interface that allows communication with the internet through a VPC managed by SageMaker. Traffic to AWS services like Amazon S3 and CloudWatch goes through an internet gateway as does traffic that accesses the SageMaker API and SageMaker runtime. Traffic between the domain and your Amazon EFS volume goes through the VPC that you specified when you onboarded to Studio or called the CreateDomain API. The following diagram shows the default configuration.
To disable direct internet access, you can specify the VPC only network access type when you onboard to Studio or call the CreateDomain API. Doing so prevents SageMaker from providing internet access to your Studio notebooks. As a result, you won't be able to run a Studio notebook unless your VPC has an interface endpoint to the SageMaker API and runtime, or a NAT gateway with internet access, and your security groups allow outbound connections. The following diagram shows a configuration for using VPC-only mode.

VPC requirements in VpcOnly

When you choose VpcOnly, your VPC must contain the following:

- Subnets with one IP address for each instance. For more information, see VPC and subnet sizing for IPv4.

  **Note**
  You can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

- One or more security groups with inbound and outbound rules that together allow the following traffic:
• NFS traffic over TCP on port 2049 between the domain and the Amazon EFS volume.
• TCP traffic within the security group. This is required for connectivity between the JupyterServer app and the KernelGateway apps.
• If you want to allow internet access, you must use NAT gateway with access to internet (for example, via an internet gateway).
• If you don’t want to allow internet access, you must create interface VPC endpoints (AWS PrivateLink) to access the following:
  • The SageMaker API and SageMaker runtime. This is required to run Studio notebooks and to train and host models.
  • Amazon S3 and other AWS services you require.
  • If you’re using SageMaker Projects in SageMaker Studio without internet access, you need a VPC endpoint for Service Catalog.

You must associate the security groups for your VPC with these endpoints.

For more information
• Securing Amazon SageMaker Studio connectivity using a private VPC.
• Security groups for your VPC
• Connect to SageMaker Through a VPC Interface Endpoint (p. 2436)
• VPC with public and private subnets (NAT)

Connect a Notebook Instance to Resources in a VPC

SageMaker notebook instances are internet-enabled by default. This allows you to download popular packages and notebooks, customize your development environment, and work efficiently. However, this could provide an additional avenue for unauthorized access to your data. For example, a malicious user or code that you accidentally install on the computer (in the form of a publicly available notebook or a publicly available source code library) could access your data. You can choose to launch your notebook instance in your Virtual Private Cloud (VPC) to restrict which traffic can go through the public Internet. When launched with your VPC attached, the notebook instance can either be configured with or without direct internet access.

When your notebook allows direct internet access, SageMaker provides a network interface that allows the notebook to communicate with the internet through a VPC managed by SageMaker. Traffic within your VPC’s CIDR goes through elastic network interface created in your VPC. All the other traffic goes through the network interface created by SageMaker, which is essentially through the public internet. Traffic to gateway VPC endpoints like Amazon S3 and DynamoDB goes through the public internet, while traffic to interface VPC endpoints (interface endpoints) still goes through your VPC. If you want to use gateway VPC endpoints, you might want to disable direct internet access.

To disable direct internet access, you can specify a VPC for your notebook instance. By doing so, you prevent SageMaker from providing internet access to your notebook instance. As a result, the notebook instance won’t be able to train or host models unless your VPC has an interface endpoint (PrivateLink) or a NAT gateway, and your security groups allow outbound connections.

For information about creating a VPC interface endpoint to use AWS PrivateLink for your notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 2438). For information about setting up a NAT gateway for your VPC, see VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide. For information about security groups, see Security Groups for Your VPC. For more information about networking configurations in each networking mode and configuring network on premise, see Understanding Amazon SageMaker notebook instance networking configurations and advanced routing options.
Security and Shared Notebook Instances

A SageMaker notebook instance is designed to work best for an individual user. It is designed to give data scientists and other users the most power for managing their development environment.

A notebook instance user has root access for installing packages and other pertinent software. We recommend that you exercise judgement when granting individuals access to notebook instances that are attached to a VPC that contains sensitive information. For example, you might grant a user access to a notebook instance with an IAM policy, as shown in the following example:

```json
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
      }
    ]
}
```

Training and Inference Containers Run in Internet-Free Mode

SageMaker training and deployed inference containers are internet-enabled by default. This allows containers to access external services and resources on the public internet as part of your training and inference workloads. However, this could provide an avenue for unauthorized access to your data. For example, a malicious user or code that you accidentally install on the container (in the form of a publicly available source code library) could access your data and transfer it to a remote host.

If you use an Amazon VPC by specifying a value for the `VpcConfig` parameter when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`, you can protect your data and resources by managing security groups and restricting internet access from your VPC. However, this comes at the cost of additional network configuration, and has the risk of configuring your network incorrectly. If you do not want SageMaker to provide external network access to your training or inference containers, you can enable network isolation when you create your training job or model by setting the value of the `EnableNetworkIsolation` parameter to `True` when you call `CreateTrainingJob`, `CreateHyperParameterTuningJob`, or `CreateModel`.

If you enable network isolation, the containers can't make any outbound network calls, even to other AWS services such as Amazon S3. Additionally, no AWS credentials are made available to the container runtime environment. In the case of a training job with multiple instances, network inbound and outbound traffic is limited to the peers of each training container. SageMaker still performs download and upload operations against Amazon S3 using your SageMaker execution role in isolation from the training or inference container.

Network isolation is required for training jobs and models run using resources from AWS Marketplace. Network isolation can be used in conjunction with a VPC. In this scenario, download and upload of customer data and model artifacts are routed via your VPC subnet. However, the training and inference containers themselves continue to be isolated from the network, and do not have access to any resource within your VPC or on the internet.

Network isolation is not supported by the following managed SageMaker containers as they require access to Amazon S3:  

2435
SageMaker Scans AWS Marketplace Training and Inference Containers for Security Vulnerabilities

To meet our security requirements, algorithms and model packages listed in AWS Marketplace are scanned for Common Vulnerabilities and Exposures (CVE). CVE is a list of publicly known information about security vulnerability and exposure. The National Vulnerability Database (NVD) provides CVE details such as severity, impact rating, and fix information. Both CVE and NVD are available for public consumption and free for security tools and services to use. For more information, see http://cve.mitre.org/about/faqs.html#what_is_cve.

Connect to SageMaker Through a VPC Interface Endpoint

You can connect directly to the SageMaker API or to the SageMaker Runtime through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the internet. When you use a VPC interface endpoint, communication between your VPC and the SageMaker API or Runtime is conducted entirely and securely within the AWS network.

The SageMaker API and Runtime support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.

The VPC interface endpoint connects your VPC directly to the SageMaker API or Runtime without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. The instances in your VPC don't need public IP addresses to communicate with the SageMaker API or Runtime.

You can create an interface endpoint to connect to SageMaker or to SageMaker Runtime with either the AWS console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint.

After you have created a VPC endpoint, you can use the following example CLI commands that use the endpoint-url parameter to specify interface endpoints to the SageMaker API or Runtime:

```bash
aws sagemaker list-notebook-instances --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
aws sagemaker list-training-jobs --endpoint-url VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
aws sagemaker-runtime invoke-endpoint --endpoint-url VPC_Endpoint_ID.runtime.sagemaker.Region.vpce.amazonaws.com \
    --endpoint-name Endpoint_Name \
    --body "Endpoint_Body" \
    --content-type "Content_Type" \
    Output_File
```

If you enable private DNS hostnames for your VPC endpoint, you don't need to specify the endpoint URL. The SageMaker API DNS hostname that the CLI and SageMaker SDK use by default (https://
api.sagemaker.Region.amazonaws.com) resolves to your VPC endpoint. Similarly, the SageMaker Runtime DNS hostname that the CLI and SageMaker Runtime SDK use by default (https://runtime.sagemaker.Region.amazonaws.com) resolves to your VPC endpoint.

The SageMaker API and Runtime support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available. SageMaker supports making calls to all of its Operations inside your VPC. The result AuthorizedUrl from the CreatePresignedNotebookInstanceUrl is not supported by Private Link. For information about how to enable PrivateLink for the authorized URL that users use to connect to a notebook instance, see Connect to a Notebook Instance Through a VPC Interface Endpoint (p. 2438).

