AWS PrivateLink and VPC endpoints

AWS PrivateLink is a highly available, scalable technology that enables you to privately connect your VPC to supported AWS services, services hosted by other AWS accounts (VPC endpoint services), and supported AWS Marketplace partner services. You do not need to use an internet gateway, NAT device, public IP address, AWS Direct Connect connection, or AWS Site-to-Site VPN connection to communicate with the service. Therefore, you control the specific API endpoints, sites, and services that are reachable from your VPC.

You can create your own VPC endpoint service, powered by AWS PrivateLink, and enable other AWS customers to access your service.

VPC endpoints concepts

The following are the key concepts for VPC endpoints:

- **VPC endpoint** — The entry point in your VPC that enables you to connect privately to a service. The following are the different types of VPC endpoints. You create the type of VPC endpoint required by the supported service.
  - Gateway endpoint (p. 20)
  - Interface endpoint (p. 3)
  - Gateway Load Balancer endpoint (p. 16)
- **Endpoint service** — Your own application or service in your VPC. Other AWS principals can create an endpoint from their VPC to your endpoint service.

To use AWS PrivateLink, create a VPC endpoint for a service in your VPC. You create the type of VPC endpoint required by the supported service. This creates an elastic network interface in your subnet with a private IP address that serves as an entry point for traffic destined to the service. The following diagram shows the basic architecture to securely connect your VPC to an AWS service that supports AWS PrivateLink.

---

Work with VPC endpoints

You can create, access, and manage VPC endpoints using any of the following:
Amazon Virtual Private Cloud AWS PrivateLink
Example endpoint configurations

- **AWS Management Console** — Provides a web interface that you can use to access your AWS PrivateLink resources.

- **AWS Command Line Interface (AWS CLI)** — Provides commands for a broad set of AWS services, including AWS PrivateLink. For more information about commands for AWS PrivateLink, see `ec2` in the
  *AWS CLI Command Reference*.

- **AWS CloudFormation** - Create templates that describe your AWS resources. You use the templates to provision and manage these resources as a single unit. For more information, see the following AWS PrivateLink resources:
  - `AWS::EC2::VPCEndpoint`
  - `AWS::EC2::VPCEndpointConnectionNotification`
  - `AWS::EC2::VPCEndpointService`
  - `AWS::EC2::VPCEndpointServicePermissions`
  - `AWS::ElasticLoadBalancingV2::LoadBalancer`

- **AWS SDKs** — Provide language-specific APIs. The SDKs take care of many of the connection details, such as calculating signatures, handling request retries, and handling errors. For more information, see
  *AWS SDKs*.

- **Query API** — Provides low-level API actions that you call using HTTPS requests. Using the Query API is the most direct way to access Amazon VPC. However, it requires that your application handle low-level details such as generating the hash to sign the request and handling errors. For more information, see
  *AWS PrivateLink actions* in the *Amazon EC2 API Reference*.

**Example endpoint configurations**

For information about AWS PrivateLink and VPC peering examples, see *Examples: Services using AWS PrivateLink and VPC peering* in the *Amazon VPC User Guide*.

**Pricing for endpoints**

For information about pricing, see *AWS PrivateLink Pricing*. 
VPC endpoints

A VPC endpoint enables connections between a virtual private cloud (VPC) and supported services, without requiring that you use an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Therefore, you control the specific API endpoints, sites, and services that are reachable from your VPC.

VPC endpoints are virtual devices. They are horizontally scaled, redundant, and highly available VPC components. The following are the different types of VPC endpoints. You create the type of VPC endpoint that's required by the supported service.

Interface endpoints

An interface endpoint (p. 3) is an elastic network interface with a private IP address from the IP address range of your subnet. It serves as an entry point for traffic destined to a service that is owned by AWS or owned by an AWS customer or partner. For a list of AWS services that integrate with AWS PrivateLink, see Services that support AWS PrivateLink (p. 68).

You are billed for hourly usage and data processing charges. For more information, see Interface endpoint pricing.

Gateway Load Balancer endpoints

A Gateway Load Balancer endpoint (p. 16) is an elastic network interface with a private IP address from the IP address range of your subnet. It serves as an entry point to intercept traffic and route it to a network or security service that you've configured using a Gateway Load Balancer. You specify a Gateway Load Balancer endpoint as a target for a route in a route table. Gateway Load Balancer endpoints are supported only for endpoint services that are configured using a Gateway Load Balancer.

You are billed for hourly usage and data processing charges. For more information, see Gateway Load Balancer endpoint pricing.

Gateway endpoints

A gateway endpoint (p. 20) is a gateway that is a target for a route in your route table used for traffic destined to either Amazon S3 or DynamoDB.

There is no charge for using gateway endpoints.

Amazon S3 supports both gateway endpoints and interface endpoints. For a comparison of the two options, see Types of VPC endpoints for Amazon S3 in the Amazon S3 User Guide.

Interface VPC endpoints (AWS PrivateLink)

An interface VPC endpoint (interface endpoint) allows you to connect to services powered by AWS PrivateLink. These services include some AWS services, services hosted by other AWS customers and Partners in their own VPCs (referred to as endpoint services), and supported AWS Marketplace Partner services. The owner of the service is the service provider, and you, as the principal creating the interface endpoint, are the service consumer.

The following are the general steps for setting up an interface endpoint:

1. Choose the VPC in which to create the interface endpoint, and provide the name of the AWS service, endpoint service, or AWS Marketplace service to which you’re connecting.
2. Choose a subnet in your VPC to use the interface endpoint. We create an endpoint network interface in the subnet. An endpoint network interface is assigned a private IP address from the IP address range of your subnet, and keeps this IP address until the interface endpoint is deleted. You can specify more than one subnet in different Availability Zones (as supported by the service) to help ensure that your interface endpoint is resilient to Availability Zone failures. In that case, we create an endpoint network interface in each subnet that you specify.

**Note**
An endpoint network interface is a requester-managed network interface. You can view it in your account, but you cannot manage it yourself. For more information, see Requester-managed network interfaces.

3. Specify the security groups to associate with the endpoint network interface. The security group rules control the traffic to the endpoint network interface from resources in your VPC. If you do not specify a security group, we associate the default security group for the VPC.

4. (Optional, AWS services and AWS Marketplace Partner services only) Enable private DNS (p. 4) for the endpoint so you can make requests to the service using its default DNS hostname.

**Important**
Private DNS is turned on by default for endpoints created for AWS services and AWS Marketplace Partner services. Private DNS is turned on in the other subnets which are in the same VPC and Availability Zone or Local Zone.

5. When the service provider and the consumer are in different accounts, see the section called “Interface endpoint Availability Zone considerations” (p. 7) for information about how to use Availability Zone IDs to identify the interface endpoint Availability Zone.

6. After you create the interface endpoint, it's available to use when it's accepted by the service provider. The service provider must configure the service to accept requests automatically or manually. AWS services and AWS Marketplace services generally accept all endpoint requests automatically. For more information about the lifecycle of an endpoint, see Interface endpoint lifecycle (p. 7).

Services cannot initiate requests to resources in your VPC through the endpoint. An endpoint only returns responses to traffic that is initiated from resources in your VPC. Before you integrate a service and an endpoint, review the service-specific VPC endpoint documentation for any service-specific configuration and limitations.

**Contents**
- Private DNS for interface endpoints (p. 4)
- Interface endpoint properties and limitations (p. 6)

- Interface endpoint Availability Zone considerations (p. 7)
- View available AWS service names (p. 8)
- Create an interface endpoint (p. 9)
- View your interface endpoint (p. 12)
- Create and manage a notification for an interface endpoint (p. 13)
- Access a service through an interface endpoint (p. 14)
- Modify an interface endpoint (p. 14)

**Private DNS for interface endpoints**

**Important**
Private DNS is not supported for Amazon S3 interface endpoints.
When you create an interface endpoint, we generate endpoint-specific DNS hostnames that you can use to communicate with the service. For AWS services and AWS Marketplace Partner services, the private DNS option (turned on by default) associates a private hosted zone with your VPC. The hosted zone contains a record set for the default DNS name for the service (for example, ec2.us-east-1.amazonaws.com) that resolves to the private IP addresses of the endpoint network interfaces in your VPC. This allows you to make requests to the service using its default DNS hostname instead of the endpoint-specific DNS hostnames. For example, if your existing applications make requests to an AWS service, they can continue to make requests through the interface endpoint without requiring any configuration changes.

In the example shown in the following diagram, there is an interface endpoint for Amazon Kinesis Data Streams and an endpoint network interface in subnet 2. Private DNS for the interface endpoint is turned off. The route tables for the subnets have the following routes.

<table>
<thead>
<tr>
<th>Subnet 1</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Destination</strong></td>
<td><strong>Target</strong></td>
</tr>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>internet-gateway-id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Subnet 2</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Destination</strong></td>
<td><strong>Target</strong></td>
</tr>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
</tbody>
</table>

Instances in either subnet can send requests to Amazon Kinesis Data Streams through the interface endpoint using an endpoint-specific DNS hostname. Instances in subnet 1 can communicate with Amazon Kinesis Data Streams over public IP address space in the AWS Region using its default DNS name.

In the next diagram, private DNS for the endpoint is turned on. Instances in either subnet can send requests to Amazon Kinesis Data Streams through the interface endpoint using either the default DNS hostname or the endpoint-specific DNS hostname.
Important
To use private DNS, you must set the following VPC attributes to true: enableDnsHostnames and enableDnsSupport. For more information, see Viewing and updating DNS support for your VPC. IAM users must have permission to work with hosted zones. For more information, see Authentication and Access Control for Route 53.

Interface endpoint properties and limitations

To use interface endpoints, you need to be aware of their properties and current limitations:

- For each interface endpoint, you can choose only one subnet per Availability Zone.
- Services might not be available in all Availability Zones through an interface endpoint. To find out which Availability Zones are supported, use the describe-vpc-endpoint-services command or use the Amazon VPC console. For more information, see Create an interface endpoint (p. 9).
- When you create an interface endpoint, the endpoint is created in the Availability Zone that is mapped to your account and that is independent from other accounts. When the service provider and the consumer are in different accounts, see the section called “Interface endpoint Availability Zone considerations” (p. 7) for information about how to use Availability Zone IDs to identify the interface endpoint Availability Zone.
- When the service provider and the consumer have different accounts and use multiple Availability Zones, and the consumer views the VPC endpoint service information, the response only includes the common Availability Zones. For example, when the service provider account uses us-east-1a and us-east-1c and the consumer uses us-east-1a and us-east-1b, the response includes the VPC endpoint services in the common Availability Zone, us-east-1a.
- By default, each interface endpoint can support a bandwidth of up to 10 Gbps per Availability Zone and automatically scales up to 40 Gbps. If your application needs higher throughput per zone, contact AWS support.
- If the network ACL for your subnet restricts traffic, you might not be able to send traffic through the endpoint network interface. Ensure that you add appropriate rules that allow traffic to and from the CIDR block of the subnet.
- Ensure that the security group that's associated with the endpoint network interface allows communication between the endpoint network interface and the resources in your VPC that communicate with the service. To ensure that command line tools such as the AWS CLI can make
requests over HTTPS from resources in the VPC to an AWS service, the security group must allow inbound HTTPS (port 443) traffic.

- An interface endpoint supports TCP traffic only.
- When you create an endpoint, you can attach an endpoint policy to it that controls access to the service to which you are connecting. For more information, see Policy Best Practices and the section called "Control access to services" (p. 36).
- Review the service-specific limits for your endpoint service.
- Participants cannot create Amazon Route53 Resolver endpoints in a VPC that they do not own. Only the VPC owner can create VPC-level resources such as inbound endpoints.
- Endpoints are supported within the same Region only. You cannot create an endpoint between a VPC and a service in a different Region.
- Endpoints support IPv4 traffic only.
- You cannot transfer an endpoint from one VPC to another, or from one service to another.
- You have a quota on the number of endpoints you can create per VPC. For more information, see AWS PrivateLink quotas (p. 82).

Connection to on-premises data centers

You can use the following types of connections for a connection between an interface endpoint and your on-premises data center:

- AWS Direct Connect
- AWS Site-to-Site VPN

Interface endpoint lifecycle

An interface endpoint goes through various stages starting from when you create it (the endpoint connection request). At each stage, there might be actions that the service consumer and service provider can take.

The following rules apply:

- A service provider can configure their service to accept interface endpoint requests automatically or manually. AWS services and AWS Marketplace services generally accept all endpoint requests automatically.
- A service provider cannot delete an interface endpoint to their service. Only the service consumer that requested the interface endpoint connection can delete the interface endpoint.
- A service provider can reject the interface endpoint after it has been accepted (either manually or automatically) and is in the available state.

Interface endpoint Availability Zone considerations

When you create an interface endpoint, the endpoint is created in the Availability Zone that is mapped to your account and that is independent from other accounts. When the service provider and the consumer are in different accounts, use the Availability Zone ID to uniquely and consistently identify the interface endpoint Availability Zone. For example, use1-az1 is an Availability Zone ID for the us-east-1 Region and maps to the same location in every AWS account. For information about Availability Zone IDs, see AZ IDs for Your Resources in the AWS RAM User Guide or use describe-availability-zones.
Services might not be available in all Availability Zones through an interface endpoint. You can use any of the following operations to find out which Availability Zones are supported for a service:

- `describe-vpc-endpoint-services` (AWS CLI)
- `DescribeVpcEndpointServices` (API)
- The Amazon VPC console when you create an interface endpoint. For more information, see the section called “Create an interface endpoint” (p. 9).

View available AWS service names

When you use the Amazon VPC console to create an endpoint, you can get a list of available AWS service names.

When you use the AWS CLI to create an endpoint, you can use the `describe-vpc-endpoint-services` command to view the service names, and then create the endpoint using the `create-vpc-endpoint` command.

Console

To view available AWS services using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints, Create Endpoint**.
3. In the **Service Name** section, the available services are listed.

Command line

To view available AWS services using the AWS CLI

- Use the `describe-vpc-endpoint-services` command to get a list of available services to which you can connect. The `ServiceType` field indicates whether you connect to the service via an interface or gateway endpoint. The `ServiceName` field provides the name of the service. The following example lists the names and owners of all the interface endpoints.

```
aws ec2 describe-vpc-endpoint-services --filter "Name=service-type,Values=Interface" --query "ServiceDetails[*].[ServiceName, Owner]" --output table
```

<table>
<thead>
<tr>
<th></th>
<th>DescribeVpcEndpointServices</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws.sagemaker.us-west-2.notebook</td>
<td>amazon</td>
</tr>
<tr>
<td>aws.sagemaker.us-west-2.studio</td>
<td>amazon</td>
</tr>
<tr>
<td>com.amazonaws.us-west-2.access-analyzer</td>
<td>amazon</td>
</tr>
<tr>
<td>com.amazonaws.us-west-2.acm-pca</td>
<td>amazon</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

To view available AWS services using the AWS Tools for Windows PowerShell

- `Get-EC2VpcEndpointService`

To view available AWS services using the API

- `DescribeVpcEndpointServices`
Create an interface endpoint

To create an interface endpoint, you must specify the VPC in which to create the interface endpoint, and the service to which to establish the connection.

For AWS services, or AWS Marketplace Partner services, you can optionally turn on private DNS (p. 4) for the endpoint so that you can make requests to the service using its default DNS hostname.

**Important**
Private DNS is turned on by default for endpoints created for AWS services and AWS Marketplace Partner services.

**Console**

**To create an interface endpoint to an AWS service using the console**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Endpoints, Create Endpoint**.
3. For **Service category**, ensure that **AWS services** is selected.
4. For **Service Name**, choose the service to which to connect. For **Type**, ensure that it indicates **Interface**.
5. Complete the following information and then choose **Create endpoint**.
   - For **VPC**, select a VPC in which to create the endpoint.
   - For **Subnets**, select the subnets (Availability Zones) in which to create the endpoint network interfaces.

Not all Availability Zones may be supported for all AWS services.

   - To turn on private DNS for the interface endpoint, for **Enable DNS Name**, select the check box.

**Important**
Private DNS is not supported for Amazon S3 interface endpoints.

This option is turned on by default. To use the private DNS option, the following attributes of your VPC must be set to **true**: `enableDnsHostnames` and `enableDnsSupport`. For more information, see Viewing and updating DNS support for your VPC.

- For **Security group**, select the security groups to associate with the endpoint network interfaces.
- (Optional) Add or remove a tag.