To learn more about AWS PrivateLink, see the AWS PrivateLink documentation. Refer to VPC Pricing for the price of VPC Endpoints. To learn more about VPC and Endpoints, see Amazon VPC. For information about how to use identity-based AWS Identity and Access Management policies to restrict access to the SageMaker API and runtime, see Control Access to the SageMaker API by Using Identity-based Policies (p. 2393).

Create a VPC Endpoint Policy for SageMaker

You can create a policy for Amazon VPC endpoints for SageMaker to specify the following:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

Note

VPC endpoint policies aren't supported for Federal Information Processing Standard (FIPS) SageMaker runtime endpoints for runtime_InvokeEndpoint.

The following example VPC endpoint policy specifies that all users who have access to the VPC interface endpoint are allowed to invoke the SageMaker hosted endpoint named myEndpoint.

```json
{
"Statement": [
{
"Action": "sagemaker:InvokeEndpoint",
"Effect": "Allow",
"Principal": "*"
}
]
}
```

In this example, the following are denied:

- Other SageMaker API actions, such as sagemaker:CreateEndpoint and sagemaker:CreateTrainingJob.
- Invoking SageMaker hosted endpoints other than myEndpoint.

Note

In this example, users can still take other SageMaker API actions from outside the VPC. For information about how to restrict API calls to those from within the VPC, see Control Access to the SageMaker API by Using Identity-based Policies (p. 2393).
Create a VPC Endpoint Policy for SageMaker Feature Store

To create a VPC Endpoint for Feature Store, use the following endpoint template substituting your VPC_Endpoint_ID.api and Region:

VPC_Endpoint_ID.api.featurestore-runtime.sagemaker.Region.vpce.amazonaws.com

Connect to a Notebook Instance Through a VPC Interface Endpoint

You can connect to your notebook instance from your VPC through an interface endpoint in your Virtual Private Cloud (VPC) instead of connecting over the internet. When you use a VPC interface endpoint, communication between your VPC and the notebook instance is conducted entirely and securely within the AWS network.

SageMaker notebook instances support Amazon Virtual Private Cloud (Amazon VPC) interface endpoints that are powered by AWS PrivateLink. Each VPC endpoint is represented by one or more Elastic Network Interfaces with private IP addresses in your VPC subnets.

**Note**
Before you create an interface VPC endpoint to connect to a notebook instance, create an interface VPC endpoint to connect to the SageMaker API. That way, when users call CreatePresignedNotebookInstanceUrl to get the URL to connect to the notebook instance, that call also goes through the interface VPC endpoint. For information, see Connect to SageMaker Through a VPC Interface Endpoint (p. 2436).

You can create an interface endpoint to connect to your notebook instance with either the AWS console or AWS Command Line Interface (AWS CLI) commands. For instructions, see Creating an Interface Endpoint. Make sure that you create an interface endpoint for all of the subnets in your VPC from which you want to connect to the notebook instance.

When you create the interface endpoint, specify aws.sagemaker.region.notebook as the service name. After you create a VPC endpoint, enable private DNS for your VPC endpoint. Anyone using the SageMaker API, the AWS CLI, or the console to connect to the notebook instance from within the VPC will connect to the notebook instance through the VPC endpoint instead of the public internet.

SageMaker notebook instances support VPC endpoints in all AWS Regions where both Amazon VPC and SageMaker are available.

**Topics**
- Connect Your Private Network to Your VPC (p. 2438)
- Create a VPC Endpoint Policy for SageMaker Notebook Instances (p. 2438)
- Restrict Access to Connections from Within Your VPC (p. 2439)

Connect Your Private Network to Your VPC

To connect to your notebook instance through your VPC, you either have to connect from an instance that is inside the VPC, or connect your private network to your VPC by using an Amazon Virtual Private Network (VPN) or AWS Direct Connect. For information about Amazon VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.

Create a VPC Endpoint Policy for SageMaker Notebook Instances

You can create a policy for Amazon VPC endpoints for SageMaker notebook instances to specify the following:
• The principal that can perform actions.
• The actions that can be performed.
• The resources on which actions can be performed.

For more information, see Controlling Access to Services with VPC Endpoints in the Amazon VPC User Guide.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the notebook instance named `myNotebookInstance`.

```json
{
  "Statement": [
    {
      "Action": "sagemaker:CreatePresignedNotebookInstanceUrl",
      "Effect": "Allow",
      "Principal": "*
    }
  ]
}
```

Access to other notebook instances is denied.

**Restrict Access to Connections from Within Your VPC**

Even if you set up an interface endpoint in your VPC, individuals outside the VPC can connect to the notebook instance over the internet.

**Important**

If you apply an IAM policy similar to one of the following, users can't access the specified SageMaker APIs or the notebook instance through the console.

To restrict access to only connections made from within your VPC, create an AWS Identity and Access Management policy that restricts access to only calls that come from within your VPC. Then add that policy to every AWS Identity and Access Management user, group, or role used to access the notebook instance.

**Note**

This policy allows connections only to callers within a subnet where you created an interface endpoint.

```json
{
  "Id": "notebook-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable Notebook Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedNotebookInstanceUrl",
        "sagemaker:DescribeNotebookInstance"
      ],
      "Resource": "*
      "Condition": { "StringEquals": { "aws:SourceVpc": "vpc-11bbbaaa" } },
    }
  ]
}
```
If you want to restrict access to the notebook instance to only connections made using the interface endpoint, use the `aws:SourceVpce` condition key instead of `aws:SourceVpc`:

```json
{
  "Id": "notebook-example-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable Notebook Access",
      "Effect": "Allow",
      "Action": [
        "sagemaker:CreatePresignedNotebookInstanceUrl",
        "sagemaker:DescribeNotebookInstance"
      ],
      "Resource": "*",
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:sourceVpce": [
            "vpce-111bbccc",
            "vpce-111bbddd"
          ]
        }
      }
    }
  ]
}
```

Both of these policy examples assume that you have also created an interface endpoint for the SageMaker API. For more information, see Connect to SageMaker Through a VPC Interface Endpoint (p. 2436). In the second example, one of the values for `aws:SourceVpce` is the ID of the interface endpoint for the notebook instance. The other is the ID of the interface endpoint for the SageMaker API.

The policy examples here include `DescribeNotebookInstance` because typically you would call `DescribeNotebookInstance` to make sure that the `NotebookInstanceStatus` is `InService` before you try to connect to it. For example:

```bash
aws sagemaker describe-notebook-instance \
  --notebook-instance-name myNotebookInstance
```

```json
{
  "NotebookInstanceArn":
  "NotebookInstanceName": "myNotebookInstance",
  "NotebookInstanceStatus": "InService",
  "Url": "mynotebookinstance.notebook.us-west-2.sagemaker.aws",
  "InstanceType": "ml.m4.xlarge",
  "RoleArn":
    "arn:aws:iam::1234567890ab:role/service-role/AmazonSageMaker-
      ExecutionRole-12345678T123456",
  "LastModifiedTime": 1540334777.501,
  "CreationTime": 1523050674.078,
  "DirectInternetAccess": "Disabled"
}
```

```bash
aws sagemaker create-presigned-notebook-instance-url --notebook-instance-name myNotebookInstance
```
Connect to SageMaker Through a VPC Interface Endpoint

```json
{
    "AuthorizedUrl": "https://mynotebookinstance.notebook.us-west-2.sagemaker.aws?
authToken=AuthToken"
}
```

For both of these calls, if you did not enable private DNS hostnames for your VPC endpoint, or if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the call to `create-presigned-notebook-instance-url` would be:

```bash
aws sagemaker create-presigned-notebook-instance-url
    --notebook-instance-name myNotebookInstance --endpoint-url
    VPC_Endpoint_ID.api.sagemaker.Region.vpce.amazonaws.com
```

Connect Your Private Network to Your VPC

To call the SageMaker API and runtime through your VPC, you have to connect from an instance that is inside the VPC or connect your private network to your VPC by using an Amazon Virtual Private Network (VPN) or AWS Direct Connect. For information about Amazon VPN, see VPN Connections in the Amazon Virtual Private Cloud User Guide. For information about AWS Direct Connect, see Creating a Connection in the AWS Direct Connect User Guide.