  [Add a tag] Choose **Add tag** and do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.

  [Remove a tag] Choose the delete button (“x”) to the right of the tag’s Key and Value.

To create an interface endpoint to an endpoint service, you must have the name of the service to which to connect. The service provider can provide you with the name.

**To create an interface endpoint to an endpoint service**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Endpoints, Create Endpoint**.
3. For **Service category**, choose **Find service by name**.
4. For **Service Name**, enter the name of the service (for example, `com.amazonaws.vpce.us-east-1.vpce-svc-0e123abc123198abc`) and choose **Verify**.

5. Complete the following information and then choose **Create endpoint**.
   - For **VPC**, select a VPC in which to create the endpoint.
   - For **Subnets**, select the subnets (Availability Zones) in which to create the endpoint network interfaces.

   Not all Availability Zones may be supported for the service.
   - For **Security group**, select the security groups to associate with the endpoint network interfaces.
   - (Optional) Add or remove a tag.

   [Add a tag] Choose **Add tag** and do the following:
   - For **Key**, enter the key name.
   - For **Value**, enter the key value.

   [Remove a tag] Choose the delete button ("x") to the right of the tag's Key and Value.

---

**To create an interface endpoint to an AWS Marketplace partner service**

1. Go to the PrivateLink page in AWS Marketplace and subscribe to a service from a software as a service (SaaS) provider. Services that support interface endpoints include an option to connect via an endpoint.

2. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).

3. In the navigation pane, choose **Endpoints**, **Create Endpoint**.

4. For **Service category**, choose **Your AWS Marketplace services**.

5. Choose the AWS Marketplace service to which you've subscribed.

6. Complete the following information and then choose **Create endpoint**.
   - For **VPC**, select a VPC in which to create the endpoint.
   - For **Subnets**, select the subnets (Availability Zones) in which to create the endpoint network interfaces.

   Not all Availability Zones may be supported for the service.
   - For **Security group**, select the security groups to associate with the endpoint network interfaces.
   - (Optional) Add or remove a tag.

   [Add a tag] Choose **Add tag** and do the following:
   - For **Key**, enter the key name.
   - For **Value**, enter the key value.

   [Remove a tag] Choose the delete button ("x") to the right of the tag's Key and Value.

---

**Command line**

**To create an interface endpoint using the AWS CLI**

1. Use the `describe-vpc-endpoint-services` command to get a list of available services. In the output that's returned, take note of the name of the service to which to connect. The **ServiceType** field indicates whether you connect to the service via an interface or gateway endpoint. The **ServiceName** field provides the name of the service.
To create an interface endpoint, use the create-vpc-endpoint command and specify the VPC ID, type of VPC endpoint (interface), service name, subnets that will use the endpoint, and security groups to associate with the endpoint network interfaces.

The following example creates an interface endpoint to the Elastic Load Balancing service.

```bash
aws ec2 create-vpc-endpoint --vpc-id vpc-ec43eb89 --vpc-endpoint-type Interface --service-name com.amazonaws.us-east-1.elasticloadbalancing --subnet-id subnet-abababab --security-group-id sg-1a2b3c4d
```

```json
{
    "VpcEndpoint": {
        "PolicyDocument": "{
            "Statement": [
                {
                    "Action": "*",
                    "Effect": "Allow",
                    "Principal": "*",
                    "Resource": "*
                }
            ],
            "VpcId": "vpc-ec43eb89",
            "NetworkInterfaceIds": [
                "eni-bf8aa46b"
            ],
            "SubnetIds": [
                "subnet-abababab"
            ],
            "PrivateDnsEnabled": true,
            "State": "pending",
            "ServiceName": "com.amazonaws.us-east-1.elasticloadbalancing",
            "RouteTableIds": [],
            "Groups": [
                {
                    "GroupName": "default",
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "VpcEndpointId": "vpce-088d25a4bbf4a7abc",
            "VpcEndpointType": "Interface",

                {
                    "HostedZoneId": "Z1K56Z6FNPJR",
                    "DnsName": "elasticloadbalancing.us-east-1.amazonaws.com"
                }
            ]
        }
    }
}
```

Alternatively, the following example creates an interface endpoint to an endpoint service in another account (the service provider provides you with the name of the endpoint service).

```bash
aws ec2 create-vpc-endpoint --vpc-id vpc-ec43eb89 --vpc-endpoint-type Interface --service-name com.amazonaws.vpce.us-east-1.vpce-svc-0e123abc123198abc --subnet-id subnet-abababab --security-group-id sg-1a2b3c4d
```

```json
{
    "VpcEndpoint": {
        "PolicyDocument": "{
            "Statement": [
                {
                    "Action": "*",
                    "Effect": "Allow",
                    "Principal": "*",
                    "Resource": "*
                }
            ],
            "VpcId": "vpc-ec43eb89",
            "NetworkInterfaceIds": [
                "eni-bf8aa46b"
            ],
            "SubnetIds": [
                "subnet-abababab"
            ],
            "PrivateDnsEnabled": true,
            "State": "pending",
            "ServiceName": "com.amazonaws.us-east-1.elasticloadbalancing",
            "RouteTableIds": [],
            "Groups": [
                {
                    "GroupName": "default",
                    "GroupId": "sg-1a2b3c4d"
                }
            ],
            "VpcEndpointId": "vpce-088d25a4bbf4a7abc",
            "VpcEndpointType": "Interface",
            "CreationTimestamp": "2017-09-05T20:14:41.240Z",
            "DnsEntries": [
                {
                    "HostedZoneId": "Z7HUB22UULQXV",
                    "DnsName": "vpce-088d25a4bbf4a7abc-ks83awe7.elasticloadbalancing.us-east-1.vpce.amazonaws.com"
                },
                {
                    "HostedZoneId": "Z7HUB22UULQXV",
                    "DnsName": "vpce-088d25a4bbf4a7abc-ks83awe7-us-east-1a.elasticloadbalancing.us-east-1.vpce.amazonaws.com"
                },
                {
                    "HostedZoneId": "Z1K56Z6FNPJR",
                    "DnsName": "elasticloadbalancing.us-east-1.amazonaws.com"
                }
            ]
        }
    }
}
```
In the output that’s returned, take note of the privateDnsNames fields. You can use these DNS names to access the AWS service.

To describe available services and create a VPC endpoint using the AWS Tools for Windows PowerShell

- Get-EC2VpcEndpointService
- New-EC2VpcEndpoint

To describe available services and create a VPC endpoint using the API

- DescribeVpcEndpointServices
- CreateVpcEndpoint

View your interface endpoint

After you've created an interface endpoint, you can view information about it.

Console

To view information about an interface endpoint using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select your interface endpoint.
3. To view information about the interface endpoint, choose Details. The DNS Names field displays the DNS names to use to access the service.
4. To view the subnets in which the interface endpoint has been created, and the ID of the endpoint network interface in each subnet, choose Subnets.
5. To view the security groups that are associated with the endpoint network interface, choose Security Groups.

Command line

To describe your interface endpoint using the AWS CLI

- You can describe your endpoint using the describe-vpc-endpoints command.

```bash
aws ec2 describe-vpc-endpoints --vpc-endpoint-ids vpce-088d25a4bbf4a7abc
```

To describe your VPC endpoints using the AWS Tools for PowerShell or API

- Get-EC2VpcEndpoint (Tools for Windows PowerShell)
- DescribeVpcEndpoints (Amazon EC2 Query API)
Create and manage a notification for an interface endpoint

You can create a notification to receive alerts for specific events that occur on your interface endpoint. For example, you can receive an email when the interface endpoint is accepted by the service provider. To create a notification, you must associate an Amazon SNS topic with the notification. You can subscribe to the SNS topic to receive an email notification when an endpoint event occurs.

The Amazon SNS topic that you use for notifications must have a topic policy that allows Amazon's VPC endpoint service to publish notifications on your behalf. Ensure that you include the following statement in your topic policy. For more information, see Identity and Access Management in Amazon SNS in the Amazon Simple Notification Service Developer Guide.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "vpce.amazonaws.com"
      },
      "Action": "SNS:Publish",
      "Resource": "arn:aws:sns:region:account:topic-name"
    }
  ]
}
```

Command line

**To create and manage a notification using the AWS CLI**

1. To create a notification for an interface endpoint, use the `create-vpc-endpoint-connection-notification` command. Specify the ARN of the SNS topic, the events for which to be notified, and the ID of the endpoint, as shown in the following example.

   ```bash
   ```

2. To view your notifications, use the `describe-vpc-endpoint-connection-notifications` command.

   ```bash
   aws ec2 describe-vpc-endpoint-connection-notifications
   ```

3. To change the SNS topic or endpoint events for the notification, use the `modify-vpc-endpoint-connection-notification` command.

   ```bash
   ```

4. To delete a notification, use the `delete-vpc-endpoint-connection-notifications` command.

   ```bash
   aws ec2 delete-vpc-endpoint-connection-notifications --connection-notification-ids vpce-nfn-008776de7e03f5abc
   ```
Access a service through an interface endpoint

After you've created an interface endpoint, you can submit requests to the supported service via an endpoint URL. You can use the following:

- If you have turned on private DNS for the endpoint (a private hosted zone; applicable to AWS services and AWS Marketplace Partner services only), the default DNS hostname for the AWS service for the Region. For example, ec2.us-east-1.amazonaws.com.

  **Important**
  Private DNS is not supported for Amazon S3 interface endpoints.

- The endpoint-specific Regional DNS hostname that we generate for the interface endpoint. The hostname includes a unique endpoint identifier, service identifier, the Region, and vpce.amazonaws.com in its name. For example, vpce-0fe5b17a0707d6abc-29p5708s.ec2.us-east-1.vpce.amazonaws.com.

- The endpoint-specific zonal DNS hostname that we generate for each Availability Zone in which the endpoint is available. The hostname includes the Availability Zone in its name. For example, vpce-0fe5b17a0707d6abc-29p5708s-us-east-1a.ec2.us-east-1.vpce.amazonaws.com. You might use this option if your architecture isolates Availability Zones (for example, for fault containment or to reduce Regional data transfer costs).

  A request to the zonal DNS hostname is destined to the corresponding Availability Zone location in the service provider's account, which might not have the same Availability Zone name as your account. For more information, see Region and Availability Zone Concepts.

- The private IP address of the endpoint network interface in the VPC.

To get the Regional and zonal DNS names, see View your interface endpoint (p. 12).

For example, in a subnet in which you have an interface endpoint to Elastic Load Balancing and for which you have not turned on the private DNS option, use the following AWS CLI command from an instance to describe your load balancers. The command uses the endpoint-specific Regional DNS hostname to make the request using the interface endpoint.

```
aws elbv2 describe-load-balancers --endpoint-url https://vpce-0f89a33420c193abc-bluzidnv.elasticloadbalancing.us-east-1.vpce.amazonaws.com/
```

If you turn on the private DNS option, you do not have to specify the endpoint URL in the request. The AWS CLI uses the default endpoint for the AWS service for the Region (elasticloadbalancing.us-east-1.amazonaws.com).

Modify an interface endpoint

You can modify the following attributes of an interface endpoint:

- The subnet in which the interface endpoint is located
- The security groups that are associated with the endpoint network interface
- The tags
- The private DNS option

  **Note**
  When you turn on private DNS, it might take a few minutes for the private IP addresses to become available.

- The endpoint policy (if supported by the service)
If you remove a subnet for the interface endpoint, the corresponding endpoint network interface in the subnet is deleted.

Console

To change the subnets for an interface endpoint
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select the interface endpoint.
3. Choose Actions, Manage Subnets.
4. Select or deselect the subnets as required, and choose Modify Subnets.

To add or remove the security groups associated with an interface endpoint
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select the interface endpoint.
3. Choose Actions, Manage security groups.
4. Select or deselect the security groups as required, and choose Save.

To add or remove an interface endpoint tag
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints.
3. Select the interface endpoint and choose Actions, Add/Edit Tags.
4. Add or remove a tag.
   [Add a tag] Choose Create tag and do the following:
   • For Key, enter the key name.
   • For Value, enter the key value.
   [Remove a tag] Choose the delete button (“x”) to the right of the tag’s Key and Value.

To modify the private DNS option
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select the interface endpoint.
3. Choose Actions, Modify Private DNS names.
4. Set the option as required, and choose Modify Private DNS names.

To update the endpoint policy
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select the interface endpoint.
3. Choose Actions, Edit policy.
4. Choose Full Access to allow full access to the service, or choose Custom and specify a custom policy. Choose Save.
Command line

To modify a VPC endpoint using the AWS CLI

1. Use the describe-vpc-endpoints command to get the ID of your interface endpoint.

   ```
   aws ec2 describe-vpc-endpoints
   ```

2. The following example uses the modify-vpc-endpoint command to add subnet subnet-aabb1122 to the interface endpoint.

   ```
   aws ec2 modify-vpc-endpoint --vpc-endpoint-id vpce-0fe5b17a0707d6abc --add-subnet-id subnet-aabb1122
   ```

To modify a VPC endpoint using the AWS Tools for Windows PowerShell or an API

- **Edit-EC2VpcEndpoint** (AWS Tools for Windows PowerShell)
- **ModifyVpcEndpoint** (Amazon EC2 Query API)

To add or remove a VPC endpoint tag using the AWS Tools for Windows PowerShell or an API

- **tag-resource** (AWS CLI)
- **TagResource** (AWS Tools for Windows PowerShell)
- **untag-resource** (AWS CLI)
- **TagResource** (AWS Tools for Windows PowerShell)

Gateway Load Balancer endpoints (AWS PrivateLink)

A Gateway Load Balancer endpoint enables you to intercept traffic and route it to a service that you've configured using Gateway Load Balancers, for example, for security inspection. The owner of the service is the **service provider**, and you, as the principal creating the Gateway Load Balancer endpoint, are the **service consumer**.

The following are the general steps for setting up a Gateway Load Balancer endpoint:

1. Ensure that a Gateway Load Balancer endpoint service is configured. For more information, see [VPC endpoint services for Gateway Load Balancer endpoints](p. 43).
2. Choose the VPC in which to create the Gateway Load Balancer endpoint, and provide the name of the service.
3. Choose a subnet in your VPC to use the Gateway Load Balancer endpoint. We create an **endpoint network interface** in the subnet. An endpoint network interface is assigned a private IP address from the IP address range of your subnet, and keeps this IP address until the Gateway Load Balancer endpoint is deleted.

   **Note**
   An endpoint network interface is a requester-managed network interface. You can view it in your account, but you cannot manage it yourself. For more information, see [Requester-managed network interfaces](p. 43).
4. After you create the Gateway Load Balancer endpoint, it's available to use when it’s accepted by the service provider. The service provider can configure the service to accept requests automatically or manually.

5. Configure your subnet route table and gateway route table to point traffic to the Gateway Load Balancer endpoint. For more information, see Routing to a Gateway Load Balancer endpoint in the Amazon VPC User Guide.

Gateway Load Balancer endpoint properties and limitations

To use a Gateway Load Balancer endpoint, be aware of the following:

- For each Gateway Load Balancer endpoint, you can choose only one Availability Zone (subnet) in your VPC. You cannot change the subnet later. To use a Gateway Load Balancer endpoint in a different subnet, create a new Gateway Load Balancer endpoint in that subnet. You can create a single Gateway Load Balancer endpoint per Availability Zone for a service, but only for the Availability Zones that the Gateway Load Balancer supports.

- Each Gateway Load Balancer endpoint supports a maximum bandwidth of up to 40 Gbps.

- If the network ACL for your subnet restricts traffic, you might not be able to send traffic through the Gateway Load Balancer endpoint. Ensure that you add appropriate rules that allow traffic to and from the CIDR block of the subnet.

- Security groups are not supported.

- Endpoint policies are not supported.

- A service might not be available in all Availability Zones through a Gateway Load Balancer endpoint. To find out which Availability Zones are supported, use the describe-vpc-endpoint-services command or use the Amazon VPC console. For more information, see Create a Gateway Load Balancer endpoint (p. 18).

- When you create a Gateway Load Balancer endpoint, the endpoint is created in the Availability Zone that is mapped to your account and that is independent from other accounts. When the service provider and the consumer are in different accounts, use the Availability Zone ID to uniquely and consistently identify the endpoint Availability Zone. For example, us1-az1 is an Availability Zone ID for the us-east-1 Region and maps to the same location in every AWS account. For information about Availability Zone IDs, see AZ IDs for Your Resources in the AWS RAM User Guide or use describe-availability-zones.

- To keep traffic within the same Availability Zone, we recommend that you create a Gateway Load Balancer endpoint in each Availability Zone that you will send traffic to.

- Network Load Balancer client IP preservation is not supported when traffic is routed through a Gateway Load Balancer endpoint, even if the target is in the same VPC as the Network Load Balancer.

- Endpoints are supported within the same Region only. You cannot create an endpoint between a VPC and a service in a different Region.

- Endpoints support IPv4 traffic only.
• You cannot transfer an endpoint from one VPC to another, or from one service to another.
• You have a quota on the number of endpoints you can create per VPC. For more information, see AWS PrivateLink quotas (p. 82).

Gateway Load Balancer endpoint lifecycle

A Gateway Load Balancer endpoint goes through various stages, starting from when you create it (the endpoint connection request). At each stage, there might be actions that the service consumer and service provider can take.

The following rules apply:

• A service provider can configure their service to accept Gateway Load Balancer endpoint requests automatically or manually.
• A service provider cannot delete a Gateway Load Balancer endpoint to their service. Only the service consumer that requested the connection can delete the Gateway Load Balancer endpoint.
• A service provider can reject the Gateway Load Balancer endpoint after it has been accepted and is in the available state.

Pricing for Gateway Load Balancer endpoints

You are charged for creating and using a Gateway Load Balancer endpoint to a service. Hourly usage rates and data processing rates apply. For more information, see AWS PrivateLink Pricing. You can view the total number of Gateway Load Balancer endpoints using the Amazon VPC console or the AWS CLI.

Create a Gateway Load Balancer endpoint

To create a Gateway Load Balancer endpoint, you must specify the VPC in which to create the endpoint, and the service to which to establish the connection.

Console

To create a Gateway Load Balancer endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, Create Endpoint.
3. For Service category, choose Find service by name.
4. For Service Name, enter the name of the service and choose Verify.
5. Complete the following information and then choose Create endpoint.
   • For VPC, select a VPC in which to create the endpoint.
   • For Subnets, select the subnet (Availability Zone) in which to create the Gateway Load Balancer endpoint.
   • (Optional) To add a tag, choose Add tag and then specify a key and value for the tag.

Command line

To create a Gateway Load Balancer endpoint using the AWS CLI

Use the create-vpc-endpoint command and specify the VPC ID, type of VPC endpoint (Gateway Load Balancer), service name, and the subnet in which to create the Gateway Load Balancer endpoint.
To create a VPC endpoint using the AWS Tools for Windows PowerShell or API

- New-EC2VpcEndpoint
- CreateVpcEndpoint

**View your Gateway Load Balancer endpoint**

After you've created a Gateway Load Balancer endpoint, you can view information about it.

**Console**

**To view information about a Gateway Load Balancer endpoint using the console**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints** and select your Gateway Load Balancer endpoint.
3. Choose **Details**.
4. To view the subnet in which the Gateway Load Balancer endpoint has been created, and the ID of the endpoint network interface, choose **Subnets**.

**Command line**

**To describe your Gateway Load Balancer endpoint using a command line tool or API**

- describe-vpc-endpoints (AWS CLI)
- Get-EC2VpcEndpoint (Tools for Windows PowerShell)
- DescribeVpcEndpoints (Amazon EC2 Query API)

**Add or remove tags for a Gateway Load Balancer endpoint**

You can add or remove the tags for your Gateway Load Balancer endpoint.

**Console**

**To add or remove a tag**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Select the Gateway Load Balancer endpoint and choose **Actions**, **Add/Edit Tags**.
4. Add or remove a tag.

[Add a tag] Choose **Create tag** and do the following:

- For **Key**, enter the key name.
- For **Value**, enter the key value.

[Remove a tag] Choose the delete button (“x”) to the right of the tag's Key and Value.
Command line

**To add or remove tags using a command line tool or an API**

- Use `create-tags` and `delete-tags`. (AWS CLI)
- Use `New-EC2Tag` and `Remove-EC2Tag` (AWS Tools for Windows PowerShell)
- Use `CreateTags` and `DeleteTags`. (Amazon EC2 Query API)

**Gateway VPC endpoints**

Gateway endpoints provide reliable connectivity to Amazon S3 and DynamoDB without requiring an internet gateway or a NAT device for your VPC. Gateway endpoints do not enable AWS PrivateLink.

To create and set up a gateway endpoint, follow these general steps:

1. Specify the VPC in which to create the endpoint, and the service to which you're connecting. A service is identified by an AWS managed *prefix list*—the name and ID of a service for a Region. An AWS prefix list ID uses the form `pl-xxxxxxxx` and an AWS prefix list name uses the form "com.amazonaws.region.service". Use the AWS prefix list name (service name) to create an endpoint.
2. Attach an *endpoint policy* to your endpoint that allows access to some or all of the service to which you're connecting. For more information, see Use VPC endpoint policies (p. 36).
3. Specify one or more route tables in which to create routes to the service. Route tables control the routing of traffic between your VPC and the other service. Each subnet that's associated with one of these route tables has access to the endpoint, and traffic from instances in these subnets to the service is then routed through the endpoint.

In the following diagram, instances in subnet 2 can access Amazon S3 through the gateway endpoint.

![Gateway endpoint diagram](image-url)

You can create multiple endpoints in a single VPC, for example, to multiple services. You can also create multiple endpoints for a single service, and use different route tables to enforce different access policies from different subnets to the same service.

After you've created an endpoint, you can modify the endpoint policy that's attached to your endpoint, and add or remove the route tables that are used by the endpoint.
Pricing for gateway endpoints

There is no additional charge for using gateway endpoints. Standard charges for data transfer and resource usage apply. For more information about pricing, see Amazon EC2 Pricing.

Routing for gateway endpoints

When you create or modify an endpoint, you specify the VPC route tables that are used to access the service via the endpoint. A route is automatically added to each of the route tables with a destination that specifies the AWS prefix list ID of the service (pl-xxxxxxxxx), and a target with the endpoint ID (vpce-xxxxxxxxx); for example:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>pl-1a2b3c4d</td>
<td>vpce-11bb22cc</td>
</tr>
</tbody>
</table>

The prefix list ID logically represents the range of public IP addresses used by the service. All instances in subnets associated with the specified route tables automatically use the endpoint to access the service. Subnets that are not associated with the specified route tables do not use the endpoint. This allows you to keep resources in other subnets separate from your endpoint.

To view the current public IP address range for a service, you can use the describe-prefix-lists command.

**Note**

The range of public IP addresses for a service may change from time to time. Consider the implications before you make routing or other decisions based on the current IP address range for a service.

The following rules apply:

- You can have multiple endpoint routes to different services in a route table, and you can have multiple endpoint routes to the same service in different route tables. But you cannot have multiple endpoint routes to the same service in a single route table. For example, if you create two endpoints to Amazon S3 in your VPC, you cannot create endpoint routes for both endpoints in the same route table.
- You cannot explicitly add, modify, or delete an endpoint route in your route table by using the route table APIs, or by using the Route Tables page in the Amazon VPC console. You can only add an endpoint route by associating a route table with an endpoint. To change the route tables that are associated with your endpoint, you can modify the endpoint (p. 35).
- An endpoint route is automatically deleted when you remove the route table association from the endpoint (by modifying the endpoint), or when you delete your endpoint.
We use the most specific route that matches the traffic to determine how to route the traffic (longest prefix match). If you have an existing route in your route table for all internet traffic (0.0.0.0/0) that points to an internet gateway, the endpoint route takes precedence for all traffic destined for the service, because the IP address range for the service is more specific than 0.0.0.0/0. All other internet traffic goes to your internet gateway, including traffic that's destined for the service in other Regions.

However, if you have existing, more specific routes to IP address ranges that point to an internet gateway or a NAT device, those routes take precedence. If you have existing routes destined for an IP address range that is identical to the IP address range used by the service, then your routes take precedence.

**Example: An endpoint route in a route table**

In this scenario, you have an existing route in your route table for all internet traffic (0.0.0.0/0) that points to an internet gateway. Any traffic from the subnet that's destined for another AWS service uses the internet gateway.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-1a2b3c4d</td>
</tr>
</tbody>
</table>

You create an endpoint to a supported AWS service, and associate your route table with the endpoint. An endpoint route is automatically added to the route table, with a destination of pl-1a2b3c4d (assume this represents the service to which you've created the endpoint). Now, any traffic from the subnet that's destined for that AWS service in the same Region goes to the endpoint, and does not go to the internet gateway. All other internet traffic goes to your internet gateway, including traffic that's destined for other services, and destined for the AWS service in other Regions.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>0.0.0.0/0</td>
<td>igw-1a2b3c4d</td>
</tr>
<tr>
<td>pl-1a2b3c4d</td>
<td>vpce-11bb22cc</td>
</tr>
</tbody>
</table>

**Example: Adjusting your route tables for endpoints**

In this scenario, 54.123.165.0/24 is in the Amazon S3 IP address range and you configured your route table to allow instances in your subnet to communicate with Amazon S3 buckets through an internet gateway. You've added a route with 54.123.165.0/24 as a destination, and the internet gateway as the target. You then create an endpoint, and associate this route table with the endpoint. An endpoint route is automatically added to the route table. You then use the describe-prefix-lists command to view the IP address range for Amazon S3. The range is 54.123.160.0/19, which is less specific than the range that's pointing to your internet gateway. This means that any traffic destined for the 54.123.165.0/24 IP address range continues to use the internet gateway, and does not use the endpoint (for as long as this remains the public IP address range for Amazon S3).

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>54.123.165.0/24</td>
<td>igw-1a2b3c4d</td>
</tr>
<tr>
<td>pl-1a2b3c4d</td>
<td>vpce-11bb22cc</td>
</tr>
</tbody>
</table>
To ensure that all traffic destined for Amazon S3 in the same Region is routed via the endpoint, you must adjust the routes in your route table. To do this, you can delete the route to the internet gateway. Now, all traffic to Amazon S3 in the same Region uses the endpoint, and the subnet that’s associated with your route table is a private subnet.

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0.0.0/16</td>
<td>Local</td>
</tr>
<tr>
<td>pl-1a2b3c4d</td>
<td>vpce-11bb22cc</td>
</tr>
</tbody>
</table>

**Gateway endpoint limitations**

To use gateway endpoints, you need to be aware of the current limitations:

• You cannot use an AWS prefix list ID in an outbound rule in a network ACL to allow or deny outbound traffic to the service specified in an endpoint. If your network ACL rules restrict traffic, you must specify the CIDR block (IP address range) for the service instead. You can, however, use an AWS prefix list ID in an outbound security group rule. For more information, see Security groups (p. 37).

• Endpoints are supported within the same Region only. You cannot create an endpoint between a VPC and a service in a different Region.

• Endpoints support IPv4 traffic only.

• You cannot transfer an endpoint from one VPC to another, or from one service to another.

• You have a quota on the number of endpoints you can create per VPC. For more information, see AWS PrivateLink quotas (p. 82).

• Endpoint connections cannot be extended out of a VPC. Resources on the other side of a VPN connection, VPC peering connection, transit gateway, AWS Direct Connect connection, or ClassicLink connection in your VPC cannot use the endpoint to communicate with resources in the endpoint service.

• You must turn on DNS resolution in your VPC, or if you’re using your own DNS server, ensure that DNS requests to the required service (such as Amazon S3) are resolved correctly to the IP addresses maintained by AWS. For more information, see Using DNS with your VPC in the Amazon VPC User Guide and AWS IP Address Ranges in the Amazon Web Services General Reference.

• Review the service-specific limits for your endpoint service.

For more information about rules and limitations that are specific to Amazon S3, see Endpoints for Amazon S3 (p. 23).

For more information about rules and limitations that are specific to DynamoDB, see Endpoints for Amazon DynamoDB (p. 30).

**Endpoints for Amazon S3**

If you’ve already set up access to your Amazon S3 resources from your VPC, you can continue to use Amazon S3 DNS names to access those resources after you’ve set up an endpoint. However, take note of the following:

• Your endpoint has a policy that controls the use of the endpoint to access Amazon S3 resources. The default policy allows access by any user or service within the VPC, using credentials from any AWS account, to any Amazon S3 resource; including Amazon S3 resources for an AWS account other than the account with which the VPC is associated. For more information, see Control access to services with VPC endpoints (p. 36).
The source IPv4 addresses from instances in your affected subnets as received by Amazon S3 change from public IPv4 addresses to the private IPv4 addresses in your VPC. An endpoint switches network routes, and disconnects open TCP connections. The previous connections that used public IPv4 addresses are not resumed. We recommend that you do not have any critical tasks running when you create or modify an endpoint; or that you test to ensure that your software can automatically reconnect to Amazon S3 after the connection break.

You cannot use an IAM policy or bucket policy to allow access from a VPC IPv4 CIDR range (the private IPv4 address range). VPC CIDR blocks can be overlapping or identical, which may lead to unexpected results. Therefore, you cannot use the `aws:SourceIp` condition in your IAM policies for requests to Amazon S3 through a VPC endpoint. This applies to IAM policies for users and roles, and any bucket policies. If a statement includes the `aws:SourceIp` condition, the value fails to match any provided IP address or range. Instead, you can do the following:

- Use your route tables to control which instances can access resources in Amazon S3 via the endpoint.
- For bucket policies, you can restrict access to a specific endpoint or to a specific VPC. For more information, see Amazon S3 bucket policies (p. 28).

Endpoints currently do not support cross-Region requests—ensure that you create your endpoint in the same Region as your bucket. You can find the location of your bucket by using the Amazon S3 console, or by using the `get-bucket-location` command. Use a Region-specific Amazon S3 endpoint to access your bucket; for example, `mybucket.s3.us-west-2.amazonaws.com`. For more information about Region-specific endpoints for Amazon S3, see Amazon Simple Storage Service (S3) in Amazon Web Services General Reference. If you use the AWS CLI to make requests to Amazon S3, set your default Region to the same Region as your bucket, or use the `--region` parameter in your requests.

**Note**

Treat the US Standard Region for Amazon S3 as mapped to the `us-east-1` Region.

Endpoints are currently supported for IPv4 traffic only.

Before you use endpoints with Amazon S3, ensure that you have also read the following general limitations: Gateway endpoint limitations (p. 23). For information about creating and viewing S3 buckets, see How Do I Create an S3 Bucket and How Do I View the Properties for an S3 Bucket in the Amazon Simple Storage Service User Guide.

If you use other AWS services in your VPC, they might use S3 buckets for certain tasks. Ensure that your endpoint policy allows full access to Amazon S3 (the default policy), or that it allows access to the specific buckets that are used by these services. Alternatively, only create an endpoint in a subnet that is not used by any of these services, to allow the services to continue accessing S3 buckets using public IP addresses.

The following table lists AWS services that might be affected by an endpoint, and any specific information for each service.

<table>
<thead>
<tr>
<th>AWS service</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon AppStream 2.0</td>
<td>Your endpoint policy must allow access to the specific buckets that are used by AppStream 2.0 for storing user content. For more information, see Using Amazon S3 VPC Endpoints for Home Folders and Application Settings Persistence in the Amazon AppStream 2.0 Administration Guide.</td>
</tr>
<tr>
<td>AWS CloudFormation</td>
<td>If you have resources in your VPC that must respond to a wait condition or custom resource request, your endpoint policy must allow at least access to the specific buckets that are used by these resources. For more information, see Setting Up VPC Endpoints for AWS CloudFormation.</td>
</tr>
<tr>
<td><strong>AWS service</strong></td>
<td><strong>Note</strong></td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CodeDeploy</td>
<td>Your endpoint policy must allow full access to Amazon S3, or allow access to any S3 buckets that you’ve created for your CodeDeploy deployments.</td>
</tr>
<tr>
<td>Elastic Beanstalk</td>
<td>Your endpoint policy must allow at least access to any S3 buckets used for Elastic Beanstalk applications. For more information, see Using Elastic Beanstalk with Amazon S3 in the AWS Elastic Beanstalk Developer Guide.</td>
</tr>
<tr>
<td>Amazon EMR</td>
<td>Your endpoint policy must allow access to the Amazon Linux repositories and other buckets that are used by Amazon EMR. For more information, see Minimum Amazon S3 Policy for Private Subnet in the Amazon EMR Management Guide.</td>
</tr>
<tr>
<td>AWS OpsWorks</td>
<td>Your endpoint policy must allow at least access to specific buckets that are used by AWS OpsWorks. For more information, see Running a Stack in a VPC in the AWS OpsWorks User Guide.</td>
</tr>
<tr>
<td>AWS Systems Manager</td>
<td>Your endpoint policy must allow access to the Amazon S3 buckets used by Patch Manager for patch baseline operations in your AWS Region. These buckets contain the code that is retrieved and run on instances by the patch baseline service. For more information, see Create a Virtual Private Cloud Endpoint in the AWS Systems Manager User Guide. For a list of S3 bucket permissions required by SSM Agent for its operations, see Minimum S3 Bucket Permissions for SSM Agent in the AWS Systems Manager User Guide.</td>
</tr>
<tr>
<td>Amazon Elastic Container Registry</td>
<td>Your endpoint policy must allow access to the Amazon S3 buckets used by Amazon ECR to store Docker image layers. For more information, see Minimum Amazon S3 Bucket Permissions for Amazon ECR in the Amazon Elastic Container Registry User Guide.</td>
</tr>
<tr>
<td>Amazon WorkDocs</td>
<td>If you use an Amazon WorkDocs client in WorkSpaces or an EC2 instance, your endpoint policy must allow full access to Amazon S3.</td>
</tr>
<tr>
<td>WorkSpaces</td>
<td>WorkSpaces does not directly depend on Amazon S3. However, if you provide WorkSpaces users with internet access, then take note that websites, HTML emails, and internet services from other companies may depend on Amazon S3. Ensure that your endpoint policy allows full access to Amazon S3 to allow these services to continue to work correctly.</td>
</tr>
</tbody>
</table>
Traffic between your VPC and S3 buckets does not leave the Amazon network.

**Endpoint policies for Amazon S3**

The following are example endpoint policies for accessing Amazon S3. For more information, see Use VPC endpoint policies (p. 36). It is up to the user to determine the policy restrictions that meet their business needs.

**Important**
All types of policies — IAM user policies, endpoint policies, S3 bucket policies, and Amazon S3 ACL policies (if any) — must grant the necessary permissions for access to Amazon S3 to succeed.

AWS recommends that you use IAM conditions, rather than the IAM **Principal** element, in VPC endpoint policies when you are restricting use of the endpoint to particular callers. Examples of such conditions are **aws:PrincipalArn**, **aws:PrincipalAccount**, **aws:PrincipalOrgId**, and **aws:PrincipalOrgPaths**. For more information about condition context keys, see AWS global condition context keys in the AWS Identity and Access Management User Guide.

**Example Example: Restricting access to a specific bucket**

You can create a policy that restricts access to specific S3 buckets only. This is useful if you have other AWS services in your VPC that use S3 buckets. The following is an example of a policy that restricts access to the specified bucket only.