Connect to SageMaker Studio Through an Interface VPC Endpoint

You can connect to Amazon SageMaker Studio from your Amazon Virtual Private Cloud (Amazon VPC) through an interface endpoint in your VPC instead of connecting over the internet. When you use an interface VPC endpoint (interface endpoint), communication between your VPC and Studio is conducted entirely and securely within the AWS network.

SageMaker Studio supports interface endpoints that are powered by AWS PrivateLink. Each interface endpoint is represented by one or more Elastic network interfaces with private IP addresses in your VPC subnets.

You can create an interface endpoint to connect to Studio with either the AWS console or the AWS Command Line Interface (AWS CLI). For instructions, see Creating an interface endpoint. Make sure that you create interface endpoints for all of the subnets in your VPC from which you want to connect to Studio.

When you create an interface endpoint, ensure that the security groups on your endpoint allow inbound access for HTTPS traffic from the security groups associated with SageMaker Studio. For more information, see Control access to services with VPC endpoints.

**Note**

In addition to creating an interface endpoint to connect to SageMaker Studio, create an interface endpoint to connect to the Amazon SageMaker API. When users call `CreatePresignedDomainUrl` to get the URL to connect to Studio, that call goes through the interface endpoint used to connect to the SageMaker API.

When you create the interface endpoint, specify `aws.sagemaker.Region.studio` as the service name. After you create the interface endpoint, enable private DNS for your endpoint. Anyone who uses the SageMaker API, the AWS CLI, or the console to connect to SageMaker Studio from within the VPC will connect to Studio through the interface endpoint instead of the public internet. You also need to setup a custom DNS with Private Hosted Zones for the Amazon VPC endpoint so SageMaker Studio can access the SageMaker API using the `api.sagemaker.$region.amazonaws.com` endpoint rather than using
Connect to SageMaker Through a VPC Interface Endpoint

the VPC Endpoint URL. For instructions on setting up a Private Hosted Zone, see Working with private hosted zones.

Studio supports interface endpoints in all AWS Regions where both Amazon SageMaker and Amazon VPC are available.

Topics
- Create a VPC Endpoint Policy for SageMaker Studio (p. 2442)
- Allow Access Only from Within Your VPC (p. 2442)

Create a VPC Endpoint Policy for SageMaker Studio

You can attach an Amazon VPC endpoint policy to the interface VPC endpoints that you use to connect to SageMaker Studio. The endpoint policy controls access to Studio. You can specify the following:

- The principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

To use a VPC endpoint with SageMaker Studio, your endpoint policy must allow the CreateApp operation on the KernelGateway app type. This allows traffic that is routed to through the VPC endpoint to call the CreateApp API. The following example VPC endpoint policy shows how to allow the CreateApp operation.

```
{
"Statement": [
{
 "Action": "sagemaker:CreateApp",
 "Effect": "Allow",
 "Principal": "*"
 }
],
}
```

For more information, see Controlling access to services with VPC endpoints.

The following example of a VPC endpoint policy specifies that all users that have access to the endpoint are allowed to access the user profiles in the SageMaker Studio domain with the specified domain ID. Access to other domains is denied.

```
{
"Statement": [
{
 "Action": "sagemaker:CreatePresignedDomainUrl",
 "Effect": "Allow",
 "Principal": "*"
 }
],
}
```

Allow Access Only from Within Your VPC

Users outside your VPC can connect to SageMaker Studio over the internet even if you set up an interface endpoint in your VPC.
To allow access to only connections made from within your VPC, create an AWS Identity and Access Management (IAM) policy to that effect. Add that policy to every IAM user, group, or role used to access Studio. This feature is only supported in IAM mode, and is not supported in SSO mode. The following examples demonstrate how to create such policies.

**Important**
If you apply an IAM policy similar to one of the following examples, users can't access SageMaker Studio or the specified SageMaker APIs through the SageMaker console. To access Studio, users must use a presigned URL or call the SageMaker APIs directly.

**Example 1**
The following policy allows connections only to callers within the subnet where you created the interface endpoint.

```json
{
   "Id": "sagemaker-studio-example-1",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Enable SageMaker Studio Access",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreatePresignedDomainUrl",
            "sagemaker:DescribeUserProfile"
         ],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "aws:SourceVpc": "vpc-111bbaaa"
            }
         }
      }
   ]
}
```

**Example 2**
The following policy allows connections only to those made through the interface endpoints specified by the `aws:sourceVpce` condition key. For example, the first interface endpoint could allow access through the SageMaker Studio Control Panel. The second interface endpoint could allow access through the SageMaker API.

```json
{
   "Id": "sagemaker-studio-example-2",
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "Enable SageMaker Studio Access",
         "Effect": "Allow",
         "Action": [
            "sagemaker:CreatePresignedDomainUrl",
            "sagemaker:DescribeUserProfile"
         ],
         "Resource": "*",
         "Condition": {
            "ForAnyValue:StringEquals": {
               "aws:sourceVpce": [
                  "vpce-111bbccc",
                  "vpce-111bbddd"
               ]
            }
         }
      }
   ]
}
```
This policy includes the `DescribeUserProfile` action. Typically you call `DescribeUserProfile` to make sure that the status of the user profile is `InService` before you try to connect to the domain. For example:

```bash
aws sagemaker describe-user-profile \
  --domain-id domain-id \
  --user-profile-name profile-name
```

Response:

```json
{
  "DomainId": "domain-id",
  "UserProfileName": "profile-name",
  "HomeEfsFileSystemUid": "200001",
  "Status": "InService",
  "LastModifiedTime": 1605418785.555,
  "CreationTime": 1605418477.297
}
```

```bash
aws sagemaker create-presigned-domain-url \
  --domain-id domain-id \
  --user-profile-name profile-name
```

Response:

```json
{
  "AuthorizedUrl": "https://domain-id.studio.us-west-2.sagemaker.aws/auth?token=AuthToken"
}
```

For both of these calls, if you are using a version of the AWS SDK that was released before August 13, 2018, you must specify the endpoint URL in the call. For example, the call to `create-presigned-domain-url` would be:

```bash
aws sagemaker create-presigned-domain-url \
  --domain-id domain-id \
  --user-profile-name profile-name \
  --endpoint-url vpc-endpoint-id.api.sagemaker.Region.vpce.amazonaws.com
```

### Example 3

The following policy allows connections only from the specified range of IP addresses using the `aws:SourceIp` condition key.

```json
{
  "Id": "sagemaker-studio-example-3",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable SageMaker Studio Access",
    }
  ]
}
Give SageMaker Processing Jobs Access to Resources in Your Amazon VPC

SageMaker runs processing jobs in an Amazon Virtual Private Cloud by default. However, processing containers access AWS resources—such as the Amazon S3 buckets where you store data—over the internet.

To control access to your data and processing containers, we recommend that you create a private VPC and configure it so that they aren't accessible over the internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your processing containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your VPC.
processing containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create processing jobs by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your processing containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

**Configure a Processing Job for Amazon VPC Access**

To specify subnets and security groups in your private VPC, use the NetworkConfig.VpcConfig request parameter of the CreateProcessingJob API, or provide this information when you create a processing job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your processing containers. The network interfaces provide your processing containers with a network connection within your VPC that is not connected to the internet. They also enable your processing job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateProcessingJob:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

**Configure Your Private VPC for SageMaker Processing**

When configuring the private VPC for your SageMaker processing jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

**Topics**

- Ensure That Subnets Have Enough IP Addresses (p. 2446)
- Create an Amazon S3 VPC Endpoint (p. 2446)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2447)
- Configure Route Tables (p. 2448)
- Configure the VPC Security Group (p. 2448)
- Connect to Resources Outside Your VPC (p. 2448)

**Ensure That Subnets Have Enough IP Addresses**

Your VPC subnets should have at least two private IP addresses for each instance in a processing job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

**Create an Amazon S3 VPC Endpoint**

If you configure your VPC so that processing containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows
access. By creating a VPC endpoint, you allow your processing containers to access the buckets where you store your data. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

**To create an S3 VPC endpoint:**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**
3. For **Service Name**, choose `com.amazonaws.region.s3`, where `region` is the name of the region where your VPC resides.
4. For **VPC**, choose the VPC you want to use for this endpoint.
5. For **Configure route tables**, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
6. For **Policy**, choose **Full Access** to allow full access to the S3 service by any user or service within the VPC. Choose **Custom** to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2447).

**Use a Custom Endpoint Policy to Restrict Access to S3**

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

**Restrict Package Installation on the Processing Container**

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the processing container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
    "Statement": [
        {
            "Sid": "AmazonLinuxAMIRepositoryAccess",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Effect": "Deny",
            "Resource": [
                "arn:aws:s3:::packages.*.amazonaws.com/*",
                "arn:aws:s3:::repo.*.amazonaws.com/*"
            ]
        }
    ]
}
{
    "Statement": [
        {
            "Sid": "AmazonLinux2AMIRepositoryAccess",
            "Principal": "*",
            "Action": [
                "s3:GetObject"
            ],
            "Effect": "Deny",
            "Resource": [
            ]
        }
    ]
}
```