```json
{
    "Sid": "AccessToSpecificBucket",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "s3:ListBucket",
        "s3:GetObject",
        "s3:PutObject"
    ],
    "Resource": [
        "arn:aws:s3:::example-bucket",
        "arn:aws:s3:::example-bucket/*"
    ]
}
```

**Example Example: Restricting use of this VPC endpoint to a specific IAM role in an account**

You can create a policy that restricts use of the VPC endpoint to a specific IAM role. The following is an example that restricts the access to the specified role in the specified AWS account.

```json
{
    "Sid": "Restrict-acess-to-specific-IAM-role",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "ArnEquals": {
            "aws:PrincipalArn": "arn:aws:iam::111122223333:role/SomeRole"
        }
    }
}
```

**Example Example: Restricting use of this VPC endpoint to a users in a specific account**

You can create a policy that restricts use of the VPC endpoint to a specific account. The following is an example that restricts the access to users in the specified AWS account.
Example Example: Enabling access to the Amazon Linux AMI repositories

The Amazon Linux repositories are Amazon S3 buckets in each Region. To allow instances in your VPC to access the repositories through an endpoint, create an endpoint policy.

The following policy allows access to the Amazon Linux repositories. Be sure to replace `region` with your AWS Region (for example, us-east-1).

```json

{  
  "Statement": [  
    {  
      "Sid": "AmazonLinuxAMIRepositoryAccess",  
      "Effect": "Allow",  
      "Principal": "*",  
      "Action": [  
        "s3:GetObject"  
      ],  
      "Resource": [  
        "arn:aws:s3:::packages.region.amazonaws.com/*",  
        "arn:aws:s3:::repo.region.amazonaws.com/*"  
      ]  
    }  
  ]
}

```

The following policy allows access to the Amazon Linux 2 repositories. Be sure to replace `region` with your AWS Region (for example, us-east-1).

```json

{  
  "Statement": [  
    {  
      "Sid": "AmazonLinux2AMIRepositoryAccess",  
      "Effect": "Allow",  
      "Principal": "*",  
      "Action": [  
        "s3:GetObject"  
      ],  
      "Resource": [  
        "arn:aws:s3:::amazonlinux.region.amazonaws.com/**"  
      ]  
    }  
  ]
}

```
Amazon S3 bucket policies

You can use bucket policies to control access to buckets from specific endpoints, VPCs, IP address ranges, or AWS accounts.

You cannot use the `aws:SourceIp` condition in your bucket policies for requests to Amazon S3 through a VPC endpoint. The condition fails to match any specified IP address or IP address range, and may have an undesired effect when you make requests to an Amazon S3 bucket. For example:

- You have a bucket policy with a `Deny` effect and a `NotIpAddress` condition that's intended to grant access from a single or limited range of IP addresses only. For requests to the bucket through an endpoint, the `NotIpAddress` condition is always matched, and the statement's effect applies, assuming other constraints in the policy match. Access to the bucket is denied.
- You have a bucket policy with a `Deny` effect and an `IpAddress` condition that's intended to deny access to a single or limited range of IP addresses only. For requests to the bucket through an endpoint, the condition is not matched, and the statement does not apply. Access to the bucket is allowed, assuming there are other statements that allow access without an `IpAddress` condition.

Instead, use `aws:VpcSourceIp` to control access from specific IP address ranges.

To enable IAM users to work with bucket policies, you must grant them permission to use the `s3:GetBucketPolicy` and `s3:PutBucketPolicy` actions.

For more information about bucket policies for Amazon S3, see Using Bucket Policies and User Policies in Amazon Simple Storage Service User Guide.

**Example: Restricting access to a specific endpoint**

You can create a bucket policy that restricts access to a specific endpoint by using the `aws:sourceVpce` condition. The following is an example of an S3 bucket policy that allows access to bucket `example_bucket` from endpoint `vpce-1a2b3c4d`. The policy denies all access to the bucket if the specified endpoint is not used. The `aws:sourceVpce` condition does not require an ARN for the VPC endpoint resource, only the endpoint ID. This example assumes that there is also a policy statement that allows the access required for your use cases.

```json
{
  "Version": "2012-10-17",
  "Id": "Access-to-bucket-using-specific-endpoint",
  "Statement": [
    {
      "Sid": "Access-to-specific-VPCE-only",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": ["arn:aws:s3:::example_bucket",
                   "arn:aws:s3:::example_bucket/*"],
      "Condition": {
        "StringNotEquals": {
          "aws:sourceVpce": "vpce-1a2b3c4d"
        }
      }
    }
  ]
}
```

**Example: Restricting access to a specific VPC**

You can create a bucket policy that restricts access to specific VPCs by using the `aws:sourceVpc` condition. This is useful if you have multiple endpoints configured in the same VPC, and you want to
manage access to your S3 buckets for all of your endpoints. The following is an example of a policy that allows VPC vpc-111bbb22 to access example_bucket and its objects. The policy denies all access to the bucket if the specified VPC is not used. The aws:sourceVpc condition does not require an ARN for the VPC resource, only the VPC ID. This example assumes that there is also a policy statement that allows the access required for your use cases.

```json
{
  "Version": "2012-10-17",
  "Id": "Access-to-bucket-using-specific-VPC",
  "Statement": [
    {
      "Sid": "Access-to-specific-VPC-only",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": ["arn:aws:s3:::example_bucket",
                   "arn:aws:s3:::example_bucket/*"],
      "Condition": {
        "StringNotEquals": {
          "aws:sourceVpc": "vpc-111bbb22"
        }
      }
    }
  ]
}
```

**Example Example: Restricting access to a specific IP address range**

You can create a policy that restricts access to specific IP address ranges by using the aws:VpcSourceIp condition. The following is an example of a policy that allows 172.31.0.0/16 to access example_bucket and its objects. The policy denies access to the bucket from other IP address ranges. This example assumes that there is also a policy statement that allows the access required for your use cases.

```json
{
  "Version": "2012-10-17",
  "Id": "Policy1415115909152",
  "Statement": [
    {
      "Sid": "Access-to-specific-VPC-CIDR-only",
      "Effect": "Deny",
      "Principal": "*",
      "Action": "s3:*",
      "Resource": ["arn:aws:s3:::example_bucket",
                   "arn:aws:s3:::example_bucket/*"],
      "Condition": {
        "NotIpAddress": {
          "aws:VpcSourceIp": "172.31.0.0/16"
        }
      }
    }
  ]
}
```

**Example Example: Restricting access to buckets in a specific AWS account**

You can create a policy that restricts access to the S3 buckets in a specific AWS account by using the s3:ResourceAccount condition. This is useful if you would like to restrict clients within your VPC from accessing buckets that you do not own. The following is an example of a policy that restricts access to resources owned by a single AWS account, with the account ID of 111122223333. This example assumes that there is also a policy statement that allows the access required for your use cases.
Endpoints for Amazon DynamoDB

If you've already set up access to your DynamoDB tables from your VPC, you can continue to access the tables as you normally would after you set up a gateway endpoint. However, take note of the following:

- Your endpoint has a policy that controls the use of the endpoint to access DynamoDB resources. The default policy allows access by any user or service within the VPC, using credentials from any AWS account, to any DynamoDB resource. For more information, see Control access to services with VPC endpoints (p. 36).
- DynamoDB does not support resource-based policies (for example, on tables). Access to DynamoDB is controlled through the endpoint policy and IAM policies for individual IAM users and roles.
- Endpoints currently do not support cross-region requests—ensure that you create your endpoint in the same Region as your DynamoDB tables.
- If you use AWS CloudTrail to log DynamoDB operations, the log files contain the private IP address of the EC2 instance in the VPC and the endpoint ID for any actions performed through the endpoint.
- The source IPv4 addresses from instances in your affected subnets change from public IPv4 addresses to the private IPv4 addresses from your VPC. An endpoint switches network routes and disconnects open TCP connections. The previous connections that used public IPv4 addresses are not resumed. We recommend that you do not have any critical tasks running when you create or modify an endpoint; or that you test to ensure that your software can automatically reconnect to DynamoDB after the connection break.

Before you use endpoints with DynamoDB, ensure that you have also read the following general limitations: Gateway endpoint limitations (p. 23).

For more information about creating a gateway VPC endpoint, see Gateway VPC endpoints (p. 20).

Endpoint policies for DynamoDB

An endpoint policy is an IAM policy that you attach to an endpoint that allows access to some or all of the service to which you're connecting. The following are example endpoint policies for accessing DynamoDB.

Important
All types of policies — IAM user policies and endpoint policies — must grant the necessary permissions for access to DynamoDB to succeed.
Example Example: Read-only access

You can create a policy that restricts actions to only listing and describing DynamoDB tables through the VPC endpoint.

```json
{
  "Statement": [
    {
      "Sid": "ReadOnly",
      "Principal": "*",
      "Action": [
        "dynamodb:DescribeTable",
        "dynamodb:ListTables"
      ],
      "Effect": "Allow",
      "Resource": "*
    }
  ]
}
```

Example Example: Restrict access to a specific table

You can create a policy that restricts access to a specific DynamoDB table. In this example, the endpoint policy allows access to StockTable only.

```json
{
  "Statement": [
    {
      "Sid": "AccessToSpecificTable",
      "Principal": "*",
      "Action": [
        "dynamodb:Batch*",
        "dynamodb:Delete*",
        "dynamodb:DescribeTable",
        "dynamodb:GetItem",
        "dynamodb:PutItem",
        "dynamodb:Update*"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/StockTable"
    }
  ]
}
```

Use IAM policies to control access to DynamoDB

You can create an IAM policy for your IAM users, groups, or roles to restrict access to DynamoDB tables from a specific VPC endpoint only. To do this, you can use the `aws:sourceVpce` condition key for the table resource in your IAM policy.

For more information about managing access to DynamoDB, see Authentication and Access Control for Amazon DynamoDB in the Amazon DynamoDB Developer Guide.

Example Example: Restrict access from a specific endpoint

In this example, users are denied permission to work with DynamoDB tables, except if accessed through endpoint `vpce-11aa22bb`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyAccessFromSpecificEndpoint",
      "Principal": "*",
      "Effect": "Deny",
      "Action": "*",
      "Resource": "*",
      "Condition": {
        "aws:sourceVpce": "vpce-11aa22bb"
      }
    }
  ]
}
```
"Statement": [
    {
        "Sid": "AccessFromSpecificEndpoint",
        "Action": "dynamodb:*",
        "Effect": "Deny",
        "Condition": {
            "StringNotEquals": {
                "aws:sourceVpce": "vpce-11aa22bb"
            }
        }
    }
]

Example Example: Restricting use of this VPC endpoint to a specific IAM role in an account

You can create a policy that restricts use of the VPC endpoint to a specific IAM role. The following is an example that restricts the access to SomeRole in account 111122223333.

{
    "Sid": "Restrict-Access-to-Specific-IAM-Role",
    "Effect": "Allow",
    "Principal": "+",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "ArnEquals": {
            "aws:PrincipalArn": "arn:aws:iam::111122223333:role/SomeRole"
        }
    }
}

Example Example: Restricting use of this VPC endpoint to a users in a specific account

You can create a policy that restricts use of the VPC endpoint to a specific account. The following is an example that restricts the access to users in account 111122223333.

{
    "Sid": "AllowCallersFromAccount111122223333",
    "Effect": "Allow",
    "Principal": "+",
    "Action": "*",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:PrincipalAccount": "111122223333"
        }
    }
}

Create a gateway endpoint

To create an endpoint, you must specify the VPC in which you want to create the endpoint, and the service to which you want to establish the connection.

To create a gateway endpoint using the console

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints, Create Endpoint.
3. For Service Name, choose the service to which to connect. To create a gateway endpoint to DynamoDB or Amazon S3, ensure that the Type column indicates Gateway.
4. Complete the following information, and choose Create endpoint.
Create a gateway endpoint

- For **VPC**, select a VPC in which to create the endpoint.
- For **Configure route tables**, select the route tables to be used by the endpoint. We automatically add a route that points traffic destined for the service to the endpoint to the selected route tables.
- For **Policy**, choose the type of policy. You can leave the default option, **Full Access**, to allow full access to the service. Alternatively, you can select **Custom**, and then use the AWS Policy Generator to create a custom policy, or enter your own policy in the policy window.
- (Optional) Add or remove a tag.

  [Add a tag] Choose **Add tag** and do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.

  [Remove a tag] Choose the delete button (“x”) to the right of the tag's Key and Value.

After you've created an endpoint, you can view information about it.

**To view information about a gateway endpoint using the console**

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose **Endpoints** and select your endpoint.
3. To view information about the endpoint, choose **Summary**. You can get the AWS prefix list name for the service in the **Service** box.
4. To view information about the route tables that are used by the endpoint, choose **Route Tables**.
5. To view the IAM policy that's attached to your endpoint, choose **Policy**.

  **Note**
  The **Policy** tab only displays the endpoint policy. It does not display any information about IAM policies for IAM users that have permission to work with endpoints. It also does not display service-specific policies; for example, S3 bucket policies.

**To create and view an endpoint using the AWS CLI**

1. Use the **describe-vpc-endpoint-services** command to get a list of available services. In the output that's returned, take note of the name of the service to which you want to connect. The **serviceType** field indicates whether you connect to the service via an interface endpoint or a gateway endpoint.

   ```bash
   aws ec2 describe-vpc-endpoint-services
   ```

   ```json
   {
     "serviceDetailSet": [
       {
         "serviceType": [
           {
             "serviceType": "Gateway"
           }
         ]
       }
   }
   ...
   ```

2. To create a gateway endpoint (for example, to Amazon S3), use the **create-vpc-endpoint** command and specify the VPC ID, service name, and route tables that will use the endpoint. You can optionally use the **--policy-document** parameter to specify a custom policy to control access to the service. If the parameter is not used, we attach a default policy that allows full access to the service.

   For Amazon S3, you must set the **--vpc-endpoint-type** parameter to **Gateway**.
Modify your security group

If the VPC security group associated with your instance restricts outbound traffic, you must add a rule to allow traffic destined for the AWS service to leave your instance.

To add an outbound rule for a gateway endpoint
1. Open the Amazon VPC console at `https://console.aws.amazon.com/vpc/`.
2. In the navigation pane, choose Security Groups.
3. Select your VPC security group, choose the Outbound rules tab, and then choose Edit outbound rules.
4. Select the type of traffic from the Type list, and enter the port range, if required. For example, if you use your instance to retrieve objects from Amazon S3, choose HTTPS from the Type list.
5. For Destination, start entering pl- to display a list of prefix list IDs and names for the available AWS services. Choose the prefix list ID for the AWS service, or enter it.
6. Choose Save.

To get the prefix list name, ID, and IP address range for an AWS service using the command line or API

- `describe-prefix-lists` (AWS CLI)
- `Get-EC2PrefixList` (AWS Tools for Windows PowerShell)
- `DescribePrefixLists` (Amazon EC2 Query API)
Modify a gateway endpoint

You can modify a gateway endpoint by changing or removing its policy, and adding or removing the route tables that are used by the endpoint.

If you want to migrate an existing Amazon S3 gateway endpoint to an interface endpoint, after you create the Amazon S3 interface endpoint, delete the Amazon S3 gateway endpoint. For more information, see the section called “Create an interface endpoint” (p. 9) and the section called “Delete a VPC endpoint” (p. 37).

To change the policy associated with a gateway endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select your endpoint.
3. Choose Actions, Edit policy.
4. You can choose Full Access to allow full access. Alternatively, choose Custom, and then use the AWS Policy Generator to create a custom policy, or enter your own policy in the policy window. When you're done, choose Save.

   Note
   It can take a few minutes for policy changes to take effect.

To add or remove route tables used by a gateway endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints and select your endpoint.
3. Choose Actions, Manage Route Tables.
4. Select or deselect the required route tables, and choose Modify Route Tables.

To modify a gateway endpoint using the AWS CLI

1. Use the describe-vpc-endpoints command to get the ID of your gateway endpoint.

   aws ec2 describe-vpc-endpoints

2. The following example uses the modify-vpc-endpoint command to associate route table rtb-aaa222bb with the gateway endpoint, and reset the policy document.

   aws ec2 modify-vpc-endpoint --vpc-endpoint-id vpce-1a2b3c4d --add-route-table-ids rtb-aaa222bb --reset-policy

To modify a VPC endpoint using the AWS Tools for Windows PowerShell or an API

- Edit-EC2VpcEndpoint (AWS Tools for Windows PowerShell)
- ModifyVpcEndpoint (Amazon EC2 Query API)

Add or remove gateway endpoint tags

Tags provide a way to identify the gateway endpoint. You can add or remove a tag.
To add or remove a gateway endpoint tag

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. Select the gateway endpoint and choose **Actions, Add/Edit Tags**.
4. Add or remove a tag.

   [Add a tag] Choose **Create tag** and do the following:
   • For **Key**, enter the key name.
   • For **Value**, enter the key value.

   [Remove a tag] Choose the delete button (“x”) to the right of the tag’s Key and Value.

To add or remove a tag using the AWS Tools for Windows PowerShell or an API

- `create-tags` (AWS CLI)
- `CreateTags` (AWS Tools for Windows PowerShell)
- `delete-tags` (AWS CLI)
- `DeleteTags` (AWS Tools for Windows PowerShell)

Control access to services with VPC endpoints

When you create an interface or gateway endpoint, you can attach an endpoint policy to it that controls access to the service to which you are connecting. Endpoint policies must be written in JSON format. Not all services support endpoint policies.

If you're using an endpoint to Amazon S3, you can also use Amazon S3 bucket policies to control access to buckets from specific endpoints, or specific VPCs. For more information, see Amazon S3 bucket policies (p. 28).

Contents
- Use VPC endpoint policies (p. 36)
- Security groups (p. 37)

Use VPC endpoint policies

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you do not attach a policy when you create an endpoint, we attach a default policy for you that allows full access to the service. If a service does not support endpoint policies, the endpoint allows full access to the service. An endpoint policy does not override or replace IAM user policies or service-specific policies (such as S3 bucket policies). It is a separate policy for controlling access from the endpoint to the specified service.

You cannot attach more than one policy to an endpoint. However, you can modify the policy at any time. If you do modify a policy, it can take a few minutes for the changes to take effect. For more information about writing policies, see Overview of IAM Policies in the IAM User Guide.

Your endpoint policy can be like any IAM policy; however, take note of the following:

- Your policy must contain a **Principal** element. For additional information related gateway endpoints, see Endpoint policies for gateway endpoints (p. 37).
- The size of an endpoint policy cannot exceed 20,480 characters (including white space).
For information about the services that support endpoint policies, see Services that support AWS PrivateLink (p. 68).

**Endpoint policies for gateway endpoints**

For endpoint policies that are applied to gateway endpoints, if you specify `Principal` in the format "AWS":"account-ID" or "AWS":"arn:aws:iam::account-ID:root", access is granted to the account root user only, and not all IAM users and roles for the account.

If you specify an Amazon Resource Name (ARN) for the `Principal` element, the ARN is transformed to a unique principal ID when the policy is saved.

For example endpoint policies for Amazon S3 and DynamoDB, see the following topics:

- Endpoint policies for Amazon S3 (p. 26)
- Endpoint policies for DynamoDB (p. 30)

**Security groups**

When you create an interface endpoint, you can associate security groups with the endpoint network interface that is created in your VPC. If you do not specify a security group, the default security group for your VPC is automatically associated with the endpoint network interface. You must ensure that the rules for the security group allow communication between the endpoint network interface and the resources in your VPC that communicate with the service.

For a gateway endpoint, if your security group's outbound rules are restricted, you must add a rule that allows outbound traffic from your VPC to the service that's specified in your endpoint. To do this, you can use the service's AWS prefix list ID as the destination in the outbound rule. For more information, see Modify your security group (p. 34).

Security groups do not apply to Gateway Load Balancer endpoints.

**Delete a VPC endpoint**

If you no longer require an endpoint, you can delete it. Deleting a gateway endpoint also deletes the endpoint routes in the route tables that were used by the endpoint, but doesn't affect any security groups associated with the VPC in which the endpoint resides. Deleting an interface endpoint or Gateway Load Balancer endpoint also deletes the endpoint network interfaces.

A Gateway Load Balancer endpoint cannot be deleted if there are routes in your route tables that point to the endpoint.

**To delete an endpoint**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoints** and select your endpoint.
3. Choose **Actions, Delete Endpoint**.
4. In the confirmation screen, choose **Yes, Delete**.

**To delete a VPC endpoint**

- delete-vpc-endpoints (AWS CLI)
- Remove-EC2VpcEndpoint (AWS Tools for Windows PowerShell)
Delete a VPC endpoint

- `DeleteVpcEndpoints` (Amazon EC2 Query API)
VPC endpoint services (AWS PrivateLink)

You can create your own application in your VPC and configure it as an AWS PrivateLink-powered service (referred to as an endpoint service). Other AWS principals can create a connection from their VPC to your endpoint service using an interface VPC endpoint (p. 3) or a Gateway Load Balancer endpoint (p. 16), depending on the type of service. You are the service provider, and the AWS principals that create connections to your service are service consumers.

VPC endpoint services for interface endpoints

The following are the general steps to create an endpoint service for interface endpoints.

1. Create a Network Load Balancer for your application in your VPC and configure it for each subnet (Availability Zone) in which the service should be available. The load balancer receives requests from service consumers and routes it to your service. Alternatively, you can configure an Application Load Balancer as a target of the Network Load Balancer, and then the Application Load Balancer can route the requests to your service. For more information, see the User Guide for Network Load Balancers.

   We recommend that you configure your service in all Availability Zones within the Region.

2. Create a VPC endpoint service configuration and specify your Network Load Balancer.

The following are the general steps to enable service consumers to connect to your service.

1. Grant permissions to specific service consumers (AWS accounts, IAM users, and IAM roles) to create a connection to your endpoint service.

2. A service consumer that has been granted permissions creates an interface endpoint to your service, optionally in each Availability Zone in which you configured your service.

3. To activate the connection, accept the interface endpoint connection request. By default, connection requests must be manually accepted. However, you can configure the acceptance settings for your endpoint service so that any connection requests are automatically accepted.
The combination of permissions and acceptance settings can help you control which service consumers (AWS principals) can access your service. For example, you can grant permissions to selected principals that you trust and automatically accept all connection requests, or you can grant permissions to a wider group of principals and manually accept specific connection requests that you trust.

In the following diagram, the account owner of VPC B is a service provider, and has a service running on instances in subnet B. The owner of VPC B has a service endpoint (vpce-svc-1234) with an associated Network Load Balancer that points to the instances in subnet B as targets. Instances in subnet A of VPC A use an interface endpoint to access the services in subnet B.

For low latency and fault tolerance, we recommend using a Network Load Balancer with targets in every Availability Zone of the AWS Region. To help achieve high availability for service consumers that use zonal DNS hostnames (p. 14) to access the service, you can enable cross-zone load balancing. Cross-zone load balancing enables the load balancer to distribute traffic across the registered targets in all enabled Availability Zones. For more information, see Cross-Zone Load Balancing in the User Guide for Network Load Balancers. Regional data transfer charges may apply to your account when you enable cross-zone load balancing.

In the following diagram, the owner of VPC B is the service provider, and it has configured a Network Load Balancer with targets in two different Availability Zones. The service consumer (VPC A) has created interface endpoints in the same two Availability Zones in their VPC. Requests to the service from instances in VPC A can use either interface endpoint.
Endpoint service Availability Zone considerations

When you create an endpoint service, the service is created in the Availability Zone that is mapped to your account and is independent from other accounts. When the service provider and the consumer are in different accounts, use the Availability Zone ID to uniquely and consistently identify the endpoint service Availability Zone. For example, use1-az1 is an AZ ID for the us-east-1 Region and maps to the same location in every AWS account. For information about Availability Zone IDs, see AZ IDs for Your Resources in the AWS RAM User Guide or use describe-availability-zones.

When the service provider and the consumer have different accounts and use multiple Availability Zones, and the consumer views the VPC endpoint service information, the response only includes the common Availability Zones. For example, when the service provider account uses us-east-1a and us-east-1c and the consumer uses us-east-1a and us-east-1b, the response includes the VPC endpoint services in the common Availability Zone, us-east-1a.

Endpoint service DNS names

When you create a VPC endpoint service, AWS generates endpoint-specific DNS hostnames that you can use to communicate with the service. These names include the VPC endpoint service ID and the Region code. For example, vpce-svc-01234567890abcdef.us-east-1.vpce.amazonaws.com. By default, your consumers access the service with that DNS name and usually need to modify the application configuration.

If the endpoint service is for an AWS service, or a service available in the AWS Marketplace, there is a default DNS name. For other services, the service provider can configure a private DNS name so consumers can access the service using an existing DNS name without making changes to their applications. For more information, see Private DNS names (p. 59).
Service providers can use the `ec2:VpceServicePrivateDnsName` condition context key in an IAM policy statement to control what private DNS names can be created. For more information, see Actions defined by Amazon EC2 in the IAM User Guide.

### Private DNS name requirements

Service providers can specify a private DNS name for a new endpoint service, or an existing endpoint service. To use a private DNS name, enable the feature, and then specify a private DNS name. Before consumers can use the private DNS name, you must verify that you have control of the domain/subdomain. You can initiate domain ownership verification using the Amazon VPC console or API. After ownership of the domain is verified, service consumers can access your service using the private DNS name.

### Connect to on-premises data centers

You can use the following types of connections for a connection between an interface endpoint and your on-premises data center:

- AWS Direct Connect
- AWS Site-to-Site VPN

### Access services through a VPC peering connection

You can use a VPC peering connection with a VPC endpoint to allow private access to consumers across the VPC peering connection. For more information, see Examples: Services using AWS PrivateLink and VPC peering in the Amazon VPC User Guide.

### Use proxy protocol for connection information

A Network Load Balancer provides source IP addresses to your application (your service). When service consumers send traffic to your service through an interface endpoint, the source IP addresses provided to your application are the private IP addresses of the Network Load Balancer nodes, and not the IP addresses of the service consumers.

If you need the IP addresses of the service consumers and their corresponding interface endpoint IDs, enable Proxy Protocol on your load balancer and get the client IP addresses from the Proxy Protocol header. For more information, see Proxy protocol in the User Guide for Network Load Balancers.

### Rules and limitations

To use endpoint services, you need to be aware of the current rules and limitations:

- An endpoint service supports IPv4 traffic over TCP only.
- Service consumers can use the endpoint-specific DNS hostnames to access the endpoint service, or the private DNS name.
- If an endpoint service is associated with multiple Network Load Balancers, then for a specific Availability Zone, an interface endpoint establishes a connection with one load balancer only.
- For the endpoint service, the associated Network Load Balancer can support 55,000 simultaneous connections or about 55,000 connections per minute to each unique target (IP address and port). If you exceed these connections, there is an increased chance of port allocation errors. To fix the port allocation errors, add more targets to the target group. For information about Network Load Balancer target groups, see Target groups for your Network Load Balancers and Register targets with your target group in the User Guide for Network Load Balancers.
• Availability Zones in your account might not map to the same locations as Availability Zones in another account. For example, your Availability Zone us-east-1a might not be the same location as us-east-1a for another account. For more information, see Regions and Zones. When you configure an endpoint service, it's configured in the Availability Zones as mapped to your account.

• An endpoint service is only available in the Region where you created it.

• Review the service-specific limits for your endpoint service.

• Review the security best practices and examples for endpoint services. For more information, see Policy best practices and the section called "Control access to services" (p. 36).

VPC endpoint services for Gateway Load Balancer endpoints

You can use a Gateway Load Balancer to distribute traffic to a fleet of network virtual appliances. The appliances can be used for security inspection, compliance, policy controls, and other networking services. You can then configure the Gateway Load Balancer as a VPC endpoint service, to enable other AWS principals to access the service through a Gateway Load Balancer endpoint.

The following are the general steps to create an endpoint service for a Gateway Load Balancer endpoint.

1. Create a Gateway Load Balancer for your virtual appliances. For more information, see Getting started with Gateway Load Balancers.

   We recommend that you configure your service in all Availability Zones within the Region.

2. Create a VPC endpoint service configuration and specify your Gateway Load Balancer.

The following are the general steps to enable service consumers to connect to your service.

1. Grant permissions to specific service consumers (AWS accounts, IAM users, and IAM roles) to create a connection to your endpoint service.

2. A service consumer that has been granted permissions creates a Gateway Load Balancer endpoint (p. 16) to your service.

3. To activate the connection, accept the endpoint connection request. By default, connection requests must be manually accepted. However, you can configure the acceptance settings for your endpoint service so that any connection requests are automatically accepted.

In the following example, a fleet of security appliances is configured behind a Gateway Load Balancer in the security VPC. An endpoint service is configured for the Gateway Load Balancer. The owner of the service consumer VPC creates a Gateway Load Balancer endpoint in subnet 2 in their VPC (represented by an endpoint network interface). All traffic entering the VPC through the internet gateway is first routed to the Gateway Load Balancer endpoint for inspection in the security VPC before it's routed to the destination subnet. Similarly, all traffic leaving the EC2 instance in subnet 1 is first routed to Gateway Load Balancer endpoint for inspection in the security VPC before it's routed to the internet.
Amazon Virtual Private Cloud AWS PrivateLink

Availability Zone considerations

For more information about the routing configuration for this scenario, see Routing to a Gateway Load Balancer endpoint in the Amazon VPC User Guide.

Availability Zone considerations

When you create an endpoint service, the service is created in the Availability Zone that is mapped to your account and is independent from other accounts. When the service provider and the consumer are in different accounts, use the Availability Zone ID to uniquely and consistently identify the endpoint service Availability Zone. For example, use1-a1 is an AZ ID for the us-east-1 Region and maps to the same location in every AWS account. For information about Availability Zone IDs, see AZ IDs for Your Resources in the AWS RAM User Guide or use describe-availability-zones.