2447
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your processing jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed processing, you must allow communication between the different containers in the same processing job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, processing jobs that use that VPC do not have access to resources outside your VPC. If your processing job needs access to resources outside your VPC, provide access with one of the following options:

- If your processing job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your processing job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give SageMaker Training Jobs Access to Resources in Your Amazon VPC

SageMaker runs training jobs in an Amazon Virtual Private Cloud by default. However, training containers access AWS resources—such as the Amazon Simple Storage Service (Amazon S3) buckets where you store training data and model artifacts—over the internet.

To control access to your data and training containers, we recommend that you create a private VPC and configure it so that they aren't accessible over the internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your training containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your training containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create training jobs by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your training containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.
Note
For training jobs, you can configure only subnets with a default tenancy VPC in which your instance runs on shared hardware. For more information on the tenancy attribute for VPCs, see Dedicated Instances.

Configure a Training Job for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateTrainingJob API, or provide this information when you create a training job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your training containers. The network interfaces provide your training containers with a network connection within your VPC that is not connected to the internet. They also enable your training job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateTrainingJob:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

Configure Your Private VPC for SageMaker Training

When configuring the private VPC for your SageMaker training jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 2449)
- Create an Amazon S3 VPC Endpoint (p. 2449)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2450)
- Configure Route Tables (p. 2451)
- Configure the VPC Security Group (p. 2451)
- Connect to Resources Outside Your VPC (p. 2451)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a training job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that training containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your training data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your training containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.
To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint.
3. For Service Name, search for com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. Choose the Gateway type.
5. For VPC, choose the VPC you want to use for this endpoint.
6. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
7. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2450).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Training Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIRepositoryAccess",
      "Principal": "*",
      "Action": ["s3:GetObject"],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::packages.*.amazonaws.com/*",
        "arn:aws:s3:::repo.*.amazonaws.com/*"
      ]
    }
  ]
}

{
  "Statement": [
    {
      "Sid": "AmazonLinux2AMIRepositoryAccess",
      "Principal": "*",
      "Action": ["s3:GetObject"],
      "Effect": "Deny",
      "Resource": [
        "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
      ]
    }
  ]
}
```
Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your training jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed training, you must allow communication between the different containers in the same training job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn’t have internet access, training jobs that use that VPC do not have access to resources outside your VPC. If your training job needs access to resources outside your VPC, provide access with one of the following options:

- If your training job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your training job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

Give SageMaker Hosted Endpoints Access to Resources in Your Amazon VPC

SageMaker hosts models in an Amazon Virtual Private Cloud by default. However, models access AWS resources—such as the Amazon S3 buckets where you store training data and model artifacts—over the internet.

To avoid making your data and model containers accessible over the internet, we recommend that you create a private VPC and configure it to control access to them. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your training containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your training containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create a model by specifying subnets and security groups. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. network interfaces allow your model containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

Configure a Model for Amazon VPC Access

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console.
SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

**Note**
You must create at least two subnets in different availability zones in your private VPC, even if you have only one hosting instance.

The following is an example of the `VpcConfig` parameter that you include in your call to `CreateModel`:

```json
VpcConfig: {
    "Subnets": [
        "subnet-0123456789abcdef0",
        "subnet-0123456789abcdef1",
        "subnet-0123456789abcdef2"
    ],
    "SecurityGroupIds": [
        "sg-0123456789abcdef0"
    ]
}
```

## Configure Your Private VPC for SageMaker Hosting

When configuring the private VPC for your SageMaker models, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

**Topics**
- Ensure That Subnets Have Enough IP Addresses (p. 2452)
- Create an Amazon S3 VPC Endpoint (p. 2452)
- Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 2453)
- Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies (p. 2453)
- Configure Route Tables (p. 2454)
- Connect to Resources Outside Your VPC (p. 2454)

### Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each model instance. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

### Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

**To create an Amazon S3 VPC endpoint:**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**, then choose **Create Endpoint**
3. For **Service Name**, choose `com.amazonaws.region.s3`, where `region` is the name of the AWS Region where your VPC resides.
4. For **VPC**, choose the VPC that you want to use for this endpoint.
5. For **Configure route tables**, choose the route tables that the endpoint will use. The VPC service automatically adds a route to each route table that you choose that points Amazon S3 traffic to the new endpoint.

6. For **Policy**, choose **Full Access** to allow full access to the Amazon S3 service by any user or service within the VPC. To restrict access further, choose **Custom**. For more information, see Use a Custom Endpoint Policy to Restrict Access to Amazon S3 (p. 2453).

### Use a Custom Endpoint Policy to Restrict Access to Amazon S3

The default endpoint policy allows full access to Amazon Simple Storage Service (Amazon S3) for any user or service in your VPC. To further restrict access to Amazon S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3.

You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

### Restrict Package Installation on the Model Container with a Custom Endpoint Policy

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the model container. If you don't want users to install packages from those repositories, create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```json
{
  "Statement": [
    {
      "Sid": "AmazonLinuxAMIREpositoryAccess",
      "Principal": "*",
      "Action": [ "s3:GetObject" ],
      "Effect": "Deny",
      "Resource": [ "arn:aws:s3:::packages.*.amazonaws.com/*", "arn:aws:s3:::repo.*.amazonaws.com/*" ]
    }
  ]
}
{
  "Statement": [
    {
      "Sid": "AmazonLinux2AMIREpositoryAccess",
      "Principal": "*",
      "Action": [ "s3:GetObject" ],
      "Effect": "Deny",
      "Resource": [ "arn:aws:s3:::amazonlinux.*.amazonaws.com/*" ]
    }
  ]
}
```