When the service provider and the consumer have different accounts and use multiple Availability Zones, and the consumer views the VPC endpoint service information, the response only includes the common Availability Zones. For example, when the service provider account uses us-east-1a and us-east-1c and the consumer uses us-east-1a and us-east-1b, the response includes the VPC endpoint services in the common Availability Zone, us-east-1a.

Rules and limitations

To use endpoint services for Gateway Load Balancer endpoints, be aware of the current rules and limitations:

• If an endpoint service is associated with multiple Gateway Load Balancers, then for a specific Availability Zone, a Gateway Load Balancer endpoint establishes a connection with one load balancer only.
• Private DNS names are not supported.
• Availability Zones in your account might not map to the same locations as Availability Zones in another account. For example, your Availability Zone `us-east-1a` might not be the same location as `us-east-1a` for another account. For more information, see Regions and Zones. When you configure an endpoint service, it's configured in the Availability Zones as mapped to your account.

Create a VPC endpoint service configuration for interface endpoints

You can create an endpoint service configuration using the Amazon VPC console or the command line. For more information about VPC endpoint limitations, see Limitations in the Amazon VPC User Guide.

Before you begin, ensure that you have created one or more Network Load Balancers in your VPC for your service. For more information, see Getting started with Network Load Balancers in the User Guide for Network Load Balancers.

In your configuration, you can optionally specify that any interface endpoint connection requests to your service must be manually accepted by you. You can create a notification (p. 51) to receive alerts when there are connection requests. If you do not accept a connection, service consumers cannot access your service.

**Note**
Regardless of the acceptance settings, service consumers must also have permissions (p. 47) to create a connection to your service.

After you create an endpoint service configuration, you must add permissions to enable service consumers to create interface endpoints to your service.

**Console**

**To create an endpoint service**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**, Create endpoint service.
3. For **Load balancer type**, select **Network**.
4. For **Available load balancers**, select the Network Load Balancers to associate with the endpoint service.
5. For **Require acceptance for endpoint**, select the check box to accept connection requests to your service manually. Otherwise, endpoint connections are automatically accepted.
6. For **Enable private DNS name**, select the check box to associate a private DNS name with the service and then enter the private DNS name.
7. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.
8. Choose **Create**.

**AWS CLI**

**To create an endpoint service**

Use the create-vpc-endpoint-service-configuration command and specify one or more ARNs for your Network Load Balancers. You can optionally specify if acceptance is required for connecting to your service and if the service has a private DNS name.
Create a VPC endpoint service configuration for Gateway Load Balancer endpoints

Before you begin, ensure that you have created one or more Gateway Load Balancers in your VPC for your service. For more information, see Getting started with Gateway Load Balancers.

In your configuration, you can optionally specify that any Gateway Load Balancer endpoint connection requests to your service must be manually accepted by you. You can create a notification (p. 51) to receive alerts when there are connection requests. If you do not accept a connection, service consumers cannot access your service.

After you create an endpoint service configuration, you must add permissions (p. 47) to enable service consumers to create a Gateway Load Balancer endpoint to your service.
Console

**To create an endpoint service**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services, Create endpoint service**.
3. For **Load balancer type**, select **Gateway**.
4. For **Available load balancers**, select the Gateway Load Balancers to associate with the endpoint service.
5. For **Require acceptance for endpoint**, select the check box to accept connection requests to your service manually. Otherwise, endpoint connections are automatically accepted.
6. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.
7. Choose **Create**.

AWS CLI

**To create an endpoint service**

Use the `create-vpc-endpoint-service-configuration` command and specify one or more ARNs for your Gateway Load Balancers. You can optionally specify if acceptance is required for connecting to your service.

```
aws ec2 create-vpc-endpoint-service-configuration --gateway-load-balancer-arns gateway-load-balancer-arn --no-acceptance-required
```

Tools for Windows PowerShell

**To create an endpoint service**

Use `New-EC2VpcEndpointServiceConfiguration`.

API

**To create an endpoint service**

Use `CreateVpcEndpointServiceConfiguration`.

Add and remove permissions for your endpoint service

After you create your endpoint service configuration, you can control which service consumers can create an interface endpoint or Gateway Load Balancer endpoint to connect to your service. Service consumers are **IAM principals**—IAM users, IAM roles, and AWS accounts. To add or remove permissions for a principal, you need its Amazon Resource Name (ARN).

- For an AWS account (and therefore all principals in the account), the ARN is in the form `arn:aws:iam::aws-account-id:root`.
- For a specific IAM user, the ARN is in the form `arn:aws:iam::aws-account-id:user/user-name`.
- For a specific IAM role, the ARN is in the form `arn:aws:iam::aws-account-id:role/role-name`.

**Note**

If you set permission to "anyone can access" and you set the acceptance model to "accept all requests," then you've just made your load balancer public. Because it's easy to obtain an AWS
account, there is no practical limitation on who can access your load balancer even though it has no public IP address.

Console

**To add or remove permissions for your endpoint service**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**.
3. Select your endpoint service and choose **Actions, Allow principals**.
4. Specify the ARN for the principal for which to add permissions. To add another principal, choose **Add principal**. To remove a principal, choose **Remove** next to the entry.
   
   Specify * to add permissions for all principals. This enables all principals in all AWS accounts to create an endpoint to your endpoint service.

5. Choose **Allow principals**.

AWS CLI

**To add permissions for your endpoint service**

Use the `modify-vpc-endpoint-service-permissions` command. Specify the `--add-allowed-principals` parameter to add one or more ARNs for the principals.

```bash
aws ec2 modify-vpc-endpoint-service-permissions --service-id vpce-svc-03d5ebb7d9579a2b3 --add-allowed-principals '["arn:aws:iam::123456789012:root"]'
```

**To view the permissions you added for your endpoint service**

Use the `describe-vpc-endpoint-service-permissions` command.

```bash
aws ec2 describe-vpc-endpoint-service-permissions --service-id vpce-svc-03d5ebb7d9579a2b3
```

The following is example output.

```json
{
  "AllowedPrincipals": [
    {
      "PrincipalType": "Account",
      "Principal": "arn:aws:iam::123456789012:root"
    }
  ]
}
```

**To remove permissions for your endpoint service**

Use the `modify-vpc-endpoint-service-permissions` command. Specify the `--remove-allowed-principals` parameter to remove one or more ARNs for the principals.

```bash
aws ec2 modify-vpc-endpoint-service-permissions --service-id vpce-svc-03d5ebb7d9579a2b3 --remove-allowed-principals '["arn:aws:iam::123456789012:root"]'
```

Tools for Windows PowerShell

**To add or remove permissions for your endpoint service**
Use **Edit-EC2EndpointServicePermission**.

**API**

**To add or remove permissions for your endpoint service**

Use **ModifyVpcEndpointServicePermissions**.

### Change the endpoint service configuration

You can modify your endpoint service configuration by changing the load balancers that are associated with the endpoint service, and by changing whether acceptance is required for requests to connect to your endpoint service.

You cannot disassociate a load balancer if there are endpoints attached to your endpoint service.

**Console**

**To change the load balancers for your endpoint service**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**.
3. Select your endpoint service and then choose **Actions, Associate or disassociate load balancers**.
4. Select or deselect the load balancers as required, and then choose **Save changes**.

**To modify the acceptance setting**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**.
3. Select your endpoint service and then choose **Actions, Modify endpoint acceptance setting**.
4. Select or deselect **Acceptance required**, and then choose **Save changes**.

**AWS CLI**

**To change the load balancers for your endpoint service**

Use the `modify-vpc-endpoint-service-configuration` command. The following example uses the `--remove-network-load-balancer-arn` parameter to remove a Network Load Balancer.

```
```

**To change whether acceptance is required**

Use the `modify-vpc-endpoint-service-configuration` command and specify `--acceptance-required` or `--no-acceptance-required`.

```
aws ec2 modify-vpc-endpoint-service-configuration --service-id vpce-svc-0922513e6e77dc86 --no-acceptance-required
```
Accept and reject endpoint connection requests

After you create an endpoint service, service consumers for which you've added permission can create an interface endpoint or Gateway Load Balancer endpoint to connect to your service. For more information, see Interface VPC endpoints (AWS PrivateLink) (p. 3) and Gateway Load Balancer endpoints (AWS PrivateLink) (p. 16).

If you specified that acceptance is required for connection requests, you must manually accept or reject endpoint connection requests to your endpoint service. After an endpoint is accepted, it becomes available. Be aware that it can take time for a validation status change to be completed and the state to be available.

You can reject an endpoint connection after it's in the available state.

Console

To accept or reject a connection request

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select your endpoint service.
4. From the Endpoint connections tab, select the endpoint. To accept a connection request, choose Actions, Accept endpoint connection request. To reject the connection request, choose Actions, Reject endpoint connection request.

AWS CLI

To view the endpoint connections that are pending acceptance

Use the describe-vpc-endpoint-connections command and filter by the pendingAcceptance state.

```bash
aws ec2 describe-vpc-endpoint-connections --filters Name=vpc-endpoint-state,Values=pendingAcceptance
```

The following is example output.

```json
{
  "VpcEndpointConnections": [
    {
      "VpcEndpointId": "vpce-0c1308d7312217abc",
      "ServiceId": "vpce-svc-03d5ebb7d9579a2b3",
      "CreationTimestamp": "2017-11-30T10:00:24.350Z",
      "VpcEndpointState": "pendingAcceptance",
      "VpcEndpointOwner": "123456789012"
    }
  ]
}
```
To accept an endpoint connection request

Use the `accept-vpc-endpoint-connections` command and specify the endpoint ID and endpoint service ID.

```bash
aws ec2 accept-vpc-endpoint-connections --service-id vpce-svc-03d5ebb77d9579a2b3 --vpc-endpoint-ids vpce-0c1308d73122117abc
```

To reject an endpoint connection request

Use the `reject-vpc-endpoint-connections` command.

```bash
aws ec2 reject-vpc-endpoint-connections --service-id vpce-svc-03d5ebb77d9579a2b3 --vpc-endpoint-ids vpce-0c1308d73122117abc
```

Tools for Windows PowerShell

To accept or reject a connection request

Use `Confirm-EC2EndpointConnection` and `Deny-EC2EndpointConnection`.

API

To accept or reject a connection request

Use `AcceptVpcEndpointConnections` and `RejectVpcEndpointConnections`.

Create and manage a notification for an endpoint service

You can create a notification to receive alerts for specific events that occur on the endpoints that are attached to your endpoint service. For example, you can receive an email when an endpoint request is accepted or rejected for your endpoint service. To create a notification, you must associate an Amazon SNS topic with the notification. You can subscribe to the SNS topic to receive an email notification when an endpoint event occurs. For more information, see the Amazon Simple Notification Service Developer Guide.

The Amazon SNS topic that you use for notifications must have a topic policy that allows the Amazon VPC endpoint service to publish notifications on your behalf. Ensure that you include the following statement in your topic policy. For more information, see Managing Access to Your Amazon SNS Topics in the Amazon Simple Notification Service Developer Guide.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "vpce.amazonaws.com"
            },
            "Action": "SNS:Publish",
            "Resource": "arn:aws:sns:region:account:topic-name"
        }
    ]
}
```
To create a notification for an endpoint service

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select your endpoint service and then choose the Notifications tab.
4. Choose Create notification.
5. For Notification ARN, choose the ARN for the SNS topic to associate with the notification.
6. For Events, select the endpoint events for the notifications that you want to receive.
7. Choose Create notification.

After you create a notification, you can modify its settings.

To modify a notification for an endpoint service

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select your endpoint service and then choose the Notifications tab.
4. Select the notification and then choose Actions, Modify notification.
5. Change the SNS topic or the endpoint events as required.
6. Choose Save changes.

If you no longer need a notification, you can delete it.

To delete a notification

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select your endpoint service and then choose the Notifications tab.
4. Select the notification and then choose Actions, Delete notification.
5. When prompted for confirmation, enter delete and then choose Delete.

AWS CLI

To create a notification for an endpoint service

Use the create-vpc-endpoint-connection-notification command. Specify the ARN of the SNS topic, the events for which to be notified, and the ID of the endpoint service.

```bash
```

The following is example output.

```json
{
  "ConnectionNotification": {
    "ConnectionNotificationState": "Enabled",
```
"ConnectionNotificationType": "Topic",
"ServiceId": "vpce-svc-1237881c0d25a3abc",
"ConnectionEvents": [
  "Reject",
  "Accept",
  "Delete",
  "Connect"
],
"ConnectionNotificationId": "vpce-nfn-008776de7e03f5abc",
}
}

To view your notifications

Use the `describe-vpc-endpoint-connection-notifications` command.

```
aws ec2 describe-vpc-endpoint-connection-notifications
```

To change the SNS topic or endpoint events for a notification

Use the `modify-vpc-endpoint-connection-notification` command.

```
```

To delete a notification

Use the `delete-vpc-endpoint-connection-notifications` command.

```
aws ec2 delete-vpc-endpoint-connection-notifications --connection-notification-ids vpce-nfn-008776de7e03f5abc
```

Tools for Windows PowerShell

To create and manage notifications

Use the following:

- `New-EC2VpcEndpointConnectionNotification`
- `Get-EC2EndpointConnectionNotification`
- `Edit-EC2VpcEndpointConnectionNotification`
- `Remove-EC2EndpointConnectionNotification`

API

To create and manage notifications

Use the following:

- `CreateVpcEndpointConnectionNotification`
- `DescribeVpcEndpointConnectionNotifications`
- `ModifyVpcEndpointConnectionNotification`
- `DeleteVpcEndpointConnectionNotifications`
Add or remove VPC endpoint service tags

Tags provide a way to identify the VPC endpoint service. You can add or remove a tag.

Console

**To add or remove a VPC endpoint service tag**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**.
3. Select the VPC endpoint service and choose **Actions, Manage tags**.
4. Add or remove tags.

   **[Add a tag]** Choose **Add new tag** and enter the tag key and tag value.

   **[Remove a tag]** Choose **Remove** to the right of the tag key and value.

AWS CLI

Use **create-tags** and **delete-tags**.

API

Use **CreateTags** and **DeleteTags**.

Delete an endpoint service configuration

You can delete an endpoint service configuration. Deleting the configuration does not delete the application hosted in your VPC or the associated load balancers.

Before you delete the endpoint service configuration, you must reject any available or pending-acceptance VPC endpoints that are attached to the service. For more information, see **Accept and reject endpoint connection requests** (p. 50).

Console

**To delete an endpoint service configuration**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose **Endpoint Services**.
3. Select the endpoint service.
4. Choose **Actions, Delete endpoint services**.
5. When prompted for confirmation, enter **delete** and then choose **Delete**.

AWS CLI

**To delete an endpoint service configuration**

Use the **delete-vpc-endpoint-service-configurations** command. Specify the ID of the service.

```
aws ec2 delete-vpc-endpoint-service-configurations --service-ids vpce-svc-03d5ebb7d9579a2b3
```
Tools for Windows PowerShell

To delete an endpoint service configuration

Use Remove-EC2EndpointServiceConfiguration.

API

To delete an endpoint service configuration

Use DeleteVpcEndpointServiceConfigurations.
Identity and access management for VPC endpoints and VPC endpoint services

Use IAM to manage access to VPC endpoints and VPC endpoints services.

**Control the use of VPC endpoints**

By default, IAM users do not have permission to work with endpoints. You can create an IAM user policy that grants users the permissions to create, modify, describe, and delete endpoints. The following is an example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:*VpcEndpoint*",
            "Resource": "*"
        }
    ]
}
```

For information about controlling access to services using VPC endpoints, see the section called “Control access to services” (p. 36).

**Control VPC endpoints creation based on the service owner**

You can use the `ec2:VpceServiceOwner` condition key to control what VPC endpoint can be created based on who owns the service (amazon, aws-marketplace, or the account ID). The following example grants permission to create VPC endpoints with the specified service owner. To use this example, substitute the Region, the account ID, and the service owner.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:CreateVpcEndpoint",
            "Resource": [
                "arn:aws:ec2:region:account-id:vpc/*",
                "arn:aws:ec2:region:account-id:subnet/*",
            ]
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateVpcEndpoint",
            "Resource": [
            ],
            "Condition": {
                "StringEqual": {
                    "ec2:VpceServiceOwner": "amazon"
                }
            }
        }
    ]
}
```
Control the private DNS names that can be specified for VPC endpoint services

You can use the `ec2:VpceServicePrivateDnsName` condition key to control what VPC endpoint service can be modified or created based on the private DNS name associated with the VPC endpoint service. The following example grants permission to create a VPC endpoint service with the specified private DNS name. To use this example, substitute the Region, the account ID, and the private DNS name.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [ "ec2:ModifyVpcEndpointServiceConfiguration", "ec2:CreateVpcEndpointServiceConfiguration" ],
      "Condition": {
        "StringEquals": { "ec2:VpceServicePrivateDnsName": [ "example.com" ] }
      }
    }
  ]
}
```

Control the service names that can be specified for VPC endpoint services

You can use the `ec2:VpceServiceName` condition key to control what VPC endpoint can be created based on the VPC endpoint service name. The following example grants permission to create a VPC endpoint with the specified service name. To use this example, substitute the Region, the account ID, and the service name.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [ "ec2:CreateVpcEndpoint" ],
    },
    {
      "Effect": "Allow",
      "Action": [ "ec2:CreateVpcEndpointService" ],
    }
  ]
}
```
"Action": "ec2:CreateVpcEndpoint",
"Resource": [
],
"Condition": {
  "StringEquals": {
    "ec2:VpceServiceName": [
      "com.amazonaws.region.s3"
    ]
  }
}
Private DNS names for endpoint services

When you create a VPC endpoint service, we generate endpoint-specific DNS hostnames for the service. These names include the VPC endpoint service ID and the Region code. For example, vpce-svc-01234567890abcdef.us-east-1.vpce.amazonaws.com. By default, your consumers access the service with that DNS name and usually need to modify the application configuration.

If the endpoint service is for an AWS service, or a service available in the AWS Marketplace, there is a default DNS name. For other services, the service provider can configure a private DNS name so consumers can access the service using an existing DNS name without making changes to their applications. For more information, see VPC endpoint services (p. 39).

Service providers can specify a private DNS name for a new endpoint service, or an existing endpoint service. To use a private DNS name, enable the feature, and then specify a private DNS name. Before consumers can use the private DNS name, you must verify that you have control of the domain/subdomain. You can initiate domain ownership verification. After ownership of the domain is verified, service consumers can access your service using the private DNS name.

To verify the domain, you must have a public hosted name, or a public DNS provider.

Private DNS names are not supported for endpoint services that you create for Gateway Load Balancer endpoints.

The high-level procedure is as follows:

1. Add a private DNS name. For more information, see the section called “Create a VPC endpoint service configuration for interface endpoints” (p. 45) or the section called “Modify an existing endpoint service private DNS name” (p. 61).
2. Note the Domain verification value and Domain verification name that you need for the DNS server records. For more information, see the section called “View endpoint service private DNS name configuration” (p. 62).
3. Add a record to the DNS server. For more information, see the section called “VPC endpoint service private DNS name verification” (p. 60).
4. Verify the private DNS name. For more information, see the section called “Manually initiate the endpoint service private DNS name domain verification” (p. 63).

You can manage the verification process by using the Amazon VPC console or the Amazon VPC API.

- the section called “VPC endpoint service private DNS name verification” (p. 60)
- the section called “Modify an existing endpoint service private DNS name” (p. 61)
- the section called “Remove an endpoint service private DNS name” (p. 63)
- the section called “View endpoint service private DNS name configuration” (p. 62)
- Amazon VPC private DNS name domain verification TXT records (p. 64)

Domain name verification considerations

Make note of the following important points about domain ownership verification:

- A consumer can only use the private DNS name to access the endpoint service when the verification status is verified.
• If the verification status changes from **verified** to **pendingVerification**, or **failed**, existing consumer connections remain, but any new connection requests are denied.

For service providers who are concerned about connections to endpoint services that are no longer in the **verified** state, we recommend using **DescribeVpcEndpointServices** to check the verification state at least one time per day.

• An endpoint service can only have one private DNS name.
• You can specify a private DNS name for a new endpoint service, or an existing endpoint service.
• You can only use public domain name servers.
• You can use wildcards in domain names, for example, "*.myexampleservice.com".
• You must perform a separate domain ownership verification check for each endpoint service.
• You can verify the domain of a subdomain. For example, you can verify `example.com`, instead of `a.example.com`. As specified in RFC 1034, each DNS label can have up to 63 characters and the whole domain name must not exceed a total length of 255 characters.

If you add an additional subdomain, you must verify the subdomain, or the domain. For example, let's say you had `a.example.com`, and verified `example.com`. You now add `b.example.com` as a private DNS name. You must verify `example.com` or `b.example.com` before your consumers can use the name.

• Domain names must be lower-cased.

---

**VPC endpoint service private DNS name verification**

Your domain is associated with a set of Domain Name System (DNS) records that you manage through your DNS provider. A TXT record is a type of DNS record that provides additional information about your domain. Each TXT record consists of a name and a value.

When you initiate domain ownership verification, we give you the name and value to use for the TXT record. For example, if your domain is `myexampleservice.com`, the TXT record settings that we generate will look similar to the following example:

**Endpoint private DNS name TXT record**

<table>
<thead>
<tr>
<th>Domain verification name</th>
<th>Domain verification type</th>
<th>Domain verification value</th>
</tr>
</thead>
<tbody>
<tr>
<td>_aksldja21i1</td>
<td>TXT</td>
<td>vpce:asjdakjshd78126eu21</td>
</tr>
</tbody>
</table>

Add a TXT record to your domain's DNS server using the specified **Domain verification name** and **Domain verification value**. The domain ownership verification is complete when we detect the existence of the TXT record in your domain's DNS settings.

If your DNS provider does not allow DNS record names to contain underscores, you can omit `_aksldja21i1` from the **Domain verification name**. In that case, for the preceding example, the TXT record name would be `myexampleservice.com` instead of `_aksldja21i1.myexampleservice.com`.

**Add a TXT record to your domain's DNS server**

The procedure for adding TXT records to your domain's DNS server depends on who provides your DNS service. Your DNS provider might be Amazon Route 53 or another domain name registrar. This section provides procedures for adding a TXT record to Route 53, and generic procedures that apply to other DNS providers.
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoint Services**.
3. Select the endpoint service.
4. On the **Details** tab, note the values shown next to **Domain verification value** and **Domain verification name**.
5. If Route 53 provides the DNS service for the domain that you're verifying, and you're signed in to the AWS Management Console under the same account that you use for Route 53, we give you the option of updating your DNS server immediately from within the Amazon VPC console.

If you use a different DNS provider, the procedures for updating the DNS records vary depending on which DNS or web hosting provider you use. The following table lists links to the documentation for several common providers. This list isn't exhaustive and inclusion in this list isn't an endorsement or recommendation of any company's products or services. If your provider isn't listed in the table, you can probably use the domain with endpoints.

<table>
<thead>
<tr>
<th>DNS/Hosting provider</th>
<th>Documentation link</th>
</tr>
</thead>
<tbody>
<tr>
<td>GoDaddy</td>
<td>Add a TXT record (external link)</td>
</tr>
<tr>
<td>Dreamhost</td>
<td>How do I add custom DNS records? (external link)</td>
</tr>
<tr>
<td>Cloudflare</td>
<td>Managing DNS records in CloudFlare (external link)</td>
</tr>
<tr>
<td>HostGator</td>
<td>Manage DNS Records with HostGator/eNom (external link)</td>
</tr>
<tr>
<td>Namecheap</td>
<td>How do I add TXT/SPF/DKIM/DMARC records for my domain? (external link)</td>
</tr>
<tr>
<td>Names.co.uk</td>
<td>Changing your domains DNS Settings (external link)</td>
</tr>
<tr>
<td>Wix</td>
<td>Adding or Updating TXT Records in Your Wix Account (external link)</td>
</tr>
</tbody>
</table>

When verification is complete, the domain's status in the Amazon VPC console changes from **Pending** to **Verified**.

6. You can now use the private domain name for the VPC endpoint service.

If the DNS settings are not correctly updated, the domain status displays a status of **failed** on the **Details** tab. If this happens, complete the steps on the troubleshooting page at the section called “Troubleshoot common domain verification problems” (p. 65). After you verify that your TXT record was created correctly, retry the operation.

---

**Modify an existing endpoint service private DNS name**

You can modify the endpoint service private DNS name for a new or existing endpoint service.
After you update the name, update the entry for the domain on your DNS server. We automatically poll the DNS server to verify that the record exists on the server. DNS record updates can take up to 48 hours to take effect, but they often take effect much sooner. For more information, see the section called “Private DNS name domain verification TXT records” (p. 64) and the section called “VPC endpoint service private DNS name verification” (p. 60).

Console

To modify an endpoint service private DNS name

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select the endpoint service, and then choose Actions, Modify private DNS name.
4. Select Associate a private DNS name with the service and then enter the private DNS name.
5. Choose Save changes.

AWS CLI

To modify the endpoint service private DNS name

Use modify-vpc-endpoint-service-configuration.

API

To modify the endpoint service private DNS name

Use ModifyVpcEndpointServiceConfiguration.

View endpoint service private DNS name configuration

You can view the endpoint service private DNS name for an endpoint service.

Console

To view an endpoint service private DNS name configuration

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services, and then select the endpoint service.
3. The Details tab displays the following information for the private DNS domain ownership check:

   • Domain verification status: The verification status.
   • Domain verification type: The verification type.
   • Domain verification value: The DNS value.
   • Domain verification name: The name of the record subdomain.

AWS CLI

To view an endpoint service private DNS name configuration

Use describe-vpc-endpoint-service-configurations.
Manually initiate the endpoint service private DNS name domain verification

The service provider must prove that they own the private DNS name domain before consumers can use the private DNS name.

Console

To initiate the verification process of the private DNS name domain

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select the endpoint service, and then choose Actions, Verify domain ownership for Private DNS Name.
4. When prompted for confirmation, enter verify and then choose Verify.

If the DNS settings are not correctly updated, the domain verification status is failed. If this happens, complete the steps on the troubleshooting page at the section called “Troubleshoot common domain verification problems” (p. 65).

AWS CLI

To initiate the verification process of the private DNS name domain

Use start-vpc-endpoint-service-private-dns-verification.

API

To initiate the verification process of the private DNS name domain

Use StartVpcEndpointServicePrivateDnsVerification.

Remove an endpoint service private DNS name

You can remove the endpoint service private DNS name only after there are no connections to the service.

Console

To remove an endpoint service private DNS name

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoint Services.
3. Select the endpoint service, and then choose Actions, Modify private DNS name.
4. Clear Associate a private DNS name with the service.
5. Choose Save changes.
Amazon VPC private DNS name domain verification TXT records

Your domain is associated with a set of Domain Name System (DNS) records that you manage through your DNS provider. A TXT record is a type of DNS record that provides additional information about your domain. Each TXT record consists of a name and a value.

When you initiate domain ownership verification using the Amazon VPC console or API, we give you the name and value to use for the TXT record. For example, if your domain is myexampleservice.com, the TXT record settings that Amazon VPC generates will look similar to the following example:

**Endpoint private DNS name TXT record**

<table>
<thead>
<tr>
<th>Domain verification name</th>
<th>Domain verification type</th>
<th>Domain verification value</th>
</tr>
</thead>
<tbody>
<tr>
<td>_aksldja21i1.myexampleservice.com</td>
<td>TXT</td>
<td>vpce:asjdakjshd78126eu21</td>
</tr>
</tbody>
</table>

Add a TXT record to your domain's DNS server using the specified **Domain verification name** and **Domain verification value**. Amazon VPC domain ownership verification is complete when Amazon VPC detects the existence of the TXT record in your domain's DNS settings.

If your DNS provider does not allow DNS record names to contain underscores, you can use the domain name for the **Domain verification name**. In that case, for the preceding example, the TXT record name would be myexampleservice.com.

You can find troubleshooting information and instructions on how to check your domain ownership verification settings in Troubleshoot common private DNS domain verification problems (p. 65).

Amazon Route 53

The procedure for adding TXT records to your domain's DNS server depends on who provides your DNS service. Your DNS provider might be Amazon Route 53 or another domain name registrar. This section provides procedures for adding a TXT record to Route 53, and generic procedures that apply to other DNS providers.

**To add a TXT record to the DNS record for your Route 53-managed domain**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose **Endpoint Services**.
3. Select the endpoint service.
4. On the **Details** tab, note the values shown next to **Domain verification value** and **Domain verification name**.

5. In the Amazon Route 53 Console, create a record for your hosted zone. For information about how to create a record, see the **Creating records by using the Amazon Route 53 console** in the *Amazon Route 53 Developer Guide*. Use the following values:

   - For **Record type**, choose **TXT**.
   - For **TTL (Seconds)**, enter **1800**.
   - For **Routing policy**, choose **Simple routing**.
   - For **Value/Route traffic to**, enter the **Domain verification value** from the Amazon VPC console.

6. On the **Details** tab of the **Endpoint Services** page in the Amazon VPC console, check the value in the **Domain verification status** column next to the endpoint. If the status is "pending verification," wait a few minutes, and then choose refresh. Repeat this process until the value in the status column is "verified". You can manually start the verification process. For more information, see the section called “Manually initiate the endpoint service private DNS name domain verification” (p. 63).

**Generic procedures for other DNS providers**

The procedures for adding TXT records to the DNS configurations vary from provider to provider. For specific steps, consult your DNS provider's documentation. The procedure in this section gives a basic overview of the steps you take when adding a TXT record to the DNS configuration for your domain.

**To add a TXT record to your domain's DNS server (general procedure)**

1. Go to your DNS provider's website. If you aren't sure which DNS provider serves your domain, you can look it up by using a free Whois service.

2. On the provider's website, sign in to your account.

3. Find the page for updating your domain's DNS records. This page often has a name such as DNS Records, DNS Zone File, or Advanced DNS. If you're unsure, consult the provider's documentation.

4. Add a TXT record with the name and value provided by AWS.

   **Important**
   
   Some DNS providers automatically append the domain name to the end of DNS records. Adding a record that already contains the domain name (such as _pmBGN/7Mjnfx.example.com) might result in the duplication of the domain name (such as _pmBGN/7Mjnfxexample.com.example.com). To avoid duplication of the domain name, add a period to the end of the domain name in the DNS record. This will indicate to your DNS provider that the record name is fully qualified (that is, no longer relative to the domain name), and will prevent the DNS provider from appending an additional domain name.

5. Save your changes. DNS record updates can take up to 48 hours to take effect, but they often take effect much sooner.

---

**Troubleshoot common private DNS domain verification problems**

To verify an endpoint service private DNS domain name with Amazon VPC, you initiate the process using either the Amazon VPC console or the API. This section contains information that can help you resolve issues with the verification process.
Common domain verification problems

If you attempt to verify a domain and you encounter problems, review the possible causes and solutions below.

- You're attempting to verify a domain that you don't own. You can't verify a domain unless you own it.
- Your DNS provider doesn't allow underscores in TXT record names. Some DNS providers don't allow you to include the underscore character in the DNS record names for your domain. If this is true for your provider, you can omit _amazovpc from the name of the TXT record.
- Your DNS provider appended the domain name to the end of the TXT record. Some DNS providers automatically append the name of your domain to the attribute name of the TXT record. For example, if you create a record where the attribute name is _amazonvpc.example.com, the provider might append the domain name, resulting in _amazonvpc.example.com.example.com. To avoid duplication of the domain name, add a period to the end of the domain name when you create the TXT record. This step tells your DNS provider that it isn't necessary to append the domain name to the TXT record.
- Your DNS provider modified the DNS record value. Some providers automatically modify DNS record values to use only lowercase letters. We only verify your domain when it detects a verification record for which the attribute value exactly matches the value that we provided when you started the domain ownership verification process. If the DNS provider for your domain changes your TXT record values to use only lowercase letters, contact the DNS provider for additional assistance.
- You want to verify the same domain multiple times. You might need to verify your domain more than once because you’re sending in different Regions, or because you’re using the same domain to send from multiple AWS accounts. If your DNS provider doesn't allow you to have more than one TXT record with the same attribute name, you might still be able to verify two domains. If your DNS provider allows it, you can assign multiple attribute values to the same TXT record. For example, if your DNS is managed by Amazon Route 53, you can set up multiple values for the same TXT record by completing the following steps:
  1. In the Route 53 console, choose the TXT record that you created when you verified your domain in the first Region.
  2. In the Value box, go to the end of the existing attribute value, and then press Enter.
  3. Add the attribute value for the additional Region, and then save the record set.

If your DNS provider doesn't allow you to assign multiple values to the same TXT record, you can verify the domain once with the value in the attribute name of the TXT record, and another time with the value removed from the attribute name. For example, you verify with "_asnbcdasd", and then with "asnbcdasd". The downside of this solution is that you can only verify the same domain two times.

How to check domain verification settings

You can verify that your private DNS name domain ownership verification TXT record is published correctly to your DNS server by using the following procedure. This procedure uses the nslookup tool, which is available for Windows and Linux. On Linux, you can also use dig.

The commands in these instructions are executed on Windows 7, and the example domain we use is example.com.

In this procedure, you first find the DNS servers that serve your domain, and then query those servers to view the TXT records. You query the DNS servers that serve your domain because those servers contain the most up-to-date information for your domain, which can take time to propagate to other DNS servers.

To verify that your domain ownership verification TXT record is published to your DNS server

1. Find the name servers for your domain by taking the following steps.
a. Go to the command line. To get to the command line on Windows 7, choose **Start** and then enter **cmd**. On Linux-based operating systems, open a terminal window.

b. At the command prompt, enter the following, where `<domain>` is your domain.