### Add Permissions for Endpoint Access for Containers Running in a VPC to Custom IAM Policies

The **SageMakerFullAccess** managed policy includes the permissions that you need to use models configured for Amazon VPC access with an endpoint. These permissions allow SageMaker to create an
elastic network interface and attach it to model containers running in a VPC. If you use your own IAM policy, you must add the following permissions to that policy to use models configured for VPC access.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeVpcEndpoints",
            "ec2:DescribeDhcpOptions",
            "ec2:DescribeVpcs",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeNetworkInterfaces",
            "ec2:DeleteNetworkInterfacePermission",
            "ec2:DeleteNetworkInterface",
            "ec2:CreateNetworkInterfacePermission",
            "ec2:CreateNetworkInterface"
         ],
         "Resource": "*"
      }
   ]
}
```

For more information about the SageMakerFullAccess managed policy, see AmazonSageMakerFullAccess Policy (p. 2414).

**Configure Route Tables**

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your models resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

**Connect to Resources Outside Your VPC**

If you configure your VPC so that it doesn't have internet access, models that use that VPC do not have access to resources outside your VPC. If your model needs access to resources outside your VPC, provide access with one of the following options:

- If your model needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.

- If your model needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.

**Give Batch Transform Jobs Access to Resources in Your Amazon VPC**

SageMaker runs batch transform jobs in an Amazon Virtual Private Cloud by default. However, model containers access AWS resources—such as the Amazon S3 buckets where you store your data and model artifacts—over the internet.
To control access to your model containers and data, we recommend that you create a private VPC and configure it so that they aren't accessible over the internet. For information about creating and configuring a VPC, see Getting Started With Amazon VPC in the Amazon VPC User Guide. Using a VPC helps to protect your model containers and data because you can configure your VPC so that it is not connected to the internet. Using a VPC also allows you to monitor all network traffic in and out of your model containers by using VPC flow logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

You specify your private VPC configuration when you create a model by specifying subnets and security groups. You then specify the same model when you create a batch transform job. When you specify the subnets and security groups, SageMaker creates elastic network interfaces that are associated with your security groups in one of the subnets. Network interfaces allow your model containers to connect to resources in your VPC. For information about network interfaces, see Elastic Network Interfaces in the Amazon VPC User Guide.

**Configure a Batch Transform Job for Amazon VPC Access**

To specify subnets and security groups in your private VPC, use the VpcConfig request parameter of the CreateModel API, or provide this information when you create a model in the SageMaker console. Then specify the same model in the ModelName request parameter of the CreateTransformJob API, or in the Model name field when you create a transform job in the SageMaker console. SageMaker uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your transform job to connect to resources in your private VPC.

The following is an example of the VpcConfig parameter that you include in your call to CreateModel:

```json
VpcConfig: {
  "Subnets": [
    "subnet-0123456789abcdef0",
    "subnet-0123456789abcdef1",
    "subnet-0123456789abcdef2"
  ],
  "SecurityGroupIds": [
    "sg-0123456789abcdef0"
  ]
}
```

If you are creating a model using the CreateModel API operation, the IAM execution role that you use to create your model must include the permissions described in CreateModel API: Execution Role Permissions (p. 2413), including the following permissions required for a private VPC.

When creating a model in the console, if you select Create a new role in the Model Settings section, the AmazonSageMakerFullAccess policy used to create the role will already contain these permissions. If you select Enter a custom IAM role ARN or Use existing role, the role ARN that you specify must have an execution policy attached with the following permissions:

```json
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateNetworkInterface",
    "ec2:CreateNetworkInterfacePermission",
    "ec2:DeleteNetworkInterface",
    "ec2:DeleteNetworkInterfacePermission",
    "ec2:DescribeNetworkInterfaces",
    "ec2:DescribeVpcs",
    "ec2:DescribeDhcpOptions",
    "ec2:DescribeSubnets",
  ]
}
```
Configure Your Private VPC for SageMaker Batch Transform

When configuring the private VPC for your SageMaker batch transform jobs, use the following guidelines. For information about setting up a VPC, see Working with VPCs and Subnets in the Amazon VPC User Guide.

Topics
- Ensure That Subnets Have Enough IP Addresses (p. 2456)
- Create an Amazon S3 VPC Endpoint (p. 2456)
- Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2456)
- Configure Route Tables (p. 2457)
- Configure the VPC Security Group (p. 2457)
- Connect to Resources Outside Your VPC (p. 2457)

Ensure That Subnets Have Enough IP Addresses

Your VPC subnets should have at least two private IP addresses for each instance in a transform job. For more information, see VPC and Subnet Sizing for IPv4 in the Amazon VPC User Guide.

Create an Amazon S3 VPC Endpoint

If you configure your VPC so that model containers don't have access to the internet, they can't connect to the Amazon S3 buckets that contain your data unless you create a VPC endpoint that allows access. By creating a VPC endpoint, you allow your model containers to access the buckets where you store your data and model artifacts. We recommend that you also create a custom policy that allows only requests from your private VPC to access to your S3 buckets. For more information, see Endpoints for Amazon S3.

To create an S3 VPC endpoint:

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, then choose Create Endpoint
3. For Service Name, choose com.amazonaws.region.s3, where region is the name of the region where your VPC resides.
4. For VPC, choose the VPC you want to use for this endpoint.
5. For Configure route tables, select the route tables to be used by the endpoint. The VPC service automatically adds a route to each route table you select that points any S3 traffic to the new endpoint.
6. For Policy, choose Full Access to allow full access to the S3 service by any user or service within the VPC. Choose Custom to restrict access further. For information, see Use a Custom Endpoint Policy to Restrict Access to S3 (p. 2456).

Use a Custom Endpoint Policy to Restrict Access to S3

The default endpoint policy allows full access to S3 for any user or service in your VPC. To further restrict access to S3, create a custom endpoint policy. For more information, see Using Endpoint Policies for Amazon S3. You can also use a bucket policy to restrict access to your S3 buckets to only traffic that comes from your Amazon VPC. For information, see Using Amazon S3 Bucket Policies.

Restrict Package Installation on the Model Container

The default endpoint policy allows users to install packages from the Amazon Linux and Amazon Linux 2 repositories on the training container. If you don't want users to install packages from that repository,
create a custom endpoint policy that explicitly denies access to the Amazon Linux and Amazon Linux 2 repositories. The following is an example of a policy that denies access to these repositories:

```
{
    "Statement": [
    {
        "Sid": "AmazonLinuxAMIPolicy",  
        "Principal": "*", 
        "Action": [ 
            "s3:GetObject"
        ],
        "Effect": "Deny",
        "Resource": [ 
            "arn:aws:s3:::packages.*.amazonaws.com/*",
            "arn:aws:s3:::repo.*.amazonaws.com/*"
        ]
    }
    ]
}
{
    "Statement": [
    {
        "Sid": "AmazonLinux2AMIPolicy",
        "Principal": "*",
        "Action": [ 
            "s3:GetObject"
        ],
        "Effect": "Deny",
        "Resource": [ 
            "arn:aws:s3:::amazonlinux.*.amazonaws.com/*"
        ]
    }
    ]
}
```

Configure Route Tables

Use default DNS settings for your endpoint route table, so that standard Amazon S3 URLs (for example, http://s3-aws-region.amazonaws.com/MyBucket) resolve. If you don't use default DNS settings, ensure that the URLs that you use to specify the locations of the data in your batch transform jobs resolve by configuring the endpoint route tables. For information about VPC endpoint route tables, see Routing for Gateway Endpoints in the Amazon VPC User Guide.

Configure the VPC Security Group

In distributed batch transform, you must allow communication between the different containers in the same batch transform job. To do that, configure a rule for your security group that allows inbound connections between members of the same security group. For information, see Security Group Rules.

Connect to Resources Outside Your VPC

If you configure your VPC so that it doesn't have internet access, batch transform jobs that use that VPC do not have access to resources outside your VPC. If your batch transform job needs access to resources outside your VPC, provide access with one of the following options:

- If your batch transform job needs access to an AWS service that supports interface VPC endpoints, create an endpoint to connect to that service. For a list of services that support interface endpoints, see VPC Endpoints in the Amazon VPC User Guide. For information about creating an interface VPC endpoint, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon VPC User Guide.
- If your batch transform job needs access to an AWS service that doesn't support interface VPC endpoints or to a resource outside of AWS, create a NAT gateway and configure your security groups.
to allow outbound connections. For information about setting up a NAT gateway for your VPC, see Scenario 2: VPC with Public and Private Subnets (NAT) in the Amazon Virtual Private Cloud User Guide.
Monitor Amazon SageMaker

Monitoring is an important part of maintaining the reliability, availability, and performance of SageMaker and your other AWS solutions. AWS provides the following monitoring tools to watch SageMaker, report when something is wrong, and take automatic actions when appropriate:

- **Amazon CloudWatch** monitors your AWS resources and the applications that you run on AWS in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For example, you can have CloudWatch track CPU usage or other metrics of your Amazon EC2 instances and automatically launch new instances when needed. For more information, see the Amazon CloudWatch User Guide.

- **Amazon CloudWatch Logs** enables you to monitor, store, and access your log files from EC2 instances, AWS CloudTrail, and other sources. CloudWatch Logs can monitor information in the log files and notify you when certain thresholds are met. You can also archive your log data in highly durable storage. For more information, see the Amazon CloudWatch Logs User Guide.

- **AWS CloudTrail** captures API calls and related events made by or on behalf of your AWS account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called AWS, the source IP address from which the calls were made, and when the calls occurred. For more information, see the AWS CloudTrail User Guide.

- **CloudWatch Events** delivers a near real-time stream of system events that describe changes in AWS resources. Create CloudWatch Events rules react to a status change in a SageMaker training, hyperparameter tuning, or batch transform job

**Topics**

- Monitor Amazon SageMaker with Amazon CloudWatch (p. 2459)
- Log Amazon SageMaker Events with Amazon CloudWatch (p. 2470)
- Log Amazon SageMaker API Calls with AWS CloudTrail (p. 2471)
- Automating Amazon SageMaker with Amazon EventBridge (p. 2473)

Monitor Amazon SageMaker with Amazon CloudWatch

You can monitor Amazon SageMaker using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. These statistics are kept for 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing. However, the Amazon CloudWatch console limits the search to metrics that were updated in the last 2 weeks. This limitation ensures that the most current jobs are shown in your namespace. To graph metrics without using a search, specify its exact name in the source view. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met. For more information, see the Amazon CloudWatch User Guide.

**SageMaker Metrics and Dimensions**

- SageMaker Endpoint Invocation Metrics (p. 2460)
- SageMaker Multi-Model Endpoint Metrics (p. 2461)
- SageMaker Jobs and Endpoint Metrics (p. 2463)
- SageMaker Ground Truth Metrics (p. 2465)
- SageMaker Feature Store Metrics (p. 2467)
SageMaker Endpoint Invocation Metrics

The AWS/SageMaker namespace includes the following request metrics from calls to `InvokeEndpoint`. Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the Amazon CloudWatch API Reference.

**Endpoint Invocation Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Invocation4XXErrors</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>Invocation5XXErrors</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise, 0 is sent. Units: None Valid statistics: Average, Sum</td>
</tr>
<tr>
<td><strong>Invocations</strong></td>
<td>The number of <code>InvokeEndpoint</code> requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td><strong>InvocationsPerInstance</strong></td>
<td>The number of invocations sent to a model, normalized by <code>InstanceCount</code> in each ProductionVariant. (1/\text{numberOfInstances}) is sent as the value on each request, where <code>numberOfInstances</code> is the number of active instances for the ProductionVariant behind the endpoint at the time of the request. Units: None Valid statistics: Sum</td>
</tr>
<tr>
<td><strong>ModelLatency</strong></td>
<td>The interval of time taken by a model to respond as viewed from SageMaker. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td><strong>OverheadLatency</strong></td>
<td>The interval of time added to the time taken to respond to a client request by SageMaker overheads. This interval is measured from the time SageMaker receives the request until it returns a response to the client, minus the</td>
</tr>
</tbody>
</table>

---

2460
Metric | Description
---|---
ModelLatency | Overhead latency can vary depending on multiple factors, including request and response payload sizes, request frequency, and authentication/authorization of the request. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count

Dimensions for Endpoint Invocation Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
</table>
| EndpointName, VariantName | Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.

SageMaker Multi-Model Endpoint Metrics

The **AWS/SageMaker** namespace includes the following model loading metrics from calls to **InvokeEndpoint**.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see **GetMetricStatistics** in the **Amazon CloudWatch API Reference**.

Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ModelLoadingWaitTime</td>
<td>The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelUnloadingTime</td>
<td>The interval of time that it took to unload the model through the container's <strong>UnloadModel</strong> API call. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelDownloadingTime</td>
<td>The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3). Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelLoadingTime</td>
<td>The interval of time that it took to load the model through the container's <strong>LoadModel</strong> API call. Units: Microseconds</td>
</tr>
</tbody>
</table>
## Multi-Model Endpoint Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Min, Max, Sample Count</td>
</tr>
<tr>
<td>ModelCacheHit</td>
<td>The number of InvokeEndpoint requests sent to the multi-model endpoint for which the model was already loaded.</td>
</tr>
<tr>
<td></td>
<td>The Average statistic shows the ratio of requests for which the model was already loaded.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum, Sample Count</td>
</tr>
</tbody>
</table>

### Dimensions for Multi-Model Endpoint Model Loading Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EndpointName, VariantName</td>
<td>Filters endpoint invocation metrics for a ProductionVariant of the specified endpoint and variant.</td>
</tr>
</tbody>
</table>

The `/aws/sagemaker/Endpoints` namespaces include the following instance metrics from calls to `InvokeEndpoint`.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see `GetMetricStatistics` in the `Amazon CloudWatch API Reference`.

## Multi-Model Endpoint Model Instance Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoadedModelCount</td>
<td>The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance.</td>
</tr>
<tr>
<td></td>
<td>The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.</td>
</tr>
<tr>
<td></td>
<td>The Sum statistic tells you the total number of models loaded across all instances in the endpoint.</td>
</tr>
<tr>
<td></td>
<td>The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint.</td>
</tr>
<tr>
<td></td>
<td>Units: None</td>

**SageMaker Jobs and Endpoint Metrics**

The `/aws/sagemaker/ProcessingJobs`, `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs` and `/aws/sagemaker/Endpoints` namespaces include the following metrics for the training jobs and endpoint instances.

Metrics are available at a 1-minute frequency.

**Processing Job, Training Job, Batch Transform Job, and Endpoint Instance Metrics**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The sum of each individual CPU core's utilization. The CPU utilization of each core can range between 0 and 100. For example, if there are four CPUs, CPUUtilization can range from 0% to 400%. For processing jobs, the value is the CPU utilization of the processing container on the instance. For training jobs, the value is the CPU utilization of the algorithm container on the instance. For batch transform jobs, the value is the CPU utilization of the transform container on the instance. For endpoint variants, the value is the sum of the CPU utilization of the primary and supplementary containers on the instance. Note For multi-instance, each instance reports CPU utilization metrics. However, the default view in CloudWatch shows the average CPU utilization across all instances. Units: Percent</td>
</tr>
<tr>
<td>MemoryUtilization</td>
<td>The percentage of memory that is used by the containers on an instance. This value can range between 0% and 100%. For processing jobs, the value is the memory utilization of the processing container on the instance. For training jobs, the value is the memory utilization of the algorithm container on the instance. For batch transform jobs, the value is the memory utilization of the transform container on the instance. For endpoint variants, the value is the sum of the memory utilization of the primary and supplementary containers on the instance. Note For multi-instance, each instance reports memory utilization metrics. However, the default view in CloudWatch shows the average memory utilization across all instances. Units: Percent</td>
</tr>
<tr>
<td>GPUUtilization</td>
<td>The percentage of GPU units that are used by the containers on an instance. The value can range between 0 and 100 and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>For processing jobs, the value is the GPU utilization of the processing container on the instance.</td>
</tr>
<tr>
<td></td>
<td>For training jobs, the value is the GPU utilization of the algorithm container on the instance.</td>
</tr>
<tr>
<td></td>
<td>For batch transform jobs, the value is the GPU utilization of the transform container on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, the value is the sum of the GPU utilization of the primary and supplementary containers on the instance.</td>
</tr>
<tr>
<td>Note</td>
<td>For multi-instance, each instance reports GPU utilization metrics. However, the default view in CloudWatch shows the average GPU utilization across all instances.</td>
</tr>
<tr>
<td>Units: Percent</td>
<td></td>
</tr>
<tr>
<td>GPUMemoryUtilization</td>
<td>The percentage of GPU memory used by the containers on an instance. The value can range between 0 and 100 and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%.</td>
</tr>
<tr>
<td></td>
<td>For processing jobs, the value is the GPU memory utilization of the processing container on the instance.</td>

<tr>
<td></td>
<td>For batch transform jobs, the value is the GPU memory utilization of the transform container on the instance.</td>
</tr>
<tr>
<td></td>
<td>For endpoint variants, the value is the sum of the GPU memory utilization of the primary and supplementary containers on the instance.</td>
</tr>
<tr>
<td>Note</td>
<td>For multi-instance, each instance reports GPU memory utilization metrics. However, the default view in CloudWatch shows the average GPU memory utilization across all instances.</td>
</tr>
<tr>
<td>Units: Percent</td>
<td></td>
</tr>
</tbody>
</table>
## Ground Truth Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DiskUtilization</td>
<td>The percentage of disk space used by the containers on an instance uses. This value can range between 0% and 100%. This metric is not supported for batch transform jobs. For processing jobs, the value is the disk space utilization of the processing container on the instance. For training jobs, the value is the disk space utilization of the algorithm container on the instance. For endpoint variants, the value is the sum of the disk space utilization of the primary and supplementary containers on the instance. Units: Percent.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> For multi-instance, each instance reports disk utilization metrics. However, the default view in CloudWatch shows the average disk utilization across all instances.</td>
</tr>
</tbody>
</table>

### Dimensions for Processing Job, Training Job and Batch Transform Job Instance Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>For processing jobs, the value for this dimension has the format [processing-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified processing job and instance. This dimension format is present only in the /aws/sagemaker/ProcessingJobs namespace. For training jobs, the value for this dimension has the format [training-job-name]/algo-[instance-number-in-cluster]. Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace. For batch transform jobs, the value for this dimension has the format [transform-job-name]/[instance-id]. Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace.</td>
</tr>
</tbody>
</table>

## SageMaker Ground Truth Metrics

### Ground Truth Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveWorkers</td>
<td>A single active worker on a private work team submitted, released, or declined a task. To get the total number of active workers, use the Sum statistic. Ground Truth attempts to deliver each individual ActiveWorkers event once. If this delivery is unsuccessful, this metric may not report the total number of active workers.</td>
</tr>

### SageMaker Pipelines Metrics

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline executions.

Two categories of Pipelines execution metrics are available:

- **Execution Metrics across All Pipelines** – Account level pipeline execution metrics (for all pipelines in the current account)
- **Execution Metrics by Pipeline** – Pipeline execution metrics per pipeline

Metrics are available at a 1-minute frequency.

### Pipelines Execution Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExecutionStarted</td>
<td>The number of pipeline executions that started.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>

### Pipelines Step Metrics

The AWS/Sagemaker/ModelBuildingPipeline namespace includes the following metrics for pipeline steps.

Metrics are available at a 1-minute frequency.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StepStarted</td>
<td>The number of steps that started.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>StepFailed</td>
<td>The number of steps that failed.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>StepSucceeded</td>
<td>The number of steps that succeeded.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
<tr>
<td>StepStopped</td>
<td>The number of steps that stopped.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td></td>
<td>Valid statistics: Average, Sum</td>
</tr>
</tbody>
</table>
Metric | Description
---|---
StepDuration | The duration in milliseconds that the step ran.
| Units: Milliseconds
| Valid statistics: Average, Sum, Min, Max, Sample Count

Dimensions for Pipelines Step Metrics

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
</table>
| PipelineName, StepName | Filters step metrics for a specified pipeline and step.

Log Amazon SageMaker Events with Amazon CloudWatch

To help you debug your processing jobs, training jobs, endpoints, transform jobs, notebook instances, and notebook instance lifecycle configurations, anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` is also sent to Amazon CloudWatch Logs. In addition to debugging, you can use these for progress analysis.

Logs

The following table lists all of the logs provided by Amazon SageMaker.

<table>
<thead>
<tr>
<th>Log Group Name</th>
<th>Log Stream Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/aws/sagemaker/Endpoints/[EndpointName]</code></td>
<td><code>[production-variant-name]/[instance-id]</code></td>
</tr>
<tr>
<td></td>
<td><code>[production-variant-name]/[instance-id]/[container-name provided in SageMaker model] (For Inference Pipelines)</code></td>
</tr>
<tr>
<td><code>/aws/sagemaker/groundtruth/WorkerActivity</code></td>
<td><code>aws/sagemaker/groundtruth/worker-activity/[requester-AWS-Id]-[region]/[timestamp]</code></td>
</tr>
<tr>
<td><code>/aws/sagemaker/LabelingJobs</code></td>
<td><code>[labeling-job-name]</code></td>
</tr>
<tr>
<td><code>/aws/sagemaker/NotebookInstances</code></td>
<td><code>[notebook-instance-name]/[LifecycleConfigHook]</code></td>
</tr>
<tr>
<td></td>
<td><code>[notebook-instance-name]/jupyter.log</code></td>

</tr>
<tr>
<td><code>/aws/sagemaker/Studio</code></td>
<td><code>[domain-id]/[user-profile-name]/[app-type]/[app-name]</code></td>
</tr>
<tr>
<td><code>/aws/sagemaker/TrainingJobs</code></td>
<td><code>[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]</code></td>
</tr>
</tbody>
</table>
Log Amazon SageMaker API Calls with AWS CloudTrail

Amazon SageMaker is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in SageMaker. CloudTrail captures all API calls for SageMaker, with the exception of InvokeEndpoint, as events. The calls captured include calls from the SageMaker console and code calls to the SageMaker API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for SageMaker. If you don’t configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to SageMaker, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

By default, log data is stored in CloudWatch Logs indefinitely. However, you can configure how long to store log data in a log group. For information, see Change Log Data Retention in CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

SageMaker Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon SageMaker, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon SageMaker, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
• CloudTrail Supported Services and Integrations
• Configuring Amazon SNS Notifications for CloudTrail
• Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All SageMaker actions, with the exception of InvokeEndpoint, are logged by CloudTrail and are documented in the Operations. For example, calls to the CreateTrainingJob, CreateEndpoint and CreateNotebookInstance actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

• Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
• Whether the request was made with temporary security credentials for a role or federated user.
• Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Operations Performed by Automatic Model Tuning

SageMaker supports logging non-API service events to your CloudTrail log files for automatic model tuning jobs. These events are not related to your tuning jobs but are the direct result of a customer request to the public AWS API. For example, when you create a hyperparameter tuning job by calling CreateHyperParameterTuningJob, SageMaker creates training jobs to evaluate various combinations of hyperparameters to find the best result. Similarly, when you call StopHyperParameterTuningJob to stop a hyperparameter tuning job, SageMaker might stop any of the associated running training jobs. Non-API events for your tuning jobs are logged to CloudTrail to help you improve governance, compliance, and operational and risk auditing of your AWS account.

Log entries that result from non-API service events have an eventType of AwsServiceEvent instead of AwsApiCall.

Understanding SageMaker Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following examples a log entry for the CreateEndpoint action, which creates an endpoint to deploy a trained model.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AIXDAYQEXAMPLEUMLYNGL",
        "arn": "arn:aws:iam::123456789012:user/intern",
        "accountId": "123456789012",
        "accessKeyId": "ASXIAGXEXAMPLEULKNXV",
        "userName": "intern"
    },
    "eventTime": "2018-01-02T13:39:06Z",
    "eventSource": "sagemaker.amazonaws.com",
    "eventName": "CreateEndpoint",
    "awsRegion": "us-east-1",
    "eventSourceAddress": "123.45.67.89",
    "requestParameters": {
        "S3DataLocation": "s3://mybucket/mydata"
    }
}
```
The following example is a log entry for the `CreateModel` action, which creates one or more containers to host a previously trained model.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AIXDAYQEXAMPLEULYNGL",
    "arn": "arn:aws:iam::123456789012:user/intern",
    "accountId": "123456789012",
    "accessKeyId": "ASXIAGXEXAMPLEQULKNXV",
    "userName": "intern"
  },
  "eventTime": "2018-01-02T15:23:46Z",
  "eventSource": "sagemaker.amazonaws.com",
  "eventName": "CreateModel",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "127.0.0.1",
  "userAgent": "USER_AGENT",
  "requestParameters": {
    "modelName": "ExampleModel",
    "primaryContainer": {
      "image": "174872318107.dkr.ecr.us-west-2.amazonaws.com/kmeans:latest"
    },
    "executionRoleArn": "arn:aws:iam::123456789012:role/EXAMPLEARN"
  },
  "responseElements": {
  },
  "requestID": "417b8dab-EXAMPLE",
  "eventID": "0f2b3e81-EXAMPLE",
  "eventType": "AwsApiCall",
  "recipientAccountId": "444455556666"
}
```
when an event matches a rule. For an example of how to create a rule, see Schedule a Pipeline with Amazon EventBridge (p. 2149).

Some examples of the actions that can be automatically triggered include the following:

- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an AWS SMS queue

**SageMaker events monitored by EventBridge**

- Training job state change (p. 2474)
- Hyperparameter tuning job state change (p. 2475)
- Transform job state change (p. 2476)
- Endpoint state change (p. 2477)
- Feature group state change (p. 2478)
- Pipeline execution state change (p. 2479)
- Pipeline step state change (p. 2479)

**Training job state change**

Indicates a change in the status of a SageMaker training job.

If the value of TrainingJobStatus is Failed, the event contains the FailureReason field, which provides a description of why the training job failed.