```bash
nslookup -type=NS <domain>
```

For example, if your domain was `example.com`, the command would look like the following.

```bash
nslookup -type=NS example.com
```

The command's output will list the name servers that serve your domain. You will query one of these servers in the next step.

2. Verify that the TXT record is correctly published by taking the following steps.

a. At the command prompt, enter the following, where `<domain>` is your domain, and `<name server>` is one of the name servers you found in step 1.

```bash
nslookup -type=TXT _aksldja21i1.<domain> <name server>
```

In our `_aksldja21i1.example.com` example, if a name server that we found in step 1 was called `ns1.name-server.net`, we would enter the following.

```bash
nslookup -type=TXT _aksldja21i1.example.com ns1.name-server.net
```

b. In the output of the command, verify that the string that follows `text =` matches the TXT value you see when you choose the domain in the Identities list of the Amazon VPC console.

In our example, we are looking for a TXT record under `_aksldja21i1.example.com` with a value of `asjdakjshd78126eu21`. If the record is correctly published, we would expect the command to have the following output.

```bash
_aksldja21i1.example.com text = "asjdakjshd78126eu21"
```
AWS services that integrate with AWS PrivateLink

The following AWS services integrate with AWS PrivateLink. You can connect to these services privately, as if they were running in your own VPC.

Choose the link in the **AWS service** column to see the documentation for services that integrate with AWS PrivateLink. The **VPC endpoint policies** column indicates whether the service supports VPC endpoint policies. The **Service name** column contains the service name that you specify when you create the interface VPC endpoint.

</tr>
</tbody>
</table>
You can use the `describe-vpc-endpoint-services` command to view the service names that support VPC endpoints.

You can run the following command to get a list of the service names for gateway or interface endpoints. The possible values for the `service-type` filter are `Interface` and `Gateway`. The `--query` option limits the output to the service names.
The following example displays the services that support interface endpoints.

```
aws ec2 describe-vpc-endpoint-services --filter Name=service-type,Values=Interface --query ServiceNames
```

The following is example output:

```
"aws.sagemaker.us-east-1.notebook",
"aws.sagemaker.us-east-1.studio",
"com.amazonaws.us-east-1.access-analyzer",
"com.amazonaws.us-east-1.acm-pca",
"com.amazonaws.us-east-1.airflow.api",
"com.amazonaws.us-east-1.airflow.env",
"com.amazonaws.us-east-1.airflow.ops",
"com.amazonaws.us-east-1.application-autoscaling",
"com.amazonaws.us-east-1.appmesh-envoy-management",
"com.amazonaws.us-east-1.appstream.api",
"com.amazonaws.us-east-1.appstream.streaming",
"com.amazonaws.us-east-1.aps-workspaces",
"com.amazonaws.us-east-1.athena",
...
```

After you have the service name, you can view detailed information using the following command.

```
aws ec2 describe-vpc-endpoint-services --service-name service-name
```

The following example displays information about the Amazon S3 interface endpoint in the us-east-1 Region. The service-type filter excludes the Amazon S3 gateway endpoint from the output.

```
aws ec2 describe-vpc-endpoint-services --service-name "com.amazonaws.us-east-1.s3" --filter Name=service-type,Values=Interface --region us-east-1
```

The following is example output:

```

]
}
CloudWatch metrics for AWS PrivateLink

AWS PrivateLink publishes data points to Amazon CloudWatch for your interface endpoints, Gateway Load Balancer endpoints, and endpoint services. CloudWatch enables you to retrieve statistics about those data points as an ordered set of time series data, known as metrics. Think of a metric as a variable to monitor, and the data points as the values of that variable over time. Each data point has an associated timestamp and an optional unit of measurement.

You can use metrics to verify that your system is performing as expected. For example, you can create a CloudWatch alarm to monitor a specified metric and initiate an action (such as sending a notification to an email address) if the metric goes outside what you consider an acceptable range.

Metrics are published for all interface endpoints, Gateway Load Balancer endpoints, and endpoint services. They are not published for gateway endpoints. By default, AWS PrivateLink sends metrics to CloudWatch in one-minute intervals, at no additional cost.

For more information, see the Amazon CloudWatch User Guide.

Contents
- Endpoint metrics and dimensions (p. 77)
- Endpoint service metrics and dimensions (p. 79)
- View the CloudWatch metrics (p. 81)

Endpoint metrics and dimensions

The AWS/PrivateLinkEndpoints namespace includes the following metrics for interface endpoints and Gateway Load Balancer endpoints.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveConnections</td>
<td>The number of concurrent active connections. This includes connections in the SYN_SENT and ESTABLISHED states.</td>
</tr>
<tr>
<td></td>
<td><strong>Reporting criteria:</strong> The endpoint received traffic during the one-minute period.</td>
</tr>
<tr>
<td></td>
<td><strong>Statistics:</strong> The most useful statistics are Average, Maximum, and Minimum.</td>
</tr>
<tr>
<td></td>
<td><strong>Dimensions</strong></td>
</tr>
<tr>
<td></td>
<td>• Endpoint Type, Service Name, VPC Endpoint Id, VPC Id</td>
</tr>
<tr>
<td></td>
<td>• Endpoint Type, Service Name, Subnet Id, VPC Endpoint Id, VPC Id</td>
</tr>
<tr>
<td>BytesProcessed</td>
<td>The number of bytes exchanged between endpoints and endpoint services, aggregated in both directions. This is the number of bytes billed to the owner of the endpoint. The bill displays this value in GB.</td>
</tr>
</tbody>
</table>
## Amazon Virtual Private Cloud AWS PrivateLink
### Endpoint metrics and dimensions

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Metric</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td><strong>Reporting criteria:</strong></td>
<td>The endpoint received traffic during the one-minute period.</td>
</tr>
<tr>
<td><strong>Statistics:</strong></td>
<td>The most useful statistics are <strong>Average</strong>, <strong>Sum</strong>, <strong>Maximum</strong>, and <strong>Minimum</strong>.</td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, Subnet Id, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td><strong>NewConnections</strong></td>
<td>The number of new connections established through the endpoint.</td>
</tr>
<tr>
<td><strong>Reporting criteria:</strong></td>
<td>The endpoint received traffic during the one-minute period.</td>
</tr>
<tr>
<td><strong>Statistics:</strong></td>
<td>The most useful statistics are <strong>Average</strong>, <strong>Sum</strong>, <strong>Maximum</strong>, and <strong>Minimum</strong>.</td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, Subnet Id, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td><strong>PacketsDropped</strong></td>
<td>The number of packets dropped by the endpoint. This metric might not capture all packet drops. Increasing values could indicate that the endpoint or endpoint service is unhealthy.</td>
</tr>
<tr>
<td><strong>Reporting criteria:</strong></td>
<td>The endpoint received traffic during the one-minute period.</td>
</tr>
<tr>
<td><strong>Statistics:</strong></td>
<td>The most useful statistics are <strong>Average</strong>, <strong>Sum</strong>, and <strong>Maximum</strong>.</td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, Subnet Id, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td><strong>RstPacketsReceived</strong></td>
<td>The number of RST packets received by the endpoint. Increasing values could indicate that the endpoint service is unhealthy.</td>
</tr>
<tr>
<td><strong>Reporting criteria:</strong></td>
<td>The endpoint received traffic during the one-minute period.</td>
</tr>
<tr>
<td><strong>Statistics:</strong></td>
<td>The most useful statistics are <strong>Average</strong>, <strong>Sum</strong>, and <strong>Maximum</strong>.</td>
</tr>
<tr>
<td><strong>Dimensions</strong></td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
<tr>
<td>- Endpoint Type, Service Name, Subnet Id, VPC Endpoint Id, VPC Id</td>
<td></td>
</tr>
</tbody>
</table>

To filter these metrics, use the following dimensions. 
### Endpoint service metrics and dimensions

The **AWS/PrivateLinkServices** namespace includes the following metrics for endpoint services.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| **ActiveConnections** | The maximum number of active connections from clients to targets through the endpoints. Increasing values could indicate the need to add targets to the load balancer.  
  **Reporting criteria:** An endpoint connected to the endpoint service sent traffic during the one-minute period.  
  **Statistics:** The most useful statistics are **Average** and **Maximum**.  
  **Dimensions**  
  - Service Id  
  - Az,Service Id  
  - Load Balancer Arn,Service Id  
  - Az,Load Balancer Arn,Service Id  
  - Service Id,VPC Endpoint Id |
| **BytesProcessed** | The number of bytes exchanged between endpoint services and endpoints, in both directions.  
  **Reporting criteria:** An endpoint connected to the endpoint service sent traffic during the one-minute period.  
  **Statistics:** The most useful statistics are **Average**, **Sum**, and **Maximum**.  
  **Dimensions**  
  - Service Id  
  - Az,Service Id  
  - Load Balancer Arn,Service Id  
  - Az,Load Balancer Arn,Service Id  
  - Service Id,VPC Endpoint Id |
| **EndpointsCount** | The number of endpoints connected to the endpoint service. |
### Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Reporting criteria: There is a nonzero value during the five-minute period.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NewConnections</td>
<td>The number of new connections established from clients to targets through the endpoints. Increasing values could indicate the need to add targets to the load balancer. Reporting criteria: An endpoint connected to the endpoint service sent traffic during the one-minute period. Statistics: The most useful statistics are Average, Sum, and Maximum.</td>
</tr>
<tr>
<td>RstPacketsSent</td>
<td>The number of RST packets sent to endpoints by the endpoint service. Increasing values could indicate that there are unhealthy targets. Reporting criteria: An endpoint connected to the endpoint service sent traffic during the one-minute period. Statistics: The most useful statistics are Average, Sum, and Maximum.</td>
</tr>
</tbody>
</table>

### Dimensions

- Service Id
- Az, Service Id
- Load Balancer Arn, Service Id
- Az, Load Balancer Arn, Service Id
- Service Id, VPC Endpoint Id

### To filter these metrics, use the following dimensions.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Az</td>
<td>Filters the metric data by Availability Zone.</td>
</tr>
<tr>
<td>Load Balancer Arn</td>
<td>Filters the metric data by load balancer.</td>
</tr>
</tbody>
</table>
View the CloudWatch metrics

You can view these CloudWatch metrics using the Amazon VPC console, the CloudWatch console, or the AWS CLI as follows.

To view metrics using the Amazon VPC console
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Endpoints. Select your endpoint and then choose the Monitoring tab.
3. In the navigation pane, choose Endpoint Services. Select your endpoint service and then choose the Monitoring tab.

To view metrics using the CloudWatch console
2. In the navigation pane, choose Metrics.
3. Select the AWS/PrivateLinkEndpoints namespace.
4. Select the AWS/PrivateLinkServices namespace.

To view metrics using the AWS CLI
Use the following list-metrics command to list the available metrics for interface endpoints and Gateway Load Balancer endpoints:

```
aws cloudwatch list-metrics --namespace AWS/PrivateLinkEndpoints
```

Use the following list-metrics command to list the available metrics for endpoint services:

```
aws cloudwatch list-metrics --namespace AWS/PrivateLinkServices
```
AWS PrivateLink quotas

The following tables list the quotas, formerly referred to as limits, for AWS PrivateLink resources per Region for your account. Unless indicated otherwise, you can request an increase for these quotas. For more information, see Requesting a quota increase in the Service Quotas User Guide.

If you request a quota increase that applies per resource, we increase the quota for all resources in the Region.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gateway VPC endpoints per Region</td>
<td>20</td>
<td>Yes</td>
<td>There is a limit of 255 gateway endpoints per VPC</td>
</tr>
<tr>
<td>Interface and Gateway Load Balancer endpoints per VPC</td>
<td>50</td>
<td>Yes</td>
<td>This is the combined quota for interface endpoints and Gateway Load Balancer endpoints for a VPC</td>
</tr>
<tr>
<td>VPC endpoint policy size</td>
<td>20,480 characters</td>
<td>No</td>
<td>The size of a VPC endpoint policy includes white spaces</td>
</tr>
</tbody>
</table>

The following apply to traffic that passes through a VPC endpoint.

- By default, each interface endpoint can support a bandwidth of up to 10 Gbps per Availability Zone and automatically scales up to 40 Gbps. If your application needs higher throughput, contact AWS support.
- The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed through the VPC endpoint. The larger the MTU, the more data that can be passed in a single packet. A VPC endpoint supports an MTU of 8500 bytes. Packets with a size larger than 8500 bytes that arrive at the VPC endpoint are dropped.
- The VPC endpoint does not generate the FRAG_NEEDEDICMP packet, so Path MTU Discovery (PMTUD) is not supported.
- The VPC endpoint enforces Maximum Segment Size (MSS) clamping for all packets. For more information, see RFC879.
The following table describes the releases for AWS PrivateLink.

<table>
<thead>
<tr>
<th>update-history-change</th>
<th>update-history-description</th>
<th>update-history-date</th>
</tr>
</thead>
<tbody>
<tr>
<td>CloudWatch metrics</td>
<td>AWS PrivateLink publishes CloudWatch metrics for your interface endpoints, Gateway Load Balancer endpoints, and endpoint services.</td>
<td>January 27, 2022</td>
</tr>
<tr>
<td>Gateway Load Balancer endpoints</td>
<td>You can create a Gateway Load Balancer endpoint in your VPC to route traffic to a VPC endpoint service that you’ve configured using a Gateway Load Balancer.</td>
<td>November 10, 2020</td>
</tr>
<tr>
<td>VPC endpoint policies</td>
<td>You can attach an IAM policy to an interface VPC endpoint for an AWS service to control access to the service.</td>
<td>March 23, 2020</td>
</tr>
<tr>
<td>Condition keys for VPC endpoints and endpoint services</td>
<td>You can use EC2 condition keys to control access to VPC endpoints and endpoint services.</td>
<td>March 6, 2020</td>
</tr>
<tr>
<td>Tag VPC endpoints and endpoint services on creation (p. 83)</td>
<td>You can add tags when you create VPC endpoints and endpoint services.</td>
<td>February 5, 2020</td>
</tr>
<tr>
<td>Private DNS names</td>
<td>You can access AWS PrivateLink based services from within your VPC using private DNS names.</td>
<td>January 6, 2020</td>
</tr>
<tr>
<td>VPC endpoint services</td>
<td>You can create your own endpoints services and enable other AWS accounts and users to connect to your service through an interface VPC endpoint. You can offer your endpoint services for subscription in the AWS Marketplace.</td>
<td>November 28, 2017</td>
</tr>
<tr>
<td>Interface VPC endpoints for AWS services</td>
<td>You can create an interface endpoint to connect to AWS services that integrate with AWS PrivateLink without using an internet gateway or NAT device.</td>
<td>November 8, 2017</td>
</tr>
<tr>
<td>VPC endpoints for DynamoDB</td>
<td>You can create a gateway VPC endpoint to access Amazon DynamoDB from your VPC without using an internet gateway or NAT device.</td>
<td>August 16, 2017</td>
</tr>
<tr>
<td>VPC endpoints for Amazon S3</td>
<td>You can create a gateway VPC endpoint to access Amazon S3 from your VPC without using an internet gateway or NAT device.</td>
<td>May 11, 2015</td>
</tr>
</tbody>
</table>