```json
{
    "version": "0",

        "Tags": {}
    }
}
```

**Endpoint state change**

Indicates a change in the status of a SageMaker hosted real-time inference endpoint.

The following shows an event with an endpoint in the IN_SERVICE state.

```
{
    'version': '0',
    'id': 'd2921b5a-b0ad-cace-a8e3-0f159d018e06',
    'detail-type': 'SageMakerEndpointStateChange',
    'source': 'aws.sagemaker',
}
```
Feature group state change

Indicates a change either in the FeatureGroupStatus or the OfflineStoreStatus of a SageMaker feature group.

```json
{
    "version": "0",
    "id": "93201303-abdb-36a4-1b9b-4c1c3e3671c0",
    "detail-type": "SageMaker Feature Group State Change",
    "source": "aws.sagemaker",
    "account": "123456789012",
    "time": "2021-01-26T01:22:01Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:sagemaker:us-east-1:123456789012:feature-group/sample-feature-group"
    ],
    "detail": {
        "FeatureGroupName": "sample-feature-group",
        "RecordIdentifierFeatureName": "RecordIdentifier",
        "EventTimeFeatureName": "EventTime",
        "FeatureDefinitions": [
            {
                "FeatureName": "RecordIdentifier",
                "FeatureType": "Integral"
            },
            {
                "FeatureName": "EventTime",
                "FeatureType": "Fractional"
            }
        ],
        "CreationTime": 1611624059000,
        "OnlineStoreConfig": {
            "EnableOnlineStore": true
        },
        "OfflineStoreConfig": {
            "S3StorageConfig": {
```
Pipeline execution state change

Indicates a change in the status of a SageMaker pipeline execution.

```json
{
  "version": "0",
  "id": "ea37ccbb-5e2b-05e9-4073-1daazc940304",

  }
}
```

Pipeline step state change

Indicates a change in the status of a SageMaker pipeline step.

If there is a cache hit, the event contains the cacheHitResult field.

If the value of currentStepStatus is Failed, the event contains the failureReason field, which provides a description of why the step failed.

For more information about the status values and their meanings for SageMaker jobs, endpoints, and pipelines, see the following links:

- AlgorithmStatus
- EndpointStatus
- FeatureGroupStatus
- HyperParameterTuningJobStatus
- LabelingJobStatus
- ModelPackageStatus
- NotebookInstanceStatus
- PipelineExecutionStatus
- StepStatus
- ProcessingJobStatus
- TrainingJobStatus
- TransformJobStatus

For more information, see the Amazon EventBridge User Guide.
Availability Zones

For the AWS Regions supported by Amazon SageMaker and the Amazon Elastic Compute Cloud (Amazon EC2) instance types that are available in each Region, see Amazon SageMaker Pricing.

Each AWS Region is divided into sub-regions known as Availability Zones. For a given Region, the Availability Zones in that Region don’t always contain the same instance types supported by SageMaker.

Amazon SageMaker Studio is available in all the AWS Regions supported by Amazon SageMaker except the AWS GovCloud (US) Regions. In the supported Regions, Studio is available in the same Availability Zones as notebook instances.

For more information, see Regions and Availability Zones in the Amazon EC2 User Guide and AZ IDs for Your Resources in the AWS RAM User Guide.

The following list provides links to the Availability Zone tables for each AWS Region supported by SageMaker. Each linked table has a column for each Availability Zone in the Region. For each Availability Zone, the SageMaker components that support each instance type are shown.

Availability Zone Tables

- US East (Ohio) us-east-2
- US East (N. Virginia) us-east-1
- US West (N. California) us-west-1
- US West (Oregon) us-west-2
- Asia Pacific (Hong Kong) ap-east-1
- Asia Pacific (Mumbai) ap-south-1
- Asia Pacific (Seoul) ap-northeast-2
- Asia Pacific (Singapore) ap-southeast-1
- Asia Pacific (Sydney) ap-southeast-2
- Asia Pacific (Tokyo) ap-northeast-1
- Canada (Central) ca-central-1
- EU (Frankfurt) eu-central-1
- EU (Ireland) eu-west-1
- EU (London) eu-west-2
- EU (Paris) eu-west-3
- EU (Stockholm) eu-north-1
- Middle East (Bahrain) me-south-1
- South America (Sao Paulo) sa-east-1
- AWS GovCloud (US-Gov-West) us-gov-west-1
- US ISO East us-iso-east-1

The following AWS Regions are supported by Amazon SageMaker. Availability Zones tables are not available at this time. For more information, contact AWS Support.

- Africa (Cape Town) af-south-1
- EU (Milan) eu-south-1
API Reference Guide for Amazon SageMaker

Overview

Amazon SageMaker provides APIs, SDKs, and a command line interface that you can use to create and manage notebook instances and train and deploy models.

- Amazon SageMaker Python SDK (Recommended)
- Amazon SageMaker API Reference
- Amazon Augmented AI API Reference
- AWS Command Line Interface
- AWS SDK for .NET
- AWS SDK for C++
- AWS SDK for Go
- AWS SDK for Java
- AWS SDK for JavaScript
- AWS SDK for PHP
- AWS SDK for Python (Boto)
- AWS SDK for Ruby
- Amazon SageMaker Spark

You can also get code examples from the Amazon SageMaker example notebooks GitHub repository.

- Example notebooks

Programming Model for Amazon SageMaker

Making API calls directly from code is cumbersome, and requires you to write code to authenticate your requests. Amazon SageMaker provides the following alternatives:

- Use the SageMaker console—With the console, you don’t write any code. You use the console UI to start model training or deploy a model. The console works well for simple jobs, where you use a built-in training algorithm and you don’t need to preprocess training data.

- Modify the example Jupyter notebooks—SageMaker provides several Jupyter notebooks that train and deploy models using specific algorithms and datasets. Start with a notebook that has a suitable algorithm and modify it to accommodate your data source and specific needs.

- Write model training and inference code from scratch—SageMaker provides multiple AWS SDK languages (listed in the overview) and the Amazon SageMaker Python SDK, a high-level Python library that you can use in your code to start model training jobs and deploy the resulting models.
• **The SageMaker Python SDK**—This Python library simplifies model training and deployment. In addition to authenticating your requests, the library abstracts platform specifics by providing simple methods and default parameters. For example:

  • To deploy your model, you call only the `deploy()` method. The method creates a SageMaker model artifact, an endpoint configuration, then deploys the model on an endpoint.

  • If you use a custom framework script for model training, you call the `fit()` method. The method creates a .gzip file of your script, uploads it to an Amazon S3 location, and then runs it for model training, and other tasks. For more information, see Use Machine Learning Frameworks, Python, and R with Amazon SageMaker (p. 16).

• **The AWS SDKs**—The SDKs provide methods that correspond to the SageMaker API (see Operations). Use the SDKs to programmatically start a model training job and host the model in SageMaker. SDK clients authenticate your requests by using your access keys, so you don’t need to write authentication code. They are available in multiple languages and platforms. For more information, see the preceding list in the overview.

In Get Started with Amazon SageMaker (p. 34), you train and deploy a model using an algorithm provided by SageMaker. That exercise shows how to use both of these libraries. For more information, see Get Started with Amazon SageMaker (p. 34).

• **Integrate SageMaker into your Apache Spark workflow**—SageMaker provides a library for calling its APIs from Apache Spark. With it, you can use SageMaker-based estimators in an Apache Spark pipeline. For more information, see Use Apache Spark with Amazon SageMaker (p. 17).
